Getting Started

This help file is intended to guide users who are new to STAAD.Pro as well as experienced users who want specific information on the basics of using the program.

Start by reading through this section which contains basic information on getting STAAD.Pro running on your computer.

It is then strongly recommended that you work through all three of the tutorials. These contain step-by-step procedures of modeling, analysis, design, and post processing different structures.

Next, read through the frequently performed tasks to learn how to perform common operations in the program.

GS. Welcome to STAAD.Pro

The ultimate power tool for computerized structural engineering.

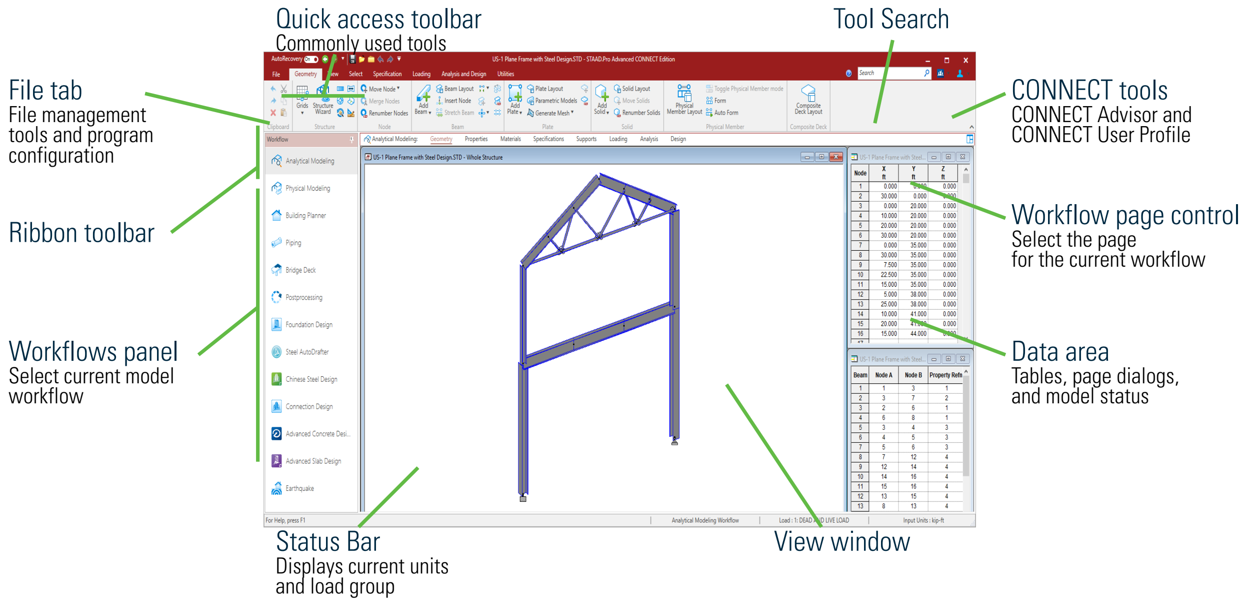
STAAD.Pro CONNECT Edition is the most popular structural engineering software product for 3D model generation, analysis and multi-material design. It has an intuitive, user-friendly graphical user interface, visualization tools, powerful analysis and design facilities and seamless integration to several other modeling and design software products. The software is fully compatible with supported Windows operating systems.

For static or dynamic analysis of bridges, containment structures, embedded structures (tunnels and culverts), pipe racks, steel, concrete, aluminum or timber buildings, transmission towers, stadiums or any other simple or complex structure, STAAD.Pro has been the choice of design professionals around the world for their specific analysis needs.

To learn about the latest features in STAAD.Pro, please refer the What's New? (on page 90).

GS. Overview of the STAAD.Pro Environment

Tip: Click on any label in the figure to jump to that section of the help.



1. File tab (on page 2694)
2. Ribbon Control Reference (on page 2694)
3. GS. Workflows in STAAD.Pro (on page 36)
4. GS. Quick Access Toolbar (on page 62)
5. GS. Tool Search (on page 64)
6. Bentley CONNECT Features (on page 2068)
7. GS. Page Control (on page 64)
8. GS.Data Area (on page 66)
9. GS. Status Bar (on page 84)
10. GS. View Window (on page 67)

GS. About STAAD.Pro Documentation

The documentation for STAAD.Pro consists of the following sections that make up the online help.

All the manuals can be accessed from the Help facilities of STAAD.Pro.

Getting Started (GS.)

This section contains information on the contents of the STAAD.Pro package, computer system requirements, installation process, copy protection issues and a description on how to run the programs in the package.

What's New?

This section contains the software release report for STAAD.Pro contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2007 build 06.

Tutorials (T.)

Tutorials that provide detailed and step-by-step explanation on using the programs are also provided.

Modeling (M.)

This section describes how to model structural elements and loads in STAAD.Pro using the Analytical Modeling workflow.

Analysis (A.)

This section of the help describes the analysis methods, data print commands, and how to perform analysis in STAAD.Pro.

Design (D.)

This section describes how to perform the design of structural elements using STAAD.Pro.

This section contains information on the various concrete, steel, timber, and aluminum design codes that are implemented in STAAD.Pro.

Postprocessing and Reports (P.)

This section describes how to review output, perform post-processing tasks, generate reports, and plot from STAAD.Pro.

Data Files and Interoperability (I.)

This section describes how to manually edit STAAD.Pro input files, import and export data, and interact with STAAD.Pro using external applications.

General Engineering Theory (G.)

This section deals with the theory behind the engineering calculations made by the STAAD engine.

Technical Reference of STAAD Commands (TR.)

This section includes an explanation of the commands available in the STAAD command file.

Ribbon Control Reference

This section describes the tools found in the ribbon toolbars.

Verification Examples (V.)

This section includes examples of STAAD.Pro example models along side reference (“textbook”) examples or a set of “hand” calculations. This provides you with validation of standard program calculations.

Application Examples (EX.)

This section includes examples of various problems that can be solved using the STAAD engine. The examples represent various structural analysis and design problems commonly encountered by structural engineers. Additional example models installed with the product are described here in brief.

OpenSTAAD (OS.)

This section describes the application programming interface for STAAD.Pro.

GS. Using Online Help

The Web help opens in your default web browser.

The Help window consists of two panes — the navigation pane on the left and the topic pane on the right.

The navigation pane has the following tabs:

- Contents — used for browsing topics.
- Index — index of help content.
- Glossary — glossary of the help content.
- Search — displays the search results.
- Tool Index — index of the tools.

Hypertext links, which appear in color and are underlined when you hover the pointer over them, let you move easily between related topics.

Note: In case you are not able to view the Web help properly in Internet Explorer, make sure you turn off the **Enable Protected Mode** check box in the Security tab of the Internet Options dialog.

Note: The text size in the topic pane on the right is controlled by your web browser. To learn how to change the web page’s text size, consult the web browser's Help file.

To open the Help window

1. Either:

   Click the **Help** tool in the top, right corner of the application window 

   or

   Press **<F1>**

   The Help window opens and the **Contents** tab is displayed.

The Help window consists of two panes — the navigation pane on the left and the topic pane on the right. At the top of the topic pane is a topic banner containing additional navigation tools.

To browse topics using the Contents tab

1. On the Contents tab, click the symbol preceding any link to expand its contents.
2. Continue expanding folders until you reach the desired topic.
3. Select a topic to display its content in the topic pane.

To display the next or previous topic according to the topic order shown in the Contents tab

1. Either:

View...	Select...
the next topic	click the right arrow in the help window's control bar 
the previous topic	click the left arrow in the help window's control bar 

To navigate in this manner, it is not necessary to first select the **Contents** tab.

To use the index to find help content

1. Select the **Index** tab.
2. Scroll through the index using the scroll bar to find a specific entry.

> **Tip:** Press **<Ctrl+F>** to use your web browser's find feature to locate instances of a word or phrase in the index.

3. Select the desired entry.
The content that the selected index entry is referencing displays in the topic pane.

To search for text in the help content

1. In the **Enter search terms** field, type the word or phrase for which you are searching.
2. Either:

   Click **Search**

   or

   Press **<Enter>**
   Results of the search display on the Search tab.
3. Click the title of any search result.
4. (Optional) Search for a term within a topic:
   a. Press **<Ctrl+F>**
   Your browser's search dialog opens.
   b. Type the word or phrase for which you are searching.
   c. Click **Next** to find each occurrence of the text in this topic.

Search results vary based on the quality of the search criteria entered in the Search field. The more specific the search criteria, the more narrow the search results. You can improve your search results by improving the search criteria. For example, a word is considered to be a group of contiguous alphanumeric characters. A phrase is a group of words and their punctuation. A search string is a word or phrase on which you search.

GS. Documentation Conventions

A number of typographical conventions are maintained throughout Bentley documentation, which makes it easier to identify and understand the information presented.

Notes, Hints, and Warnings	Items of special note are indicated as follows: **Note:** This is an item of general importance. **Tip:** This is optional time-saving information. **Warning:** This is information about actions that should not be performed under normal operating conditions.
File Path/File Name.extension	A fixed width typeface is used to indicate file names, file paths, and file extensions (e.g., .../`STAAD/Staadpro.exe`)
Interface Control	A bold typeface is used to indicate user controls, such as ribbon tabs, tool names, and dialog controls. (e.g., **File** > **Save As**).
User Input	A bold, fixed width typeface is used to indicate information which must be manually entered. (e.g., Type `DEAD LOAD` as the title for Load Case 1).

Terminology

- Click - This refers to the action of pressing a mouse button. When not specified, click means to press the left mouse button.
- Select - Synonymous with Click. Used when referring to an action in a menu, drop-down list, list box, or other control where multiple options are available to you.
- pop-up menu - A pop-up menu is displayed typically with a right-click of the mouse on an item in the interface.
- Window - Describes an on screen element which may be manipulated independently. Multiple windows may be open and interacted with simultaneously.
- Dialog - This is an on screen element which (typically) must be interacted with before returning to the main window.
- Cursor - Various selection tools are referred to as “cursors” in STAAD.Pro. Selecting one of these tools will change the mouse pointer icon to reflect the current selection mode.

Mathematical Notation

Similar to spelling conventions, American mathematical notation is used throughout the documentation. A serif typeface is typically used to clarify numbers or letters which might otherwise appear similar.

- Numbers greater than 999 are written using a comma (,) to separate every three digits.

  For example, the U.S. value of Young's Modulus is taken as 29,000,000 psi.

Warning: Do *not* use commas or spaces to separate digits within a number in a STAAD input file.

- Numbers with decimal fractions are written with a period to separate whole and fraction parts. For example, a beam with a length of 21.75 feet.
- Multiplication is represented with a raised –or middle– dot (·) or a multiplication symbol (×). For example, $P = F \cdot A$ or $P = F \times A$.
- Operation separators are used in the following order:

  1. parenthesis ( )
  2. square brackets [ ]
  3. curly brackets (i.e., braces) { }

  For example,

  $$F_a = [1 - (Kl/r)^2/(2 \cdot C_c^2)]F_y / \{5/3 + [3(Kl/r)/(8 \cdot C_c)] - [(Kl/r)^3/(8 \cdot C_c^3)]\}$$

  Which may also be represented as:

  $$F_a = \frac{\left[1 - \frac{\left(\frac{Kl}{r}\right)^2}{2C_c^{\,2}}\right]F_y}{\left\{\frac{5}{3} + \left[\frac{3\left(\frac{Kl}{r}\right)}{8C_c}\right] - \left[\frac{\left(\frac{Kl}{r}\right)^3}{8C_c^{\,3}}\right]\right\}}$$

GS. Where are the old manuals?

For many versions of STAAD.Pro, the help was primarily a collection of the user manuals in an online format. Though the organization has changed somewhat, all of the existing content is still available to you.

Technical Reference Manual

This chapters of this document have been separated into the logical portions of this help file. You can find each of the sections as follows:

1. "General Description" - General Engineering Theory (on page 2085)
2. "American Steel Design" - D1. American Codes (on page 1086)
3. "American Concrete Design" - D1.F. American Codes - Concrete Design per ACI 318 (on page 1198)
4. "American Timber Design" - D1.G. American Codes - Timber Design per AITC Code (on page 1248)
5. "Commands and Input Instructions" - Technical Reference of STAAD Commands (on page 2196)

International Design Codes Manual

This content is included in the D. Design Codes (on page 1086) section of the online help.

The American codes are now included here for consistency. The sections including American aluminium design, American transmission tower design, API steel design code, ANSI/AISC N690 design, and ASME NF codes have all been moved to the chapter for American design codes as well.

Release Report

This document is included as the What's New? (on page 90) section of the online help.

Getting Started and Tutorials

This document has been reorganized and is included primarily within the Getting Started section of the online help.

Graphical User Interface

This content is no longer collected into a sub-section, but has been expanded to cover modeling, analysis, design, post-processing, and interopability as described elsewhere in the online help.

Examples Manual

Most complete input examples, verification examples, and extended modeling examples have been collected into the Application Examples section of the help.

GS. About STAAD.Pro

STAAD.Pro is a general purpose structural analysis and design program with applications primarily in the building industry — commercial buildings, bridges and highway structures, industrial structures, chemical plant structures, dams, retaining walls, turbine foundations, culverts and other embedded structures, etc. The program hence consists of the following facilities to enable this task.

1. Graphical model generation utilities as well as text editor based commands for creating the mathematical model. Beam and column members are represented using lines. Walls, slabs and panel type entities are represented using triangular and quadrilateral finite elements. Solid blocks are represented using brick elements. These utilities allow you to create the geometry, assign properties, orient cross sections as desired, assign materials like steel, concrete, timber, aluminum, specify supports, apply loads explicitly as well as have the program generate loads, design parameters etc.
2. Analysis engines for performing linear elastic and p-delta analysis, finite element analysis, frequency extraction, and dynamic response (spectrum, time history, steady state, etc.).
3. Design engines for code checking and optimization of steel, aluminum and timber members. Reinforcement calculations for concrete beams, columns, slabs and shear walls. Design of shear and moment connections for steel members.
4. Result viewing, result verification and report generation tools for examining displacement diagrams, bending moment and shear force diagrams, beam, plate and solid stress contours, etc.
5. Peripheral tools for activities like import and export of data from and to other widely accepted formats, links with other popular software programs for niche areas like reinforced and prestressed concrete slab design, footing design, steel connection design, etc.
6. A library of exposed functions called OpenSTAAD which allows you to access the internal functions and routines in STAAD.Pro as well as its graphical commands to tap into STAAD.Pro's database and link input and output data to third-party software written using languages like C, C++, VB, VBA, FORTRAN, Java, Delphi, etc. Thus, OpenSTAAD can be used to link in-house or third-party applications with STAAD.Pro.

GS. System Requirements

The following hardware requirements are suggested minimums. Systems with increased capacity provide enhanced performance.

Processor	Intel® Pentium or AMD® processor 3.0 GHz or greater.
Memory	1 GB minimum, 2 GB recommended (4GB for STAAD.Pro Advanced). More memory almost always improves performance, particularly when working with larger models. 4 GB (8 GB for STAAD.Pro Advanced) or more can help speed up solutions for very large complex models with large numbers of load cases.
Video	Graphics card supported by OpenGL. See the graphics card manufacturer for latest information on graphics drivers. 256 MB of video RAM or higher is recommended. If insufficient video RAM or no graphics card supported by OpenGL can be found, the application will attempt to use software emulation. For optimal performance, graphics display color depth should be set to 24-bit or higher. When using a color depth setting of 16-bit, some inconsistencies will be noted.
Screen Resolution	A minimum screen resolution of 1280x1024 is required, but higher is recommended. **Note:** 4k displays are currently *not* supported.
Hard Disk	Requirements will vary depending on the modules you are installing. A typical minimum is 500MB free space.

Supported Operating Systems	• Windows 11 (64-bit) - Enterprise • Windows 10 (64-bit) - Home, Pro, Enterprise, and Education • Windows 8.1 (64-bit) - Standard, Pro, and Enterprise **Note:** You must have the following Microsoft updates installed on your machine: • KB4340917 - For Windows 10 Version 1803 Builds prior to 10.0.17134.191. The changes in KB4340917 are built into the August 2018 monthly update of Windows 10. • KB2999226 - For Windows 8.1, Windows Server 2008 R2 SP1, and Windows Server 2012 • KB2999226 - For Windows 8.1 (64bit) • KB2919355 - For Windows 8.1 and Windows Server 2012 Bentley does not support its software running on Microsoft operating systems versions that Microsoft has "retired". For more information on Microsoft's application retirement policy, click here. For similar information on Bentley products, refer to the Bentley Product Support article. **Note:** Testing is performed on the latest operating system updates from Microsoft at the time of release.

Additional RAM, disk space, and video memory will enhance the performance of STAAD.Pro.

The minimum amount of physical + virtual memory required by the program is over 600MB. You may need to ensure that adequate amounts of virtual memory are available and that parameters such as paging file sizes should be large enough or span over multiple drives if the free space on any one drive runs low.

Another issue to keep in mind is the location of the `TEMP` parameter as in the `SET TEMP` environment variable in Windows. While performing calculations, depending on the structure size, the program may create very large scratch files which are placed in the folder location associated with the `TEMP` parameter. You may want to point the `SET TEMP` variable to a folder on a drive that has disk space sufficiently large to accommodate the requirements for large size structures.

You should have a basic familiarity with Microsoft® Windows® systems in order to use the software.

GS. Installation and Licensing

For details on installation and licensing of this product, please refer to the product Readme file, which is installed in the same location as the product and this help file.

GS. STAAD.Pro License Options

	STAAD.Pro	STAAD.Pro Advanced	Structural Enterprise License
Structural Analysis and Design	✓	✓	✓
Advanced Analysis	-	✓	✓
Building Planner[1]	Included with SELECT	Included with SELECT	✓
AutoDrafter	Included with SELECT	Included with SELECT	✓
Separate license are required for the following:			
Foundation Design	Isolated, combined, and pile cap foundations only		✓
Connection Design	A subset of basic BCF and BCW connections only		✓
STAAD Advanced Concrete Design	Beam, column, and wall design only	✓	✓
Nuclear Design Codes	Separate license required		

[1]Building Planner was formerly known as STAAD PlanWin.

Related Links

- *GS. Starting STAAD.Pro* (on page 33)

GS. Limits on Models

The following limits to model size are effective for STAAD.Pro CONNECT Edition V22 Update 2 (release 22.02.00) and later.

- Number of joints: 400,000*
- Joint number 1 to 999,999
- Number of Members, Physical Members, Plates, and Solids: 500,000*
- Member/Element numbers: 1 to 999,999
- Number of primary and combination cases: 10,101
- Load Case numbers: 1 to 99,999
- Number of modes and frequencies: 2,700
- Number of load cases that may be combined by a Repeat Load or Load Combination command: 550

* Some STAAD.Pro copies are available with much smaller limits, please check what limits you have purchased.

Notes:

The numerical limits should be considered as upper limits built into the software for those quantities on an individual basis. In practice, the actual maximums the program can handle are determined by the hardware resources as well as the limits imposed by the operating system. For example, it is highly improbable that a single model with 500,000 members and 10,101 load cases can be solved.

The memory demand of the program is determined by the combined effect of two or more of these terms. For example, when a steel design is performed, the memory required depends on the product of the members being designed (NMD) as well as the number of load cases being designed for (NL). That is, NMD ×NL. So the smaller the NMD, the larger the NL capacity and vice versa.

GS. Fundamentals

This section introduces you to some of the fundamental concepts necessary for using STAAD.Pro. You are strongly encouraged to review this section to gain a firm understanding of the core concepts of the program.

GS. Starting STAAD.Pro

1. Start STAAD.Pro by one of the following methods:

   double-click the STAAD.Pro CONNECT Edition icon on your desktop

   or

   click the Windows Start button and then select **Bentley Engineering** > **STAAD.Pro CONNECT Edition V22**

   or

   in the program group, select the STAAD.Pro icon.

   or

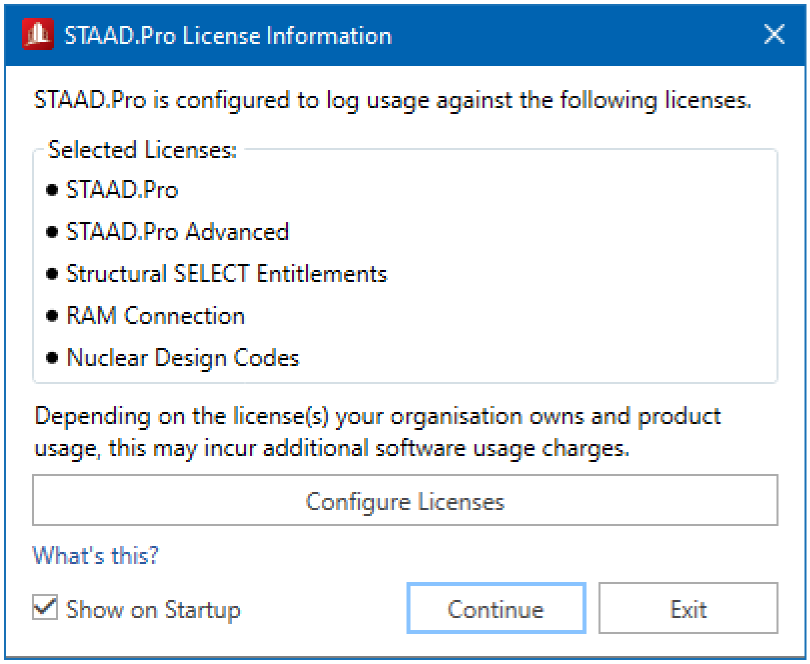
   in Windows Explorer, double-click a STAAD.Pro file (with the file extension `.std`)

   or

   in Windows Explorer, double-click the icon for `STAADPro.exe`.

   Note: Until you have activated a license for the program, it will remain in Limited mode and only function for 15 minutes before shutting down the application.

   The **STAAD.Pro License Information** dialog opens.



2. (Optional) To configure the license for this session:
   a. Click **Configure Licenses**.
   The **STAAD.Pro License Configuration** dialog opens.

   b. Select the **Product Type** and any **Additional Licenses** you need to use for this session.
   Please refer to the product ReadMe or click the **Help with license selection** link for additional details.
   c. Click **Accept**.

The STAAD.Pro window opens to the Start page.

3. Click **Continue**.
   The STAAD.Pro window opens to the Start page.

Related Links

- *GS. STAAD.Pro License Options* (on page 32)
- *GS. STAAD.Pro License Configuration dialog* (on page 57)
- *GS. STAAD.Pro License Configuration dialog* (on page 57)

GS. To create a new STAAD.Pro model

To create a new STAAD.Pro model, use the following procedure.

1. On the Start page, select **New**.

   The **New** page opens to the **Model Info** tab.
2. Enter a **File Name**.
3. Specify a **Location** where the STAAD input file will be located on your computer or network.

   You can directly type a file path or click **Browse** to open the **Browse by Folder** dialog, which is used to select a location using a Windows file tree.
4. Select the **Type** of model.
   This option selects the modeling method you want to use:

Analytical	For creating a model using either the STAAD.Pro analytical modeling interface or the command input file editor.
Physical	For creating a model using the STAAD.Pro Physical Modeler interface.
Building	For creating a building model structure using the Building workflow.

Note: When the **Z up** option is selected in the **Application Configuration** dialog, then the **Physical** model option is disabled for creating new models.

5. Select the system of **Units**.

English	English Imperial units: feet, pounds, seconds
Metric	System International units: meters, kilograms, seconds

Tip: The units can be changed later if necessary, at any stage of the model creation.

6. (Optional) Select the Job Info tab to enter related project details, names and dates for quality analysis, and ProjectWise Project information.
7. (Optional) Type a **Title** for the model.
8. Select a **Model Seed File** file by either:

   clicking **Browse** to locate a seed file

   or

   selecting a previously used seed file from the drop-down list
   A seed file is a STAAD.Pro input file that has been pre-populated with model data for use as a template.
9. Click **Create**.

The new STAAD.Pro model is opened in either the Analytical Modeling workflow, STAAD.Pro Physical Modeler, or the Building workflow based on your selection.

Related Links

- *GS. Start Page* (on page 54)
- *ProjectWise Project Association* (on page 2068)

GS. To open a STAAD.Pro model

To open an existing STAAD.Pro model, use the following procedure.

1. On the Start page, select **Open**.
   The New page opens to the **Recent** tab.

   Recently opened models are organized by the following categories:

   Analytical
   Physical
   ProjectWise
   Archive
   All
2. Either:

   select a recently used model from one of these tabs

   or

   select **Open Other Models** to search for a STAAD input file

   or

   select either **Sample Models** or **Verification Models** to open the example models which are installed with the program

   If you select a recent model, it will open. If you select to browse for a model, an **Open** dialog opens.
3. In the Open dialog, navigate to and select a STAAD.Pro file (file extension `*.std`) and then click **Open**.
   The selected file opens.

If the STAAD.Pro file does not have a ProjectWise Project associated with it, then you will be prompted to select one.

Related Links

- *GS. Start Page* (on page 54)
- *ProjectWise Project Association* (on page 2068)

GS. Workflows in STAAD.Pro

The program is organized to reflect the typical process of modeling, analyzing, and post-processing for a structure.

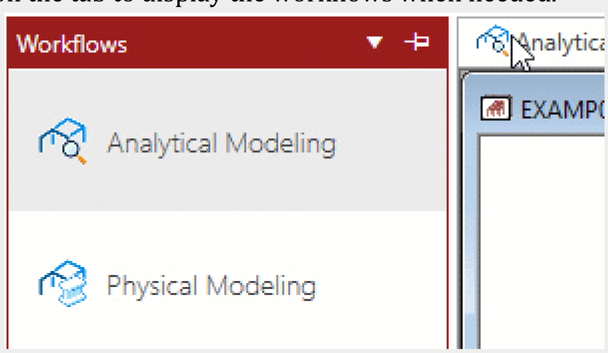
A workflow in STAAD.Pro groups all of the common tasks associated with a major stage of your structural project.

Overview of Workflows

Modeling (on page 629)	used to model your structure using analytical objects
M. Physical Modeling workflow (on page 919)	opens the STAAD.Pro Physical Modeler application, which is used to model using physical objects which will be subsequently decomposed into analytical objects when exported back into the STAAD.Pro interface
M. Building Planner workflow (on page 920)	used to generate concrete building models with the integrated STAAD Building Planner interface
M. Piping workflow (on page 902)	used to import piping support geometry and reactions from Bentley AutoPIPE
P. Postprocessing Workflow (on page 1979)	used to review the results of analysis and design as well as to build reports
D. Foundation Design (on page 1078)	used to select load and support data to send to STAAD Foundation Advanced for design
P. Steel AutoDrafter Workflow (on page 2018)	used to generate construction drawings for steel-framed structures
D. To open a model in the Chinese Steel Design workflow (on page 979)	used to design the analyzed steel structure per the Chinese design code in SSDD

D. Connection Design workflow (on page 1014)	used to specify steel connection types and design them in RAM Connection
D. Advanced Concrete Design (on page 1071)	opens the Advanced Concrete Design (RCDC) application, which is used for the design of concrete building structures
D. Advanced Slab Design (on page 1073)	used to define concrete slabs and transfer data to RAM Concept
P. Earthquake workflow (on page 2032)	this postprocessing workflow is used to check if the structure conforms to the basic geometric recommendations made in Eurocode 8 (EC8).

Tip: Once you are familiar with the Workflows, you can free up some screen area by unpinning the **Workflows** panel from the program window. It will then collapse to a tab on the left side of the application window. You can expand the panel by clicking on the tab to display the workflows when needed.



Where did the Modes and Page Controls go?

In previous generations of STAAD.Pro, a series of page controls were listed vertically along the left side of the view window. A series of operation modes were listed along the top of the view window (and also accessed via the **Modes** menu.

These modes have now been replaced by the **Workflows** panel. Similarly, the page controls are available for the current workflow just below the ribbon bar. These are now organized in a single row, rather than the former groupings.

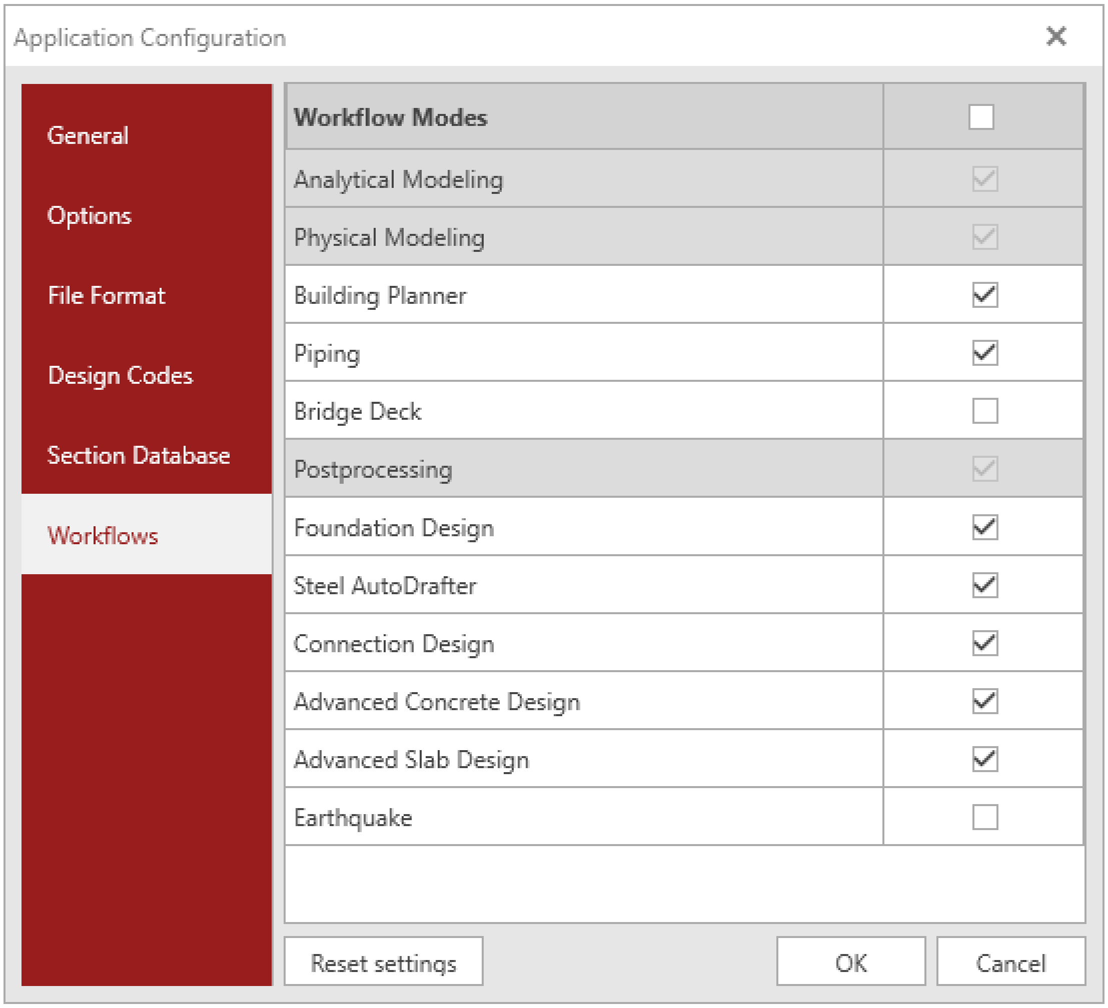
GS. To customize the workflows panel

To hide unused workflows in the STAAD.Pro interface, use the following procedure.

Close any open STAAD.Pro models to display the Start page.

1. On the **Start** page, click **Configure**.

   The **Configure Program** dialog opens.
2. Select the **Workflows** tab.



3. Uncheck any workflows you want hidden in the application interface.

   Tip: To reset the Workflows display to the default, check the **Workflow Modes** option.

4. Click **OK**.

The next time you open a model in STAAD.Pro these workflows will be hidden. You can un-hide them at any time by checking the options in the **Application Configuration** dialog.

Related Links

- *GS. Application Configuration dialog* (on page 59)

GS. Selecting Objects in STAAD.Pro

With even relatively small structural models containing many nodes, beams, plates, loads, and other model objects, it is important that you be able to select the correct objects for assigning parameters. STAAD.Pro has a variety of tools to allow you to select objects by type, filter, boolean logic, and more.

In certain modes of selection, objects are chosen by clicking on their entry in a list. For selecting more than one object, press and hold **<Ctrl>** while clicking.

Selection Method

STAAD.Pro allows you to select one of several methods for graphical selection. These are described in the table below.

To choose a different the selection method, either:

- Select it from the **Select** ribbon tab in the **Modes** group, or
- right-click in the view window and select **Selection Mode** from the pop-up menu.

Selection Type	Description	Mouse Action	Resulting Selection Set	Shortcut
 **Drag box**	A rectangular selection box activated by holding down the left mouse button and dragging the pointer to create a windowed area in the View window. **Tip:** This is sometimes referred to as a “rubber band” window. 			
 **Drag line**	Click and hold down the left mouse button to draw a line. All entities which the line passes through will be selected. 			**<Crtl+Shift+F3>**

Selection Type	Description	Mouse Action	Resulting Selection Set	Shortcut
 **Region**	Click the outer points of any polygonal region. Close the polygon by double-clicking. All entities fully enclosed in the polygon are selected. 			**<Crtl+Shift+F2>**

GS. Units in STAAD.Pro

STAAD.Pro uses a set of base units, called current units, for all input and output. The Current Units can be changed at any time to simplify entering input or interpreting results. The current input units are set using the **Set Current Input Units** dialog.

Tip: There are several some instances in the program where the Current Units cannot be changed, such as when an input dialog is open. In this case, you can use the **<F2>** key to input different units.

STAAD.Pro also includes an extensive unit conversion utility.

Display Units

STAAD.Pro can use a different set of units for displaying values in the active view window. These are controlled through several tabs on the **Options** dialog.

Base Unit System

There are two base unit systems in the program which control the units (i.e., length, force, temperature, etc.) in which, values, specifically results and other information presented in the tables and reports, are displayed in. The base unit system also dictates what type of default values the program will use when attributes such as Modulus of Elasticity, Density, etc., are assigned based on material types - Steel, Concrete, Aluminum - selected from the program's library (Please refer to Technical Reference of STAAD Commands (on page 2196) for details). These two unit systems are:

English (Foot, Pound, etc.) and
Metric (KN, Meter, etc.)

Tip: If you recall, one of the choices made at the time of installing STAAD.Pro is this base unit system setting. That choice will serve as the default until you specifically change it.

Selecting Different Input Units in Dialogs

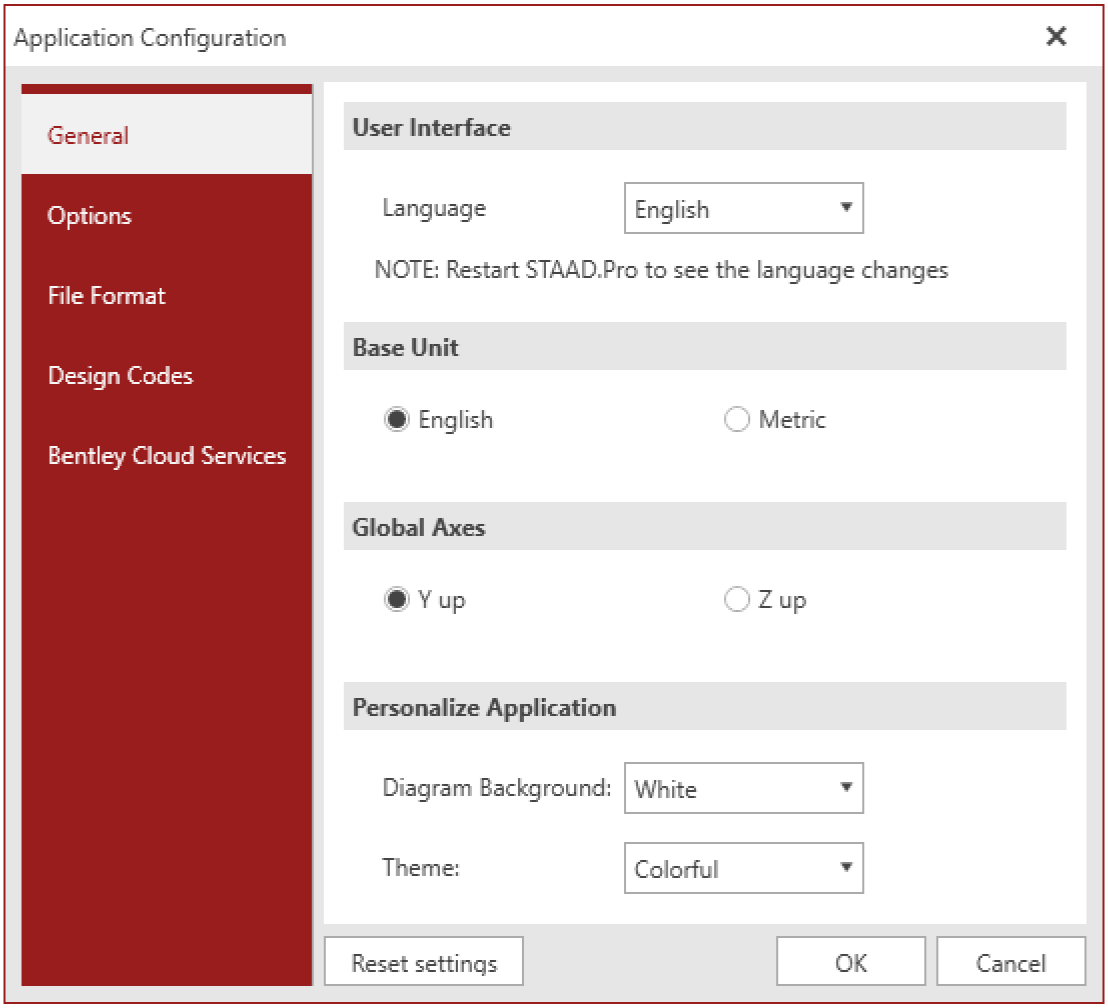
While you may typically wish to work in one unit system - or even with a specific unit of force or length, it is not uncommon to use a different unit for input. STAAD.Pro allows for the input of a value in any unit in most dialog boxes. This avoids the need to manually change the unit before and after adding a command or to convert a unit to something less commonly used. A unit is entered in the most convenient format and then converted to the current units for you. This is especially useful when adding or editing loads, where the current input units cannot be changed.

GS.To change the system units

There are two base unit systems in the program which control the units (length, force, temperature, etc.) in which values — specifically results and other information presented in the tables and report— are displayed. The base unit system also dictates what type of default values the program uses when attributes such as Modulus of Elasticity, Density, etc., are assigned based on material types (i.e.., steel, Concrete, Aluminum) selected from the program's library (Please refer to Built-In Material Constants (on page 2308)). These two unit systems are English (Foot, Pound, etc.) and Metric (KN, Meter, etc.).

1. On the **Start** page, click **Configure**.

   The **Configure Program** dialog opens.
2. Select appropriate system of units in the **Base Unit** group on the **General**.



3. Click **OK**.

- *TR.26.2 Specifying Constants for Members and Elements* (on page 2305)
- *GS. Application Configuration dialog* (on page 59)

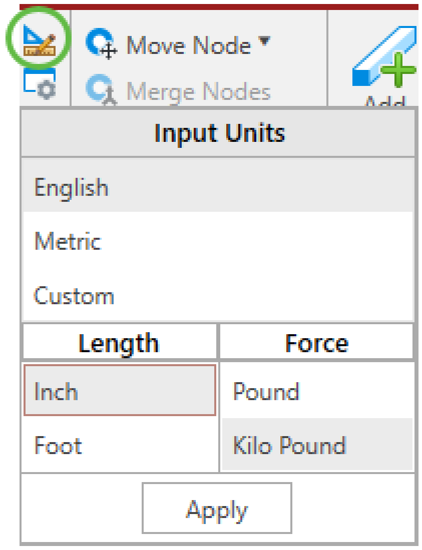
GS. To set the current input units

To change the current length and force units for inputs, use the following procedure.

The current input units used for creating the model and assigning attributes such as properties, offsets, loads, etc. can be changed to use convenient units.

1. On the **Geometry** ribbon tab, select the **Input Units** tool in the **Structure** group.

The **Set Input Units** pop-up opens.



2. Select the base system of **Input Units**:

   English

   or

   Metric

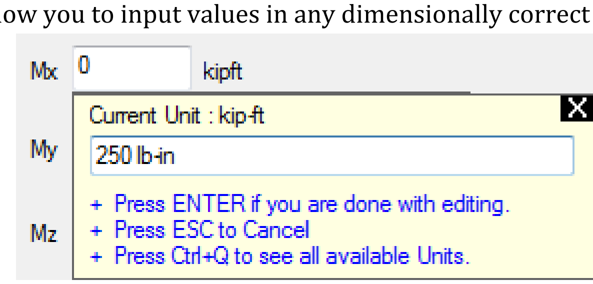
   or

   Custom - to mix different systems of units
3. Select a unit for **Length** on the left and unit for **Force** on the right.
4. Click **Apply**.

GS. To convert units within a dialog field

To input a unit different than the current unit within a dialog field, use the following procedure.

1. Click within a field that takes a dimensional value as input.
2. Press **<F2>**.
   A pop-up dialog opens to allow you to input values in any dimensionally correct unit.



3. (Optional) Press **<Ctrl+Q>** to open a list of dimensionally correct units and select one to populate this pop-up dialog.
4. Type the value in the known units.

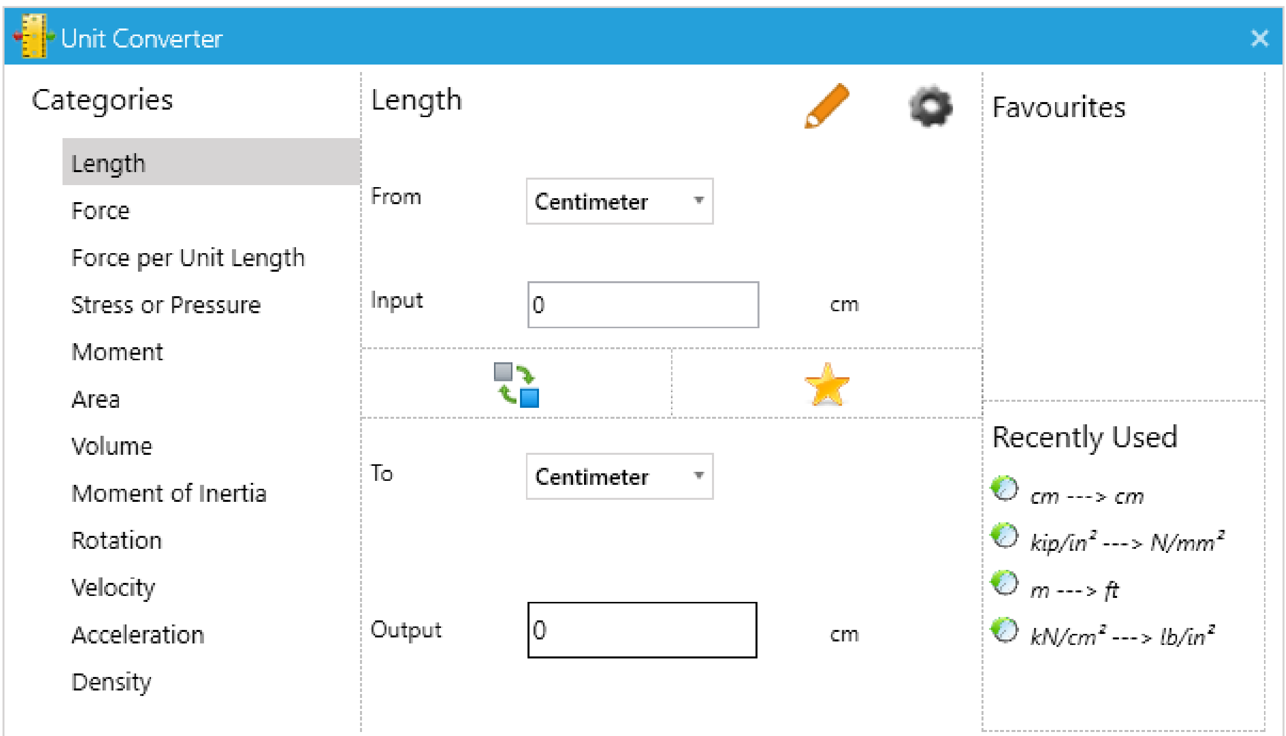
   Tip: Values can also be input using a fractional system (e.g., 5 7/8").

5. Once you are finished entering the units, press **<Return>**.
   The unit is converted into the Current Unit system.

GS. **STAAD.Pro Converter** utility

An extensive unit converter is included with the program which can convert values from one unit system to another.

Opens when the **Unit Converter** tool is selected from the **Tools** group on the **Utilities** ribbon tab.



Tools

<table>
<tr><th>Tool icon</th><th>Description</th></tr>
<tr><td>
Custom</td><td>Click to add a custom unit conversion to the current unit category. In the Custom Units table, type a From unit label, the conversion Factor, and a To unit label and then click Ok.

For example, you can type the following to add yards to the Length conversion:
<table><tr><th>From</th><th>Factor</th><th>To</th></tr><tr><td>Feet</td><td>3</td><td>Yards</td></tr></table></td></tr>
</table>

Tool icon	Description
 **Settings**	Click to open the **Settings** dialog.
 **Swap units**	Click to switch the From and To units for the current category.
 **Add to favourites**	Click to add the current conversion settings to the **Favourites** list on the right.

Settings dialog

Click the **Settings** tool to display the **Unit Converter** settings.

Setting	Description
Theme	Select a display theme from the drop-down list.
Output decimal places	Set the decimal places to display in the conversion output.
Max no of favourite items	Set the number of items to display in the favourites list.
Max no of recently used items	Set the number of items to display in the recently used items list.
Top Most	Check this settings to keep the **Unit Converter** dialog on top of all other windows on your screen, even when other windows are active.

GS. Coordinates in STAAD.Pro

STAAD.Pro Physical Modeler uses a conventional Cartesian coordinate system, with the global Y axis assumed as vertical (i.e., “Y up”, or the height of the structure is parallel to the global Y axis).

Global Coordinate System

This coordinate system is a rectangular coordinate system (X, Y, Z) which follows the orthogonal “right hand” rule. This coordinate system may be used to define the joint locations and loading directions. The translational degrees of freedom are denoted by u1, u2, & u3 and the rotational degrees of freedom are denoted by u4, u5, & u6.

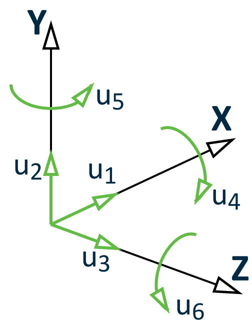


Figure 1: Degrees of freedom as used in STAAD.Pro

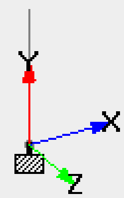
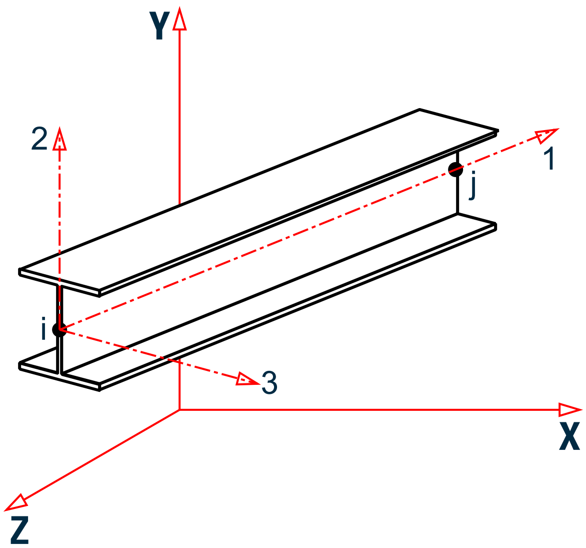
Note: You can toggle on a color-coded axes label placed at the origin (**<Shift+I>**) in which: X is blue, Y is red, and Z is green.



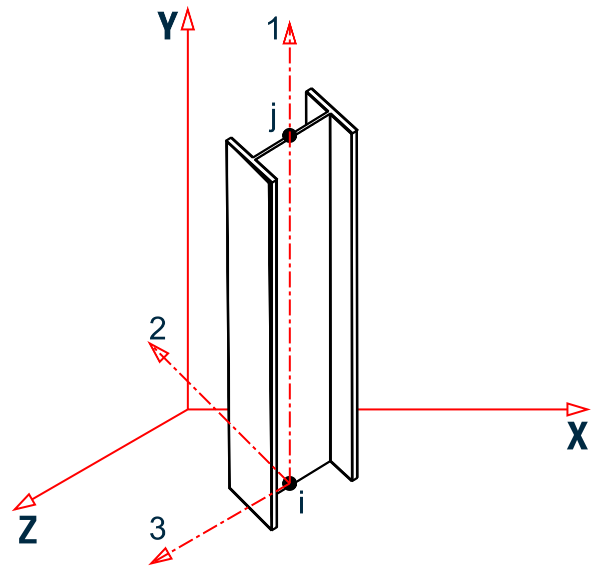
Local Coordinates

Each member or surface has its own local Cartesian coordinate system which is also oriented using the “right hand” rule.

The longitudinal axis of a member is the first axis, with the positive axis taken from the i to the j ends (i.e, Ni and Nj). The second axis is the oriented such that the 1-2 plane is then parallel to the global Y axis. The third axis is then normal to the first and second local axes as defined by the right hand rule. The local 2 and 3 axes coincide with the two principle moments of inertia of the cross-section. In the special case of a vertical member (where the local 1 axis is parallel to the global Y axis; i.e., a column), the local 3 axis is then made parallel to the global Z axis and the 2 axis is oriented respectively.



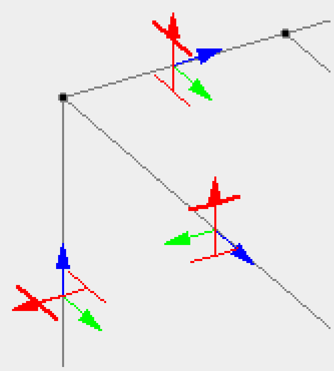
(A)



(B)

Figure 2: Local coordinates of (A) a member with arbitrary orientation and (B) oriented vertically

Note: Local axes (**<Shift+O>**) are color-coded as follows in the graphical view window: x is blue, y is red, and z is green.



For surfaces, the local x axis is aligned with the edge defined by the first two nodes of the surface (i.e., N1 and N2). The program then calculates the area of each triangle formed by any other nodes to determine the largest area. This triangle determines the plane of the surface and the local y axis lies perpendicular to the x axis within this plane. The third axis is then orthogonal to the surface as defined by the “right hand” rule.

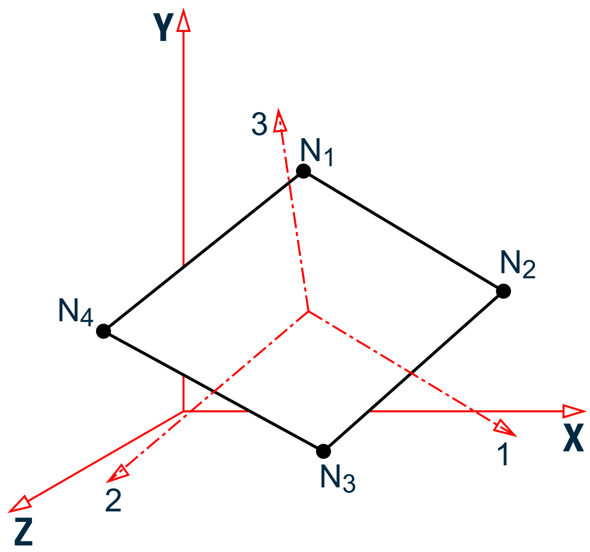


Figure 3: Local coordinates of a surface

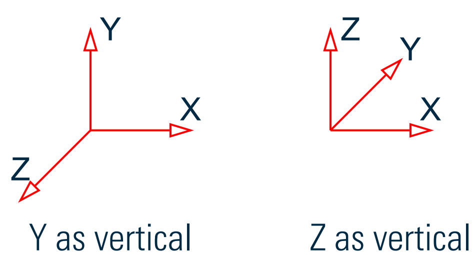
GS. To use Z as the vertical axis

To re-orient the global axis so that Z is vertical, use the following procedure.

You must close any open STAAD.Pro models in order change program configuration.



Note: Both options follow the "right hand rule."

Figure 4: Global axis orientation options in STAAD.Pro

Important: Not all STAAD.Pro features are compatible with Z UP orientation. Refer to SET { Y | Z } UP (on page 2210) for additional details.

1. On the Start page, select **Configure**.
   The **Application Configuration** dialog opens.
2. On the **General** tab, select **Z up** in the **Global Axis** group.
3. Click **OK**.

New models will use the Z up orientation of the global axis.

Tip: You can repeat this procedure except to select Y up to return to set Y as vertical.

Any input files which have the `SET Z UP` command will automatically use this orientation.

GS. Load Types in STAAD.Pro

Several load cases may be created for a structure and each load case may contain several individual load specifications. Load cases may also be created by combining several existing load cases. A load case consisting of explicitly defined loads is called a Primary Load Case. A load case which combines the results of previously defined cases is called a Combination Load Case.

Tip: Here, we wish to introduce you to some of the load terminology and types used in STAAD.Pro. These concepts are critical in understanding how to correctly model loads on a structure.

Primary Load Cases

A primary load case is a set of explicitly defined loads, presumably from the same physical source, which will be passed to the analysis engine during the analysis of the model. Each of these explicitly defined loads is referred to as a Load Item.

In the STAAD input file, a primary load case is indicated by the `LOAD n` command.

Refer to TR.32 Loading Specifications (on page 2461) for details.

Some examples of where a primary load case would be used are:

- All dead load on a structure.
- The reducible live load on an office building.
- The easterly wind load.
- The dead and live composite load on a pedestrian bridge.
- The superimposed dead load on a post-tensioned floor.

Load Combinations

A load combination is a set of load results which are combined algebraically to produce a superimposed set of results for post-processing. Therefore, a load combination instructs the program to take the results of previously solved primary load cases, factor them appropriately, and combine the values using Algebraic, SRSS or Absolute methods.

In the STAAD input file, a load combination is indicated by the `LOAD COMBINATION n` command.

Refer to TR.35 Load Combination Specification (on page 2616) for details.

Reference Loads

Large models can include multiple load cases which do not require analysis in their own right and are simply the building blocks for inclusion in primary load cases. Reference Loads may be defined for this purpose. This is similar to a Repeat Load command, but has the added benefit of not being solved in its own right.

This converts a real load case to something similar to a load case definition. A reference load case is solved only when it is later called in a load case. The benefit is that it enables you to define as many load cases as you wish, but instruct the program to actually solve only a limited number of "real" load cases, thus limiting the amount of results to be examined.

Refer to TR.33 Reference Load Cases - Application (on page 2613) for details.

Notional Loads

A number of design codes require that a notional load be considered. Typically, this is defined lateral load equal to a percentage of the gravity loads. STAAD.Pro uses a feature similar to a the Repeat Load, but one that Primary and /or Reference load cases can be selected and a percentage of them can be applied in the appropriate global direction at each framing level.

These lateral loads are a requirement for some design codes (e.g., AISC 360-10).

Refer to TR.32.13 Notional Loads (on page 2610) for details.

Load Lists

A load list is primarily used to specify a list of existing load cases and load combinations to be used for subsequent processes, such as design, printing, etc.

Refer to TR.39 Load List Specification (on page 2662) for details.

Load Envelopes

Load Envelopes are a means for clustering a set of load cases under a single moniker (number). If one or more tasks have to be performed for a set of load cases (such as, serviceability checks under steel design for one set of load cases, strength checks under steel design for another set of cases, etc.) this feature is convenient.

This is an alternative to Load Lists, and is primarily used in post-processing and design. Load Envelopes also have keyword types which identify their intended use in design.

Refer to TR.40 Load Envelope (on page 2663) for details.

Load Definitions

Definitions contain the options you use to define data required to create wind load cases, seismic load cases like IBC and UBC, moving load cases, snow load cases, and time history load cases.

Refer to TR.31 Definition of Load Systems (on page 2345) for details.

GS. STAAD Input Files

A STAAD model consists of a data file made up of simple, English-language like commands, using a format native to STAAD.Pro. This file specifies all input, analysis, and output commands used to inform the STAAD engine as to the geometry of the structural model, loads acting on this model, and instructs the engine on the analysis and design operations to be performed.

There are two methods for building a model and assigning the structure data using STAAD.Pro:

a. using the graphical model generation, or
b. directly editing the command input file using the STAAD.Pro Editor

The graphical method of creation (a) involves using either the Analytical Modeling or Physical Modeling workflow to draw the model using the graphical tools, and assigning data such as properties, material constants, loads, etc., using the various tools and dialog boxes of that mode. In this approach, the command file is automatically created by the program while you work. The input command file is updated whenever your structure is saved.

The direct editing method (b) involves creating or editing the command input file (file extension `.std`) directly using the STAAD Editor utility. These commands are explained in detail in Technical Reference of STAAD Commands (on page 2196) and several examples which illustrate this method are provided in the Application Examples (on page 6251).

Tip: The command input file is a plain text file so you can use any plain text editing software you prefer. However, it is recommended you use the STAAD.Pro Editor as this program contains tools such as Intellisense to complete commands and syntax checking.

Tip: For a hands on illustration of both these methods, it is recommend that you take a look at the Tutorials (on page 387).

Regardless of the means used to *create* the STAAD input file, once the model is ready for analysis, you will use the graphical environment to initiate analysis, review the analysis and/or design output data, and perform advanced design operations.

GS. Object Properties Inspection

You can inspect the properties and results of most analytical and physical model objects by double-clicking them in the view window.

The dialog that opens reflects the type of object selected as well as the assigned specifications, properties, available analysis and design results, etc.

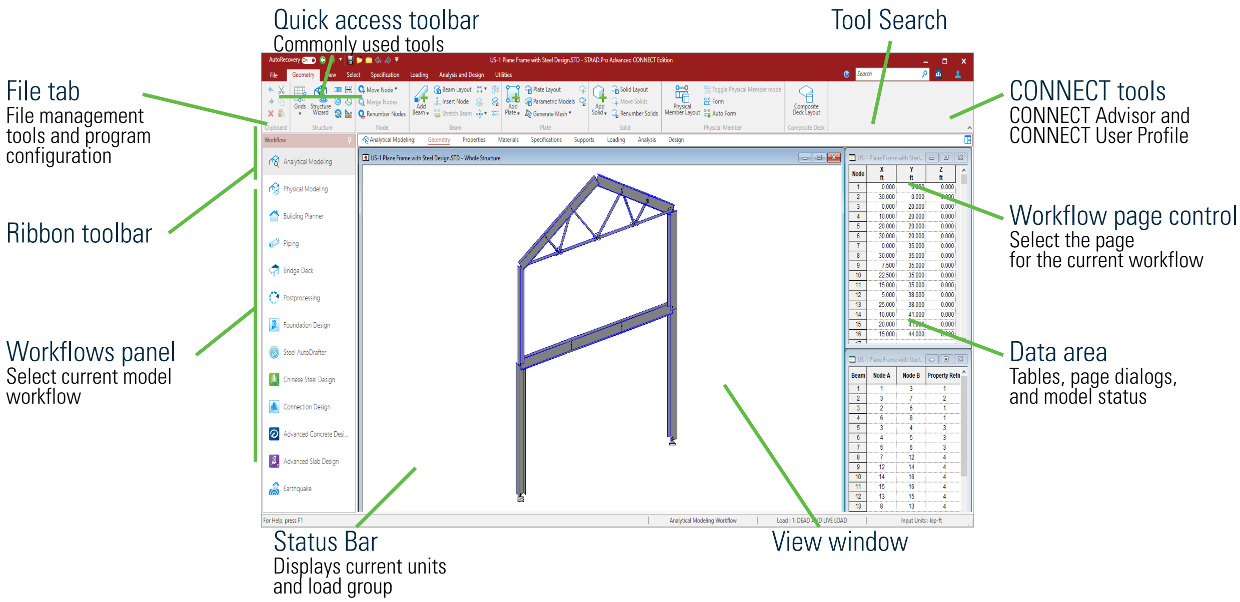
GS. Application Window Layout

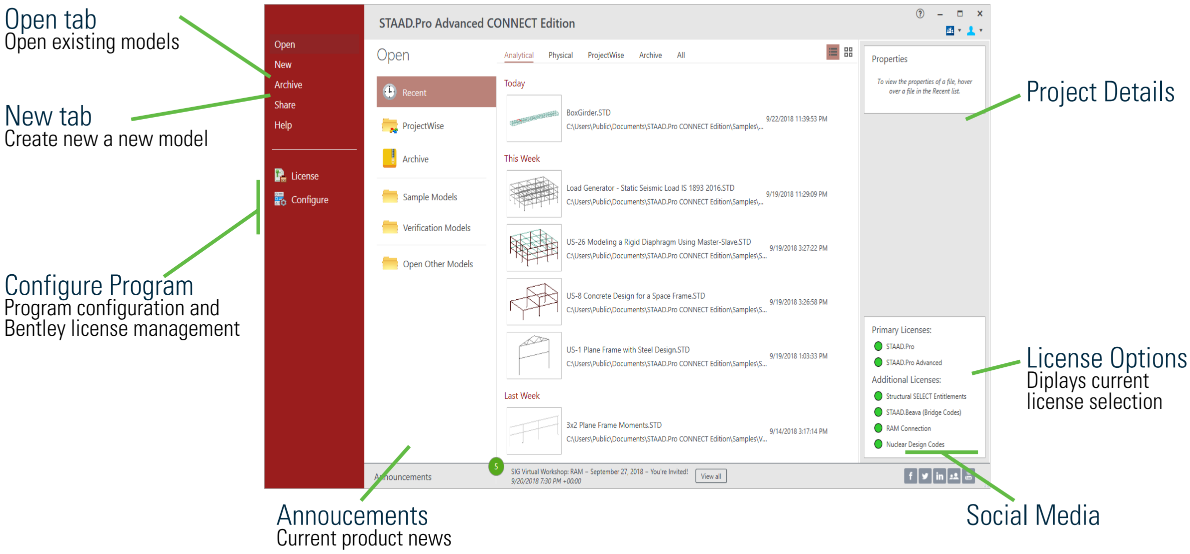
It is helpful to take some time to familiarize yourself with the components of the window.



1. File tab (on page 2694)
2. Ribbon Control Reference (on page 2694)
3. GS. Workflows in STAAD.Pro (on page 36)
4. GS. Quick Access Toolbar (on page 62)
5. GS. Tool Search (on page 64)
6. Bentley CONNECT Features (on page 2068)
7. GS. Page Control (on page 64)
8. GS.Data Area (on page 66)
9. GS. Status Bar (on page 84)
10. GS. View Window (on page 67)

GS. Start Page

The start page is displayed when STAAD.Pro opens or there is no model currently open.



Open tab

Used to open an existing STAAD input file or Archive. You can also open STAAD projects from a ProjectWise data source.

Select the **Recent** tab to view recent files by type. Hover your mouse pointer over any file to display the file and CONNECT Project properties.

The **Additional License** options are available here to allow you to select which license options you want to use before opening a file.

Tip: If you hover your mouse pointer over any item in the recent files list, you will see several tool icons on the right-hand side:

- **Pint to list** – pin this project to the top of the list
- **Remove from list** – remove this project from the list
- **Open Containing Folder** – open the folder where the project is saved in Windows Explorer

New tab

Used to create a new STAAD project. Options are available to start with an analytical model, a physical model, or in STAAD Building Planner.

The **Additional License** options are available here to allow you to select which license options you want to use before creating a file.

Archive tab

Used to create or extract STAAD.Pro archive files.

Share tab

Table 1: Share menu items

Tool name	Description
 **Send Mail**	Used to share STAAD.Pro project files as an e-mail attachment. The selected project files associated with a STAAD.Pro input file are saved as a STAAD.Pro ZIP file (file extension `.stz`).
 **ProjectWise**	Used to save STAAD.Pro project files to a ProjectWise data source. The selected project files associated with a STAAD.Pro input file are saved as a STAAD.Pro ZIP file (file extension `.stz`).

Help tab

Table 2: Help menu items

Tool name	Description
Contents	Opens the online help in your web browser.
OpenSTAAD Help	Opens the online help in your web browser to the OpenSTAAD reference section.
Technical Support	Opens the Worldwide Technical Support Resources dialog, which offers a map of worldwide technical support contacts for STAAD.Pro.
ReadMe	Opens the STAAD.Pro Read Me file in your web browser.
Knowledge Base and FAQs	Opens the STAAD.Pro Support Solutions page on Bentley Communities in your web browser.
Discussion Group	Opens the RAM | STAAD Forum on Bentley Communities in your web browser.
Tutorials	Opens the Bentley LEARNserver in your web browser. Here you can access training and learning paths for STAAD.Pro and other Bentley products.

Table 3: About menu items

Tool name	Description
About STAAD.Pro	Opens the About STAAD.Pro CONNECT Edtion dialog, which contains version, licensing, and legal information about the product. Any Technical Preview items contained in the current version will also be listed here.
Product News	Opens the STAAD.Pro product page at Bentley.com in your web browser.
Home Page	Opens the Bentley.com home page in your web browser.
Ideas	Provide feedback with any ideas you have to improve STAAD.Pro.

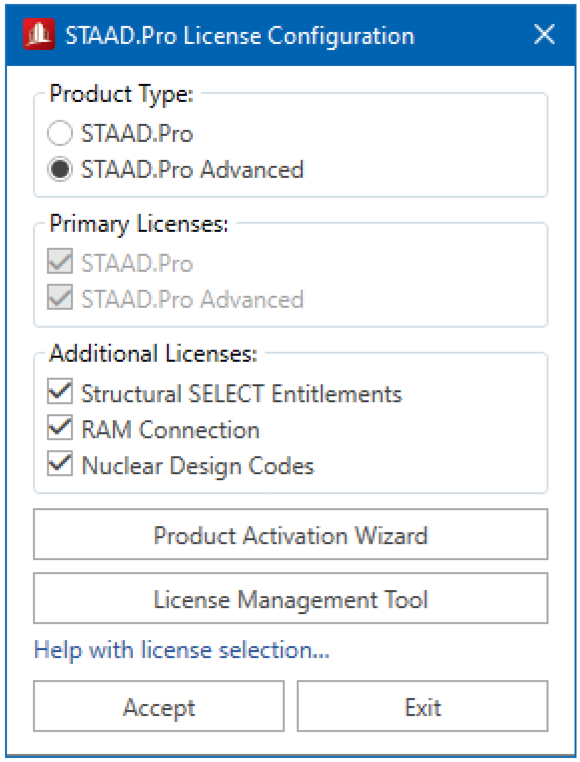
GS. **STAAD.Pro License Configuration** dialog

Used to manage license options for STAAD.Pro.

Opens when you select **License** from the Start page menu.



Product Type

Select the primary license to use for the application here.

- **STAAD.Pro** – using this license you will have access to the primary features and capabilities available in STAAD.Pro, including all design codes
- **STAAD.Pro Advanced** – The extends the basic STAAD.Pro application with additional capabilities such as an eigen-based advanced buckling analysis, geometric non-linear analysis, and other advanced analysis methods, a faster analysis solver, and access to advanced concrete design using RCDC.

Primary Licenses

This displays the status of each license type associated with your account.

Additional License

Select additional licenses to use:

- Structural SELECT Entitlements
- RAM Connection
- Nuclear Design Codes

Product Activation Wizard

Opens the CONNECT License Client Activation window, which is used to activate or to reserve a license.

License Management Tool

Opens the Bentley Licensing Tool window, which is used to manage your current license entitlements, managed reserved licenses, and review the status of product licenses available to you.

Help with license selection

Click to open the latest details on license selection information on Bentley Communities.

Accept

Save the changes to the license configuration and close the dialog.

Exit

Close the dialog without saving any changes to the license configuration.

- *GS. Starting STAAD.Pro* (on page 33)

GS. **Application Configuration** dialog

Used to set program-wide parameters for STAAD.Pro.

Opens when **Configure** is selected on the application Start page.

General tab

Language	Select the user interface language from the drop-down list. You must restart the program to see that language used in user interface.
Base Unit	There are two base unit systems in the program which control the units (length, force, temperature, etc.) in which, values – specifically results and other information presented in the tables and reports – are displayed. The base unit system also dictates what type of default values the program will use when attributes such as Modulus of Elasticity, Density, etc., are assigned based on material types – Steel, Concrete, Aluminum – selected from the program's library . These two unit systems are **English** (Foot, Pound, etc.) and **Metric** (KN, Meter, etc.)
Global Axis	Select which axis represents the gravity direction in your model by default. Subsequently all modeling, analysis, and post-processing items would be based on this coordinate system. Select either the **Y up** or **Z up** option. **Note:** Some features in STAAD.Pro require that Y up be used for the global axis orientation. **Note:** When the **Z up** option is selected in the **Application Configuration** dialog, then the **Physical** model option is disabled for creating new models.
Diagram Background	Select either a **White** or **Black** background for the view window. This selection will also set some default colors in which beams, plates and solids are drawn. For example, a white background is accompanied by black lines for drawing beams.
Theme	Select the basic color theme used in the application.

Options tab

Startup	**Display License Options**	Check this option during the application launch to be prompted with License Information dialog (see GS. Starting STAAD.Pro (on page 33)) listing enabled licensing options.
	Display STAAD News Feed	Check this option to open the news feed reader when the program starts.
	Display CONNECT Project Chooser when opening STAAD model	Check this option to display the CONNECT Project Chooser dialog when opening a STAAD model.

Analysis	**Warn if analysis performed across network**	Check this option to receive a warning if the analysis file is located on a network location. In some network instances, this can cause a drastric increase in analysis time.
	Use temporary location	Check this option to use a temporary location on your local computer for analysis. This can improve analysis speed for network files. The **Folder** used can be typed in or selected using by clicking **Browse**.
Additional Options	**Save Auxiliary Data on close**	During the course of performing analysis, design, and post-processing operations, multiple files associated with a STAAD project are generated. Set this option to direct the program to save all files in the STAAD project when the project is closed.
	Delete Results Data If Out of Sync	Set this option to delete results files when a project is opened if the input file has been modified more recently than those input files. This option is helpful in ensuring that results invalidated by recent changes to the input file will not be used in error.
	Remove Bentley (B) logo from Report	Set this option to remove the Bentley logo from reports generated in STAAD.Pro. **Tip:** You can always add a custom logo and branding to your reports.
	Save AutoRecovery information every X minutes	Check this option and specify the AutoRecovery time interval in order to have the program automatically save a backup of your program status. In the event of a program crash, the program will detect the autorecovery file the next time you open the STAAD project and prompt you to open the recovered state.

File Format tab

Input format	**Single Line Format Commands**	Select whether **Joint** coordinates as well as **Member**, **Plate**, and **Solid** incidences will be written one per input line or multiple per input line by setting the associated options here.
	Write expanded list	Set this option to instruct the program to write out joint, member or element numbers individually, for example: `1 2 3 4 5` instead of `1 TO 5` and consequently, creates voluminous input.
	Joint Coordinate Significant Figures	Specify the number of significant digits used for nodal coordinates. This is used for models which require a high degree of precision.
Output format	**Add key file information**	Set this option to Instruct the program to list all the key files that were used with the analysis including the date of the principal files. **Note:** Even if the general case is that the Key Information is displayed, it can be tuned off in a particular analysis if the data file contains the command `SET NOFILE`.

Error format	**Create Error File**	You may choose not to have the error file created at all, though this isn't advisable. Un-check the box provided for that purpose if you choose to do so.
	Log maximum errors per single input	A single line of input may contain more than one error. We can set how many such errors we want shown for each input line.
	Log maximum errors	You can also set the maximum number of errors you want reported for the entire file. That number is 100 by default.

Design Codes tab

STAAD.Pro supports several major international design codes. Select the default design code to use when selecting the material-based design in the program.

Note: You may not use more than one design code in one single run, even if the Input Command File has more than one `CODE` command. Also note the design code specified by the Design Code tab must match that specified in the Input Command File.

Section Database tab

Select this tab to open the Section Database dialog, which is used to select the default catalog section database file to use for each country. You can also specify user-defined tables for use in the program.

Workflows tab

Select this top to choose which workflows are displayed in the **Workflows** panel of the application.

Related Links

- *GS.To change the system units* (on page 43)
- *GS. To customize the workflows panel* (on page 39)

GS. To remove missing files from the recent files list

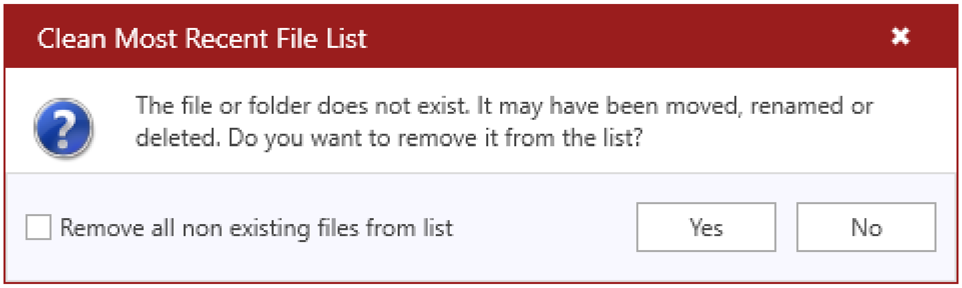
If you have some files that have moved or cannot be accessed currently, you can remove them from the recent files list on the Start page by using the following procedure.

You can access the **Recent** files list from the program Start page when no models are open.

Though this procedure is entirely optional, having many recent files can slow the performance of STAAD.Pro when opening the program.

1. Click on the yellow information icon that indicates a missing file.

   A message dialog opens with the option to remove this file entry from the list.



2. (Optional) You can check the **Remove all non existing files from list** option to remove all the files that are missing.
3. Click **Yes**.

GS. Quick Access Toolbar

The quick access toolbar is located just above the ribbon controls. It contains some of the most frequently used tools in a convenient location.

To customize the Quick Access Toolbar by adding other tools, click the menu arrow and then select **More Commands**. The **Customize Quick Access Toolbar** dialog opens, which allows you to select which tools are displayed in the Quick Access Toolbar.

Note: The **Command File** and **Analysis Output** are hidden by default. Click the menu arrow in the to toggle the display of these or other tools.

Table 4: Default Quick Access Toolbar tools

Tool	Description	Shortcut
 **AutoRecovery**	Used to toggle the AutoRecovery feature on and off. This can be helpful if AutoRecovery causes performance issues with larger model files.	
 **Back**	Navigates to the previous workflow page.	
 **Forward**	Navigates to the next workflow page in the page history. **Note:** Click the down arrow next to this tool to jump to a page anywhere in the page history. A checkmark is placed by the current page.	

Tool	Description	Shortcut
 **Save**	Saves any changes made to the current model. Saves any changes made to the current model.	**<Ctrl+S>**
 **Open**	Opens the Start page open tab, which is used to select a model to open in the program.	**<Ctrl+O>**
 **Close**	Closes the current model and returns to the Start page.	
 **Undo**	Undoes the previous operation.	**<Ctrl+Z>**
 **Redo**	Undoes the previous undo operation.	**<Ctrl+Y>**
 **Command File**	Opens the current input command file (file extension `.std`.) in the STAAD.Pro Editor. If any change has been made in the structure that has not been saved, you are prompted to save the structure first. **Note:** Refer to I. STAAD.Pro Editor (on page 2043) for additional assistance.	
 **Analysis Output**	Opens the results of a successful Analysis and Design run in the STAAD.Pro Editor window.	

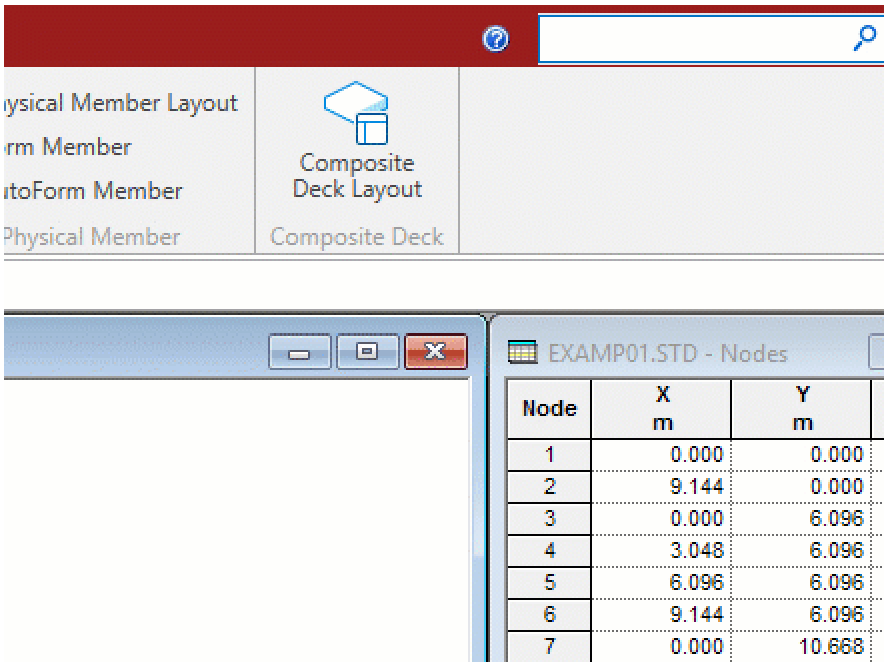
Related Links

- *I. To enable auto-recovery* (on page 2065)

GS. Tool Search

You can search for any tool by typing part of the name in the Search field.

Tip: Hover your mouse pointer over any search result to see the location of the tool in each workflow, ribbon tab, and group.



In the search results drop-down, click **Show Details** to display the tool tip description for each tool in the results list.

GS. Page Control

Within each workflow, there are a series of Pages available which layout the order of that workflow.

Though not required, it is recommended to work from left to right along the pages within any workflow.

Tip: If you close some of the dialogs for a page and need to display them again, simply click the **Restore View** tool () on the right-hand side of the page control bar.

Tip: You can use the **Navigate Backward** and **Navigate Forward** buttons found in the Quick Access Toolbar to move along your page navigation history.

Note: The **Physical Modeling** workflow and **Concrete Design** workflow do not have pages, but instead launch separate application windows.

GS.Data Area

The dialogs and tables to enter and review data for your model open along the right-hand side of the View window.

As you select different workflows and pages in each workflow, the data area updates with the corresponding dialogs and tables for that page.

GS. View Window

The graphical view window allows you to view the model or portions of the model using selected views.

This is where the model drawings and results are displayed in graphical form. You can use tools to draw your mode model as well as graphically assign loads or specifications.

GS. Right-Click Pop-up Menu

Provides convenient access to frequently used tools and utilities. The menu pops up when the right mouse button is clicked.

Note: Some of the items in the menu are context-sensitive - that is, they vary depending on previous actions or selected elements in the window.

No Selection

Menu item		Description
Cut		Used to cut selected object(s) (delete and copy to clipboard). The deleted objects may then be pasted.
Copy		Used to copy selected object(s) to clipboard for subsequent pasting.
Paste		Opens the **Paste With Move** dialog, which is used to specify the insertion point for pasting clipboard elements into the model.
Select Cursor >	Nodes	Used to graphically select nodes.
	Beams	Used to graphically select beams.
	Plates	Used to graphically select plates.
	Surface	Used to graphically select surface elements.
	Solids	Used to graphically select solids.
	Plates & Solids	Used to graphically select plates and solids with one cursor (ignores other object types).
	Geometry	Used to graphically select nodes, members and elements of the structure simultaneously. To select nodes, members or elements using the Geometry Cursor, simply click on the desired structural components. To select multiple nodes, members and elements, hold **<Ctrl>** while selecting. We may also select the structural components graphically by creating a window on screen with the cursor around these components.

Menu item		Description
	Physical Member	Used in Steel Design or Concrete Design to graphically select all those beams defined as a same member in the member set up of member design, simultaneously. Members may be user defined or may be generated automatically using the Auto Form Member tool. To select all the beams defined as a same member using the Member Cursor, just click on one beam. The other beams having the same member name as the selected one will automatically be selected. To select multiple physical members, hold down **<Ctrl>** while selecting. You may also select the physical members graphically by dragging a fence area around these physical members using the cursor.
Selection Mode >	Drag Box	Click to activate the drag box selection mode.
	Drag Line	Click to activate the drag line selection mode.
	Region	Click to activate the region selection mode.
Take Picture		Used to take a snapshot image of current view. The picture is automatically added to a picture album.
Add Beam		Used to add beam by clicking start and end nodes.
Tables		Opens the **Tables** dialog, which is used to display and close different tables, such as Node coordinates, Beam incidences, Node displacements, etc. irrespective of the current page.
Connection Tags >	View Connection Tags	Opens the **Assign Connection Tags** dialog.
	Check Connection Tags	(Active only after a successful analysis has been performed) Opens the **Assign Connection Tags** dialog and **Check Connection Tags** dialog, the latter of which is used to check the load case results from the analysis against the defined connection capacities in the Connection Tags XML data file.
Open View		Opens the **Open View** dialog, which is used to open a previously saved structural view window.
Labels		Opens the **Diagrams** dialog to the **Labels** tab, which is used to select various display labels for different components of the structure.
Orientation		Opens the **Orientation** dialog, which is used to modify the settings that define various view orientations of the structure, such as Plan view, Elevation view, Perspective view, etc.

Menu item	Description
Structure Diagrams	Opens the **Diagrams** dialog, which is used to customize the view of the structure by setting different view-related parameters.
Model View Details	Opens the **Structural Diagram Info** dialog, which contains counts of the objects in your model.
3D Rendering	Used to render the model using true lighting, reflection and shading in a separate window. It enables walk-through, dynamic zoom and panning capabilities in the 3D rendered view. Once the 3D Rendering option is chosen, a separate window opens displaying the rendered view. The structure can be dynamically rotated about all three axes by simply holding the left mouse button down and dragging the structure in the intended direction. Right-clicking the mouse button will display a myriad of viewing options. Depending on the material used (steel, concrete, etc.), an appropriate texture will be applied to the structure. A property or material must be assigned to the entities of the model before this feature can be used. This is for visual and presentation purposes only.

Beam Selection

Menu item		Description
Move		Opens the Move Entities dialog, which is used to specify the translational offset for moving a selection of beams.
Insert Node		Opens the **Insert Node into Beam #** dialog, which is used to insert one or more nodes at specified distances along selected members.
Form Member		Used to manually form a physical structural member from a selection of one or more connected analytical beam segments.
Assign Loads		
Properties		Opens the **Beam** dialog which displays properties for the selected member. Additional tabs become available after analysis and design is performed.
Define Section Profile		(disabled)
Connection Tags >	Assign	Opens the **Assign Connection Tags** dialog and **New Connection tag** dialog, which are used to assign existing connection tags to member ends in the model and to create new connection tags, respectively.

Menu item		Description
	Remove	Opens the **Assign Connection Tags** dialog and initiates the remove connection tag tool for the connections on the selected member. A confirmation dialog opens to confirm the remove action.
New View		Opens the **New View** dialog, which is used to create a new view window for displaying the selected structural elements. You are prompted to indicate whether the selected view would be opened in a new (child) window or whether it would replace the current (parent) view. Any number of “child” view windows in this way. **Note:** This option becomes active only after you select one or more structural elements on screen.
Create Seismic Frame		Opens the **Seismic Frames** dialog, which is used to specify the type of seismic frame used for the selected members creating a seismic frame definition during connection design.
Add Member Attribute		Opens the Member Attribute which is used to select and apply a member attribute to selected members. Refer to TR.29.1 Struclink Member Attribute (on page 2340) for additional information on the Struclink attribute which is assigned using this dialog.
List/Delete Member Attribute		Opens the Member Attribute dialog to display the currently used Member Attribute for a single selected member.

GS. Right-Click View Tools menu

Hold **<Shift>** when right-clicking in the View window to display the **View** ribbon tab **Tools** group at the mouse pointer.

Table 5: Tools group

Tool name	Description	Shortcut
 **Zoom Window**	Used to define the boundaries of a rectangular area of the active view to be displayed within the current view.	
 **Whole Structure**	Fits the current view to display the entire structure limits. Resets view rotation to orthogonal.	

Tool name	Description	Shortcut
 **Zoom In**	Zoom in the current view by a preset percentage magnification.	scroll wheel up
 **Zoom Out**	Zoom out the current view by a preset percentage magnification.	scroll wheel down
 **Pan**	Used to view a different part of the design without changing the view magnification. **Tip:** Press and hold the middle mouse button (typically the scroll wheel button) to quickly pan in the view window.	
 **Zoom Extents**	Adjusts the view magnification so that the entire model is visible in the view.	
 **Zoom Factor**	Opens the **Zoom Factor** dialog, which is used to zoom in or out of the structure by specifying a magnification factor. Factors less than one Zoom out.	
 **Zoom Previous**	Undoes the last **Zoom Factor** or **Zoom Window** operation.	
 **Dynamic Zoom**	Used to define the boundaries of a rectangular area of the active view to be displayed within a new view. The previous view window highlights the location of the zoomed portion.	

Tool name	Description	Shortcut
 **Magnifying Glass**	Provides a magnified portion of the current view window when you click and drag the pointer.	
 **Isometric View**	(Default view) View the model as an isometric projection.	
 **Front View**	View the structure model from the positive Z axis.	
 **Left View**	View the structure model from the negative X axis.	
 **Top View**	View the foundation mode in plan; from the positive Y axis.	
 **Back View**	View the structure model from the negative Z axis.	
 **Right View**	View the structure model from the positive X axis.	

Tool name	Description	Shortcut
 **Bottom View**	View the structure model from the negative Y axis.	
 **Rotate Up**	Rotate the structure model forward about the X axis.	**<↑>** (Up arrow key)
 **Rotate Left**	Rotate the structure model forward about the Y axis.	**<←>** (Left arrow key)
 **Spin Left**	Rotate the structure model forward about the Z axis.	**<Ctrl+←>** (Ctrl +Left arrow keys)
 **Rotate Down**	Rotate the foundation mode backward about the X axis.	**<↓>** (Down arrow key)
 **Rotate Right**	Rotate the structure model backward about the Y axis.	**<→>** (Right arrow key)
 **Spin Right**	Rotate the structure model backward about the Z axis.	**<Ctrl+→>** (Ctrl +Right arrow keys)

Tool name	Description	Shortcut
 **Toggle View Rotation Mode**	Used to select an node as the center of rotation. When toggled on, pressing **<Ctrl+Shift>** and clicking a node will set that node as the center of rotation.	
 **Orientation**	Opens the **Orientation** dialog, which is used to modify the settings that define various view orientations of the structure, such as Plan view, Elevation view, Perspective view, etc.	**<F4>**
 **Always Fit in Current Window**	Instructs the program on what guidelines to use when drawing a selected set of objects on the screen. It displays the selected portion of the model to a size governed by optimum usage of the dimensions of the current window. When you select various tools the program or switch workflows the size of the drawing window frequently changes. With this tool turned on, the model or selected portions of it, will be drawn in such a manner that all the entities will be drawn within the bounds of the drawing area. This means, the size to which the entities are drawn will correspondingly increase or decrease. With this tool turned off, the size of the entities will remain constant, but that means it may or may not fit within the bounds of the drawing window.	

GS. Quick Commands Pop-up menu

This menu Opens when you press the space bar when the View window has the application focus.

You can customize the Quick Commands with any tool by clicking the icon and then adding tools from the **Customize Quick Commands Popup** dialog.

Table 6: Selection group

Tool name		Description
 **Geometry >**	**Geometry Cursor**	Used to graphically select nodes, members and elements of the structure simultaneously. To select nodes, members or elements using the Geometry Cursor, simply click on the desired structural components. To select multiple nodes, members and elements, hold **<Ctrl>** while selecting. We may also select the structural components graphically by creating a window on screen with the cursor around these components.
	All Geometry	Selects all nodes, members, elements, and solids in the model.
	Inverse Geometry Selection	Used to select all objects but the ones which are currently selected.
	Geometry List	Opens the **Select Geometry** dialog, which is used to select one or more model entities (other than nodes) from a list of all entities in the model.
	Entities Parallel To > **XY** | **YZ** | **XZ**	Used to select all beams, elements, and surfaces which are parallel to a specified global axis. Select the desired global axis from the sub-menu.
	Geometry Connecting To > **Node** | **Beam** | **Plate** | **Solid**	Used to find out all the entities that are connected to (i.e., have a common node with) any particular node, beam, plate, or solid. A dialog opens prompting you to select the node, beam, plate, or solid number. You can select to apply immediately or click OK to see all the model entities that are connected to the selection.
	Highlight Entities Sequentially	Opens the **Visual Check** dialog, which is used to sequentially highlight a specific group of entities (beams, plates, or solids) in numerical order. Controls on the speed of the selection are also included.
 **Solids >**	**Solids Cursor**	Used to graphically select solids.
	All Solids	Selects all solids in the model.
	Inverse Solids Selection	All solids in the selection set are deselected and any previously unselected solids are added to the selection set.
	Solids List	Opens the **Select Solids** dialog, which is used to select one or more solids from a list of all solids in the model.

Tool name		Description
	Solids Connecting To > **Node | Beam | Plate | Solid**	Select solids that connect to the selected object type.
 **Members**		Used in Steel Design or Concrete Design to graphically select all those beams defined as a same member in the member set up of member design, simultaneously. Members may be user defined or may be generated automatically using the Auto Form Member tool. To select all the beams defined as a same member using the Member Cursor, just click on one beam. The other beams having the same member name as the selected one will automatically be selected. To select multiple physical members, hold down **<Ctrl>** while selecting. You may also select the physical members graphically by dragging a fence area around these physical members using the cursor.
 **Nodes >**	**Nodes Cursor**	Used to graphically select nodes.
	All Nodes	Selects all nodes in the model.
	All Supports	Selects all supported nodes in the model.
	Inverse Node Selection	All nodes in the selection set are deselected and any previously unselected nodes are added to the selection set.
	Nodes List	Opens the **Select Nodes** dialog, which is used to select one or more nodes from a list of all nodes in the model. A free list of node numbers may also be specified.
 **Beams >**	**Beams Cursor**	Used to graphically select beams.
	All Beams	Used to select all beams.
	Inverse Beam Selection	All beams in the selection set are deselected and any previously unselected beams are added to the selection set.
	Beam List	Opens the **Select Beams** dialog, which is used to select one or more beams from a list of all beams in the model.
	Beams Parallel To > **X | Y | Z**	Select beams that are parallel to the selected global axis.

Tool name		Description
	Beams Connecting To > **Node** | **Beam** | **Plate** | **Solid**	Select beams that connect to the selected object type.
 **Plates >**	**Plates Cursor**	Used to graphically select plates.
	All Plates	Selects all plates in the model.
	Inverse Plate Selection	All plates in the selection set are deselected and any previously unselected plates are added to the selection set.
	Plate List	Opens the **Select Plates** dialog, which is used to select one or more plates from a list of all plates in the model.
	Plates Parallel To > **XY** | **YZ** | **XZ**	Select plates that are parallel to the selected global axes plane.
	Plates Connecting To > **Node** | **Beam** | **Plate** | **Solid**	Select plates that connect to the selected object type.
 **Text Cursor**		Used to add comments and titles to pictures and result diagrams. The added text can be plotted, too. The inserted text can be deleted, moved and modified using the text cursor. Refer to the **Insert Text** on the **Utilities** ribbon for a detailed description on inserting text and modifying it using the text cursor.
 **Filtered Selection Cursor**		Used to select multiple types of geometric entities (nodes, beams, surfaces, etc.) with specific attributes in one pass. This will reduce the time required to create new views and help quickly identify the location of certain entities on your structure. **Note:** Before this cursor can be used, the actual filter parameters must be defined in advance in the **Selection Filters** dialog.
 **Group Selection**		Opens the **Select Groups** dialog, which is used to select objects in a named group.

Tool name	Description
 **By Property Name**	Used to select nodes and members based on specifications associated with them. A number of specification types are included in the sub-menu list.
 **Missing Properties**	Used to select beams, plates, or solids that lack critical input data (Property, Density, Elasticity, Poisson's ratio, and Alpha) in the active view.
 **Drag Box**	Click to activate the drag box selection mode.
 **Drag Line**	Click to activate the drag line selection mode.
 **Region**	Click to activate the region selection mode.
 **Previous Selection Cursor**	Selects the last object(s) selected (if they have been deselected).
 **Loads Cursor**	Used to modify any load already applied on the model by double clicking it.. When selected, the mouse pointer changes to the Load Edit Cursor.

Table 7: Labels group

Tool name	Description	Shortcut
Labels Settings	Opens the **Diagrams** dialog to the **Labels** tab, which is used to customize the view of the structure by setting different view-related parameters.	
Node Labels	Select any of the label types from the drop-down list to turn the display of that label on or off. **Tip:** Additional labels are controlled on the **Diagrams** dialog **Labels** tab.	**<Shift+N>**
Beam Labels		**<Shift+B>**
Plate Labels		**<Shift+P>**
Solid Labels		**<Shift+C>**
Individual Node Labels	When the object label type is activated, use these tools to show or hide the individual labels of objects. This can be useful for large models or views where you wish to display multiple types of labels simultaneously. **Note:** These tools require you to select the **Always Use Current Label Settings** option and then check the **Use Partial Labeling Mode** option on the **Diagrams** dialog **Labels** tab.	
Individual Beam Labels		

Tool name	Description	Shortcut
Individual Plate Labels		
Individual Solid Labels		

Table 8: Display group

Tool name	Description
Load	Select the active load case, load combination, or load envelope from the pop-up dialog.
View Loading Diagram	Click to toggle the display of the current load case on the structure.

Table 9: Geometry Tools group

Tool Name		Description
Structure Tools >	**Multiple Structures**	Opens the **List of Structures** dialog, which is used to determine if the current model consists of more than one unconnected structure. Select a Structure in the list to see each structure highlighted.
	Beam Plate Connectivity	Used to check for plates that are improperly connected to beams. Beams must be connected to plates at their nodes in order to ensure proper coupling and load transfer. This tool will inform the user if any improper connections are present in the model.

Tool Name		Description
	Merge Properties	Used to merge the properties of two or more similar objects. When a STAAD input file has a number of references of the same property, this tool can be used to consolidate all these properties into a single command. When a STAAD file has a number of references of the same property, there is now a tool to consolidate all these properties into a single command. Clicking the Yes button, all instances of a given section property will be collated into a single property reference. **Note:** Properties references with differing additional parameters will not be collated. Properties references with differing assigned material properties will not be collated.
	Cut Section	Opens the **Section** dialog, which is used to cut a section through the structure along a specified global plane at a desired location of the 3rd axis.
 **Node Tools >**	**Duplicate Nodes**	Opens the **Remove Duplicate Nodes** dialog, which is used to set the tolerance distance between two nodes the program should consider as duplicate. Used for detecting the presence of two or more instances of the same node.
	Orphan Nodes	Highlights all nodes in the structure which are not connected to any member, element, or solid.
	Remove Orphan Nodes	Used to remove all detected orphan nodes.
	Node to Node Distance	Display the distance between nodes.
	Remove Node to Node Distance	Used to remove the display of all node to node dimensions from the current view.
 **Beam Tools >**	**Duplicate Beams**	Opens the **Remove Duplicate Beams** dialog, which is used to set the tolerance distance between two beams the program should consider as duplicate. Used for detecting the presence of two or more instances of the same beam.

Tool Name		Description
	Zero Length	Opens the **Zero Length Tolerance** dialog, which is used to set the tolerance for zero length members. A member connected between duplicate nodes, which have the same (X,Y,Z) coordinates, will have a length of zero. This tool detects such members.
	Overlapping Collinear Members	When two members are collinear, and further, at least one of the nodes of one of those members happens to lie within the span of the other, but the two members are not connected at that node, those two members are considered as overlapping collinear members. This tool detects such members. The usefulness of this tool comes from the fact that it enables you to detect modeling errors which are not easily visible. Two lines overlapping on the drawing area become indistinguishable on large models, and this is one of the tools that can spot such errors.
	Beam Incidence	Used to reverse the incidence of selected beams so that the global coordinates of the end node are farther from the origin than that of the start node.
	Dimension Beams	Display the dimension of the members in the structure.
 **Plate Tools >**	**Duplicate Plates**	Opens the **Remove Duplicate Plates** dialog, which is used to set the tolerance distance between two plates the program should consider as duplicate. Used for detecting the presence of two or more instances of the same plate.
	Warped Plates	A warped plate is defined as a four-noded plate whose nodes do not lie on the same plane. This tool detects such plates.
	Plate Connectivity	Checks the model for plates that overlap or intersect each other at their boundaries and, if found, opens the Overlapping Collinear Plates dialog. Typically, these overlaps cause improper load transfers or instabilities in the model.
 **Solid Tools >**	**Negative Volume**	Used to verify that the solid elements in their model have the proper sequence (order) of node numbering to prevent warnings in the output file of solids containing negative volumes.
	Warped Solids	Used to check if a solid element is warped. Warped solids cannot be analyzed and will produce errors in the output file.

Tool Name	Description
 **Physical Member Restraints**	Used to automatically generate top and bottom flange restraint conditions for the selected physical members. **Note:** The PBRACE command generated by this menu item is valid only for D2.B.12 Physical Member Design (on page 1372) per AS 4100-1998 (Australian) steel design. When selected, the program will search through all the nodes along the Physical Member and determine if any other beam is connected besides the beams in the current physical member definition. If another beam is present, a full restraint is placed on both the flanges. Otherwise, an unrestrained condition is imposed on both the flanges.
 **Groups**	Opens the **Create Group** dialog, which is used to cluster a set of joints, beams, plates or solids into a single entity identified by a distinct name. **Note:** If no groups exist, you will be prompted to create a group using the **Define Group Name** dialog.

Table 10: Tools group

Tool Name		Description
 **Connection Tags >**	**Load Connection Tag File**	
	Edit Connection Tag File	
	View Connection Tags	Opens the **Assign Connection Tags** dialog.
	Check Connection Tags	(Active only after a successful analysis has been performed) Opens the **Assign Connection Tags** dialog and **Check Connection Tags** dialog, the latter of which is used to check the load case results from the analysis against the defined connection capacities in the Connection Tags XML data file.
 **Calculator**		Opens the **STAAD.Pro Calculator** window, which is capable of performing mathematical operations.

Tool Name	Description
 **Unit Converter**	Opens the **STAAD.Pro Converter** window, which is used to convert data from one unit system to another.
 **Take Picture**	Used to take a snapshot image of current view. The picture is automatically added to a picture album. **Tip:** The picture is stored in a STAAD-native format and can be subsequently included in custom reports during Report Setup. The Copy Picture and Export View tools may be used to copy a model image or to save it to a common file format.
Copy Picture	Used to copy the current picture to the clipboard for pasting in other Windows applications such as image editors, spreadsheet applications, or word processors,.
 **AVI File**	Opens the **Create AVI File** dialog, which is used to create a video file recording of for animated deflection, section displacement, mode shape, and plate stress contour diagrams.

GS. Status Bar

The program window status bar displays the current workflow along with tips on next actions based on the current tools. The active load case and current input units are also displayed.

GS. Keyboard Shortcuts

Shortcut keys for menu commands are indicated in the menus and/or related dialog boxes.

Note: Most ribbon tabs are accessible by pressing the **<Alt>** key and then the letter key corresponding in the tooltip over that ribbon tab. STAAD.Pro also supports shortcut keys for window and dialog box navigation and other functions.

Table 11: Working with files

Action	Shortcut
Create a new STAAD.Pro project file.	**<Ctrl+N>**
Open an existing STAAD.Pro project file.	**<Ctrl+O>**

Action	Shortcut
Save the current project file.	**<Ctrl+S>**
Print the output report.	**<Ctrl+P>**
Quit the program.	**<Alt+F4>**

Table 12: Editing models

Action	Shortcut
Undo an action.	**<Ctrl+Z>**
Redo an action	**<Ctrl+Y>**
Cancel an action.	**<Esc>**
Copy a selected element.	**<Ctrl+C>**
Paste an element from the clipboard.	**<Ctrl+V>**
Cut an element (copies the selected element to the clipboard and deletes the selected copy).	**<Ctrl+X>**
Delete a selected element.	**<Del>**
Move selected objects.	**<F2>**

Table 13: Navigating the view window

Action	Shortcut
Rotate model up or down in the view window.	Up or Down arrow keys (<↑>, <↓>)
Rotate model left or right in the view window.	Left or Right arrow keys (<←>, <→>)
Spin mode left or right in the view window.	**<Ctrl+Left>** or **<Ctrl+Right>** arrow keys
Close the current active view; except when the active view is the main structure view.	**<Ctrl+F4>**
Open the **Orientation** dialog, which is used to precisely control the zoom and rotation of the active view window.	**<F4>**
Refresh the active view window.	**<F5>**
Tile all view windows, tables, forms, etc. horizontally.	**<Shift+F4>**
Cascade all view windows, tables, forms, etc.	**<Shift+F5>**

Action	Shortcut
Tile all view windows, tables, forms, etc. vertically.	**<Ctrl+Shift+F4>**
Animation in full screen (Postprocessing mode).	**<F12>**
Restore default window layout for the current page.	**<Ctrl+Tab>**

Table 14: Working with models

Action	Shortcut
Create a new group from selected entities.	**<Ctrl+G>**
Initiate the analysis and, if used, batch design for the current input file.	**<Ctrl+F5>**
Open the relevant help topic.	**<F1>**

Table 15: Toggling the display of model labels

Action	Shortcut
Display member specifications (i.e., truss, beta angle, etc.).	**<Shift+A>**
Show axes window.	**<Ctrl+Shift+A>**
Display beam numbers.	**<Shift+B>**
Display the design brief for physical members.	**<Ctrl+Shift+B>**
Display solid element numbers.	**<Shift+C>**
Display dimensions.	**<Shift+D>**
Display the beam ends, color coded for start and end.	**<Shift+E>**
Display the design envelope for physical members.	**<Ctrl+Shift+E>**
Display floor loading.	**<Shift+F>**
Show the diagram information.	**<Shift+G>**
Display the design group for physical members.	**<Ctrl+Shift+G>**
Display the wind load tributary area.	**<Shift+H>**

Action	Shortcut
Show axes at origin. Axes are color-coded: X is blue, Y is red, and Z is green. 	**<Shift+I>**
Display the entity reference numbers.	**<Shift+J>**
Display node point labels.	**<Shift+K>**
Display the control-dependent links.	**<Shift+L>**
Display the material label for each entity.	**<Shift+M>**
Display physical member numbers.	**<Ctrl+Shift+M>**
Display node numbers.	**<Shift+N>**
Display the local beam axis (beam orientation). Local axes are color-coded: x is blue, y is red, and z is green. 	**<Shift+O>**
Display plate element numbers.	**<Shift+P>**
Display surface element numbers.	**<Ctrl+Shift+P>**
Display member/element releases.	**<Shift+R>**
Display the support node labels.	**<Shift+S>**
Display the local plate element axis (plate orientation).	**<Shift+T>**
Display the local surface element axis (surface orientation).	**<Ctrl+Shift+T>**

Action	Shortcut
Display load values.	**<Shift+V>**
Display wind loads.	**<Shift+W>**
Display member sections.	**<Shift+X>**
Display the floor load distribution.	**<Shift+Y>**

Table 16: Model rendering

Action	Shortcut
View the analytical model (no outline)	**<Ctrl+0>**
View the model in wireframe (outline of members)	**<Ctrl+1>**
View the model filled (members drawn solid)	**<Ctrl+2>**
View the rendered model window	**<Ctrl+4>**

GS. Services and Support Information

These resources are provided to help you get answers for your technical questions on STAAD.Pro.

Service Request Manager

http://apps.bentley.com/srmanager/ProductSupport — Create and track a service request using Bentley Systems' online site for reporting problems or suggesting new features.

Communities Support

https://communities.bentley.com/support — Find solutions to issues, get answers to questions, or get priority assistance for critical issues.

FAQ and TechNotes

https://communities.bentley.com/products/structural/structural_analysis___design/w/structural_analysis_and_design__wiki/4057.staad-pro-support-solutions

Forums

http://communities.bentley.com/products/structural/structural_analysis___design/f/5932 — Post questions in the Bentley Communities forums to receive help and advice from fellow users and members of Bentley's product support groups.

GS.Nuclear Safety Related Features

An installation of STAAD.Pro provides users with an extensive set of features and capabilities. It is recognized that STAAD.Pro can be used on projects that require the highest level of safety such as nuclear power stations. Therefore, a set of key features as listed below have been defined as "Nuclear Safety Related Features." For any user who has signed up to the QA&R program, any serious defect discovered in any of these features in a build of STAAD.Pro supplied as part of the QA&R that is determined to be of Critical or High Severity, will be notified as per the reporting requirements.

The following input command driven features of STAAD Analysis and Design engine under default axis system (Y-up) are consider as "Nuclear Safety Related Features" of the software product.

1. Static Analysis
   a. first order elastic analysis
   b. P-Delta analysis
2. Dynamic Analysis
3. Features related to application of general loadings applied at/on nodes, members, plates and solids.
4. Features related to application of local boundary conditions (e.g., member releases, offsets etc.)
5. Features related to application of global boundary conditions (e.g., fixed, pinned, fixed but, spring supports)
6. Automated load generation features as per US codes (e.g., ASCE, IBC, UBC) such as:
   a. Wind load generation per ASCE 7
   b. Seismic load generation
   c. Response spectrum load generation
   d. Moving load generation

Design Codes:

1. The following STAAD command file driven Steel design are available:
   a. AISC 360-2016
   b. AISC 360-2010
   c. AISC 360-2005
   d. AISC ASD 9th Edition (1989)
   e. AISC LRFD 2nd Edition (1994), 3rd Edition (2001)
   f. AISC N690 1984 and 1994 with Supplements S1 and S2
   g. ASME NF3000 1974, 1977, 1989, 1998, and 2004
   h. CAN/CSA S16-14
   i. CAN/CSA S16-09
2. The following STAAD command file driven Concrete design are available:
   a. ACI 318 1999, 2002, 2005, 2008, 2011

The "Nuclear Safety Related Features" are limited to the STAAD Analysis & Design engine only. Note that any other features, such as the graphical user interface and interfaces to link to external applications such as AutoPipe, RAM Connection, RAM Concept etc. are *not* considered as "Nuclear Safety Related Features" of the product/program.

2 What's New?

The Software Release Report for STAAD.Pro contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2007 build 06. This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

STAAD.Pro CONNECT Edition V22

CONNECT Edition V22 Update 10

The Software Release Report for STAAD.Pro CONNECT Edition V22 Update 10 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition V22 Update 9 (release 22.09). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 22.10.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 22.10.00-1.1 Auto-Recovery Enhancements

The auto-recovery process in STAAD.Pro has been further enhanced to protect your files from unexpected application failures.

These enhancements include the following:

STAAD Backup File

During opening and saving of the STAAD file, a file with model name and extension `.SBK` (i.e., `*<modelname>*.sbk`) will be created in the model folder. This file is a duplicate the STAAD input file.

To recover the STAAD input file, simply rename the file replacing the `.SBK` extension with `.STD`.

> **Note:** The `.SBK` file is not automatically modified or updated with the given time interval in auto-recovery process.

Auto-Recovery Backups Directory

In addition to the creation of auto-recovery file (i.e. *<modelname>_autorecovery.zip*) in the model folder, a copy of the same will be preserved under:

```
%localappdata%\Bentley\Engineering\STAAD.Pro CONNECT Edition\AutoRecovery Backups
\<modelname>-<unique id>
```

Since the auto-recovery file gets removed when saving or closing the model, this ensures the preservation of last changes made in the event of an unexpected application failure.

In case of any failures in which the STAAD input file and its ancillary files gets corrupted, you can retrieve the auto-recovery backups from the above-mentioned location.

Note: To ensure uniqueness of the folder name, the unique id suffixed is derived from the model path. Hence, two files with same name existing in two different folders, will have the different unique ids and thus prevented from overwritten.

Refactored Auto-Recovery Process

Also, the process has been restructured such that an auto recovery zip file is created when a model is opened (this is by design for unexpected crash), and the auto recovery process is paused until the next modification of the analytical model.

Note: For the physical model (e.g., when STAAD.Pro Physical Modeler is open), the auto-recovery process does not stop. Rather, the auto-recovery process is triggered at a given time interval.

RR 22.10.00-2 Features Affecting the Preprocessor

The following section describes the new features that have been added that affect the preprocessor section of the program, also known as the Analytical Modeling workflow and Physical Modeling workflow (or STAAD.Pro Physical Modeler).

RR 22.10.00-2.1 Individual Member Design using RAM SBeam

You can now perform member design on single beam members using RAM SBeam within STAAD.Pro Physical Modeler.

Steel beams can be designed as composite or non-composite members.

Note: You must have a separate license for RAM SBeam to use this feature. RAM SBeam must be installed on the computer along with STAAD.Pro.

RAM SBeam is used for designing single-span, steel beams (with or without cantilever on each end). The beams can be designed with or without composite decking. The following requirements must be applicable to the members for exporting:

- only wide flange, channel, and rectangular hollow tubes sections may be used
- multiple members must be connected and colinear

Refer to the STAAD.Pro Physical Modeler help for additional details on exporting members to RAM SBeam for design.

RR 22.10.00-2.2 Variable Surface Thickness

STAAD.Pro Physical Modeler is now capable of assigning thicknesses to physical surfaces.

Refer to the STAAD.Pro Physical Modeler help for additional details on specifying thickness to surfaces.

RR 22.10.00-2.3 Modular Tank with Tapered Walls

A new template has been added to the Structure Wizard in STAAD.Pro Physical Modeler for modelling tanks with tapered walls.

Note: This feature requires Structural SELECT Entitlements, which are provided with an active SELECT or ELS subscription.

This tank model includes discrete wall and slab sections for use with concrete design in the RCDC application. This model can have tapered wall thickness. The lateral load due to the sloped walls are calculated as both vertical and horizontal components.

Limitations:

- this tank can only have a single level
- this tank cannot contain interior columns or beams

Refer to the STAAD.Pro Physical Modeler help for additional details on creating a tank model with tapered walls.

RR 22.10.00-2.4 Automatic Load Combination Enhancements per 2021 Chinese Code

The load combinations per the Chinese GB 55002-2021 code have been added to the automatic load combination generator.

The ultimate load combination (ULC) and service load combination (SLC) categories are labeled as a prefix in the **Select Load Combination Category** drop-down list on the **Auto Load Combination** dialog.

Related Links

- *Auto Load Combination dialog* (on page 2872)

RR 22.10.00-3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 22.10.00-3.1 Tapered Member Design per EC3

Design of tapered members per EN 1993-1-1:2005 is now available in STAAD.Pro.

STAAD.Pro can design the following section profiles per EN 1993-1-1:2005:

- tapered I-section (constant flanges, web tapered)
- tapered tube (tapered square hollow section)
- tapered pipe (tapered round hollow section)

A new D5.C.6 Design Parameters (on page 1502), HGT, has been added for use with the design of tapered I-sections. Other design parameters directly related to the tapered member checks are LY and EFT.

The following clauses of EN 1993-1-1:2005 are checked for tapered sections:

- 6.2.3 - tension
- 6.2.4 - compression
- 6.2.6 - shear
- 6.2.5 - moment
- 6.2.7 - torsion:

  (1) - pure torsion
  (5) - yield criteria for interaction of axial, bending and shear (including shear from torsion)
  (9) - reduced shear due to torsion
- 6.2.8 - reduced moment due to shear
- 6.2.9.1 - combined moment and axial force
- BB.3.2 - Stable length for tapered members (applies to tapered I-sections) - see Tapered Members (on page 1484)

Related Links
- *D5.C.6 Design Parameters* (on page 1502)

RR 22.10.00-3.2 Single Angle Brace Members in AISC 360-16

The engineer now has control over the use of how the provisions of Section E5 are applied to the design of single angle members in compression per AISC 360-16.

Previously, it was assumed that all of the conditions for single angle members were met such that the effects of eccentricity could be ignored and that the effective slenderness ratio may be used. Further, it was assumed that any single angle was an individual member and that the modified slenderness ratio of Cl. E5(a) always applied. These are conservative assumptions and may result in sections that are not the most economical. Therefore, two new parameters have been added which allow the engineer to control the specifics of how single angle members in compression are designed per E5.

For AISC 360-16, single angle members in compression can be designed using a modified slenderness method provided a set of conditions are met for that member. It is left to the engineer to confirm that conditions E5.(1) through E5.(3) are met and to specify this for single angle member using the `E5P` parameter. Those conditions are:

1) Members are loaded at the ends in compression through the same leg.
2) Members are attached by welding or by connections with a minimum of two bolts.
3) There are no intermediate transverse loads.

If one or more of these conditions are not met, then the `E5P 1` parameter value should be assigned to those members.

Note: Conditions E5.(4) and E5.(5) are checked by the program:

4) Slenderness ratio, $L_c / r \le 200$
5) For unequal leg angles, the ratio of leg widths is < 1.7.

The effective slenderness ratio method used for single angles also depends on if those angle members are:

1. individual members or are web members of planar trusses (in which case, Cl. E5(a) applies - `IMM 0`)
2. web members of box or space trusses (in which case, Cl. E5(b) applies - `IMM 1`)

A message is issued if the `E5P` or `IMM` parameter is used with any section type other than a single angle.

Note: The E5P and IMM parameters are only applicable to standard catalog or UPT angles which also are assigned as truss members.

RR 22.10.00-3.3 Chinese Response Spectrum Enhancements

Reponse spectra per the GB50011 2010 code may now consider torsional effects of the load.

Inherent and Accidental Torsion

Note: STAAD.Pro does not support the coupled torsion methodology as per GB50011-2010. This implementation enables the general "inherent and accidental torsion" for GB50011 response spectrum analysis. Note that this implementation does *not* comply with Cl. 5.2.3 of GB50011-2010.

In response spectrum analysis all the response quantities (i.e., joint displacements, member forces, support reactions, plate stresses, etc.) are calculated for each mode of vibration considered in the analysis. These response quantities from each mode are combined using a modal combination method (either CQC or SRSS) to produce a single positive result for the given direction of acceleration. This computed result represents a maximum magnitude of the response quantity that is likely to occur during seismic loading. The actual response is expected to vary from a range of negative to the positive value of this maximum computed quantity.

No information is available from response spectrum analysis as to when this maximum value occurs during the seismic loading and what will be the value of other response quantities at that time. For example, consider two joints J2 and J3 whose maximum joint displacement in the global X direction come out to be X1 and X2 respectively. This implies that during seismic loading joint J1 will have X-direction displacement that is expected to vary from -X1 to +X1 and that for joint J2 from -X2 to +X2. However, this does not necessarily mean that the point of time at which the X displacement of joint J1 is X1, the X displacement of joint J2 will also be X2.

For the reason stated above, the torsional moment at each floor arising due to dynamic eccentricity along with accidental eccentricity (if any) is calculated for each mode. Lateral story shear from this torsion is calculated forming global load vectors for each mode. Static analysis is carried out with this global load vector to produce global joint displacement vectors for each mode due to torsion. These joint displacements from torsion for each mode are algebraically added to the global joint displacement vectors from response spectrum analysis for each mode. The final joint displacements from the response spectrum along with torsion for all modes are combined using a specified modal combination method to get the final maximum possible joint displacements.

RR 22.10.00-4 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the post processing and interactive design workflows. These are explained in the following pages.

RR 22.10.00-4.1 Design of General Sections in Chinese Steel Design Workflow

The Chinese Steel Design Workflow now supports the design of combined (i.e., built-up) sections which have been specified as "general" prismatic sections in analysis.

Related Links

- *General Section dialog* (on page 3014)

CONNECT Edition V22 Update 9

The Software Release Report for STAAD.Pro CONNECT Edition V22 Update 9 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition V22 Update 8 (release 22.08). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 22.09.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 22.09.00-1.1 Mass Model Generation

STAAD.Pro can now automatically generate mass model loads based on a selection of load cases for inclusion as a new reference load case or in a existing dynamic load case.

Both primary load cases and reference loads can be used for generating the mass model. A load factor is applied to masses which act in the X, Y, and Z directions.

Related Links

- *Create Mass Model dialog* (on page 2870)
- *M. To generate a mass model* (on page 899)

RR 22.09.00-2 Features Affecting the Preprocessor

The following section describes the new features that have been added that affect the preprocessor section of the program, also known as the Analytical Modeling workflow and Physical Modeling workflow (or STAAD.Pro Physical Modeler).

RR 22.09.00-2.1 Cable and Truss Specifications

STAAD.Pro Physical Modeler is now capable of assigning cable and truss specifications to physical members.

The cable specification details can also be assigned directly to the physical members.

Now, when any axial behavior (tension-only, compresison-only, cable, or truss) is assigned, the program will default to not segmenting those members when the analytical model is generated.

Refer to the STAAD.Pro Physical Modeler help for additional details on specifying axial behavior properties of members.

RR 22.09.00-2.2 Notional Load Enhancements

You may now directly specify the notional load factor and directions for notional loads in automatically generated load combinations.

There is also now an option to specify the notional load factor to be calculated based on number of floors as per the Chinese GB 50017-2017 code.

Related Links

- *Auto Load Combination dialog* (on page 2872)
- *M. To automatically generate load combinations* (on page 888)

RR 22.09.00-3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 22.09.00-3.1 Tension Slenderness Checks in AISC 360-16

The slenderness checks for members in tension have been refactored to allow greater control over the limits in STAAD.Pro.

Two new parameters have been added for AISC 360-16 to control the checks made for slenderness:

- `SRT` specifies the method used for checking slenderness. The default is to now use the conventional method from in AISC 360-10 (using the length given by the `TSL` parameter). An option is also available to check per clause D1 of the specification
- `TSL` is available to specify the length considered for tension slenderness checks. This defaults to the analytical member length.

Related Links

- *D1.A.6 Design Parameters* (on page 1100)

RR 22.09.00-3.2 Projected Loading on Plates

Full pressure loads on plate elements can now be applied along global axes on the projected plate area.

The resulting pressure, $p' = p\frac{A_{xz}}{A_{xyz}}$

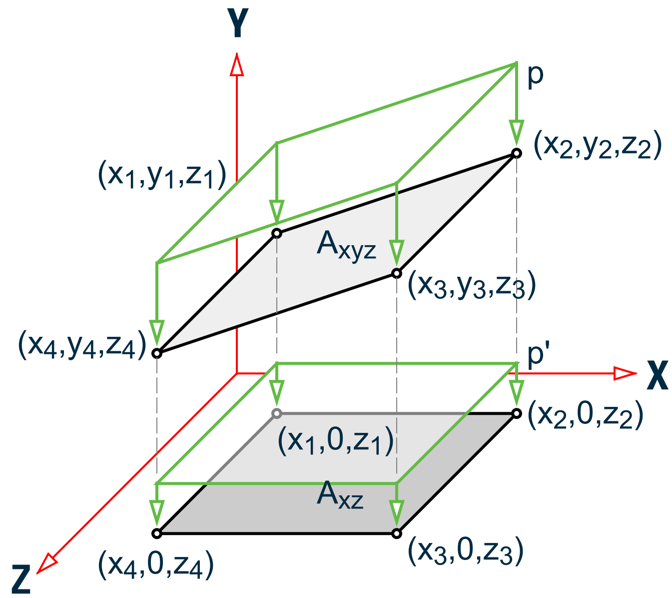

Figure 5: Projected pressure, p, in the PY direction

RR 22.09.00-4 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the post processing and interactive design workflows. These are explained in the following pages.

RR 22.09.00-4.1 RAM Connection Workflow Update

RAM Connection CONNECT Edition V13.6 is now supported in STAAD.Pro CONNECT Edition.

- Now compatible with versions of RAM Connection CONNECT Edition up through release 13.6 (CONNECT Edition V13.6).
- New truss-gusset-branch connection for AS4100, NZS3404 and AISC360.
- New tubular connections for mitred knee and beam and column splices joints for AISC360, CSAS16 and EN1993.
- And other enhancements and additions.

See the full list of RAM Connection v13.6 Release Notes at Bentley Communities.

RR 22.09.00-4.2 P-Delta Analysis Support for Chinese Steel Design Workflow

Design of members using a P-Delta analysis is now supported in the Chinese Steel Design Workflow.
Related Links

- *D. To add a new solution set* (on page 979)

CONNECT Edition V22 Update 8

The Software Release Report for STAAD.Pro CONNECT Edition V22 Update 8 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition V22 Update 7 (release 22.07). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 22.08.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 22.08.00-1.1 ProjectWise 365 Compatibility

STAAD.Pro is compatible with Bentley's ProjectWise 365 project collaboration product.

RR 22.08.00-2 Features Affecting the Preprocessor

The following section describes the new features that have been added that affect the preprocessor section of the program, also known as the Analytical Modeling workflow and Physical Modeling workflow (or STAAD.Pro Physical Modeler).

RR 22.08.00-2.1 Indian Wind Load Calculator per IS-875 (Part 3): 2015

The program can now calculate wind load vs height intensity values per the Indian IS-875 (Part 3): 2015 code.
Related Links
- *IS-875 (Part 3): Wind Load dialog* (on page 2890)
- *Wind Load Generation - IS 875 (Part 3): 2015 dialog* (on page 2867)

RR 22.08.00-2.2 Chinese Wind Load Calculator Enhancements

Several enhancements have been made to the wind load definition calculator used for the Chinese GB 50009 2012 code.

The program can now accommodate circular building cross sections (i.e., chimneys).

The method for identifying the structure faces has also been improved when defining the shape factors.

Related Links
- *Generate Wind Definition and Wind Load Case for Chinese GB 50009 dialog* (on page 2887)
- *M. To add a GB50009 wind load definition* (on page 848)

RR 22.08.00-2.3 Modular Tank with Stepped Walls

The Structure Wizard tank module in STAAD.Pro Physical Modeler is now capable of modeling stepped walls.

Note: This feature requires Structural SELECT Entitlements, which are provided with an active SELECT or ELS subscription.

Refer to the STAAD.Pro Physical Modeler help for additional details on creating a tank model with stepped walls.

RR 22.08.00-2.4 Group Management in SPPM

When creating groups in STAAD.Pro Physical Modeler from a selection, you now have the option to select which object types are included in the group.

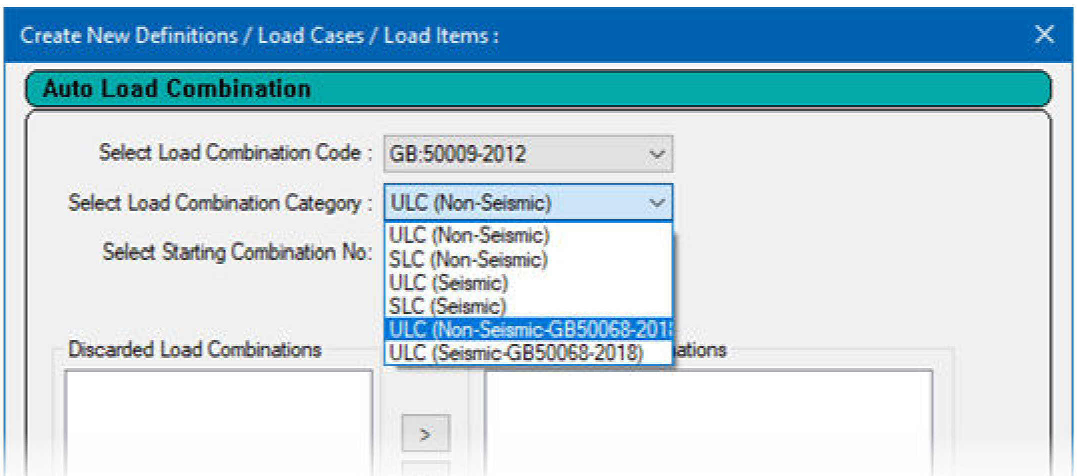
Groups created in STAAD.Pro Physical Modeler are now transferred to the STAAD input file.

Refer to the STAAD.Pro Physical Modeler help for additional details on creating groups.

RR 22.08.00-2.5 Chinese Automatic Load Combination Enhancements

The load combinations per the Chinese GB 50009-2012 code have been separated into ultimate load combination (ULC) and service load combination (SLC) categories.

These categories are labeled as a prefix in the **Select Load Combination Category** drop-down list on the **Auto Load Combination** dialog.



Related Links

- *Auto Load Combination dialog* (on page 2872)

RR 22.08.00-3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 22.08.00-3.1 Steel Design per CSA S16 2019

Design of hot-rolled steel members per the Canadian CSA S16 2019 code are now available in STAAD.Pro.

Member sizes can be checked against the requirements of the design code as well as be selected for the current loading conditions.

RR 22.08.00-4 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the post processing and interactive design workflows. These are explained in the following pages.

RR 22.08.00-4.1 RAM Connection Workflow Update

RAM Connection CONNECT Edition V13.5 is now supported in STAAD.Pro CONNECT Edition.

- Now compatible with versions of RAM Connection CONNECT Edition up through release 13.5 (CONNECT Edition V13.5).
- IS800 vertical bracing connections for column - beam - brace joints.
- Tubular end plates and mitred knee connections for AS and NZS codes.

RR 22.08.00-4.2 Plate Stress Envelopes

You can now view an envelope of plate stresses for either plate center stresses or plate corner stresses in the postprocessing workflow.

The Plate Center Stress and Plate Corner Stress tables now include additional tabs for displaying the envelopes.

You can now also select an envelope of all loads or a previously defined envelope from the Load Type drop-down in the Diagrams dialog Plate Stress Contour tab (on page 2758).

You can also include plate stress envelope tables in reports.

Related Links

- *P. Plate Corner Stress table* (on page 2009)
- *P. Plate Center Stress table* (on page 2009)
- *Diagrams dialog* (on page 2751)

RR 22.08.00-4.3 Custom Materials in Chinese Steel Design

You can now add custom steel material definitions for use in the Chinese Steel Design workflow.

A new **Materials** tool is used to open the dialog where user-defined materials can be added. The dialog also included the default material values (taken from Table 4.4.1 of GB50017-2017).

Related Links

- *Material Parameter dialog* (on page 3013)
- *D. To add a custom material definition* (on page 982)

RR 22.08.00-4.4 Multiple Parameters in Chinese Steel Design

You can now create “solution sets” with in the Chinese Steel Design workflow to quickly compare different sets of parameters within the same model.

Related Links

- *Configure Solution dialog* (on page 3019)
- *D. To add a new solution set* (on page 979)

CONNECT Edition V22 Update 7

The Software Release Report for STAAD.Pro CONNECT Edition V22 Update 7 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition V22 Update 6 (release 22.06). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 22.07.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 22.07.00-1.1 ASCE 7-2016 Load Combination Generation

STAAD.Pro can now automatically generate load combinations per the ASCE 7-16 specification.

Seismic Load Type Directions

To aid in the load combinations per ASCE 7-16, load cases marked with the “seismic” load type are now divided into “horizontal” and “vertical” directions.

This is used to accommodate load combinations which separate between vertical and horizontal seismic directions. With “Y up” models, the horizontal seismic loads act in the global X and Z directions. When the “Z up” option is used, then the horizontal seismic loads act in the global X and Y directions.

Note: Any existing STAAD file opened which contains load cases labeled as “Seismic” will be automatically converted to the “Seismic - Horizontal” type.

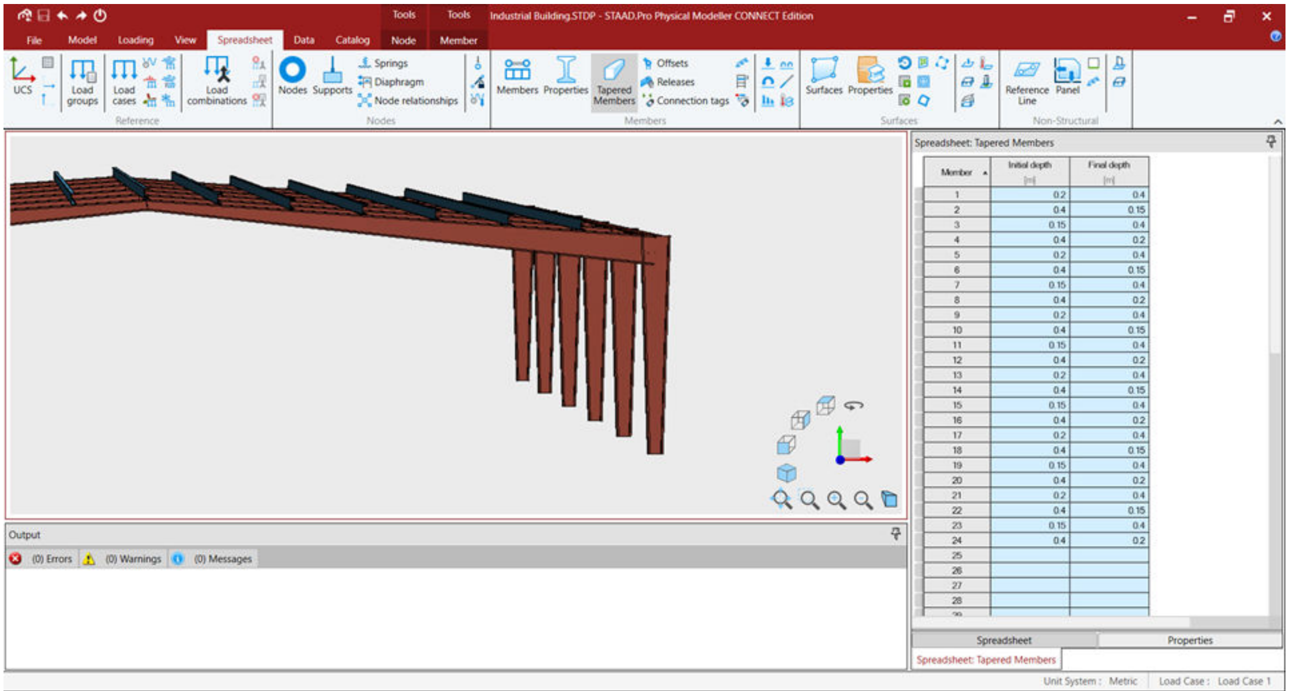
RR 22.07.00-2 Features Affecting the Preprocessor

The following section describes the new features that have been added that affect the preprocessor section of the program, also known as the Analytical Modeling workflow and Physical Modeling workflow (or STAAD.Pro Physical Modeler).

RR 22.07.00-2.1 Tapered Members in Physical Modeler

STAAD.Pro Physical Modeler can now be used to model web-tapered I shape, rectangular tube, and pipe members.

Refer to the STAAD.Pro Physical Modeler help for additional details on assigning web tapers in the physical modeler.



RR 22.07.00-2.2 Multiple Analyses in Physical Modeler

You can now specify multiple analysis commands within STAAD.Pro Physical Modeler. These may utilize different analysis methods, different load sets, or both.

You can also manage multiple analyses in **Analysis Sets** to quickly set each as active or inactive and edit them individually.

Refer to the STAAD.Pro Physical Modeler help for additional details on assigning web tapers in the physical modeler.

RR 22.07.00-2.3 Improved Structure Wizard in Physical Modeler

Additional templates and script-editing capabilities have been added to the STAAD.Pro Physical Modeler Structure Wizard.

Refer to the STAAD.Pro Physical Modeler help for additional details on using the Structure Wizard.

RR 22.07.00-2.4 Chinese Wind Load Calculator per GB 50009-2012

The program can now calculate wind load vs height intensity values per the Chinese GB 50009-2012 code.

- *M. To add a GB 50011-2010 response spectrum* (on page 869)

RR 22.07.00-3.2 Element Offsets Use with Additional Analysis Methods

The program can now analyze models with element offsets using dynamic analysis, direct analysis, and P-Delta analysis.
Related Links
- *TR.25.2 Element Offset Specification* (on page 2298)

RR 22.07.00-4 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the post processing and interactive design workflows. These are explained in the following pages.

RR 22.07.00-4.1 Chinese Steel Design Workflow

The design of steel sections to the Chinese code is now integrated into the STAAD.Pro interface as the Chinese Steel Design workflow

Note: Previously, the SSDD application was only available as a standalone application.

CONNECT Edition V22 Update 6

The Software Release Report for STAAD.Pro CONNECT Edition V22 Update 6 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition V22 Update 5 (release 22.05). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 22.06.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 22.06.00-1.1 Improved Surface Mesh Workflow

The workflow and dialogs to generate automatically meshed surfaces has been improved.

You can also specify the usage of a surface by wall or slab, as well as a sub-type definition for the use in tank structures.

Related Links

- *Add Parametric Model dialog* (on page 2737)

RR 22.06.00-1.1 Ideas Submission Button

Do you have a suggestion for STAAD.Pro you would like to share with us?

On the **File** ribbon tab, select the **Help** tab and then click the **Ideas** button. You can then share your suggestion in our Bentley Communities forum specifically for submitting STAAD suggestions.

You can also vote for other suggestions that you would like to see implemented.

Related Links

- *Help tab* (on page 2704)

RR 22.06.00-2 Features Affecting the Preprocessor

The following section describes the new features that have been added that affect the preprocessor section of the program, also known as the Analytical Modeling workflow and Physical Modeling workflow (or STAAD.Pro Physical Modeler).

RR 22.06.00-2.1 Physical Modeler Analysis Commands

STAAD.Pro Physical Modeler can now be used to specify the analysis method and parameters used in STAAD.Pro.

Refer to the STAAD.Pro Physical Modeler help for additional details on analysis in the physical modeler.

RR 22.06.00-2.2 Surface Releases

You can now specify edge and corner releases for surfaces in STAAD.Pro Physical Modeler.

Refer to the STAAD.Pro Physical Modeler help for additional details on changing surface boundary or node releases.

RR 22.06.00-2.3 Modular Tank Structure Wizard

You can now rapidly model concrete tanks in STAAD.Pro Physical Modeler using the new Structure Wizard facility.

Note: This feature requires Structural SELECT Entitlements, which are provided with an active SELECT or ELS subscription.

Refer to the STAAD.Pro Physical Modeler help for additional details on creating a tank model.

RR 22.06.00-2.4 Direct Analysis Properties

You can now assign direct member properties for use with the AISC direct analysis directly in STAAD.Pro Physical Modeler.

Refer to the STAAD.Pro Physical Modeler help for additional details on assigning direct analysis properties.

RR 22.06.00-2.5 iTwin Synchronizer

You can now use Bentley's iTwin Synchronizer to push and pull updates to and from ISM repositories via either a local ISM repository or iModelHub.

Note: This functionality replaces the previous ISM Structural Synchronizer workflow.

Refer to the STAAD.Pro Physical Modeler help for additional details on using iTwin Synchronizer and how to synchronize data with iModelHub.

Technical Preview: This feature is part of a Technical Preview. It has not been reviewed per Bentley's standard quality assurance program and should be considered for review only.

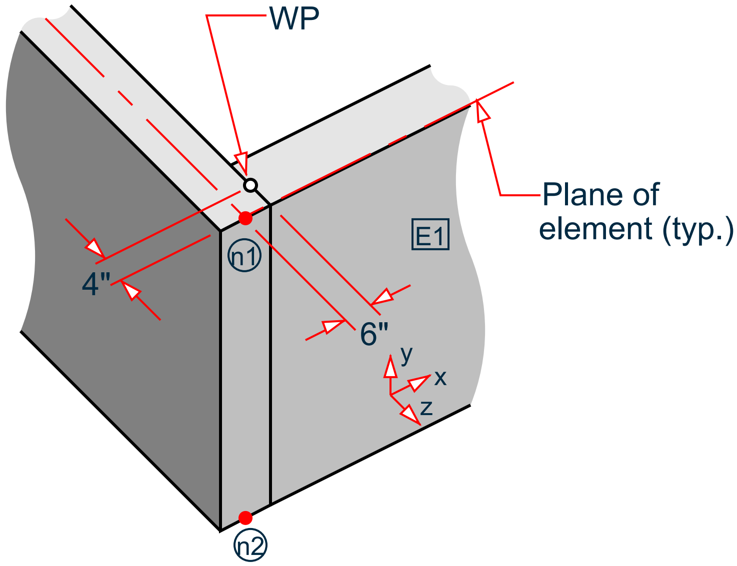
RR 22.06.00-3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 22.06.00-3.1 Element Offsets

The program can now use rigid link offsets at the corners of plate elements.

This feature is limited to use with linear, static analysis for this release.



Related Links

- *TR.25.2 Element Offset Specification* (on page 2298)
- *Plate Specs dialog* (on page 2791)
- *To assign plate offsets* (on page 813)

RR 22.06.00-3.2 Design of Solid Rods per IS800

The program can now design solid rod sections per IS 800-2007 using both the LSD and WSD methods.

Note: Solid round sections can be found in the Dutch (Netherlands) profiles. Alternatively, solid round prismatic shapes with steel material can be used.

RR 22.06.00-3.3 Static Seismic Loading per GB50011-2010

The program can now apply static seismic loading per the Chinese GB50011-2010 (2016 edition) code.

Note: As GB50011-2010 static seismic was added in CONNECT Edition V22 Update 6, in order to use the 2001 edition you must directly specify the code year. Otherwise, the program will default to the latest code edition as is typical for STAAD.Pro.

- *Add New Seismic Definitions dialog* (on page 2895)

RR 22.06.00-3.4 Design of Lipped Sections per AISI 2016

The program can now design lipped sections (C shapes, Z shapes, and angles) per the 2016 edition of the AISI design code.

RR 22.06.00-4 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the post processing and interactive design workflows. These are explained in the following pages.

RR 22.01.00-4.2 RAM Connection Workflow Update

RAM Connection CONNECT Edition V13.4 is now supported in STAAD.Pro CONNECT Edition.

- Now compatible with versions of RAM Connection CONNECT Edition up through release 13.4 (CONNECT Edition V13 Update 4).
- Seismic design enhancements for AISC 360-16 / AISC 358-16
- New gusset to brace connections
- Enhancements to gusset CVR and CBB connections for AISC codes
- Enhancements to horizontal gussets - HCBB and HBBB connections
- Enhancements to base plate connections
- Update databases
- Drawing joints

CONNECT Edition V22 Update 5

The Software Release Report for STAAD.Pro CONNECT Edition V22 Update 5 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition V22 Update 4 (release 22.04). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 22.05.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 22.05.00-1.1 Model Seed File

You can now use an existing STAAD input file as a template, or “seed” file, to include initial data in a new model.

When creating a new model, you will have the option to locate a STAAD input file to use as a seed file or to select a previously used seed file from a drop-down list.

Related Links

- *GS. To create a new STAAD.Pro model* (on page 35)

RR 22.05.00-1.2 Auto-Recovery Enhancements

The auto-recovery feature in STAAD.Pro has been enhanced to improve performance with large models.

The improved auto-recovery facility will only run if the model has been changed since the last Save action.

Auto-recovery can be turned on or off by selecting the option in the Quick Access toolbar. This allows you to prevent any performance issues while working with larger files between your Save actions. This will not stop an active auto-recovery process, but will prevent it running subsequently.

Related Links

- *GS. Quick Access Toolbar* (on page 62)
- *I. To enable auto-recovery* (on page 2065)

RR 22.05.00-1.3 iTwin Design Review Ad Hoc Method

STAAD.Pro Physical Modeler now incorporates Bentley's Design Review Ad Hoc method for collaborating on design projects.

iTwin Design Review Ad Hoc Workflow enables quick peer reviews of design work-in-progress deliverables while eliminating the inefficiency of traditional design review workflows and provides a great opportunity for collaboration with team members. You can learn more by visiting https://www.bentley.com/en/products/product-line/digital-twins/itwin-design-review .

Design Review is found by selecting the **iTwin Services** tool on the **Model** ribbon tab in STAAD.Pro Physical Modeler. Refer to the STAAD.Pro Physical Modeler help section iTwin Services for additional details.

Technical Preview: This feature is part of a Technical Preview. It has not been reviewed per Bentley's standard quality assurance program and should be considered for review only.

RR 22.05.00-1.4 Cloud Analysis

STAAD.Pro now allows you to upload and analyze your STAAD models in Bentley's Cloud Services.

For large or complex models, this can save you significant computing time.

Technical Preview: This feature is part of a Technical Preview. It has not been reviewed per Bentley's standard quality assurance program and should be considered for review only.

Related Links

- *A. To run analysis on the cloud* (on page 967)

RR 22.05.00-2 Features Affecting the Preprocessor

The following section describes the new features that have been added that affect the preprocessor section of the program, also known as the Analytical Modeling workflow and Physical Modeling workflow (or STAAD.Pro Physical Modeler).

RR 22.05.00-2.1 Physical Modeler Automatic Load Combinations

STAAD.Pro Physical Modeler can now generate automatic load combinations based on load case type.

Refer to the STAAD.Pro Physical Modeler help for additional details on creating automatic load combinations.

RR 22.05.00-2.2 Notional Loads in the Physical Modeler

STAAD.Pro Physical Modeler can now generate load combinations with notional loads.

Refer to the STAAD.Pro Physical Modeler help for additional details on adding a notional load.

RR 22.05.00-2.3 Physical Modeler ASCE 7 Wind Loads

STAAD.Pro Physical Modeler can now generate wind loads per ASCE 7-10 or ASC 7-16.

Refer to the STAAD.Pro Physical Modeler help for additional details on adding an ASCE 7 wind load definition.

RR 22.05.00-2.4 Physical Modeler Node Relationships

STAAD.Pro Physical Modeler can now define rigid links and other relationships between control and dependent nodes.

Refer to the STAAD.Pro Physical Modeler help for additional details on defining node relationships.

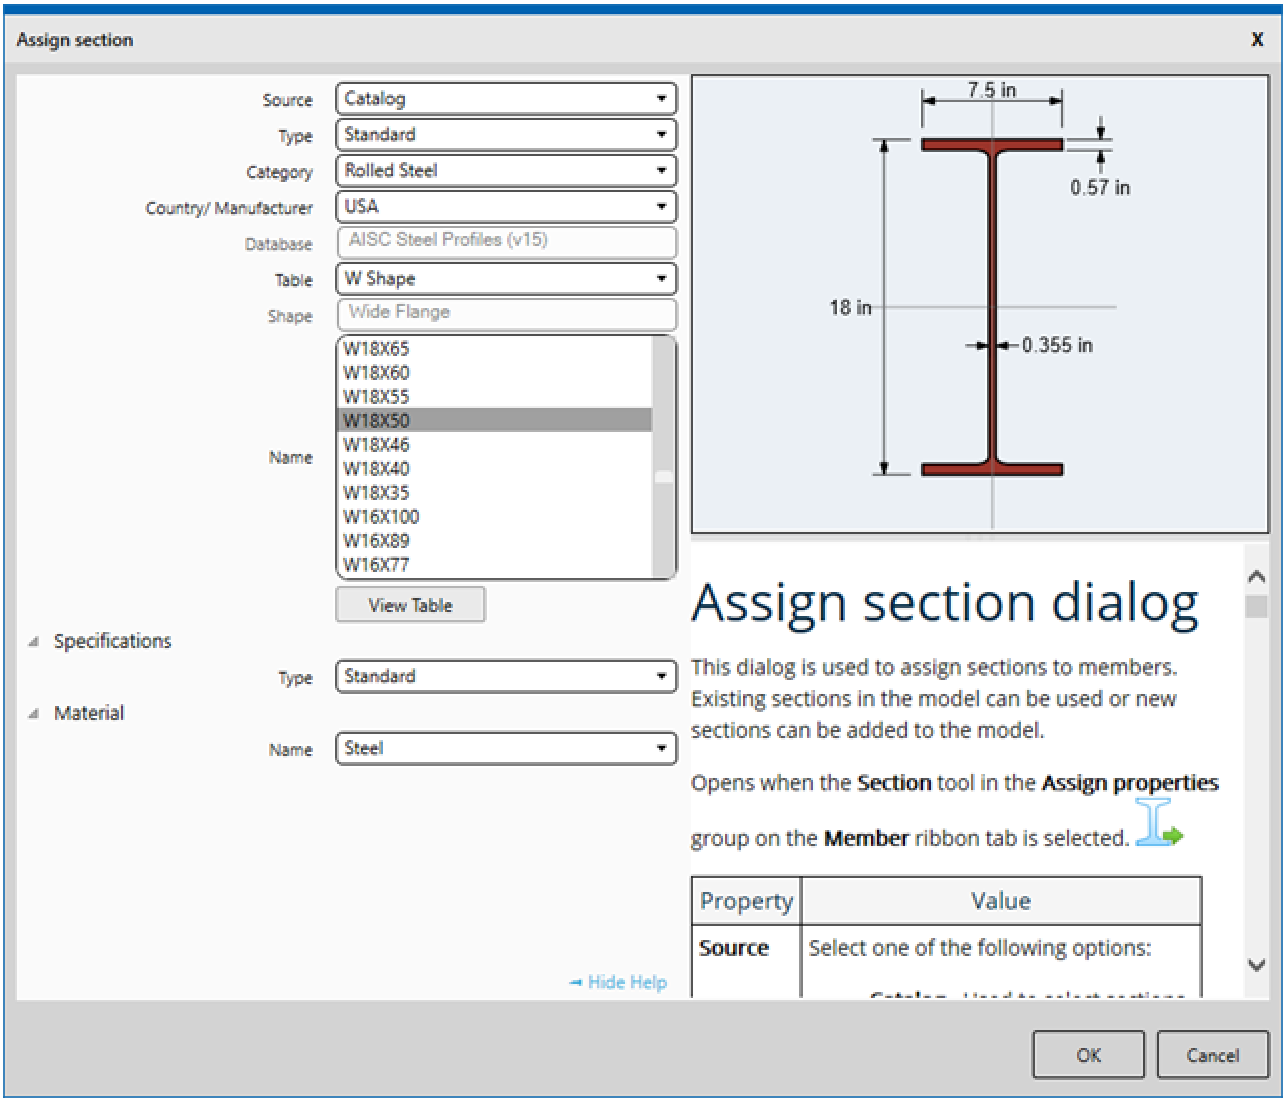
RR 22.05.00-2.5 Physical Modeler Section Database

STAAD.Pro Physical Modeler now shares the same section database as STAAD.Pro.

The Section Database Manager can now be accessed from within STAAD.Pro Physical Modeler. This means there is a 1:1 correlation between the available sections in both the physical and analytical modeling workflows. This ensures that any section assigned in STAAD.Pro Physical Modeler will exactly correspond to the same during analysis, design, and post-processing.

Note: Castellated rolled steel beams, R-Ceco rolled steel sections, European bulb flat sections, European flat bar sections, European solid square sections, steel joists, some cold-formed steel sections, AITC glulam sections, and aluminium profiles are not supported in STAAD.Pro Physical Modeler.

The **Assign section** dialog in STAAD.Pro Physical Modeler has further been enhanced to include a dimensioned preview of the currently selected cross section to assist in member section assignment. This is available in the Help panel.



RR 22.05.00-3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 22.05.00-3.1 IS 800-2007 Seismic Detailing per Section 12

The program can now check seismic detailing per Section 12 of IS 800 2007 when a IS 1893 seismic definition is used for earthquake loading.

Note: This is only available for design using the LFD method. It is not applicable to design using the ASD method.

Additional load combinations for use with IS800-2007 section 12. These are contained in a new load combination table in the automatic load combinations generator.

New design parameters are available for this check. The `SEISMIC` is used to initiate a seismic check per Section 12. The `IMM` parameter is used to specify the member type. The values of the `SSY` and `SSZ` parameters are used to specify the frame type (as previous) or to indicate that the member is not part of a lateral earthquake load in that direction (the default for these parameters).

RR 22.05.00-3.2 SP 16.13330.2017 Steel Design

The program can now perform steel design based on the Russian code Сп 16.13330.2017 *стальные конструкции* (SP 16.13330.2017 *Steel Structures*).

Note: This feature was released as Technical Preview. It has been released as a commercial feature in a more recent release.

RR 22.05.00-3.3 Wind Loads per ASCE 7-16

The program can now automatically generate wind load intensity values per the 2016 edition of ASCE 7 *Minimum Design Loads for Buildings and Other Structures*.

The 2016 edition ASCE 7 now accounts for the height above sea level of the structure through a new coefficient, K_e as well as changes to the values used for other coefficients. These include the horizontal cross-section types used in the calculation of K_d as well as a new enclosure classification, partially open, for GC^{pi}.

$$q_z = 0.00256 K_z K_{zt} K_d V^2 \quad \text{(eq. 26.10-1)}$$

Related Links

- *ASCE 7 Wind Load dialog box* (on page 2882)
- *M. To add an ASCE 7 wind load definition* (on page 845)

RR 22.05.00-4 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the post processing and interactive design workflows. These are explained in the following pages.

RR 22.05.00-4.1 General and UPT Shapes in Steel AutoDrafter

The Steel AutoDrafter workflow has been updated to support section profiles defined as general shapes or user-provided table shapes.

RR 22.05.00-4.2 SSDD Integration in STAAD.Pro

Design of steel members per the Chinese code GB50017-2017 can now be initiated directly from STAAD.Pro.

The SSDD application can be launched by selecting the **Chinese Steel Design** workflow.

Related Links

- *D. To open a model in the Chinese Steel Design workflow* (on page 979)

RR 22.05.00-4.2 RC Designer is Retired

The Interactive Concrete Design workflow, formerly named RC Designer, has been completely retired from STAAD.Pro.

In order to perform interactive concrete design, the Advanced Concrete Design workflow may be used.

RR 22.05.00-4.4 RAM Connection Workflow Update

RAM Connection CONNECT Edition V13.3 is now supported in STAAD.Pro CONNECT Edition.

- Now compatible with versions of RAM Connection CONNECT Edition up through release 13.3 (CONNECT Edition V13.3).
- Support for channel sections for AISC, CSA, AS, NZS, EN, and IS code designs of single plate, through plate, standard tee, flexible end plate, double-angle web cleats, flange plate beam splices, and base plates.
- CSA S16-14 bracing connections for column - beam - brace joints.

CONNECT Edition V22 Update 4

The Software Release Report for STAAD.Pro CONNECT Edition V22 Update 4 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition V22 Update 3 (release 22.03). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

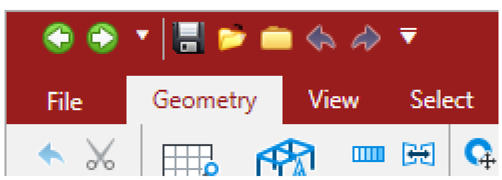
RR 22.04.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 22.04.00-1.1 Workflow Navigation Buttons

Forward and back buttons have been added to help navigate through the workflow pages.

When selecting workflow pages or ribbon tabs, you may want to move to a previously selected page. The **Back to** tool can be used for this. The **Forward to** tool can then be used to move to the next page in the history (i.e., the reverse order of the backwards navigation).



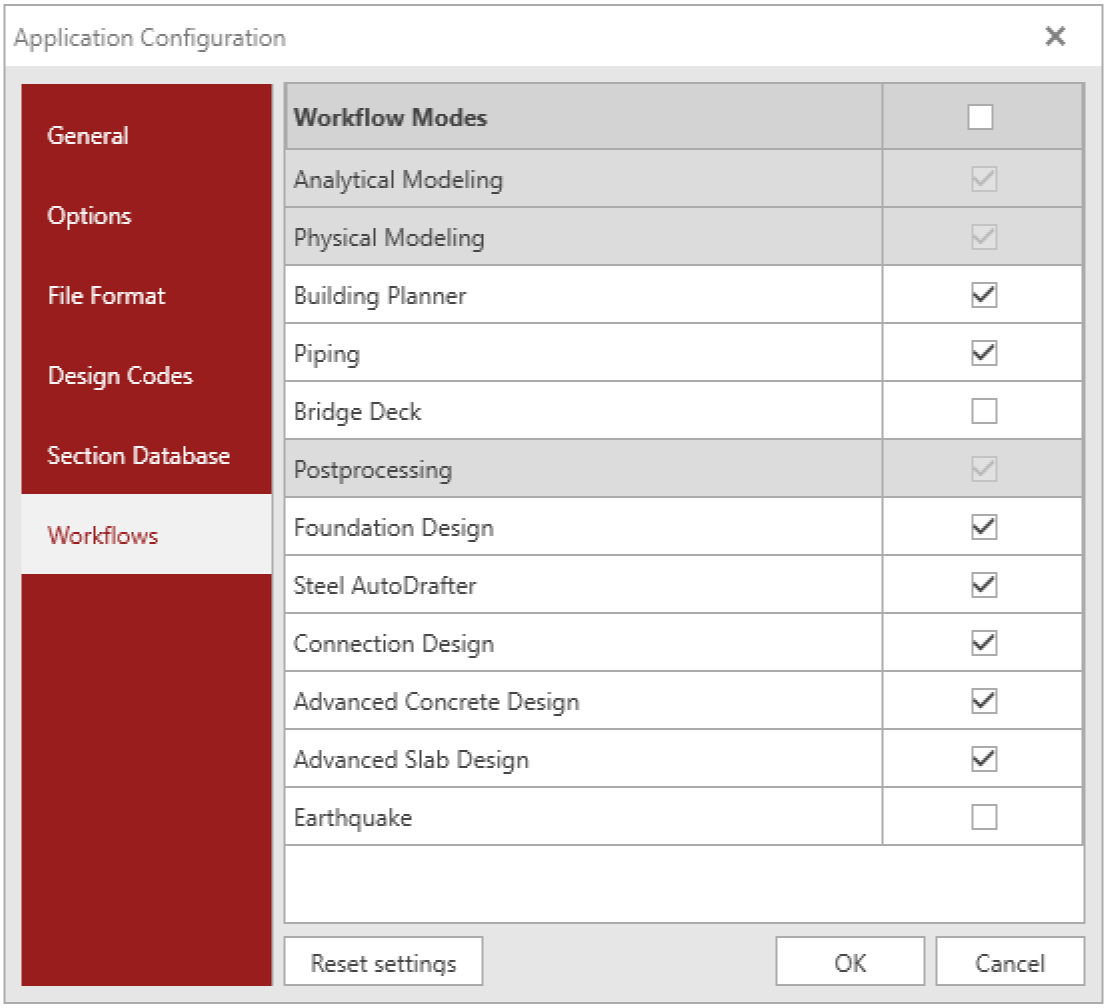
Related Links

- *GS. Page Control* (on page 64)
- *GS. Quick Access Toolbar* (on page 62)

RR 22.04.00-1.2 Workflow Display Customization

You can select which STAAD.Pro workflows are displayed.

The **Application Configuration** dialog contains a **Workflows** tab that allows you to select which workflows are displayed. Uncheck any workflows you want hidden to clean up your work space.



Tip: To reset the Workflows display to the default, check the **Workflow Modes** option.

Related Links

- *GS. Application Configuration dialog* (on page 59)
- *GS. To customize the workflows panel* (on page 39)

RR 22.04.00-1.3 Compare Restore Points

You can compare previously created restore points (backups) with one another or with the current model.

Related Links

- *I. To compare backups* (on page 2066)

RR 22.04.00-1.4 Remove Missing Files from Recent Files List

You can now remove one or all missing files from the recent files list.

Related Links

- *GS. To remove missing files from the recent files list* (on page 61)

RR 22.04.00-2 Features Affecting the Preprocessor

The following section describes the new features that have been added that affect the preprocessor section of the program, also known as the Analytical Modeling workflow and Physical Modeling workflow (or STAAD.Pro Physical Modeler).

RR 22.04.00-2.1 Physical Modeler Move Tool

STAAD.Pro Physical Modeler includes a Move tool which can be used to move selected portions of the model.

This tool also includes an option to retain connectivity, so the connections between the moved portions and unmoved portions remain intact.

Refer to the STAAD.Pro Physical Modeler help for additional details on moving selected portions of the model.

RR 22.04.00-2.2 Physical Modeler Reference Line Supports

You can now model linear supports along any reference line in STAAD.Pro Physical Modeler.

These supports can be restraints or springs and act similar to surface edge supports.

Refer to the STAAD.Pro Physical Modeler help for additional details on adding reference line supports.

RR 22.04.00-3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 22.04.00-3.1 Consolidation to Advanced Solver

The advanced solver is now solely used in STAAD.Pro, regardless of license.

The Basic solver has been deprecated. No action is required when launching the program or when running an analysis.

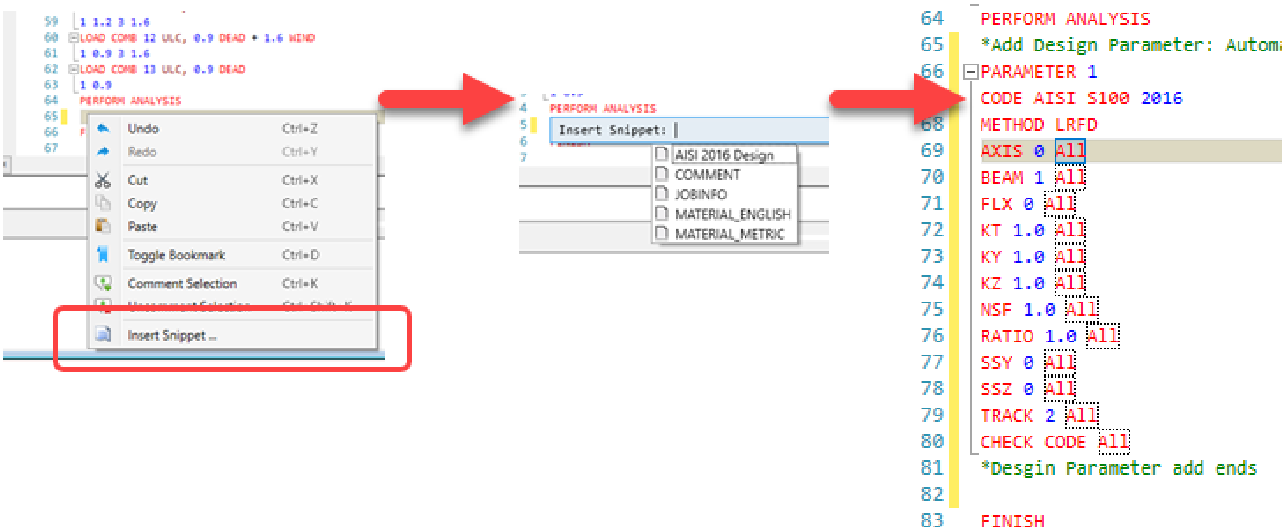
Note: The STAAD.Pro Advanced license is still required for advanced features, such as time history analysis.

RR 22.04.00-3.2 AISI S100-16 Cold Formed Steel Design

The program can now perform cold-formed steel design based on the 2016 edition of the AISI S100 code “North American Specification for the Design of Cold-Formed Steel Structural Members”.

Note: The 1996 edition of the AISI design code has been deprecated. If this edition of the code is specifying using `AISI 1996` in the input file, an error message will be presented in the output.

Tip: When using the STAAD.Pro Editor, you can right-click and select **Insert Snippet** from the pop-up menu and then select **AISI 2016 Design** from the snippets list. This will insert the Parameter block with the commonly used parameters set to their defaults for all members. Refer to I. To insert a code snippet (on page 2051) for details on using snippets.



RR 22.04.00-3.3 IS 1893 2015 Part 4 Static Seismic Loads

The program can now add static seismic loads per IS 1893 2015 (Part 4) *Industrial Structures Including Stack-Like Structures*.

Note: This implementation is only applicable to industrial structures. It is *not* valid for stack-like structures.

Related Links

- *TR.31.2.12 IS:1893 (Part 4) 2015 Codes - Lateral Seismic Load* (on page 2398)

RR 22.04.00-3.4 IS 1893 2015 Part 4 Response Spectra

The program can now add response spectra loads per IS 1893 2015 (Part 4) *Industrial Structures Including Stack-Like Structures*.

Related Links

- *TR.32.10.1.9 Response Spectrum Specification per IS: 1893 (Part 4)-2015* (on page 2555)

RR 22.04.00-3.5 Eurocode 3 Belgian NA Updated to 2018

The program can now perform steel design based on the 2018 edition of the Belgian national annex to EN 1993-1-1 ANB: 2018.

RR 22.04.00-3.6 SP 16.13330.2017 Steel Design

The program can now perform steel design based on the Russian code Сп 16.13330.2017 *стальные конструкции* (SP 16.13330.2017 *Steel Structures*).

Note: This feature was released as Technical Preview. It has been released as a commercial feature in a more recent release.

RR 22.04.00-4 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the post processing and interactive design workflows. These are explained in the following pages.

RR 22.04.00-4.1 RAM Connection Templates in Connection Tags

An additional element has been added to the connection tag XML structure to allow associating connection tag types with RAM Connection templates.

Related Links

- *D. Connection Tags XML File Schema* (on page 1052)

RR 22.04.00-4.2 Prismatic Shapes in Steel AutoDrafter

The Steel AutoDrafter workflow has been updated to support section profiles defined as prismatic.

This includes prismatic shapes of the following type:

- Solid Circle (defined with YD),
- Solid Rectangle (defined with YD and ZD),
- Tee (defined with TD, ZD, YB and ZB),
- Trapezoidal (defined with YD, ZD and ZB),
- General (displayed as a rectangular solid using the values of YD and ZD),
- Tapered I (displayed using the average dimensions of web and flange),
- Tapered Tube (displayed using the average dimensions).

CONNECT Edition V22 Update 3

The Software Release Report for STAAD.Pro CONNECT Edition V22 Update 3 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition V22 Update 2 (release 22.02). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 22.03.00-1 Features Affecting the Preprocessor

The following section describes the new features that have been added that affect the preprocessor section of the program, also known as the Analytical Modeling workflow and Physical Modeling workflow (or STAAD.Pro Physical Modeler).

RR 22.03.00-1.1 Physical Modeler Surface Regions and Region Loads

You can now designate surface regions within STAAD.Pro Physical Modeler surfaces. These can be used to model drop panels, surface recesses, and patch loadings.

Surface regions are “children” of surfaces but can have different material properties and thicknesses. You can also align the thickness of a surface region to either the face or center of the “parent” surface.

Refer to the STAAD.Pro Physical Modeler help for additional details on:

- creating a surface region
- applying a pressure load over a surface region
- applying a hydrostatic load to a surface region

RR 22.03.00-1.2 Physical Modeler Reference Lines and Loads

You can now add reference lines to surfaces in STAAD.Pro Physical Modeler. A reference line can be used to control meshing as well as to add a line load anywhere within a surface.

Refer to the STAAD.Pro Physical Modeler help for additional details on:

- drawing a reference line
- adding a reference line load

RR 22.03.00-2 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the post processing and interactive design workflows. These are explained in the following pages.

RR 22.03.00-2.1 RAM Connection Workflow Update

RAM Connection CONNECT Edition V13.2 is now supported in STAAD.Pro CONNECT Edition.

- Now compatible with versions of RAM Connection CONNECT Edition up through release 13.2 (CONNECT Edition V13.2).
- Connection Design per the CSA S16-14 (Canadian) code

RR 22.03.00-2.2 RCDC Features for STAAD.Pro License Users

Some features of the Advanced Concrete Design workflow using the RCDC application is now available to STAAD.Pro (basic) license users.

The full set of features in RCDC is available to STAAD.Pro Advance license users. For STAAD.Pro (basic), the following features are now available:

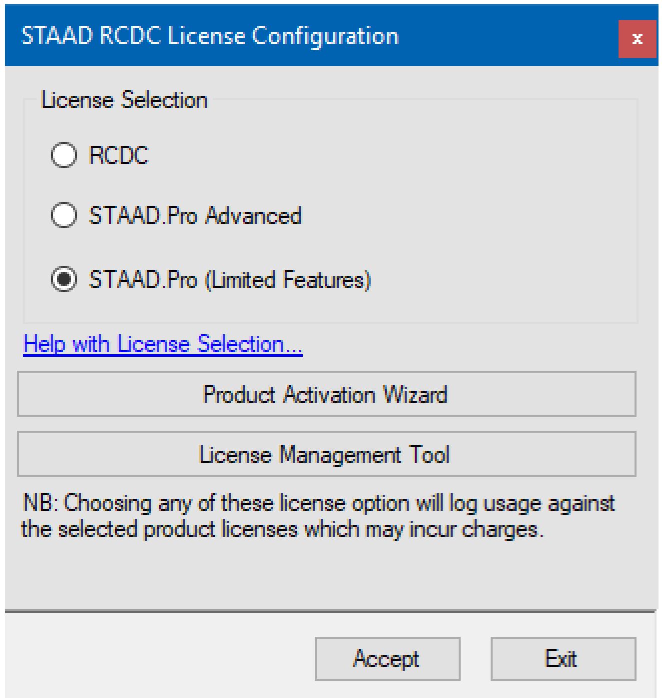
- beam design
- column design
- shear wall design

Other features available to STAAD.Pro (basic) license users include generation of the following, limited to on-screen only with no editing:

- Bill of Quantities summary
- Bar Bending Schedule generation
- Drawing generation

Other RCDC features are disabled under a STAAD.Pro (basic) license.

Note: Use caution when opening and saving an RCDC model created under a STAAD.Pro (basic) license. Opening and saving that file in RCDC under a RCDC or STAAD.Pro Advance license will result in that file no longer being able to be opened under a STAAD.Pro (basic) license.



Interactive Concrete Designer

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

The legacy Concrete Design workflow has been fully deprecated as of CONNECT Edition V22 Update 5, you will no longer be prompted with the option to switch to Concrete Design Workflow and launch RC Designer; even for the legacy projects which used the Concrete Design Workflow. Advanced Concrete Design Workflow only opens RCDC

CONNECT Edition V22 Update 2

The Software Release Report for STAAD.Pro CONNECT Edition V22 Update 2 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition V22 Update 1 (release 22.01). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 22.02.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 22.02.00-1.1 Temporary Folder for Analysis Over Network

Analysis of input file located on a network drive can result in significantly increases analysis times. STAAD.Pro now gives you the option to specify a local temporary folder to use for when the input files are on a network.

There is also a setting to provide a warning message when the analysis is being performed over a network. Both warning message and temporary folder locations are configured in the **Application Configuration** dialog **Options** tab.

Related Links

- *GS. Application Configuration dialog* (on page 59)

RR 22.02.00-1.2 Updated Backup and Restore of Projects

A new system for creating backups and restoring from backups has been implemented. This now includes physical model files for projects.

A restore point is a backup of all files associated with a STAAD input model, including a physical model if one is present. The option to include analysis output files is also available when creating a restore point.

Note: This method replaces the previous method of creating backups, including automated backups, in STAAD.Pro.

A new auto-recovery feature has been added to replace the previous Autosave method. This feature will automatically create backups based on a specified time interval (default of 5 minutes) of your entire STAAD project, including physical models. In the event of a program crash or if the program is simply closed without saving changes, the program will detect the auto recovery files and prompt you to open from that recovery state when you re-open the associated STAAD model.

Related Links

- *I. To create a restore point* (on page 2065)
- *I. To restore a model from a backup* (on page 2066)
- *I. To enable auto-recovery* (on page 2065)

RR 22.02.00-1.3 Chinese Steel Sections Update

The database of Chinese steel profiles has be updated to GB/T 706 2016.

RR 22.02.00-2 Features Affecting the Preprocessor

The following section describes the new features that have been added that affect the preprocessor section of the program, also known as the Analytical Modeling workflow and Physical Modeling workflow (or STAAD.Pro Physical Modeler).

RR 22.02.00-2.1 Physical Modeler Snow Loads

STAAD.Pro Physical Modeler can now generate snow load cases for use directly in the Analytical Modeling workflow.

STAAD.Pro Physical Modeler also now allows you to “group” model objects (members, surfaces, and nodes) together for applying loads such as snow loads.

Refer to the STAAD.Pro Physical Modeler help for additional details on using snow loads.

RR 22.02.00-2.2 Physical Modeler Wind Loads

STAAD.Pro Physical Modeler can now generate wind load cases for use directly in the Analytical Modeling workflow.

Refer to the STAAD.Pro Physical Modeler help for additional details on using wind loads.

RR 22.02.00-2.3 Physical Modeler Temperature & Strain Loads

STAAD.Pro Physical Modeler can now apply temperature and strain loads for use directly in the Analytical Modeling workflow.

Refer to the STAAD.Pro Physical Modeler help for additional details on using temperature or strain loads on members and applying temperature loads to surfaces.

RR 22.02.00-2.4 Physical Modeler Variable Pressure and Hydrostatic Loads

STAAD.Pro Physical Modeler can now apply variable pressure loads and hydrostatic to surfaces.

Refer to the STAAD.Pro Physical Modeler help for additional details on using variable pressure loads.

Hydrostatic loads are a means of generating a variable pressure loads using fluid density and depth parameters.

Refer to the STAAD.Pro Physical Modeler help for additional details on using hydrostatic loads.

RR 22.02.00-2.5 Physical Modeler Inclined Nodal Loads

STAAD.Pro Physical Modeler can now apply nodal loads along user-defined directions in addition to global axes.

Refer to the STAAD.Pro Physical Modeler help for additional details on using inclined nodal loads.

RR 22.02.00-2.6 Physical Modeler Edit Surface Mode

STAAD.Pro Physical Modeler has a new tool which allows you to edit surfaces (such as materials, thickness, openings, etc.) in an isolated, elevation view. You can then merge the surface edits back to your main model.

Refer to the STAAD.Pro Physical Modeler help for additional details on adding polygonal openings and adding circular openings to surfaces using this feature.

RR 22.02.00-3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 22.01.00-3.3 IS 13920 2016 Seismic Joint Checks

STAAD.Pro can now check the relative strength of beams and columns at a joint per Clause 7.2 of IS 13920-2016.

Clause 7.2 of IS:13920-2016 checks the relative strength of beams and columns at a joint to evaluate if any column at a joint is acting as a gravity column or is a part of lateral load resisting system. After the concrete design is completed per IS 13920-2016, then this relative strength check is automatically performed at joints in which *all* connecting beams and columns were designed. Thus, no new commands are required for this check to be performed so long as all concrete members at a joint are designed. Per Cl 7.2, the sum of all column moment resistances at a joint shall be greater that 1.4× the sum of all beam moment resistances at the same point.

Note: STAAD.Pro does not have designate columns as gravity load structural elements. Rather, the program considers all columns as lateral load resisting. If this check fails at any joint, the column dimensions, beam dimension, or both should be changed to make the column suitable for the lateral load resisting system.

It is recommend that the design of all concrete beams and columns be performed in one concrete block (a “concrete block” is the information contained in the `START CONCRETE DESIGN … END CONCRETE DESIGN` input section) so this check can be performed. If multiple concrete blocks are defined, all previous relative strength check result will be deleted since multiple design of beams and column designs may change the relative strength of beams and columns at a joint. The strength check performed after the last concrete block will be considered valid and is available as result.

The output file will issue a note regarding the results of this check. A detailed output of the checks can be included in the output using the `TRACK 4` parameter in the concrete design. The detailed output of the joint relative strength checks are also included in the *`filename`*`_13920.txt` file (which is generated regardless of the `TRACK` parameter used or check status).

Note: The program assumes that all beams connected to a column are horiztonal and parallel to global X and Z axes. If beams do not meet this requirement a warning message is issued in the analysis output.

Related Links

- *D8.F.4 Design Parameters* (on page 1686)

RR 21.03.00-3.1 Response Spectra per IBC 2018 / ASCE 7-16

Automatically generated response spectra loads per IBC 2018 / ASCE 7-16 are now available in STAAD.Pro.

The spectral acceleration data is now retrieved using the USGS dynamic web service (where as in older editions of the code this was extracted from text files made available from the USGS).

Notes:

- Exceptions 1 in Clause 11.4.8 of ASCE 7-16 is implemented. In exception 1, for Site class E and S_s > 1.0, Fa value is taking the same for site class C. In this case, there is slight reduction in the seismic force generated.
- The exception of Clause 2 in 11.4.8 of ASCE 7-16 is *not* implemented in STAAD.Pro for response spectra.
- The vertical ground motion for seismic design as described in clause 11.9 is *not* implemented as the program cannot determine the vertical time period, T_v.
- ASCE 7-2016 Clause 12.9.1.4 stipulates that if the combined response for modal base shear, V, is less than that of the calculated base shear from the equivalent lateral force procedure, V_t, then the response spectra values should be scaled up by V/V_t. STAAD.Pro does not automatically check this nor increase the response quantities in this situation. You can check this by simply analyzing TR.31.2.17 IBC 2018 Seismic Load Definition (on page 2416) and comparing the base shear values. The X, Y, or Z factors for the response spectrum can be then increased accordingly if required.

Related Links

- *TR.32.10.1.13 Response Spectrum Specification per IBC 2018* (on page 2578)

RR 22.01.00-3.3 ASCE 7 Seismic Irregularities Checks

STAAD.Pro can now check for vertical and plan irregularities per the ASCE 7 05, 10, and 2016 codes for structures with defined rigid floor diaphragms.

Note: The program can additionally check for soft stories per the ASCE 7 code.

For ASCE 7-05/10/16, the program can check horizontal irregularities (torsional and reentrant corners) and vertical irregularies (mass). Irregular modes of oscillation are not considered for this code.

ASCE 7 Example Output

An example output section of an ASCE 7-2016 seismic irregularities check:

```
                    STAAD.PRO IRREGULARITIES CHECK - (  ASCE7-2016   )   v1.0
                    ****************************************************

RR 22.02.00-4 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the post processing and interactive design workflows. These are explained in the following pages.

RR 22.02.00-4.1 RAM Connection Workflow Update

RAM Connection CONNECT Edition V13.1 is now supported in STAAD.Pro CONNECT Edition.

- Now compatible with versions of RAM Connection CONNECT Edition up through release 13.1 (CONNECT Edition V13.1).
- Connection Design per the NZS 3404 1997 (New Zealand) code

RR 22.02.00-4.2 Multiple Steel Design Results

The program can now display the results from different steel designs (parameter blocks).

If an input file contains multiple parameter blocks (steel design parameter sets) or multiple design commands (steel code check or member selections) within a single parameter block, then the results are available in the Postprocessing workflow. Parameter sets are numbered and multiple design commands in the same parameter block are given as decimals.

Note: This feature is compatible with AISC 360-16 only in this release.

Note: For AISC 360-2016, a maximum of nine (9) design commands may be specified in a parameter block.

The **Layouts** > **Utilization** table displays results from each parameter block or design command. Similarly, the STAAD Output Viewer displays the results for each in the Contents pane.

Multiple Parameter Blocks

```
PARAMETER 1
CODE AISC UNIFIED 2016
METHOD ASD
CHECK CODE MEMBER 1 TO 10
*
PARAMETER 2
CODE AISC UNIFIED 2016
METHOD LRFD
CHECK CODE MEMBER 1 TO 10
```

Multiple Design Commands

```
PARAMETER 1
CODE AISC UNIFIED 2016
TRACK 2 ALL
```

```
CHECK CODE MEMBER 1 TO 5
SELECT MEMBER 1 to 5
```

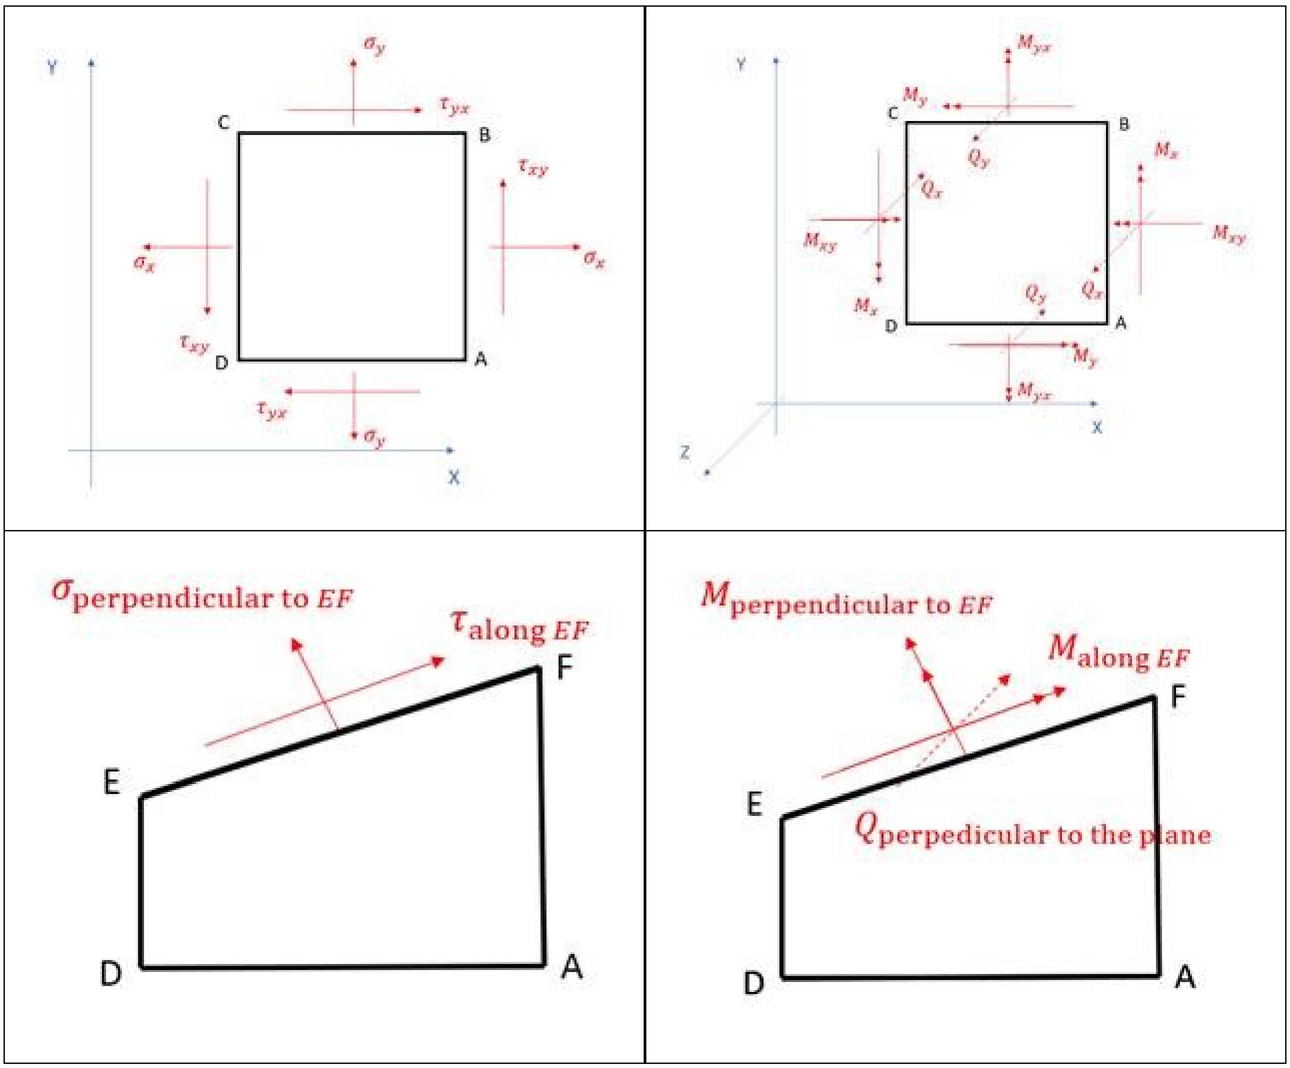
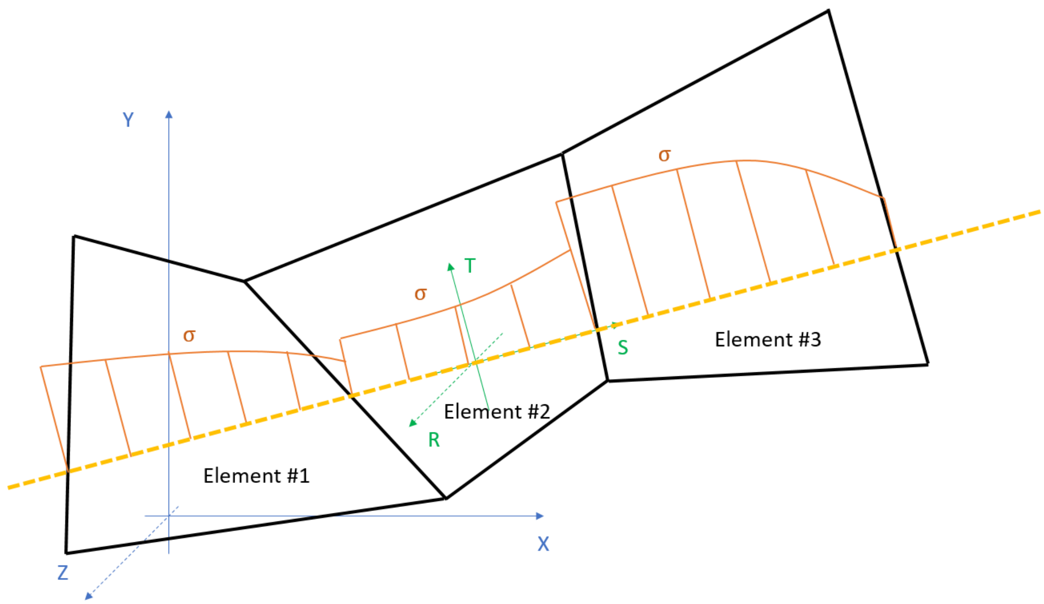
RR 22.02.00-4.3 Results Along a Cut Line

Stresses that are continuous across element boundaries and forces which are equilibrium can now be obtained any arbitrary cut line for elements in the Post Processing workflow.

Given a finite element, ABCD, which is subject to a set of stresses, it is possible using mechanics theory to cut that element along an arbitrary line, EF, and resolve the forces at the cut surface.



However, the forces of adjacent finite elements obtained this way are not balanced (i.e., not in equilibrium) and the stress values are discontinuous across element boundaries.



STAAD.Pro has stress result options for cut lines which employ a method of mathematically processing the FEA stress results which are then in equilibrium against the cross-section forces and are continuous across element boundaries. The cut line coordinate system, STR, is used (i.e., a local coordinate system with S as the axis along the cut line, T in the plane of the elements, and R normal to those elements).

The following nomenclature is used for the cut line-oriented results available in STAAD.Pro:

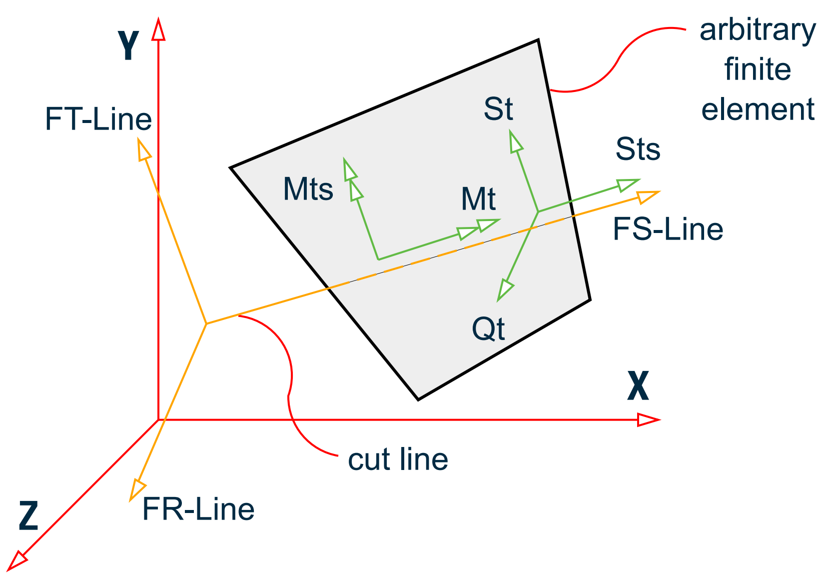


Figure 6: Stresses along a cut line for "-Line" stress types

St Normal stress perpendicular to the cut line, σ_t.

Sts Shear stress along the cut line, τ_t.

Mt Bending moment along the cut line, M_t.

Mts Bending Moment about the T axis. This is in the plane of the plate and perpendicular to the cut line (i.e. the S axis).

Qt Out-of-plane shear, Q_t

Forces listed in the table when these results are selected are given in the in a coordinate system relative to the cut line (i.e., “FS” is along the cut line, “FT” is in the plane of the element, and “FR” is normal to the element). This is indicated by the “-Line” suffix of the results.

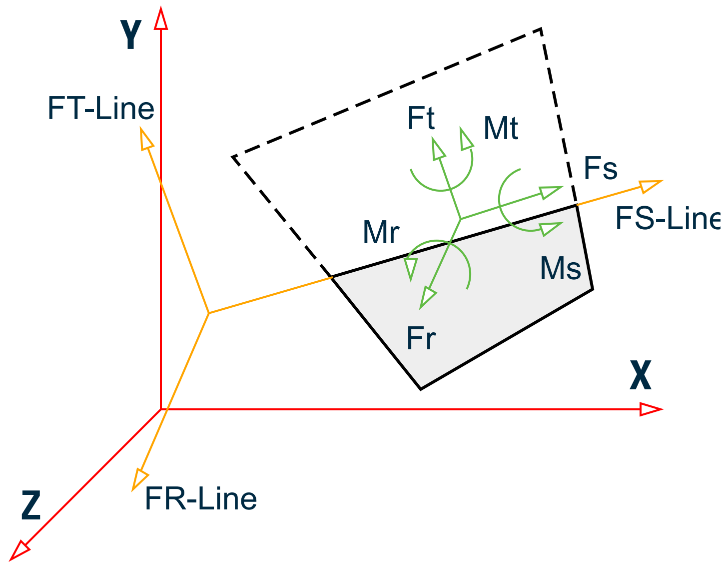

Figure 7: Forces along a cut line for “-Line” stress types

Fs Resultant force along the cutline

Ms Resultant moment about the cutline

Ft Resultant force perpindicular to the culine in the plane of the plate

Mt Resultant moment about the line perpindicular to the cutline in the plane of the plate

Fr Resultant force perpindicular to the cutline out of the plane of the plate

Mr Resultant moment about the line perpindicular to the cutline out of the plane of the plate

CONNECT Edition V22 Update 1

The Software Release Report for STAAD.Pro CONNECT Edition V22 Update 1 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition V22 (release 22.00). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 22.01.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 22.01.00-1.1 Reduced Section Properties per IS1893 2016

IS1893 2016 Clause 6.4.3 calls for a reduction of moment of inertia values by 0.35 for beams and 0.7 for columns of concrete members only while analyzing the structure for static seismic and response spectrum/linear dynamic analysis. STAAD.Pro now includes a code-specific option for reduced section properties of concrete members which will automatically generate a separate stiffness matrix for these IS1893 2016 load cases. For all other load cases, the analysis will be performed using the unreduced stiffness matrix.

You may use this feature by either selecting the new **Code Specific** option and then selecting **IS1893 2016** as the code in the **Member Specification** dialog Property Reduction Factors tab. You can manually enter the command using the `MEMBER CRACKED CODE IS1893 2016` command.

Note: Automated stiffness reduction requires a STAAD.Pro Advanced license.

Using the code-specific member reduction properties helps by automating the analysis for when reduced section properties are required by the IS1893 2016 code. A separate stiffness matrix is produced using the reduced stiffness values for use with load cases containing IS1893 2016 static seismic and response spectrum loads. The unreduced stiffness matrix is then used for all other load cases.

The prime advantage of this feature is that this analysis is completely automated once the reduction factors are defined. Previously, in order to comply with the IS1893 2016 Clause 6.4.3 provision, you would have to specify reduced section properties for members, analyze the structure for only the IS1893 2016 seismic load cases, then use a `CHANGE` command to reset the stiffness reduction factors back to unity, and then re-analyze the structure for the remaining load cases. Care had to be taken that only concrete members had the reduction factor applied, as the global `MEMBER CRACKED` command can be applied to *any* member. For large models with hundreds and thousands of members and hundreds of load cases, the implementation of clause 6.4.3 using the previous reduction command would be very cumbersome.

Use of the code-specific reduction factors automates the analysis procedure. These reduction factors are only applied to concrete members with the member list or member groups (non-concrete members are ignored for this command). The separate stiffness matrix is automatically created using these reduction factors for use with IS1893 2016 seismic loads only while the unreduced stiffness matrix is used for all other load cases. No re-analysis or change commands are required.

RR 22.01.00-1.2 Import General Sections from Section Wizard

General shapes can now be imported from Section Wizard for use in the program.

Note: This profile shape should consist of only an outer contour. Any internal voids such as internal contours or openings will be ignored, though section properties calculated by Section Wizard based on sections with voids will be used.

Tip: Changing the structure diagram to display 3D rendering types for Full Sections or Sections Outline will display the shape profile. Similarly, 3D renderings of the structure will also display the shape profile.

RR 22.01.00-2 Features Affecting the Preprocessor

The following section describes the new features that have been added that affect the preprocessor section of the program, also known as the Analytical Modeling workflow and Physical Modeling workflow (or STAAD.Pro Physical Modeler).

RR 22.01.00-2.1 Physical Modeler Static Seismic Loads

STAAD.Pro Physical Modeler can now generate static (equivalent lateral force) seismic load cases for use directly in the Analytical Modeling workflow.

Refer to the STAAD.Pro Physical Modeler help for additional details on using static seismic loads.

RR 22.01.00-2.2 Physical Modeler Response Spectra Loads

STAAD.Pro Physical Modeler can now generate response spectra load cases for use directly in the Analytical Modeling workflow.

Refer to the STAAD.Pro Physical Modeler help for additional details on using response spectrum loads.

RR 22.01.00-2.3 Physical Modeler Time History Loads

STAAD.Pro Physical Modeler can now generate time history load cases for use directly in the Analytical Modeling workflow.

Refer to the STAAD.Pro Physical Modeler help for additional details on using time history loads.

RR 22.01.00-3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 22.01.00-3.1 Static Seismic Loads per IBC 2018 / ASCE 7-16

Automatically generated equivalent lateral seismic loads per IBC 2018 / ASCE 7-16 are now available in STAAD.Pro.

The load parameters are assigned using the User Interface or can be manually entered in the STAAD editor.

Automatic load combinations using the tables from IBC 2018 can be added using the Auto Load Combination dialog (on page 2872), as well.

Changes from IBC 2015/ASCE 7-10 Code

The changes in seismic provisions of IBC 2018/ASCE 7-16 over the previous version IBC 2015/ASCE 7-10 are mainly observed in Mapped Spectral Acceleration parameters outlined in chapter 22. STAAD.Pro uses the spectral acceleration data in text format available in USGS site https://earthquake.usgs.gov/hazards/designmaps/datasets/.

Note: The mapped spectral response acceleration values for IBC 2018 are retrieved from dynamic data provided by the USGS when `ZIP` code or `LAT/LONG` methods are used. An internet connection is required for this. If an internet connection is not available, then the values should be input using the `SS` and `S1` parameters.

The other significant change in the seismic provisions are in long-period site coefficient, F_a, and short-period site coefficient, F_v. Table 11.4-1 and 11.4-2 of the code provides the value of F_a and F_v respectively. These values are used for the IBC 2018 implementation in STAAD.Pro.

Note: Other changes to this portion of the code from the previous edition are not relevant to the calculations performed by STAAD.Pro.

RR 22.01.00-3.2 IS 801 Cold-Formed Steel Design

The design of cold-formed steel members per the IS 801 code is again available in STAAD.Pro.

RR 22.01.00-3.3 IS 1893 2016 Seismic Irregularities Checks

STAAD.Pro can now check for vertical and plan irregularities per the IS 1893 2016 code for structures with defined rigid floor diaphragms.

Note: The program can additionally check for soft stories per the IS 1893 2016 code.

For IS 1893 2016, the program can check horizontal irregularities (torsional and reentrant corners) per Table 5 and vertical irregularities (mass irregularities and irregular modes of oscillation) per Table 6.

IS 1893 2016 Example Output

An example output section of an IS 1893 2016 seismic irregularities check:

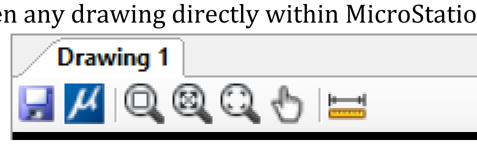
RR 22.01.00-4 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the post processing and interactive design workflows. These are explained in the following pages.

RR 22.01.00-4.1 Steel AutoDrafter Workflow

The Steel AutoDrafter can now open any drawing directly within MicroStation.



Note: If you have MicroStation PowerDraft installed instead of MicroStation, you will have that product's icon instead of the MicroStation icon in the drawing toolbar.

- *P.To open a drawing in MicroStation* (on page 2027)

RR 22.01.00-4.2 RAM Connection Workflow Update

RAM Connection CONNECT Edition V13.0 is now supported in STAAD.Pro CONNECT Edition.

- Now compatible with versions of RAM Connection CONNECT Edition up through release 13.0 (CONNECT Edition V13).
- Connection Design per the AS4100 1998 (Australian) code

CONNECT Edition V22

The Software Release Report for STAAD.Pro CONNECT Edition V22 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition Update 3 (release 21.03). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 22.00.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

Related Links

- *GS. STAAD.Pro License Configuration dialog* (on page 57)
- *GS. Starting STAAD.Pro* (on page 33)

RR 22.00.00-1.1 CONNECT Licensing

STAAD.Pro now uses Bentley's CONNECT License system, Bentley's new process for product activation and usage tracking, improving our licensing capabilities with features such as:

- License alert notifications when you are approaching a custom usage threshold
- Replacing site activation keys with user validation, enhancing security around your Bentley licenses and subscriptions

With traditional SELECT Licensing, product activation has been through an activation key that an Organization distributed to all users. With CONNECT Licensing, product activation is managed by user sign in through the CONNECTION Client, which is installed on each machine that uses Bentley applications. This offers a more secure and manageable system as it offers usage alerts, notifying your users when they are about to reach a certain usage limit set by the Administrator.

Detailed information is available at Bentley Communities Licensing and Activation Wiki: https://communities.bentley.com/products/licensing/w/licensing__wiki/37813/connect-licensing for detailed information.

Related Links

- *GS. STAAD.Pro License Configuration dialog* (on page 57)

- *GS. STAAD.Pro License Configuration dialog* (on page 57)

STAAD.Pro CONNECT Edition

CONNECT Edition Update 3

The Software Release Report for STAAD.Pro CONNECT Edition Update 3 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition Update 2 (release 21.00.02). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 21.03.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 21.03.00-1.1 APL Apollo Structural Tube Sections

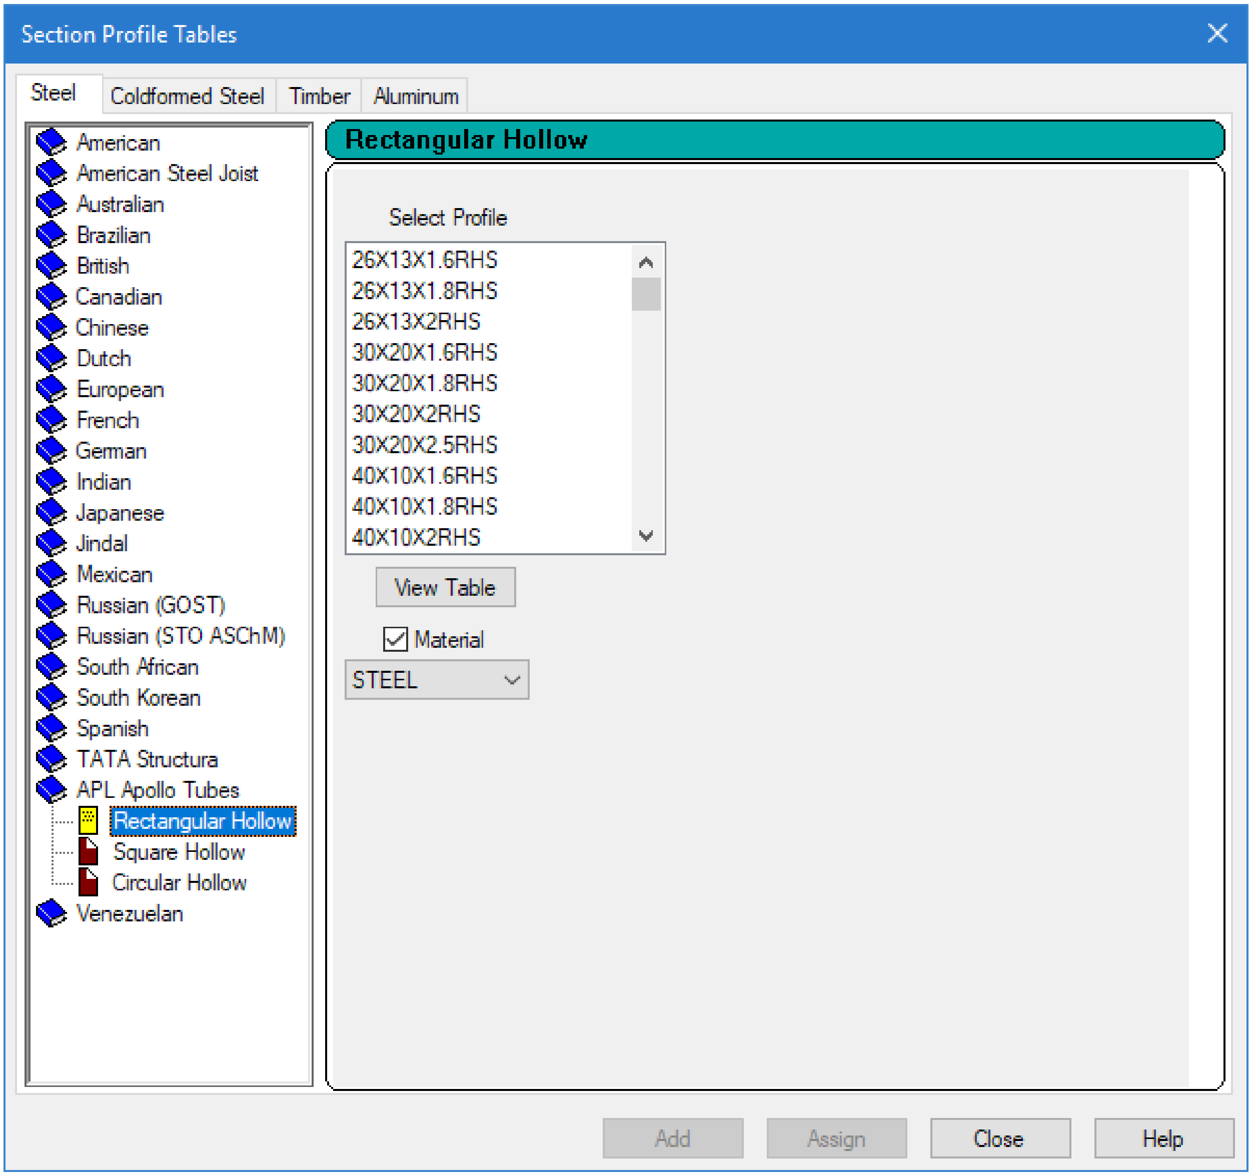
The catalog of available steel sections has been expanded to include the hollow sections from APL Apollo (India).

To specify an APL Apollo tube section

1. Select the **Specifications** ribbon tab.
2. On the **Properties - Whole Structure** dialog, click **Section Databse**.

   The **Section Profiles Table** dialog opens.
3. Select **APL Apollo Tubes** in the list of tables on the **Steel** tab.
4. Select the profile type to use from the list of tables:

   Rectangular Hollow
   Square Hollow
   Circular Hollow



5. Select the profile from the **Select Profile** list.
6. (Optional) Check the **Material** option to specify the selected material with the profile.
7. Click **Add**.

   The section is now added to the Section tab in the **Properties - Whole Structure** dialog box and can be assigned to members.

- *Section Profile Tables dialog* (on page 2793)
- *RR 21.03.00-3.1 Static Seismic Loads per IBC 2015 / ASCE 7-10* (on page 136)

RR 21.03.00-1.2 Steel Grade A1085 Profiles in AISC 360-16 and 360-10

Steel pipes and tubes using A1085 grade material can now be designed using AISC 360-16 and AISC 360-10 design codes.

A new set of section tables are available in the American Steel Tables for HSS Rectangle and HSS Round shapes to make use of the A1085 steel grade. Sections using this steel grade have properties which use the *full* nominal wall thickness.

Note: Use of profiles from the _A1085 steel tables will result in that material be used, regardless of the SGR parameter for AISC 360-16 or WTYP parameter for AISC 360-10.

RR 21.03.00-1.3 Inclined Loads Input via Create New Load Items Dialog

Inclined loads can now be easily added via the graphical user interface in the **Create New Load Items** dialog.

Previously, an inclined nodal load –that is a nodal load applied in coordinate system other than the global coordinate system– required editing the STAAD input file. These loads can now be applied by defining a reference node, relative reference point, or absolute reference point in the graphical user interface's Analytical Modeling workflow.

RR 21.03.00-2 Features Affecting the Preprocessor

The following section describes the new features that have been added that affect the preprocessor section of the program, also known as the Analytical Modeling workflow and Physical Modeling workflow (or STAAD.Pro Physical Modeler).

RR 21.03.00-2.1 Physical Modeling Load Cases and Combinations

STAAD.Pro Physical Modeler can now generate load cases and combinations for use directly in the Analytical Modeling workflow.

RR 21.03.00-2.1 Physical Modeling Circular Openings

STAAD.Pro Physical Modeler can now model circular openings in surfaces with a defined radius.

RR 21.03.00-2.3 Physical Modeling Connection Tags

You can now assign connection tags from with STAAD.Pro Physical Modeler. These will be exported to the analytical model in STAAD.Pro as well as to a corresponding ISM repository.

RR 21.03.00-2.4 Miscellaneous Enhancements to the Physical Modeler

The following additional enhancements have been made to the STAAD.Pro Physical Modeler.

- A new file format is used. When opening a model created in a previous version of STAAD.Pro Physical Modeler, you will be prompted to save to the new format.
- New **Spreadsheet** and **Data** ribbon tabs have been added to make the spreadsheet controls consistent with other tools in the application. The **Spreadsheet** ribbon tab is used to select the current spreadsheet. The **Data** ribbon tab is used to perform actions on the current spreadsheet, view window, or output panel (similar to right-click pop-up menus in each of those respective application areas).
- The ISM workflow has been enhanced to place common settings in the program configuration. This helps to streamline ISM repository actions.

RR 21.03.00-2 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 21.03.00-3.1 Static Seismic Loads per IBC 2015 / ASCE 7-10

Automatically generated equivalent lateral seismic loads per IBC 2015 / ASCE 7-10 are now available in STAAD.Pro.

The load parameters are assigned using the User Interface or can be manually entered in the STAAD editor.

Automatic load combinations using the tables from IBC 2015 can be added using the Auto Load Combination dialog (on page 2872), as well.

- *RR 21.03.00-3.1 Static Seismic Loads per IBC 2015 / ASCE 7-10* (on page 136)

RR 21.03.00-3.5 Soft Story Checks per IS 1893 2016

The check soft story option may be added to a floor diaphragm command set to check for soft stories per IS1893:2016. The previous (approximate) method for checking soft stories implemented for IS 1893 2002 has been deprecated in favor of a displacement-based approach using rigid diaphragms.

Soft story checking a process by which designers check stiffness of a story with that of the story above. If the stiffness of a story is lower than that of the story above, the story is considered as a Soft story. Having a soft story in the building makes that story venerable to Earthquake. As per the revised IS 1893 Part-1:2016, if a soft story is detected, structural configuration needs to be change with the introduction of additional lateral load resisting elements in the story detected as soft story. The previous version of IS 1893 Part-1, had provisions to increase design story shear in the soft story and increase percent of steel in the lateral load resisting elements in that soft story. This provision has been withheld in the present version of the code. This makes the situation a stringent one for the designer if a story is detected as a soft story.

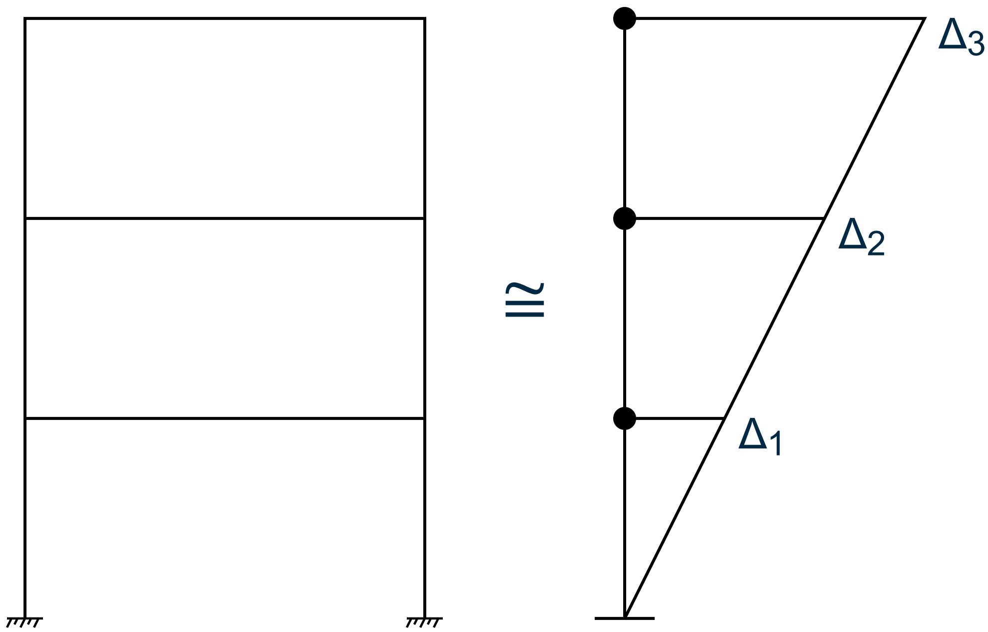
Soft Story Checking

There was an approximate methodology available in STAAD.Pro. The program used to compute story stiffness of a story by summing up the lateral stiffness of columns and shear walls (modelled using surface elements). The stiffness of a column is calculated as $12EI / L^3$ where E is the Young's modulus, I is the moment of inertia and L is the length of the column respectively and that for a shear wall (without opening) is calculated as $Ph^3/3EI + 1.2Ph/AG$ (i.e. summation of flexural stiffness and shear stiffness, obtained as deflection of a cantilever wall under a single lateral load P at its top) where h is the height, A is the cross-sectional area and G is the shear modulus of the wall (E and I carry usual meaning).

This method is approximate one and works in the presence of FLOOR HEIGHT commands. On studying the literatures available on this subject, this method proved to be approximate as it fails to capture actual story stiffness including the effect of bracings. Story stiffness should be computed using a displacement based approach. STAAD.Pro is currently equipped with the facility to consider the in-plane stiffness of slabs as Rigid Diaphragm. In STAAD.Pro lateral stiffness is calculated only when the floor is modeled as rigid floor diaphragm since it functions as transferring story shears and torsional moments to lateral force-resisting members during earthquake.

Story Stiffness Computation Example

Consider a multi-story building:



The points are control nodes. The story stiffness is it defined as the inverse of inter-story drift when a *unit load* is applied at that story only.

The unit load applied is along X, Z and θY.

Consider the displacement of 2nd story. The displacements are:

Story 1: ΔX1, ΔZ1, θY1;
Story 2: ΔX2, ΔZ2, θY2

Relative Displacement for story 2 is:

RX2 = ΔX2 - ΔX1; RZ2 = ΔZ2 – ΔZ1; RθY2 = θY2 - θY1

Story Stiffness X =1/((ΔX2 – ΔX1))

Story Stiffness Z =1/((ΔZ2 – ΔZ1));

Story Stiffness θY = 1/((θY2 - θY1))

The rest is the same for all the other stories.

Note: This story stiffness is not the same as column story stiffness which is calculated as *(nCol × 12EI/L3)*, n= number of columns.

Command Input

The story stiffness can be printed using the `PRINT STORY STIFNESS` command.

If soft story check is required to be performed following commands are required to be defined immediately after rigid floor diaphragm is specified in the `FLOOR DIAPHRAGM` command.

CONNECT Edition Update 2

The Software Release Report for STAAD.Pro CONNECT Edition Update 2 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition Update 1 (release 21.00.01). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 21.00.02-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 21.00.02-1.1Select ribbon tab

A new ribbon tab containing tools for selecting model objects has been added to several of the workflows.

Having quick access to the selection tools on a single ribbon tab makes selecting objects and then further refining the selection set easier.

The Select ribbon tab is available in multiple workflows, so you no longer have to switch to the Analytical modeling workflow to change the object selection as required in some instances in previous releases.

Related Links

- *Select tab* (on page 2769)

RR 21.00.02-1.2 New Output Viewer

The STAAD.Pro Editor is now used to view the analysis results file in the Analytical modeling workflow.

The updated editor is now used to navigate the results file (file extension `.anl`).

Related Links

- *P. To view analysis results* (on page 1978)

RR 21.00.02-2 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 21.00.02-2.1 AISC 360-16

The program can now perform steel design of members per ANSI/AISC 360-16 *Specifications for Structural Steel Buildings*.

The seismic provisions of AISC 341-16 are also implemented.

Performance Enhancements - Design for `CODE CHECK` / `MEMBER SELECT` up to 20 times faster than AISC 360-10.

Detailed Design output - `TRACK` 0,1, & 2 reports improved to display more intermediate results.

AISC 360-16 Design

To use the 2016 edition, specify the command:

```
CODE AISC UNIFIED 2016
```

The checking or selection of members is performed per the following sections of AISC 360-16 and AISC 341-16:

- Section Classification: Chapter B
- Tension Chapter D
- Compression: Chapter E
- Flexure: Chapter F
- Shear: Chapter G
- Torsion (Including checks as per DG-9 for certain profile shapes – see below): Chapter H & Design Guide 9 for Torsion design
- Combined actions – Chapter H for:
  - Axial and/or

- Flexure and/or
- Shear and/or
- Torsion
- Checks for Seismic suitability – AISC 341-16

The following section profile shapes are allowed for design:

- Rolled Shapes
  - I-Shape
  - Channel
  - Single angle
  - Solid Circular bar
  - Solid Rectangular bar
  - Tee
  - HSS rectangular
  - HSS round
- Built Up Shapes
  - Built Up Channel
  - Built Up I
  - Double Channels – back to back
  - Double Channels – face to face
  - Double Angles
  - Built Up Box
  - I With Cover Plates (Top and/or bottom)
- Tapered Shapes
  - I with web tapered
  - Square hollow shape with wall tapered
  - Circular hollow shape diameter tapered

Note: Certain checks (e.g., DG-9 torsion checks) will only be performed for certain profile shapes (non-HSS shapes).

RR 21.00.02-2.2 ACI 318-14

The program can now design concrete columns and beams per ACI 318-14 *Building Code Requirements for Structural Concrete*

The following describes the code clauses from ACI 318-14 implemented for beams and columns.

Note: Plate elements and deep beams cannot be designed per ACI 318-14. Use an older edition of the ACI code to design these elements if needed.

Materials

- Beams

  19.2.2
  19.2.3.1

19.2.4.2

- Columns

  19.2.2
  19.2.4.2

Minimum Reinforcement

- Beams

  9.6.1.1
  9.6.1.2
  9.6.1.3
  9.7.2.1
  9.7.6.4.2
  9.7.6.4.3

- Columns

  10.6.1
  10.7.2.1
  10.7.3.1
  10.7.6.1
  10.7.6.2
  25.2.3

Clauses 9.7.6.4.2 and 9.7.6.4.3 are not included in the standard design criteria of the minimum reinforcement since the design of these criteria should consider the rebar including the bar detailing and thus they should be applied in a second design after performing the strength design and the bar detailing.

Clause 9.6.1.3 is also not included in the standard criteria since the reduction of the minimum reinforcement is optional.

Service

- Beams

  9.7.2.2
  9.7.2.3

25.4.3
- Columns

  25.4.1.4
  25.4.2
  25.4.3

Span Detailing

- Beams

  9.7.3.3
  9.7.3.8
  9.7.7

RR 21.00.02-2.3 Russian Wind Load per SP 20.13330.2016

Static and dynamic wind loads per the SP 20.13330.2016 SNiP 2.01.07-85 code can now be applied in STAAD.Pro.

In order to perform dynamic wind load generation in STAAD.Pro you must previously define a static load case. The static load case could be any primary static load case which is defined before the Russian dynamic load case, including a static wind loading per the same code. This static load case will provide static load vector to the dynamic wind load module.

As the Russian dynamic wind load component requires modal masses and eigen vectors to calculate the dynamic wind load component at nodes, modal analysis must be performed before the dynamic wind load definition. Therefore, you must also include a separate load case for modal analysis with reference mass defined before the load case. See G.17.3.2 Mass Modeling (on page 2157) for details. Alternatively, if the mass loads are not needed for use with other load cases (that is, a reference load case is not needed for other loads), then you may define the mass loads within the dynamic load case prior to the `WIND LOAD` command.

CONNECT Edition Update 1

The Software Release Report for STAAD.Pro CONNECT Edition Update 1 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition (release 21.00.00). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 21.00.01-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 21.00.01-1.1 Share to ProjectWise

You can now share a STAAD.Pro project directly to a ProjectWise data source. STAAD.Pro lets you select which files associated with the input (`.std`) file you want to include.

Related Links

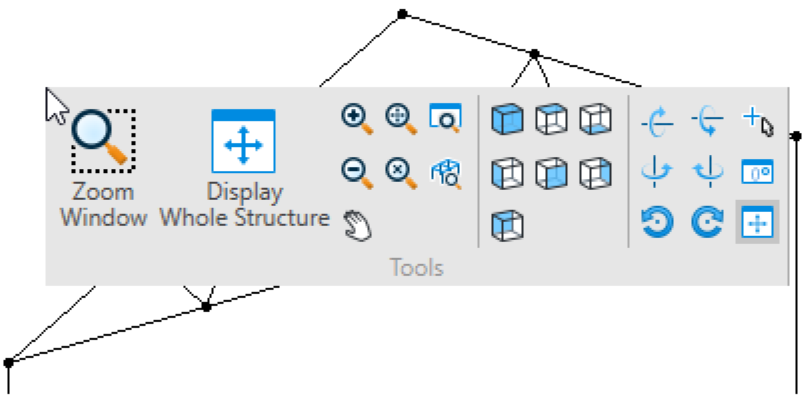
- *I. To share a STAAD.Pro project in ProjectWise* (on page 2076)

RR 21.00.01-1.2 Quick Commands

Two new sets of quick commands have been added to the graphical view window to allow for quicker model navigation and modeling.

Quick Navigation

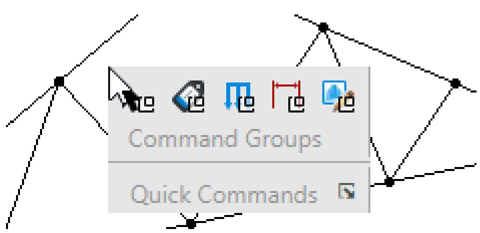
Press **<Shift>** when right-clicking in the view window to open the **View** ribbon tab **Tools** group and your mouse pointer location.



Quick Commands

Press the space bar when the view window has the application focus to open the Quick Commands menu. This customizable pop-up menu contains the following groups of tools:

- **Geometry** ribbon tab **Selection** group
- **View** ribbon tab **Labels** group
- **Loading** ribbon tab **Display** group
- **Utilities** ribbon tab **Geometry Tools** group
- **Utilities** ribbon tab **Utilities** group



You can customize the Quick Commands with any tool by clicking the icon and then adding tools from the **Customize Quick Commands Popup** dialog.

Related Links

- *GS. Right-Click View Tools menu* (on page 70)
- *GS. Quick Commands Pop-up menu* (on page 74)

RR 21.00.01-2 Features Affecting the Preprocessor

This section describes features that have been added that affect the preprocessor section of the program, also known as the Modeling Mode.

RR 21.00.01-2.1 Ritz Vector Analysis with User-Defined Starting Load Vectors

You can now directly specify the starting load vectors for use with load dependent Ritz vector method for the eigen solution.

Related Links

- *TR.31.9 Defining Starting Load* (on page 2459)
- *M. To use starting vectors with load-dependent Ritz vectors* (on page 885)

RR 21.00.01-3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 21.00.01-3.1 AISC 360-16 Technical Preview

The program can now perform steel design of members per ANSI/AISC 360-16 *Specifications for Structural Steel Buildings*.

Note: This feature was released as Technical Preview. It has been released as a commercial feature in a more recent release.

Related Links

- *D1.A. American Codes - Steel Design per AISC 360 Unified Specification* (on page 1086)

CONNECT Edition

The Software Release Report for STAAD.Pro CONNECT Edition contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8*i* (SELECTseries 6) (release 20.07.11). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 21.00.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 21.00.00-1.1 New User Interface

The STAAD.Pro user interface has been updated and refined.

Ribbon Controls

The menus and toolbars have been replaced with a series of tabbed toolbars along the top of the application window. These are context sensitive to the current “workflow” as well as to the current model selection. There are fewer tools displayed at one time, so they can be larger and thus easier to identify. However, the tools you need are always available by selecting the tab (similar to menus in a tradition Windows program).

The icons for the tools are updated to reflect a consistent theme, further making the correct tool easy to identify.

Workflows Panel

The system of application modes has been replaced with the Workflows panel.

Tip: Once you become familiar with the workflows, you can hide the panel to display a larger viewing area. Simply click the Workflow tab again to select a different workflow.

Page Control Bar

The pages within each workflow have been streamlined from those in the previous modes. A single row of pages is displayed for the current workflow, just above the view window. Select the appropriate page for your current task to display the corresponding dialogs and tables.

Tip: If you close some of the dialogs for a page and need to display them again, simply click the **Restore View** tool () on the right-hand side of the page control bar.

RR 21.00.00-1.2 CONNECT Advisor

CONNECT Advisor has since been deprecated and is no longer installed with STAAD.Pro. Please refer to the CONNECTION Client application.

RR 21.00.00-1.3 64-bit Analysis Engine

The STAAD analysis and design engine now utilizes a 64-bit solver.

This allows you to analyze larger, more complex models with more objects and load cases. The analysis engine is faster for models of all sizes.

RR 21.00.00-1.4 Web Help

The product documentation is now delivered as a browser-based “Web Help.” The Web help opens in your default browser.

Refer to GS. Using Online Help (on page 25) for additional details on using Web Help.

RR 21.00.00-1.5 STAAD.Pro Script Editor

A new macro editor is available to create and edit custom scripts to extend STAAD.Pro.

You can launch the new STAAD.Pro Script Editor application by selecting the **Macro Editor** tool in the **Developer** group on the **Utilities** ribbon tab.

RR 21.00.00-2 Features Affecting the Preprocessor

This section describes features that have been added that affect the preprocessor section of the program, also known as the Modeling Mode.

RR 21.00.00-2.1 STAAD.Pro Physical Modeler

You can use physical modeling concepts to generate structure geometry and reference load cases through the STAAD.Pro Physical Modeler interface.

You can launch STAAD.Pro Physical Modeler by selecting this as the modeling method when creating a new model on the Start page or by selecting the **Physical Modeling** workflow for an empty model.

Notes:

- Syncing physical model data will overwrite any model geometry created in the analytical modeling interfaces (i.e, traditional STAAD.Pro user interface or STAAD.Pro Editor).
- You cannot edit geometry, materials, reference loads, etc. created in the physical modeling interface from either the STAAD.Pro user interface or the STAAD.Pro Editor. Physical models must be edited in STAAD.Pro Physical Modeler.
- It is recommend that you begin a physical model by selecting the Physical Modeler from the New Model Wizard.

The Tutorials (on page 387) have been re-written to incorporate the physical modeling workflow. It is recommended that even experienced STAAD users work through these tutorials to familiarize themselves with STAAD.Pro Physical Modeler.

Similarly, take some time to review the **Quick Overview** and **Getting Started** sections of the STAAD.Pro Physical Modeler help as they describe many of the differences in working in STAAD.Pro Physical Modeler versus the traditional STAAD.Pro interface and STAAD input files.

RR 21.00.00-2.2 NBCC 2010 Seismic Load

The program can now generate seismic loads per the National Building Code of Canada, 2010 edition.

Both the equivalent lateral force method and seismic response spectra are now supported per the NRC 2010.

Related Links

- *TR.31.2.4 Canadian Seismic Code (NRC) - 2010* (on page 2362)
- *TR.32.10.1.3 Response Spectrum Specification per NRC 2010* (on page 2512)

RR 21.00.00-3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 21.00.00-3.1 NZS3404:1997 Steel Design

The program can now perform steel design per NZS3404: 1997 *New Zealand Standard for Steel Structures*, Parts 1 & 2, including Amendments 1 & 2.

Refer to D11.A. New Zealand Codes - Steel Design per NZS 3404-1997 (on page 1765) for details on this code implementation.

RR 21.00.00-3.2 ACI 318-14 Technical Preview

The program can now design concrete columns and beams per ACI 318-14 *Building Code Requirements for Structural Concrete*.

Note: This feature was released as Technical Preview. It has been released as a commercial feature in a more recent release.

Related Links

- *D1.F.1 Design Operations* (on page 1198)

RR 21.00.00-4 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the post processing and interactive design workflows. These are explained in the following pages.

RR 21.00.00-4.1 RAM Connection Workflow Update

RAM Connection CONNECT Edition is now supported in STAAD.Pro CONNECT Edition.

- Now compatible with versions of RAM Connection CONNECT Edition up through release 11.1 (CONNECT Edition Update 1).
- Connection Design per the IS800-2007(Indian) code

STAAD.Pro V8*i*

The Software Release Reports for STAAD.Pro V8*i* contain detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2007 build 03. These documents should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

V8*i* (SELECTseries 6)

The Software Release Report for STAAD.Pro V8*i* (SELECTseries 6) contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8i (SELECTseries 5) (release 20.07.10) This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-11.1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

Note: Items labeled with an asterisk (*) were added or updated in the Service Pack 1 release of V8i (SELECTseries 6).

Note: Items labeled with an obelisk (i.e., dagger) (†) were added or updated in the Service Pack 2 release of V8i (SELECTseries 6).

AD.2007-11.1.1 Mode Bar Reorganization

The modes in STAAD.Pro have been reorganized to reflect a linear workflow through modeling, postprocessing, and design stages of a project.

Note: This feature has been replaced by the Workflows feature with the CONNECT Edition Edition of STAAD.Pro.

Additionally, the tabs are color coded by group:

- Blue: preprocessing and modeling
- Light green: postprocessing
- Dark green: foundation design
- Yellow: steel design
- Red: concrete design
- Magenta: earthquake checks

AD.2007-11.1.2 Advanced Analysis Engine Enhancements

The advanced analysis engine has been completely reformatted with new routines to provide even faster methods to build and solve the stiffness matrix.

Arnoldi/Lanczos Eigen Method

In addition to the standard supbspace iteration method for eigen solution, the Advanced Math Solver can use the Arnoldi/Lanczos method. For large scale eigen value problems, the Arnoldi method is very efficient.

Load Dependent Ritz Vectors

Ritz vector analysis can be used for dynamically loaded structures to more efficiently evaluate the relevant modes. It can require significantly less computational effort to evaluate a large structure when compared to natural free-vibration methods.

Autoshfiting of Eigen Vectors

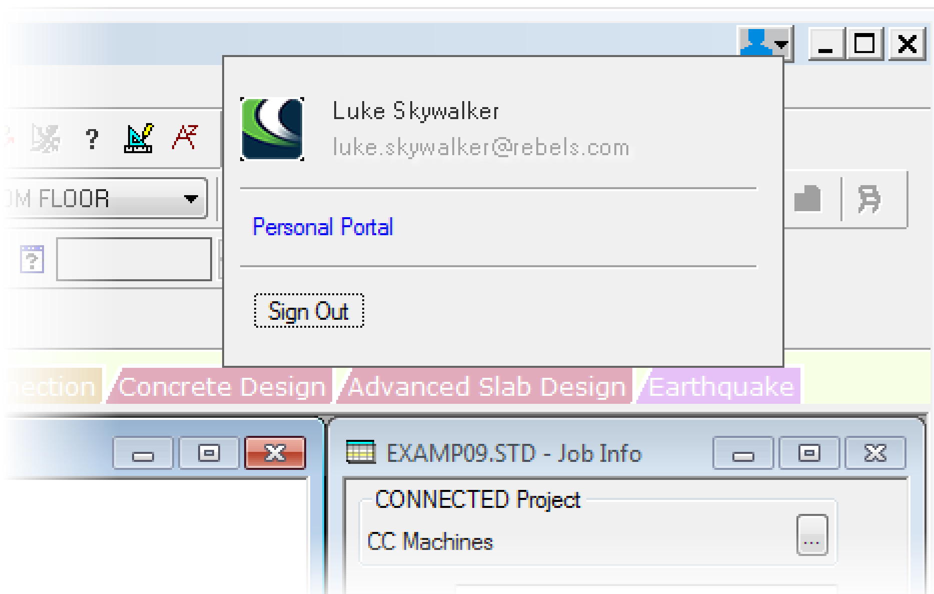
For subspace iteration and the Arnoldi/Lanczos methods, an autoshift option can be used to reduce memory demand for large structures.

Refer to G.17.3.1 Solution of the Eigenproblem (on page 2155) for details.

AD.2007-11.1.3* CONNECT Enabled

STAAD.Pro is now CONNECT Enabled. This means that you can associated your STAAD.Pro models with ProjectWise Projects from within the application to track application usage per project.

You must sign in with your Bentley CONNECT account. The Bentley CONNECTION Client is used to sign in and the status is displayed in the user icon in the top-right corner of the STAAD.Pro application window.



A new menu, **Cloud Services**, has been added which contains ProjectWise Project features, links to cloud portals, and a link to AD.2007-10.1.3* Scenario Services (on page 161) .

Once you start a new model or open an existing model that is not yet associated with a ProjectWise Project, you will be prompted to assign a ProjectWise Project to your model. A list of all registered projects in your organization is displayed. You can also register new projects (Only users with Admin/Co-admin roles can register a project). STAAD.Pro will display the ProjectWise Project name in the **Job Info** dialog as well as in the window title bar.

Tip: As of CONNECT Edition, the **Cloud Services** tools can be found on the **File** ribbon tab in the Backstage.

For additional information on CONNECTED Projects, please see http://www.bentley.com/en-US/Promo/CONNECT/why+connect.htm.

Refer to Cloud Services tab (on page 2703) for details.

AD.2007-11.1.4† RAM Connection CONNECT Edition v11 Support

STAAD.Pro now supports RAM Connection CONNECT Edition (v11.0) and in the Connection Design workflow.

- STAAD.Pro is now compatible with versions of RAM Connection CONNECT Edition up through release 11.0. The following design codes are supported:
  - AISC 360-10 (LRFD and ASD)
  - GB 50017-2003 (China)
  - EN 1993-1-8 (Eurocode 3)
- You can D. To Export Connection Designs to a Report (on page 1037) directly to a Microsoft® Office Word® document from the STAAD.Pro interface.

AD.2007-11.1.5† Connection Tags Enhancements

You can now assign user-defined equations for checking connection tags in STAAD.Pro. The XML Schema for the connection tag files has been updated. See " D. Connection Tags XML File Schema (on page 1052) " in the User Interface help for details on the schema, as well as on using wildcards and created user-defined equations.

AD.2007-11.1.6† Add Member Enhancements

The Add Member functionality in the graphical user interface has been enhanced to facility the saving, loading, and managing of user-defined attribute sets.

Select **Geometry** > **Add Beam** > **Set New Member Attributes** to open the Define Member Attributes dialog (on page 2729). Here you can define the default attributes for various predefined attribute sets, as well as create user-defined attribute sets.

AD.2007-11.1.7† ISM Integration

STAAD.Pro is now capable of transferring data to and from v5 of Bentley's Integrated Structural Modeling technology by means of the StructLink utility.

ISM v5 includes support information, ProjectWise integration, and substructures. Refer to the ISM documentation for additional details.

AD.2007-11.2 Features Affecting the Preprocessor

This section describes features that have been added that affect the preprocessor section of the program, also known as the Modeling Mode.

AD.2007-11.2.1 Building Planner

This modeling tool allows you to rapidly generate concrete building structure models for analysis and design in STAAD.Pro.

PlanWin and FrameWin have now been directly integrated into the STAAD.Pro user interface as the **Building Planner** mode.

The Building Planner workflow is included in SELECT or in a Structural Enterprise License.

Refer to M. Building Planner workflow (on page 920) for details.

AD.2007-11.2.2 STAAD Editor

A new STAAD editor has been added which has advanced features for manually editing your STAAD input files, including IntelliSense.

Model Navigation

Associated commands are "blocked" together in the editor such that can be managed easier. Larger blocks can be collapsed to show only the first line/command, making it easier to navigate through large models.

A document outline of the model is also in a separate pane. You can double-click any entry in the outline to jump to that point in the input file.

IntelliSense

Intelligent code completion is now integrated into the STAAD editor. This allows context-aware code completion suggestions when you type in the editor.

Hover your mouse pointer over the suggested keywords to view tool tips for each.

Section profiles in standard tables are also linked to the editor. When entering a table shape, simply select it from the list of shapes in the drop-down list.

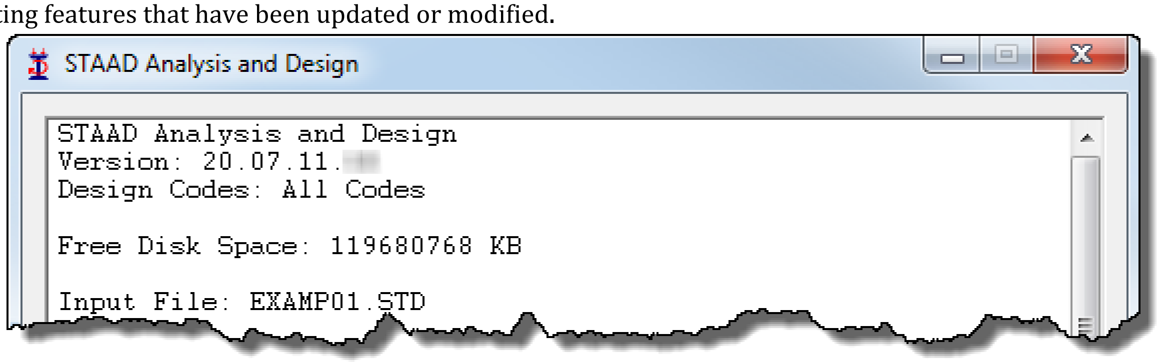
Enhanced Help

Press **<F1>** to view the help topic related to the command keyword from the Technical Reference help.

Refer to the I. STAAD.Pro Editor (on page 2043) help for details.

AD.2007-11.3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.



Note: Items labeled with an obelisk (i.e., dagger) (†) were added or updated in the Service Pack 2 release of V8i (SELECTseries 6).

Note: Items labeled with a double obelisk (i.e., dagger) (††) were added or updated in the Service Pack 3 release of V8i (SELECTseries 6).

AD.2007-11.3.1 ACI 318-11 Concrete Design

Concrete design per the 2011 edition of the ACI 318 specification (ACI 318-11) is now available in STAAD.Pro.

Several new parameters have been introduced to accommodate design of slender columns using the moment magnification procedure for sway and non-sway frames.

Refer to D1.F.5.6.1 Slenderness Effects and Analysis Consideration (on page 1243) for details.

To design concrete columns per ACI 318-11

The general outline of this procedure applies to designing all concrete members per ACI 318-11, but the specific parameters mentioned pertain only to the design of columns using the moment magnification method.

1. In the Modeling mode, select the **Design | Concrete** tab.

   The **Concrete Design - Whole Structure** dialog opens.
2. In the **Current Code** drop-down list, select **ACI 318-11**.

   This will insert the following commands into the STAAD.Pro input file:
   ```
   CODE ACI
   ```
3. Click **Define Parameters**.

   The **Design Parameters** dialog opens.
4. Select the **MMAG** parameter and type **0** for the option and then click **Add**.

   This instructs the program to use the detailed calculations considering sway or non-sway frames. .
5. Select the SWY parameter and select the appropriate bracing condition for the frame containing the columns to be designed and then click **Add**.
6. (Optional) Set values for BDY, BDZ, SKY, SKZ, SLY, SLZ, SQY, SQZ, SWY, and TRN parameters as necessary (i.e., when the defaults to not match the column conditions).
7. Close the Design Parameters dialog and assign the parameters to the appropriate members.

> **Tip:** The parameters mentioned here are only applicable to columns. They will be ignored for beam members.

AD.2007-11.3.2 CAN/CSA S16-14 Steel Design

Steel design per the 2014 edition of the Canadian S16 code, *Limit States Design of Steel Structures*, is now available.

The performance of designs per CAN/CSA S16-09 has also been improved. The changes in code checks from the 09 and 14 edition of the codes are noted in D4.E.6.1 Members Subject to Axial Forces (on page 1450).

To specify a design using CAN/CSA-S16-14

1. Select the **Design | Steel** page.

   The **Steel Design - Whole Structure** dialog opens.
2. In the **Current Code** list, select the **CAN/CSA-S16-14**.
3. Click **Define Parameters** list.

   The **Define Parameters** dialog opens.
4. Specify one or more design parameters as necessary.

   > **Note:** Refer to the descriptions in the dialog or to D4.E.7 Design Parameters (on page 1458) for definitions of the design parameters and default values used.
5. Click **Add**.

   This will insert the following commands into the STAAD input file:
   ```
   CODE CANADIAN
   ```

   > **Tip:** To use the older edition of the Canadian steel design code, the command `CODE CANADIAN 2009` is required.

AD.2007-11.3.3 SANS 10162-1:2011 Steel Design

Steel design per the South African SANS 10162-1:2011 code is now available.

Specifying a design using SANS 10162-1:2011

1. Select the **Design | Steel** page.

   The **Steel Design - Whole Structure** dialog opens.
2. In the **Current Code** list, select the **SANS10162-1:2011**.
3. Click **Define Parameters** list.

   The **Define Parameters** dialog opens.
4. Specify one or more design parameters as necessary.

   Note: Refer to the descriptions in the dialog or to D14.C.7 Design Parameters (on page 1974) for definitions of the design parameters and default values used.
5. Click **Add**.

   This will insert the following commands into the STAAD input file:

   ```
   CODE SANS10162-1: 2011
   ```

   Tip: Alternately, `SANS10162` will also use the latest edition. To use the older edition of the South African steel design code, `SANS10162-1: 1993` is required.

Refer to D14.C. South African Codes - Steel Design Per SANS 10162-1:2011 (on page 1966) for details.

AD.2007-11.3.4 SP 63.13330-2012 Concrete Design

Concrete design per the Russian code SP 63.13330-2012 is now supported.

Refer to D13.D. Russian Codes - Concrete Design Per SP 63.1330.2012 (on page 1918) help for details.

AD.2007-11.3.5 AISC 360-05/10 Metric Steel Design

Steel design in metric per the AISC 360-05/10 code is now supported.

When you select metric units in STAAD.Pro, the full user interface (including section properties, results, etc.) displays the correct metric units for AISC 360-05/10 steel design. Additionally, the results are also fully in metric units.

AD.2007-11.3.6 AISC 360-05/10 Tapered Member Design

The design of tapered square and round tube shapes as well as tapered I-shaped members is now available per the AISC 360-10 code.

The design of tapered members was previously available under the AISC 360-05 code, but the performance of design per this code has also been enhanced.

Refer to D1.A.5.7 Design of Web-Tapered Members (on page 1098) for details.

AD.2007-11.3.7 AISC 341-05/10 Seismic Provision Checks

Seismic provisions of AISC 341-05/10 can now be checked as part of an AISC 360-05/10 member design.

Several additional parameters have been added to the AISC 360 unified codes (both 2005 and 2010 editions) to check the additional seismic provisions of AISC 341.

Refer to D1.A.9 Seismic Provision Checking per AISC 341 (on page 1112) for details.

AD.2007-11.3.8 IBC 2012 / ASCE 7-10 Seismic Loads

Automatically generated equivalent lateral seismic loads and response spectra per IBC 2012 / ASCE 7-10 are now available in STAAD.Pro.

The load parameters are assigned using the User Interface or can be manually entered in the STAAD editor.

Automatic load combinations using the tables from IBC 2012 can be added using the Auto Load Combination dialog (on page 2872), as well.

To specify an IBC 2012/ASCE 7-10 static seismic load

1. Either:

   Select **Commands** > **Loading** > **Definitions** > **Seismic Load** > **IBC 2012 Load**

   or

   Select the **Definitions** section in the **Load & Definitions** dialog and then click **Add.**

   The **Create New Definitions / Load Cases / Load Items** dialog opens with the Add New Seismic Definitions dialog (on page 2895) tab selected.

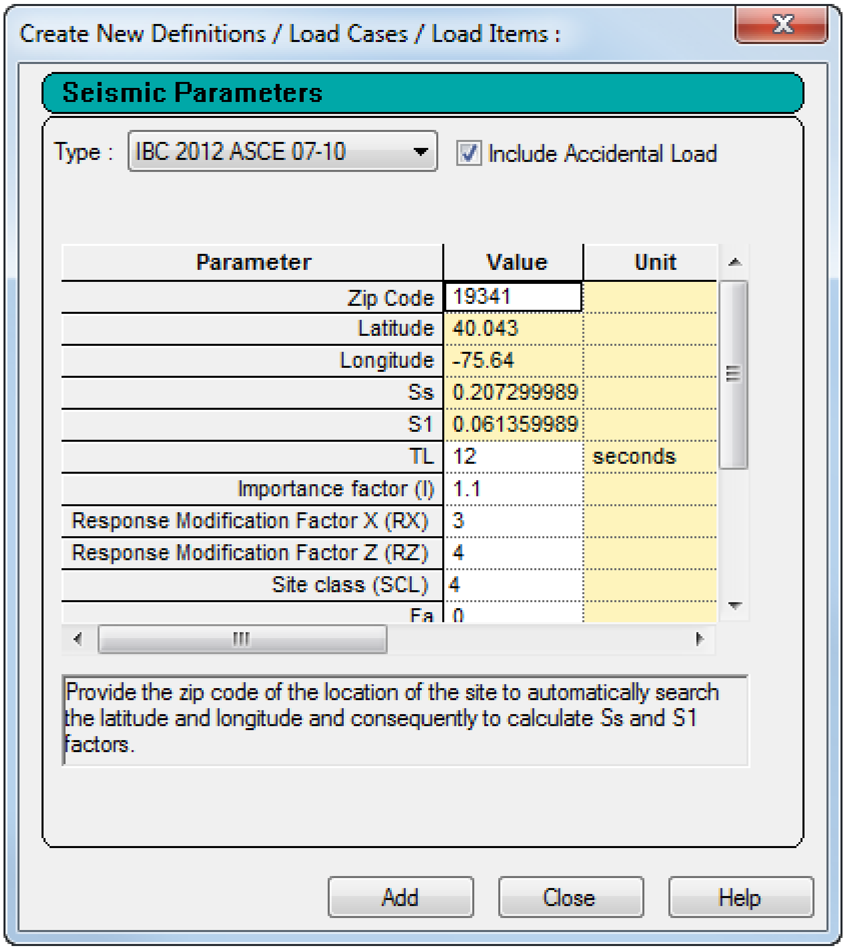


Figure 8: The Seismic Parameters as a stand-alone dialog

2. Select **IBC 2012 ASCE 7-10** in the **Type** drop-down list.
3. (Optional) Select the **Include Accidental Load** checkbox to consider accidental torsion.
4. Either:

   Type a **ZIP code**

   or

   Type **Latitude** and **Longitude** values

   or

   Type **Ss** and **S1** mapped values.
5. Specify the required seismic load parameters:
   a. Type long-period transition time, **TL**, value in the indicated units.
   b. Type an **Importance factor (I)** value.
   c. Type **Response Modification Factor X (RX)** and **Response Modification Factor Z (RZ)** values, respectively.
   d. Select the **Site class (SCL)** from the drop-down list.
6. (Optional) Specify the following optional seismic parameters as necessary:

a. Type short-period site coefficient, **Fa**, and long-period site coefficient, **Fv**, values, respectively.

> **Note:** These values are required if **Site class (SCL)** of **6** is selected (corresponds to IBC 2012 site class of F).

b. Type a **CT** value used to calculate the time period.
c. Type the **Period in X Direction (PX)** and **Period in Z Direction (PZ)** values, respectively. Otherwise these values are calculated from the code.
d. Type an exponent value, **x**, for use in ASCE 7-10 equation 12.8-7.

7. Click **Add**.

   The IBC 2012 parameters are added to the **Seismic Definitions** section of the **Load & Definition** dialog.

Refer to TR.31.2.15 IBC 2012 Seismic Load Definition (on page 2409) for details.

AD.2007-11.3.9 Eurocode 3 Steel Grades

SGR values now are aligned with Table 3.1: EN 1993-1-1: 2005.

`SGR` 3, 4 have been changed to represent S450 and S275 N/NL grades respectively.

Related Links

- *D5.C.6 Design Parameters* (on page 1502)

AD.2007-11.3.10 AIJ 2002 and 2005 New Design Parameters

The following design parameters have been added or updated in the AIJ 2002 and 2005 design codes in STAAD.Pro.

- The `MISES` parameter now has an option to ignore torsion in the calculation of the Von Mises stresses.
- A new parameter, `MBG`, has been added to ignore the web of H-shape, I-shape, and channel sections in calculating the section modulus about the local Z axis.
- A new parameter, `YNG`, has been added to the AIJ 2002 implementation to instruct the design engine how to evaluate Young's Modulus, E.

Refer to the codes in D9. Japanese Codes (on page 1713) help for details.

AD.2007-11.3.11 Steel Design Code Performance Improvements

Performance of steel design per CSA S16-S09 and IS800:2007 codes has been improved.

AD.2007-11.3.12† NRC 2005 Seismic Loads Updates and Additions

Seismic loads per the National Building Code of Canada's NRC 2005 have been updated and expanded to include torsion in the static load equivalent method as well as response spectrum loading.

AD.2007-11.3.13† IS 800 Design of Additional Steel Shapes

The design of both double-channel face-to-face and I-sections with cover plates is now available per the IS 800 2007 specification.

Refer to “ TR.20.1 Assigning Properties from Steel Tables (on page 2257) ” for details on assigning double-channel front-to-front sections (FR) and I-sections with top and bottom plates (TB).

AD.2007-11.3.14† AISC 360 Design of I-Sections with Cover Plates

The design of I-sections with cover plates is now available per the AISC 360 2005 and 2010 specifications.

Refer to " TR.20.1 Assigning Properties from Steel Tables (on page 2257) " for details on the assumptions and limit states used in the design of these sections.

Refer to " TR.20.1 Assigning Properties from Steel Tables (on page 2257) " for details on assigning I-sections with top and bottom plates (TB).

AD.2007-11.3.15†† IS 800 Design Updates

The following additions and enhancements were added to steel design per the IS 800 2007 specification:

- Flexural-torsional buckling of single angles per Cl. 7.5.1.2.
- Minimum web thickness is checked against the serviceability requirements in Cl. 8.6.1.1 and the compression flange buckling requirement of Cl. 8.6.1.2.
- The various sections of Amendment-1 to the IS:800-2007 Code, dated January 2012, are implemented in STAAD.Pro as applicable.

AD.2007-11.3.16†† Floor and One-Way Load Panel Information Printing

The program can now include floor load and one-way load panel information in the output (.ANL) file or in a external text file.

Refer to the Floor Load tab (on page 2845) in the User Interface help for information on using this feature through the graphical user interface.

Refer to TR.32.4 Area, One-way, and Floor Load Specifications (on page 2475) for information on the command input for this feature.

V8*i* (SELECTseries 5)

The Software Release Report for STAAD.Pro V8*i* (SELECTseries 5) contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8i (SELECTseries 4) (release 20.07.09) This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-10.1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

Note: Items labeled with an asterisk (*) were added or updated in the QA&R release of V8i (SELECTseries 5) (Build 20.07.10.XX).

AD.2007-10.1.1 Bentley Trust Licensing

STAAD.Pro now utilizes Benltey's Trust Licensing program.

This allows you or your organization the flexibility to utilize the program as needed without interruption, regardless of the availability of licenses. The usage data is collected periodically for billing at a later time for your convenience.

Refer to the *Getting Started & Troubleshooting Guide* (installed with STAAD.Pro) for additional information on license setup for STAAD.Pro.

Visit Bentley.com for more information on Bentley's licensing solutions.

AD.2007-10.1.2 Brazilian Steel Databases

Brazilian steel section databases have been added to the section profile tables included in STAAD.Pro.

To select a Brazilian steel profile shape

1. Select the **General | Property** page.

   The **Properties - Whole Structure** dialog opens.
2. Click **Section Database** on the **Properties - Whole Structure** dialog.

   The **Section Profile Table** dialog opens.
3. On the Steel tab, expand the **Brazilian** entry to select a shape class.
4. Select a shape and specify any shape parameters in the dialog.
5. Click **Add**.

   The section is added to the list on the **Properties - Whole Structure** dialog Section tab.

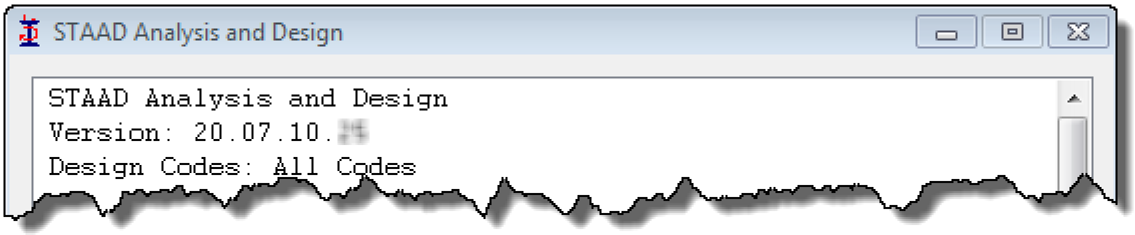
AD.2007-10.1.3* Scenario Services

STAAD.Pro projects can be run in Bentley's Scenario Services (formerly ProjectWise Scenario Services or Bentley CONNECT Scenario Services) server with a SELECT account. This allows you to run large models or complex, nonlinear analyses in the “cloud,” leveraging extensive computing power. Additionally, STAAD.Pro models can be added Multiple Discipline Optimization (MDO) projects.

Refer to Cloud Services tab (on page 2703) for additional information on using this feature.

AD.2007-10.2 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.



Note: Items labeled with an asterisk (*) were added or updated in the QA&R release of V8i (SELECTseries 5) (Build 20.07.10.XX).

AD.2007-10.2.1 Advanced Cable Analysis

An advanced, nonlinear cable analysis has been added to STAAD.Pro. The nonlinear nature of the static solver can utilize either the Newton-Rapshon method or a modified Newton-Raphson method for reduced computational effort. The cables are considered as geometrically nonlinear.

Refer to the following procedures:

- M. To add a member specification (on page 802)
- A. To specify a nonlinear cable analysis (on page 955)
- A. To specify post-analysis print commands (on page 963)

Refer to G.17.2.8 Advanced Nonlinear Cable Analysis (on page 2150) for details on the analysis methodology used by STAAD.Pro.

AD.2007-10.2.2 Colombian Seismic Code

Static lateral forces for seismic loads based on *Reglamento Colombiano Sismo Resistente* (NSR-10) (2010 edition of Colombian seismic code)

Note: Refer to TR.31.2.8 Colombian NSR-10 Seismic Load (on page 2384) for details on the command parameters.

AD.2007-10.2.3 Canadian Steel Code Update

Steel design CAN/CSA-S16-09, *Design of Steel Structures*, is now available in STAAD.Pro.

Refer to D4.E. Canadian Codes - Steel Design per CAN/CSA-S16-09/14/19 (on page 1447) for additional information.

To specify a design using CAN/CSA-S16-09

1. Select the **Design | Steel** page.

   The **Steel Design - Whole Structure** dialog opens.

2. In the **Current Code** list, select the **CAN/CSA-S16-09**.
3. Click **Define Parameters** list.

   The **Define Parameters** dialog opens.
4. Specify one or more design parameters as necessary.

   Note: Refer to the descriptions in the dialog or to D4.E.7 Design Parameters (on page 1458) for definitions of the design parameters and default values used.
5. Click **Add**.

   This will insert the following commands into the STAAD input file:

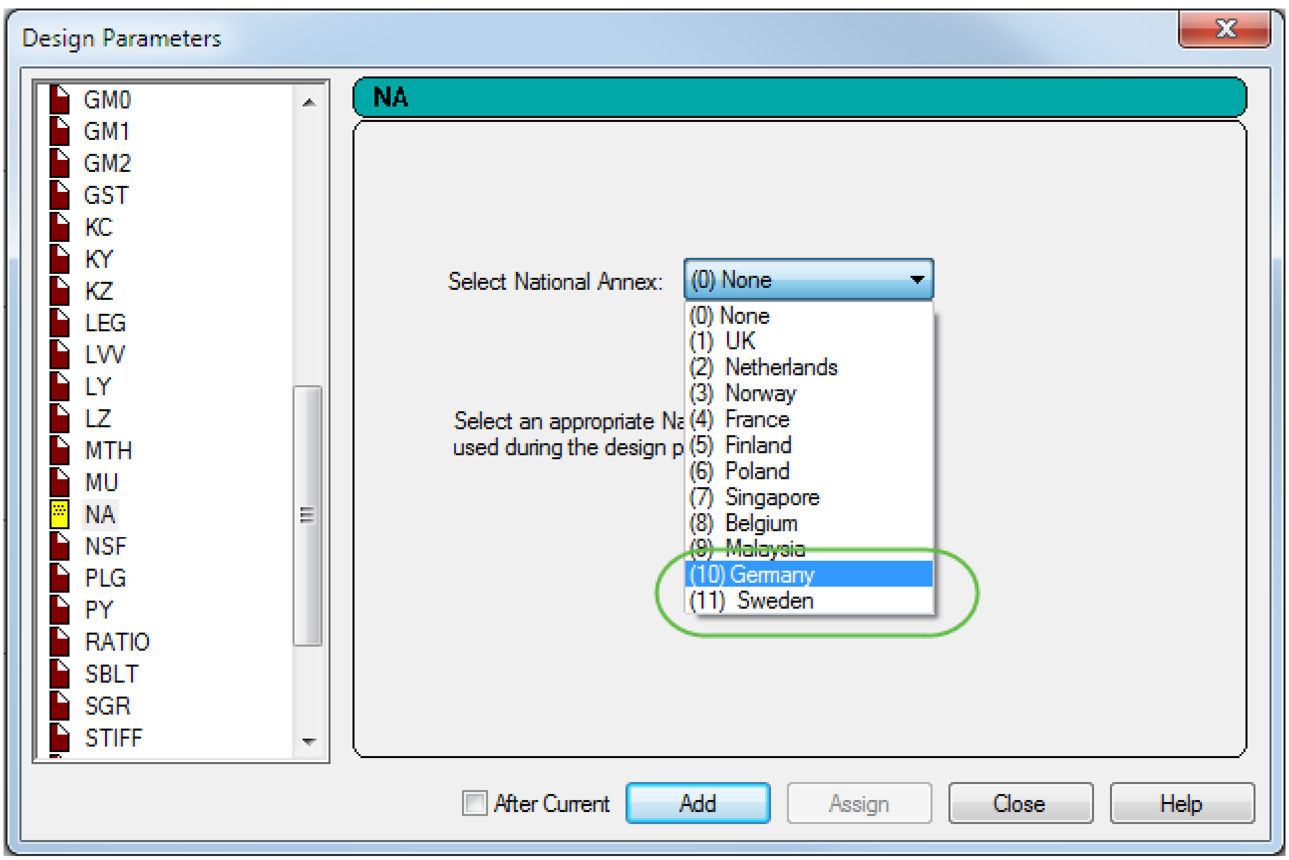
```
CODE CANADIAN
```

   Tip: To use the older edition of the Canadian steel design code, the command `CODE CANADIAN 2001` is required.

AD.2007-10.2.4 Eurocode 3 National Annexes

Two additional country's National Annex to Eurocode 3 have been incorporated into the Steel design module in STAAD.Pro: Germany and Sweden.

As with the other National Annexes to EC-3, this implementation will make use of the NA parameter.



AD.2007-10.2.4.1 German National Annex to Eurocode 3 (EN 1993-1-1:2005)

To specify a design using the German NA to EC3, use the following procedure.

The German National Annex document referred to is “DIN EN 1993-1-1:2005.”

When the German National Annex to EC3 is used for design, the output section title is revised to include the German National Annex (National Annex to DIN EN 1993-1-1:2005). Additionally, the partial safety factors used are included in the output and are specified in the German NA.

For additional information, please refer to D5.D.12 German National Annex to EC3 (on page 1575) and D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) .

1. In the Modeling mode, select the **Design | Steel** tab.
   The **Steel Design - Whole Structure** dialog opens.
2. In the **Current Code** drop-down list, select **EN 1993-1-1:2005**.
3. Click **Define Parameters**.
   The **Design Parameters** dialog opens.
4. Select the **NA** parameter in the list box.
5. Select the **(10) Germany** in the **Select National Annex** drop-down list.
6. Click **Add**.

   This will insert the following commands into the STAAD.Pro input file:

```
CODE EN 1993-1-1:2005
NA 10
```

AD.2007-10.2.4.2 Swedish National Annex to Eurocode 3 (EN 1993-1-1:2005)

To specify a design using the Swedish NA to EC3, use the following procedure.

The Swedish National Annex document referred to is “BFS EN 1993-1-1:2005.”

When the Swedish National Annex to EC3 is used for design, the output section title is revised to include the Swedish National Annex (National Annex to EN 1993-1-1:2005). Additionally, the partial safety factors used are included in the output and are specified in the Swedish NA.

For additional information, please refer to D5.D.13 Swedish National Annex to EC3 (on page 1579) and D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) .

1. In the Modeling mode, select the **Design | Steel** tab.
   The **Steel Design - Whole Structure** dialog opens.
2. In the **Current Code** drop-down list, select **EN 1993-1-1:2005**.
3. Click **Define Parameters**.
   The **Design Parameters** dialog opens.
4. Select the **NA** parameter in the list box.
5. Select the **(11) Sweden** in the **Select National Annex** drop-down list.
6. Click **Add**.

   This will insert the following commands into the STAAD.Pro input file:

```
CODE EN 1993-1-1:2005
NA 11
```

AD.2007-10.2.5 AISC 360-10 Torsion Design

STAAD.Pro can now design open shapes for stresses due to torsion per AISC Design Guide #9, *Torsional Analysis of Structural Steel Members*.

A new `TORSION` parameter for the AISC 360-10 steel design code which can be set to instruct the program to perform torsion checks per this guide.

Refer to D1.A.5.6 Design for Torsion (on page 1096) for details on the checks performed.

To include torsion checks per Design Guide #9

1. In the Modeling mode, select the **Design | Steel** tab.

   The **Steel Design - Whole Structure** dialog opens.
2. In the **Current Code** drop-down list, select **AISC 360-10**.
3. Click **Define Parameters**.

   The **Design Parameters** dialog opens.
4. Select the **TORSION** parameter and select **1** for the option.
5. (Optional) Select the **TRACK** parameter and select **3** for the option.

   This will include detailed output for the Design Guide #9 checks in the output.
6. Click **Add**.

   This will insert the following commands into the STAAD.Pro input file:

   ```
   CODE AISC UNIFIED 2010
   ```

   ```
   TORSION 1
   ```

   ```
   TRACK 3
   ```
7. For the `TORSION` parameter (and for the optional `TRACK` parameter), you must specify a member list using the assignment tools in the **Steel Design - Whole Structure** dialog.

AD.2007-10.2.6 Missing Mass

Missing mass can now be specified for time history load definitions.

Missing mass and rigid body modes are reported in the output and can be selected in the post-processing mode drop-down (* for mm & + for rb)

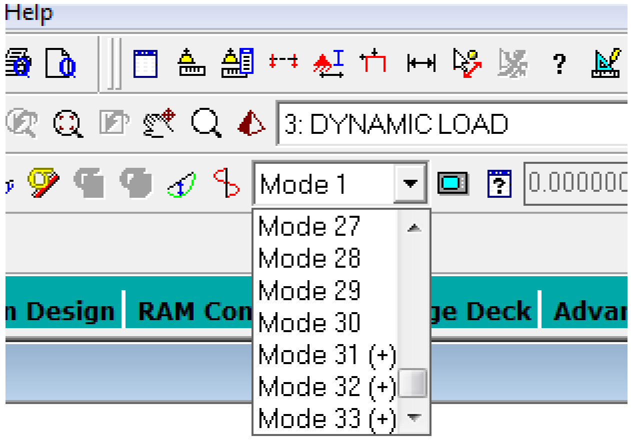


Figure 9: Missing mass modes are marked with an (*) in the Modes drop-down list

Rigid body modes are used internally to establish relative and absolute structure displacement, particularly for structures supported on relatively weak springs.

Refer to TR.31.4 Definition of Time History Load (on page 2441) and TR.34.2 Modal Calculation Command (on page 2615) for additional information.

AD.2007-10.2.7* Wind Loads per Russian Design Code SP 20.13330.2011

Refer to TR.31.3 Definition of Wind Load (on page 2435) for additional information.

AD.2007-10.2.8* Response Spectrum Specification per SP 14.13330.2011

Refer to TR.32.10.1.15 Response Spectrum Specification per SP 14.13330.2011 (on page 2589) for additional information.

AD.2007-10.2.9* Steel Design per Russian Design Code SP 16.13330.2011

Steel member design per SP 16.13330.2011, *Steel Structures*, is now available in STAAD.Pro.

Refer to D13.C. Russian Codes - Steel Design Per SP 16.13330.2011 (on page 1905) for additional information.

Specifying a design using SP 16.13330.2011

1. Select the **Design | Steel** page.

   The **Steel Design - Whole Structure** dialog opens.
2. In the **Current Code** list, select the **SP 16.13330.2011**.
3. Click **Define Parameters** list.

   The **Define Parameters** dialog opens.
4. Specify one or more design parameters as necessary.

> **Note:** Refer to the descriptions in the dialog or to D13.C.4 Design Parameters (on page 1910) for definitions of the design parameters and default values used.

5. Click **Add**.

   This will insert the following commands into the STAAD input file:

   ```
   CODE RUSSIAN
   ```

   > **Tip:** To use the older edition of the Russian steel design code, the command `CODE RUSSIAN 1990` is required.

6. Assign the code parameters to members as necessary.

AD.2007-10.3 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the Post Processing modes. These are explained in the following pages.

> **Note:** Items labeled with an asterisk (*) were added or updated in the QA&R release of V8i (SELECTseries 5) (Build 20.07.10.XX).

AD.2007-10.3.1 RAM Connection Mode Update

RAM Connection V8i features are now supported in STAAD.Pro V8i (SELECTseries 5) RAM Connection mode.

- Now compatible with versions of RAM Connection V8i up through release 8.0 (SELECTseries 4).
- New templates:
  - US: MEP Knee BCF, Moment End Plate BCF, Moment End Plate BCW, Moment End Plate BS Apex, and Moment End Plate BS
  - UK: Bolted End Plate BS Apex
- New sections added to the RAM Connection database for connection design:
  - Canadian WS, MS, S, HP, Angel, Channel, MC Channel, and HSS Round shapes
  - Brazilian I, Angle, and Channel shapes

AD.2007-10.3.2* CAN/CSA-A23.3-10 in RC Designer

> **Note:** The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

V8*i* (SELECTseries 4)

The Software Release Report for STAAD.Pro V8*i* (SELECTseries 4) contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8i (SELECTseries 3) (release 20.07.08) This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-09.1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

Note: Items labeled with an asterisk (*) were added in the QA&R release of V8i (SELECTseries 4) (Build 20.07.09.22).

AD.2007-09.1.1 I-Section with Different Flange Shapes

User-provided steel table Wide Flange sections can now have different flange sizes on top and bottom.

Previously, the sections were required to be doubly symmetric. Now, you may specify a different bottom flange size.

To add a UPT I-Section with different flange sizes

1. (Optional) Select **Tools** > **Select Input Units**. Select appropriate units for length and click **OK**.
2. Select **Tools** > **Create User Table**.

   If no User Defined Table exists, you will be prompted to create one.

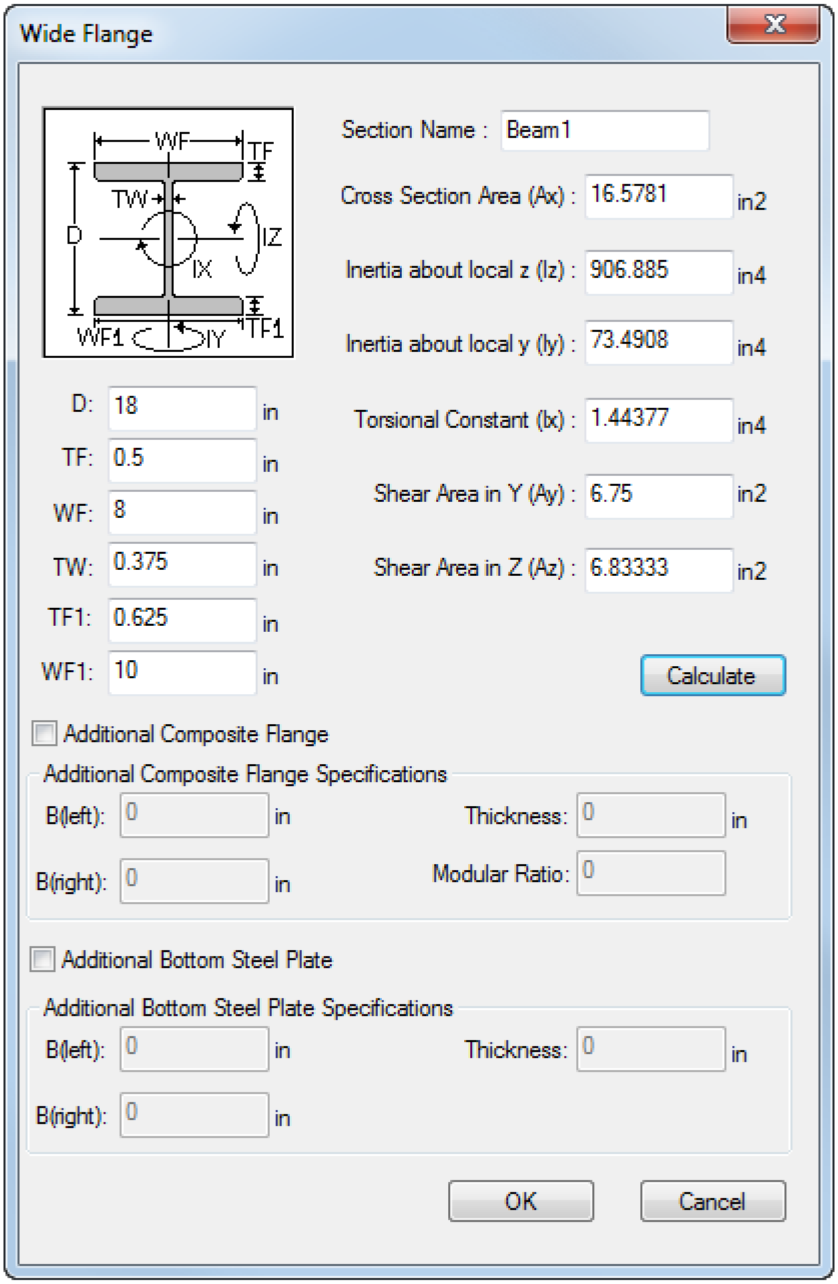
   The **Create User Provided Table** dialog opens.
3. Click **New Table**.

   The **Select Section Type** dialog opens.
4. In the **Select Section Type** list, select **WIDE FLANGE** and then click **OK**.

   Tip: You can also use this dialog to save the User Provided Table as a separate file.

   The dialog closes and the **Select Existing Table** list in the **Create User Provided Table** dialog now has at least one entry.
5. Click **Add New Property**.

   The **Wide Flange** dialog opens.



6. Type dimensions in the **D**, **TF**, **WF**, **TW**, **TF1**, and, **WF1** fields to define the section.

   Two new fields— **TF1** and **WF1** —are used to specify different dimensions for the bottom flange. If these fields are left empty, the values for the top flange are used (doubly symmetric section).

   Note: Refer to TR.19.1 Wide Flange (on page 2244) for detailed descriptions on properties of Wide Flange sections in User Steel tables.

7. Click **Calculate**.

   The derivative cross section properties are calculated.

8. Click **OK**.

The dialog closes and the section is added to the **Table Data** list in the **Create User Provided Table** dialog.

AD.2007-09.1.2 I-Section with Flange Plates or Composite Slab

User-provided steel table Wide Flange sections can now have an additional bottom flange plate or composite concrete on the top flange.

These options are available in the Wide Flange dialog in the user interface. The additional flange plates or composite slab data is then used along with the base section properties.

To add a UPT I-Section with flange plates and composite slab

1. (Optional) Select **Tools** > **Select Input Units.** Select appropriate units for length and click **OK**.
2. Select **Tools** > **Create User Table**.

   If no User Defined Table exists, you will be prompted to create one.

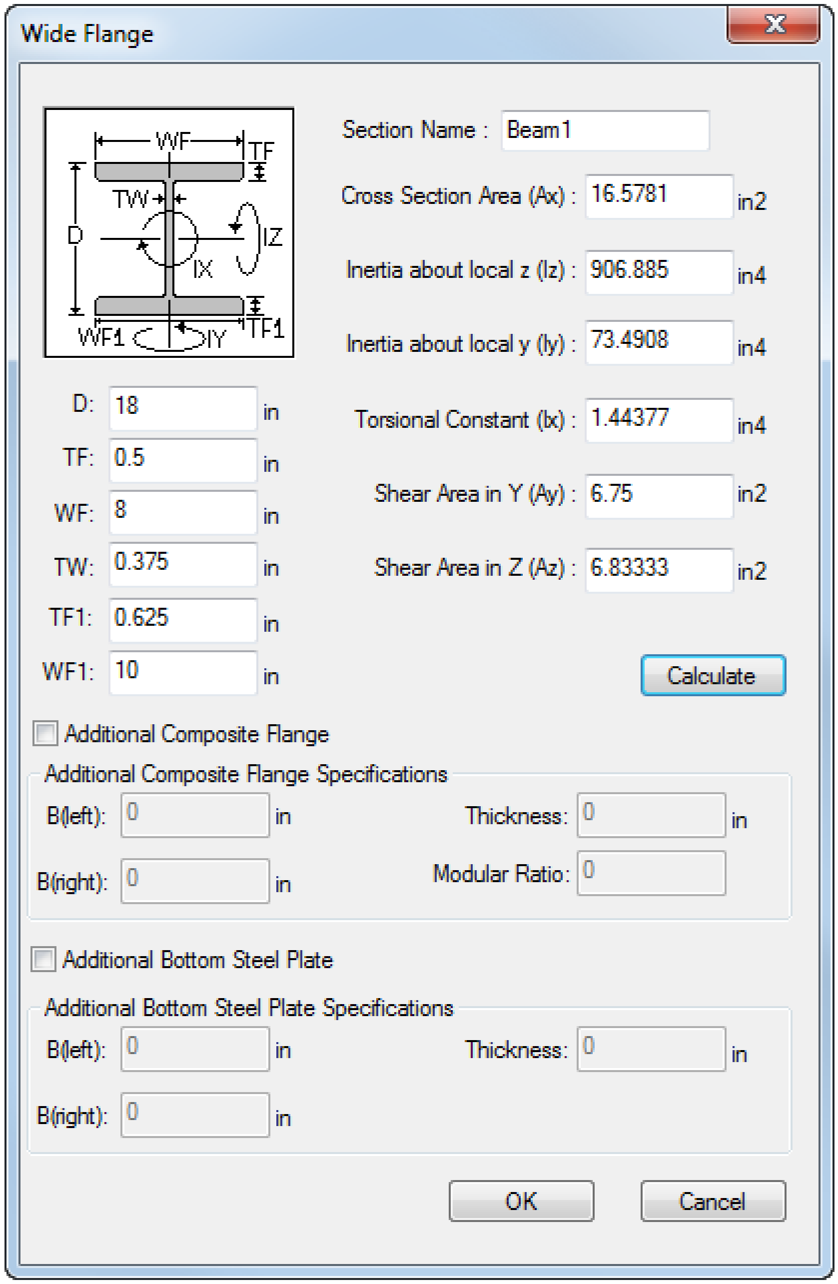
   The **Create User Provided Table** dialog opens.
3. Click **New Table**.

   The **Select Section Type** dialog opens.
4. In the **Select Section Type** list, select **WIDE FLANGE** and then click **OK**.

   Tip: You can also use this dialog to save the User Provided Table as a separate file.

   The dialog closes and the **Select Existing Table** list in the **Create User Provided Table** dialog now has at least one entry.
5. Click **Add New Property**.

   The **Wide Flange** dialog opens.



6. Add a composite flange:
   a. Check the option for **Additional Composite Flange**.
   b. Type dimensions in the **B(letf)**, **B(right)**, **Thickness**, and, **Modular Ratio** fields to define the composite slab.

Note: Refer to TR.19.1 Wide Flange (on page 2244) for detailed descriptions on properties of Wide Flange sections in User Steel tables.

7. To add a bottom cover plate, select the **Additional Bottom Steel Plate** option and type values for **B(left)**, **B(right)**, and **Thickness**.

Tip: Top cover plates cannot be added in association with a composite slab, only bottom cover plates.

8. Click **Calculate**.

   The derivative cross section properties are calculated.
9. Click **OK**.

   The dialog closes and the section is added to the **Table Data** list in the **Create User Provided Table** dialog.

AD.2007-09.1.3 ISM Integration

STAAD.Pro is now capable of transferring data to and from v3 of Bentley's Integrated Structural Modeling technology by means of the StructLink utility.

ISM v3 includes support for foundation information. STAAD Foundation Advanced is now ISM Enabled, so this allows for an improved method for transferring and updating support information for STAAD Foundation Advanced, as well as other ISM Enabled products using v3 of ISM, such as detailing products like ProConcrete.

AD.2007-09.1.4* Connection Tags

This feature is used to both create connection data within STAAD.Pro and to transfer it to other programs via the ISM link. This data can then be used in third-party programs, such as Tekla Structures®. The connections can then be checked against a defined capacity.

Connection tags are assigned and checked from within the STAAD.Pro User Interface by use of the right-click pop-up menu. When a beam member is selected (using the beam cursor), a sub-menu for Connection Tags is provided with tools for using connection tags.

Note: Refer to D. Connection Tags sub menu (on page 1066) for additional information on using this feature.

Connection tags consist of two pieces of data:

i. A Connection Tags XML file, which contains the connection categories, tag names, and member end releases for the connection tag. Connection capacities are also specified for each combination of member and connecting member which may utilize a connection tag. Refer to D. Connection Tags XML File Schema (on page 1052) for additional information on the required structure of this XML file.
ii. Assignments of connection tags to members are stored in the STAAD input file. Though this is done within the `DEFINE MEMBER ATTRIBUTE` command, it is strongly recommended that the user interface features be used to make connection tag assignments as these must utilize only the connection categories and tag names in the associated XML file. Refer to TR.29.2 Connection Tag Member Attribute (on page 2341) for additional information on this command.

AD.2007-09.2 Features Affecting the Pre-Processor

This section describes features that have been added that affect the pre-processor section of the program, also known as the Modeling Mode.

AD.2007-09.2.1 Print Center of Rigidity

The `PRINT DIAPHRAGM CR` command may be used to obtain a print-out of the center of rigidity and center of mass at each rigid diaphragm in the model.

The lateral force at each floor, as generated by earthquake and wind loading, acts at the center of rigidity of each floor which is modeled as rigid floor diaphragm. The center of mass of each floor is defined as the mean location of the mass system of each floor. The mass of the floor is assumed to be concentrated at this point when the floor is modeled as rigid diaphragm. The distance between these two is the lever arm for the natural torsion moment for seismic loads when that option is used.

Related Links

- *TR.42 Print Specifications* (on page 2666)
- *A. To output the center of rigidity* (on page 964)

AD.2007-09.2.2 Load & Definition

A new feature has been added to include horizontal torsion for rigid floor diaphragms in the equivalent static seismic analysis. This torsion —referred to as the natural torsion— accounts for the static eccentricity which is the difference between center of mass and center of rigidity of a rigid floor diaphragm, to be used to multiply the UBC, IBC, 1893, etc.

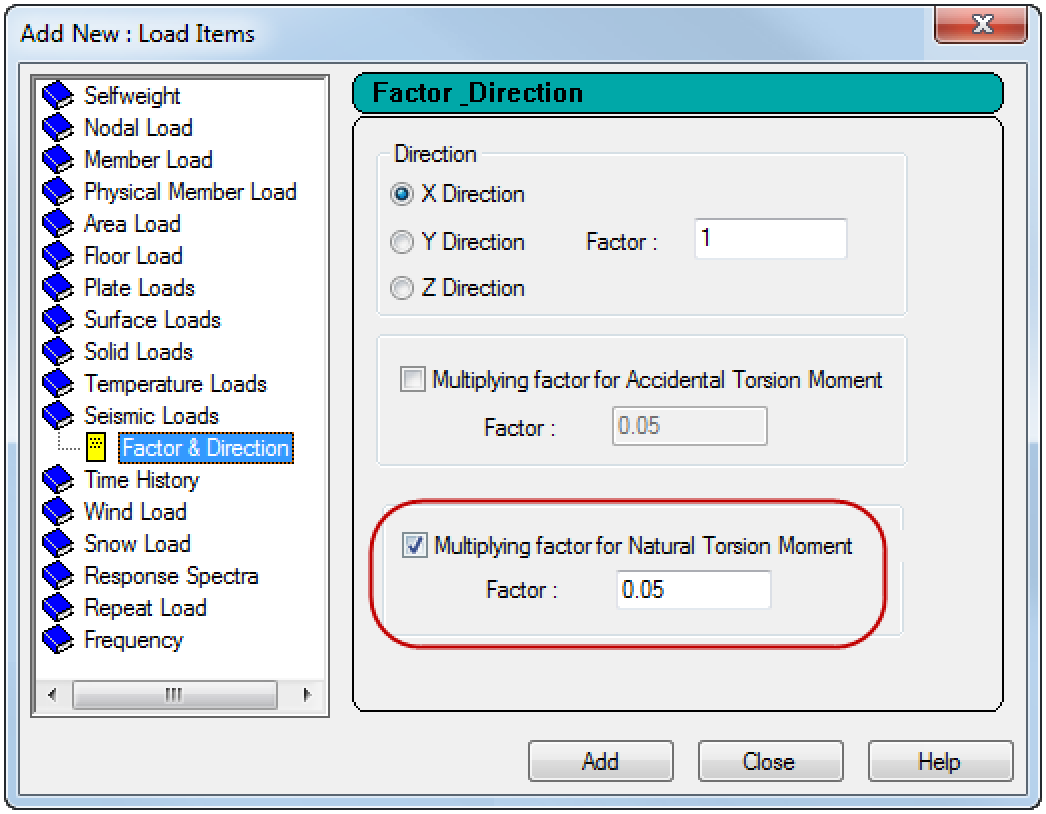
Refer to TR.32.12.2 Generation of Seismic Loads (on page 2598) for additional details.

Adding Natural Torsion factor to a static seismic load

The natural torsion factor is specified along with the accidental torsion factor.

1. Add a Seismic Load definition to your model.
2. Add a Load Case with the Loading Type of **Seismic** to your model.
3. Select the seismic load case in the **Load & Definition** dialog and click **Add**.

   The **Add New: Load Items** dialog opens.
4. Select the Seismic Loads tab.
5. Set the option to use the **Multiplying factor for Natural Torsion Moment** and type a value (less than or equal to one).



6. Select the direction and specify the accidental torsion option as necessary.
7. Click **Add**.

Related Links

- *TR.32.12.2 Generation of Seismic Loads* (on page 2598)
- *M. To add a seismic load* (on page 860)

AD.2007-09.2.3 Check for Soft Story

The `CHECK SOFT STORY` option may added to a `FLOOR DIAPHRAGM` command set to check for soft stories per either IS1893:2002 or ASCE7-95 codes.

Additionally, the story stiffnesses used in calculating story drift or checking soft stories can be added to STAAD.Pro output by including the command `PRINT STORY STIFFNESS` in the post analysis print commands section.

Related Links

- *Floor Diaphragm Options dialog* (on page 2930)
- *TR.28.2.1 Soft Story Checking* (on page 2331)
- *TR.28.2 Floor Diaphragm* (on page 2328)
- *TR.42 Print Specifications* (on page 2666)
- *A. To check for soft stories and seismic code irregularities* (on page 962)

AD.2007-09.2.4 Check Story Drift

The `PRINT STORY DRIFT` command can now be used to check the story drift against a code-specified maximum drift ratio.

Story drift is calculated as the relative horizontal displacement of two adjacent floors in a building. Inter-story drift can also be expressed as some factor times the story height. The allowable factor generally varies from one country code to another and may also vary depending on the type of loading. For example, in IS 1893: 2002 for seismic loading the allowable limit for inter-story drift is 0.004 times the story height whereas in IS 875 for wind loading it is 0.002 times the story height.

The drift at a particular story level in either lateral direction is calculated as the average of all the joint displacements present in that floor level. However if floor diaphragm is present, the drift is calculated at the center of mass (i.e,. control joint) of the floor.

Note: Additionally, the story stiffnesses used in calculating story drift or checking soft stories can be added to STAAD.Pro output by including the command `PRINT STORY STIFFNESS` in the post analysis print commands section.

Refer to TR.42 Print Specifications (on page 2666) for additional information.

Note: For dynamic IS 1893: 2002 response spectrum, the story drift check is performed by adding a command line within the load case, rather than in the post-analysis print commands. Refer to TR.32.10.1.7 Response Spectrum Specification per IS: 1893 (Part 1)-2002 (on page 2534) for additional information.

Related Links

- *TR.42 Print Specifications* (on page 2666)

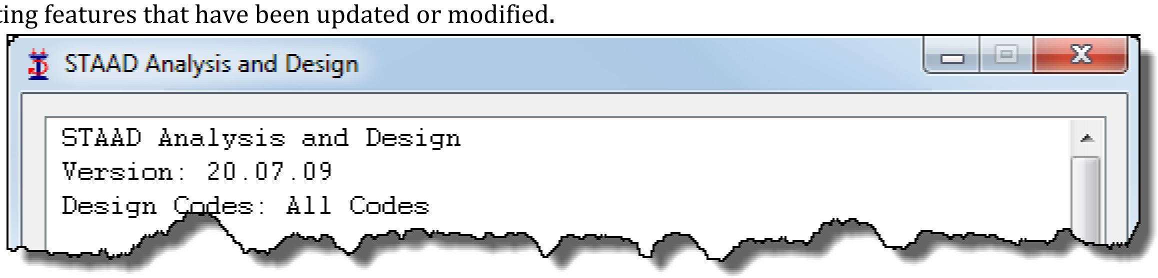
AD.2007-09.3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.



Note: Items labeled with an asterisk (*) were added in the QA&R release of V8i (SELECTseries 4) (Build 20.07.09.22).

AD.2007-09.3.1 Steel Design per AISC 360-10

The design of steel sections per ANSI/AISC 360-10 *Specification for Structural Steel Buildings* (AISC 360-10) is now available in STAAD.Pro.

Refer to D1.A. American Codes - Steel Design per AISC 360 Unified Specification (on page 1086) for additional information.

To specify a design using AISC 360-10

1. Select the **Design | Steel** page.

   The **Steel Design - Whole Structure** dialog opens.
2. In the **Current Code** list, select the **AISC 360-10**.
3. Click **Define Parameters** list.

   The **Define Parameters** dialog opens.
4. Specify one or more design parameters as necessary.
5. Click **Add**.

   This will insert the following commands into the STAAD input file:

```
CODE AISC UNIFIED 2010
```

AD.2007-09.3.2 Concrete Design per ACI 318-08

The design of concrete members per the ACI code in STAAD.Pro has been updated to the 2008 edition of the code.

A new parameter, LWF, has been added to account for the lightweight concrete reduction factor, λ, in equations 11-3, 11-4, and 11-5 of the code.

Refer to D1.F. American Codes - Concrete Design per ACI 318 (on page 1198) for additional information.

To specify a design using ACI 318-08 in batch mode

Note: Design per the 2008 edition of the ACI code is currently only available in the batch mode.

1. Select the **Design | Concrete** page.

   The **Concrete Design - Whole Structure** dialog opens.
2. In the **Current Code** list, select the **ACI 318 2008**.
3. Click **Define Parameters** list.

   The **Define Parameters** dialog opens.
4. Specify one or more design parameters as necessary.
5. Click **Add**.

   This will insert the following commands into the STAAD input file:

```
CODE ACI
```

AD.2007-09.3.3 Malaysian National Annex to Eurocode 3 (EN 1993-1-1:2005)

To specify a design using the Malaysian NA to EC3, use the following procedure.

The Malaysian National Annex document referred to is “MS EN 1993-1-1:2005.”

When the Malaysian National Annex to EC3 is used for design, the output section title is revised to include the Malaysian National Annex (National Annex to MS-EN 1993-1-1). Additionally, the partial safety factors used are included in the output and are as specified in the Malaysian NA. The value for C1 and k factors used in the calculation of the elastic critical moment are also included in the report.

Note: For additional information, please refer to D5.D.11 Malaysian National Annex to EC3 (on page 1570) and D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) .

1. In the Modeling mode, select the **Design | Steel** tab.
   The **Steel Design - Whole Structure** dialog box opens.
2. In the **Current Code** drop-down menu, select **EN 1993-1-1:2005**.
3. Click **Define Parameters…**.
   The **Design Parameters** dialog box opens.
4. Select the **NA** parameter in the list box.
5. Select the option for **(9) Malaysia**.
6. Click **Add**.

   This will insert the following commands into the STAAD input file:

```
CODE EN 1993-1-1:2005
NA 9
```

AD.2007-09.3.4 Star Angle Design per IS-800

The design of “star” angle arrangements per IS 800:2007 have been implemented in STAAD.Pro to for members subjected to axial force only. Such star angles are often used for the legs of transmission or communication towers and as bracing members in industrial buildings.

Refer to D8.A. Indian Codes - Steel Design per IS 800 - 2007 (on page 1607) for details on Limit States and Member Property Specifications in IS 800:2007 design.

Notes

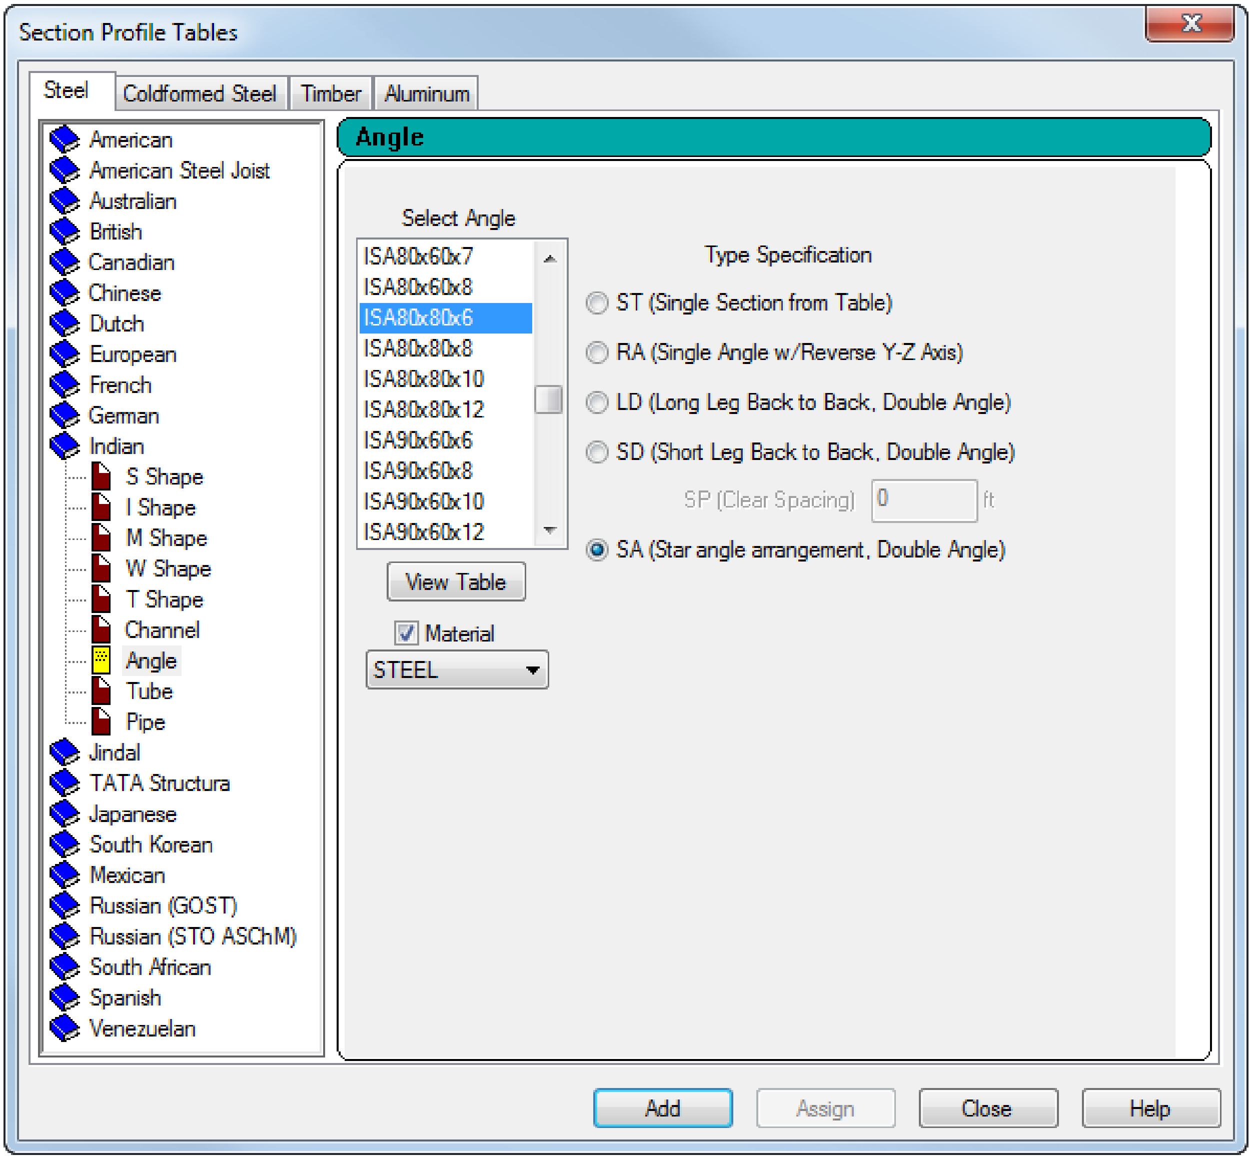
- The design of star angles is only supported for IS 800:2007.
- Members must be declared as a TRUSS member (axial only). An error will be reported in the output if any other member specification is used.
- It is assumed that the star angle arrangement is a welded shape. Plated shapes are not accounted for in the program.

To specify a star angle arrangement for IS 800:2007 design

Refer to TR.20.1 Assigning Properties from Steel Tables (on page 2257) for additional information on assigning properties from steel tables.

1. Select **Commands** > **Member Property** > **Steel Table** > **Indian**.

   The **Section Profile Tables** dialog opens to the Indian steel table.



2. Select the **Angle** tab.
3. Chose an angle section from the **Select Angle** list.
4. Select the **SA (Star angle arrangement, Double Angle)** Type Specification.
5. Click **Add**.

   The section is added to the model and is available for member assignment.

AD.2007-09.3.5 IS 1893 (Part 4) 2005 Seismic Loads

Seismic loads per IS 1893 (Part 4) 2005 for industrial and stack-like structures can be generated in STAAD.Pro. These loads have been incorporated into the existing implementation of IS 1893 (Part 1) 2002 loads.

To add a seismic load per IS 1893 (Part 4) 2005

1. Select **Commands** > **Loading** > **Definitions** > **Seismic Load** > **IS 1893 - 2002**.

The Create New Definitions / Load Cases / Load Items dialog opens to the Seismic Parameters tab (only tab visible in this interface) and the **IS 1893 - 2002/2005** code is selected.

2. Set the option for **Include 1893 Part 4**.
3. Do either of the following:
   - Click Generate to open the IS:1893 Seismic Parameters dialog, or
   - Type values for the command parameters directly in the current dialog table.
4. Click **Add**.

Note: Refer to TR.31.2.10 IS:1893 (Part 1) 2002 & Part 4 (2005) Codes - Lateral Seismic Load (on page 2387) for additional information.

AD.2007-09.3.6* ABS/SRSS Combination

A modification to the ABS (Absolute value) and SRSS (square root sum of the squares) results combinations methods.

Additional processing is now used so the resulting combination of results contain appropriate sign/direction as is required when used for design or code checking when used with the ASME NF or AISC 360 05/10 codes.

To instruct the analysis and design engine to automatically generate these load combinations for ABS or SRSS combinations, either:

- use the new, optional `GENERATE` parameter in the `LOAD COMBINATION` command, or

  Note: Refer to TR.35 Load Combination Specification (on page 2616) for additional information.
- select the **Generate Combination** option in the Define Load Combinations dialog (on page 2836).

All of the permutations of positive or negative sign effects in each DOF (degree of freedom) are now considered by the analysis engine. That is, in each of the 6 DOF, both positive and negative sign are considered which results in 64 possible cases (i.e, 2^6). As a result of this, the SRSS and ABS combinations are now presented as load envelopes (i.e., maximum and minimum values) at each member end. This is reflected in both reports and post-processing mode tables. Similarly, in the structure view in the post-processing mode, the force diagrams are now displayed graphically as an envelope rather than a single curve.

Output from the following commands displays pairs of results rows for a load at a joint (marked by an asterisk in the output):

```
PRINT SUPPORT REACTION
```

```
PRINT MEMBER FORCE
```

```
PRINT SECTION FORCE
```

```
PRINT PMEMB FORCE
```

```
PRINT MEMBER STRESS
```

V8*i* (SELECTseries 3)

The Software Release Report for SELECTseries 3 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8i SELECTseries 2 (release 20.07.07) This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

The Software Release Report for STAAD.Pro V8*i* SELECTseries 3 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8i SELECTseries 2 (release 20.07.07) This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-08.1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

AD.2007-08.1.1 ISM Integration

STAAD.Pro is now capable of transferring data to and from Bentley's Integrated Structural Modeling technology by means of the StructLink utility.

STAAD.Pro is now capable of transferring data to and from Bentley's Integrated Structural Modeling technology by means of the StructLink utility.

AD.2007-08.1.2 Export to SACS

A new macro is included with STAAD.Pro which is used to export the current STAAD.Pro model to a SACS model, which can be opened in the SACS system Interactive Modeling program.

SACS (Structural Analysis Computer System) is a finite element structural analysis suite of programs for the offshore and civil engineering industries.

Related Links

- *I. To export to a SACS input file* (on page 2081)

AD.2007-08.1.3 European Cold Formed Sections per EN10219-2

Sections defined in the publication, EN10219-2:*1997 Cold formed welded structural hollow sections of non-alloy and fine grained structural steel. Part 2: Tolerances, dimensions and sectional properties* have been added to library of cross sections available in the program.

The following section profiles are included as separate tables in the program:

- Table 6: Circular Hollow Sections (CHS)
- Table 7: Square Hollow Sections (SHS)
- Table 8: Rectangular Hollow Sections (RHS)

To Specify a European cold formed section

1. Select the **General | Property** page.

   The **Properties - Whole Structure** dialog box opens.
2. In the **Properties - Whole Structure** dialog box, click **Section Database**.

   The **Section Profile Tables** dialog box opens.
3. Select the **Coldformed Steel** tab.
4. Select one of the tables available in the **European Cold Formed** section.
5. Select an entry from the **Select Profile** list.
6. Click **Add**.

   The section is now added to the Section tab in the **Properties - Whole Structure** dialog box and can be assigned to members..

AD.2007-08.1.4 Japanese JIS Hollow Sections

The catalog of available Japanese hot rolled steel sections has been expanded to include the hollow sections from JIS publications.

- JIS G3444:2005 *Design Standard for Steel Structures - Based on Allowable Stress Concept* defines properties for circular hollow sections and are classed as "General pipe sections". The existing `PIPE` table has been updated to ensure that it is consistent with this table.
- JIS G3475:2005 *Design Standard for Steel Structures - Based on Allowable Stress Concept* defines properties for circular hollow sections and are classed as "Architectural pipe sections". A new table for these Circular Hollow (CHS) will be added.
- JIS G3466:2005 *Design Standard for Steel Structures - Based on Allowable Stress Concept* defines properties for square and rectangular hollow sections. These will be added to the existing Japanese Sections database as two new tables: Rectangular Hollow (RHS) and Square Hollow (SHS)

Refer to D9.C.4 Built-in Japanese Steel Section Library (on page 1729) for additional details on using the Built-in Japanese Steel Section Library.

To specify a Japanese hollow section

1. Select the **General | Property** page.

   The **Properties - Whole Structure** dialog box opens.
2. In the **Properties - Whole Structure** dialog box, click **Section Database**.

   The **Section Profile Tables** dialog box opens.
3. Select the **Steel** tab.
4. Select one of the tables available in the **Japanese** section: Pipe, Rectangular Hollow, Square Hollow, or Circular Hollow.
5. Select an entry from the **Select Profile** list.
6. Click **Add**.

   The section is now added to the Section tab in the **Properties - Whole Structure** dialog box and can be assigned to members..

AD.2007-08.2 Features Affecting the Pre-Processor

This section describes features that have been added that affect the pre-processor section of the program, also known as the Modeling Mode.

AD.2007-08.2.1 Wind Load Generation per ASCE 7-10

Wind loads intensity values may now be automatically generated per the 2010 edition of SEI/ASCE 7 using the ASCE 7 Wind Load dialog box (on page 2882) in the user interface. This dialog allows you to generate a wind loading pattern based on the parameters used in this specification.

The primary change in wind load evaluation between the 2002 and 2010 editions of the ASCE 7 specification involve the method of calculating the force coefficient, C_f, for solid freestanding walls and solid signs. The formula provided in the commentary related to Figure 6-20 in the specification is used:

$$C_f = \{1.563 + 0.008542 ln(x) - 0.06148 \cdot y + 0.009011[ln(x)]^2 - 0.2603 \cdot y^2 - 0.08393 \cdot y ln(x)\}/0.85$$

Where:

$x = B/s$

$y = s/h$

To generate a wind load intensity per ASCE 7-10

1. Add a wind load definition to the model.
2. Select this definition in the **Load & Definition** dialog box and click **Add**.

   The **Add New: Wind Definition** dialog box opens.
3. On the Intensity tab, select the as **Custom** in the drop-down list and click **Calculate as per ASCE-7**.

   The **ASCE-7: Wind Load** dialog box opens.
4. On the Common Data tab, select **2010** as the ASCE 7 - edition.
5. Specify or set the parameters needed to define the load.

   Click **Apply** prior to selecting a different dialog tab to update the dialog for the specified parameters.
6. Click **OK**.

AD.2007-08.2.2 Single Mass Model

A new load type, mass, is available for reference load cases. This is used to create a single mass model for all dynamic loads (i.e., seismic, response spectrum, time history, etc.). This load case can be used for seismic loads in lieu of a weight table, reducing repetitive data entry for analysis methods which would require the same data.

A new load type, mass, is available for reference load cases. This is used to create a single mass model for all dynamic loads (i.e., seismic, response spectrum, time history, etc.). This load case can be used for seismic loads in lieu of a weight table, reducing repetitive data entry for analysis methods which would require the same data.

- *M. To add mass loads to the mass model reference load* (on page 900)

- *M. To add weight by a reference load to a seismic load definition* (on page 859)

AD.2007-08.2.3 Eurocode Load Combination Generator

A new macro has been included with the program to generate load combinations for the Strength limit state per *Eurocode – Basis of structural design, BS EN 1990:2002+A1:2005*.

The load combination generator is capable of creating load combinations per equations 6.10, 6.10a, or 6.10b found in Cl. 6.4.3.2.

These equations specify the following combinations of loads:

$$\sum_{j\geq 1} \gamma_{G,j}G_{k,j} + \gamma_p P + \gamma_{Q,1}Q_{k,1} + \sum_{i>1} \gamma_{Q,1}\psi_{0,1}Q_{k,1}$$

Alternatively, for the strength limit state, the less favorable of equations 6.10a and 6.10b may be used:

$$\sum_{j\geq 1} \gamma_{G,j}G_{k,j} + \gamma_p P + \gamma_{Q,1}\psi_{0,1}Q_{k,1} + \sum_{i>1} \gamma_{Q,1}\psi_{0,1}Q_{k,1} \tag{6.10a}$$

$$\sum_{j\geq 1} \xi_j\gamma_{G,j}G_{k,j} + \gamma_p P + \gamma_{Q,1}Q_{k,1} + \sum_{i>1} \gamma_{Q,1}\psi_{0,1}Q_{k,1} \tag{6.10b}$$

where

Gk	=	Permanent actions
P	=	Prestress actions
Qk	=	Variable actions

Note: The effects in each of the above equations are always additive. If any effect is negative (that is, would reduce the final sum), its effect is taken as zero.

AD.2007-08.2.4 Rigid Floor Diaphragms

A new feature has been added to easily model a rigid floor diaphragm without the need to specify a control joint at each. When specified, this command directs the engine to perform the following:

a. Calculate the center of mass for each rigid diaphragm (where control joint is to be located) considering the mass model of the structure. The mass must be modeled using mass reference load. See TR.31.6 Defining Reference Load Types (on page 2453)

b. Create, internally, an analytical node at the center of mass location to be included during analysis (unless a control node is specified) if an existing analytical node exists at this point, then the existing joint is used in lieu of creating a new joint.

Tip: The center of mass of each diaphragm is included in the preprocessing output. To include the center of rigidity in the post-processing output, you must include the `PRINT DIAPHRAGM CR` command. See TR.42 Print Specifications (on page 2666)

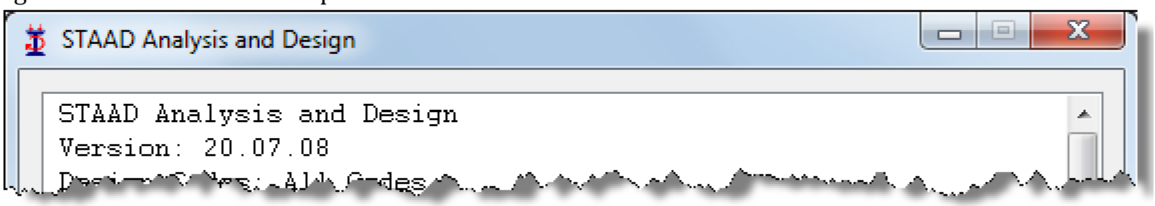
c. Search all nodes available within a diaphragm and add them as dependent nodes; with the control node located at the center of mass for the diaphragm (or at the specified control node)

Related Links

- *TR.28.2 Floor Diaphragm* (on page 2328)
- *Node Specification dialog* (on page 2784)
- *M. To assign nodes to a floor diaphragm* (on page 818)

AD.2007-08.3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.



AD.2007-08.3.1 API 2A WSD 21st Ed. Update

Joint checking for tubular members per the American Petroleum Institute 2A-WSD code has been updated to the 21st Edition (December 2000) of that code, including errata and supplements 1 to 3 (latest: Supplement 3 - March 2008). Additionally, the process of joint design has been simplified.

Note: Only simple joints and overlapping joints will be considered by the program. Other type such as grouted joints, joints with ring stiffeners etc are not be considered.

The clauses/sections in the API code that have been dealt with are:

- 4.2.1 Material strength
- 4.2.3 Minimum Capacity
- 4.2.4 Joint Classification
- 4.3 Simple joints
- 4.4 Overlapping joints

Refer to D1.J. American Codes - Steel Design per API 2A-WSD 2000 (on page 1283) for additional information on the methodology used.

External Joint Data File

In previous versions, the `LEG` design parameter was used to direct the program to generate a separate joint data file or to check a user-specified file. This file is now automatically generated or checked as needed.

As the API code allows for mixed joint types, the PUNCH column in the input file has been replaced with K, X, and Y columns which are used to designate fractional contributions of each joint class. Similarly, overlapping joints are indicated by using a negative value for the `GAP` between braces and the member number of the overlapping member in the `OB` column (replaces THETAT used in previous versions).

If the `filename.PUN` file is not detected in the same folder as the current STAAD input file (where "`Filename`" is the same as the `.STD` file), then the program assumes this is the initial joint design and this file is created. If, however, this file is detected, the program assumes that the that the joint design has been performed at least once and will use this file to perform the joint checks.

To check tubular member joints per API

The checking of joints is an iterative process done by means of an automatically generated text file.

1. Model a structure as you normally would.

> **Note:** Only circular pipe members are considered.

> **Tip:** Using `TRUSS` specifications helps to reduce analysis time.

2. In the **Steel Design - Whole Structure** dialog box, select `API` as the design code.
3. (Optional) Specify the factor of safety used for joint checks using the new `FSJ` design parameter.
4. (Optional) Specify all other necessary design parameters.

   The `LEG` parameter is no longer used to generate or check joint data files.
5. Specify `CODE CHECK` or `SELECT MEMBER` commands as needed and perform the analysis.

   If this the `filename.PUN` file is not detected in the same folder as the input file, the program assumes this is the first time the structure is being analyzed and generates this input file with default data for the detected joints. Each joint is assumed to be a Y joint by default.
6. Modify the default joint data in the `filename.PUN` as needed to describe the actual joint conditions.

   A text editor can be used to make changes to this file. Be sure to save changes once complete.
7. Re-analyze the STAAD input file.

   Joint check results follow the steel design output.
8. Repeat steps 3 through 7 as needed to make changes in the structure.

AD.2007-08.3.2 Shear Buckling per EC3

The design code checks performed per Eurocode 3 have been updated to include checks for shear buckling in I Sections and PFC Sections. Eurocode 3 – Part 1 (EN 1993-1-1:2005) states in Cl.6.2.6 that the checks for Shear buckling are to be based on the procedure in EN 1993-1-5. STAAD.Pro performs checks based on the methods Section 5 of EN 1993-1-5:2006.

In the case of an unstiffened web, the program will check the unstiffened web capacity. If the demand due to applied loads is greater than this capacity, the program will calculate a suitable spacing for transverse stiffener plates in order to meet the demand.

In the case of a web with transverse stiffeners, the program will check the capacity of the web considering the provided stiffener spacing. The program will consider both the buckling capacity of the web as well as the flange. If the demand due to applied loads is greater than this capacity, the program will calculate a reduced stiffener spacing for transverse stiffener plates in order to meet the demand.

> **Note:** Only transverse stiffeners are taken into account. The effect of any longitudinal stiffeners is ignored.

The distance between transverse stiffeners is specified by the `STIFF` parameter, in the current units of length. If no value is specified, the program assumes a spacing equal to either the member length or depth of beam, whichever is greater.

The output file provides recommendations on the evaluation of stiffeners (e.g., adding stiffeners at a spacing or increasing the web thickness).

Refer to D5.C.5.3 Members Subject to Shear (on page 1486) for additional information.

AD.2007-08.3.3 IS800:2007 Working Stress Method

The IS:800-2007 Steel code was deviated in concept from its -1984 version (based on Working Stress Method) and introduced the Limit State Method of Design. The entire 2007 version of the code is devoted to the Limit State Method of Design, except Chapter 11. This Chapter comprises of a couple of pages and has the guideline for the Design of Steel sections as per working stress method (WSM). The approach of this new working stress method is different from its earlier version and utilizes the concept of Section Slenderness and Section Classification.

The program now includes design per the Working Stress Method (WSM) methodology in addition to Limit State method for design of steel structures per IS800:2007.

Some minor corrections to the Limit State Design option have also been made.

To specify a design using IS 800:2007 Working Stress Method

1. In the Modeling mode, select the **Design | Steel** tab.

   The **Steel Design - Whole Structure** dialog box opens.
2. In the **Current Code** drop-down menu, select **IS800 2007 WSD**.
3. Click **Define Parameters...**.

   The **Design Parameters** dialog box opens.
4. Click **Add**.

   This will insert the following commands into the STAAD input file:
   ```
   CODE IS800 WSD
   ```

AD.2007-08.3.4 Surface Element Selfweight

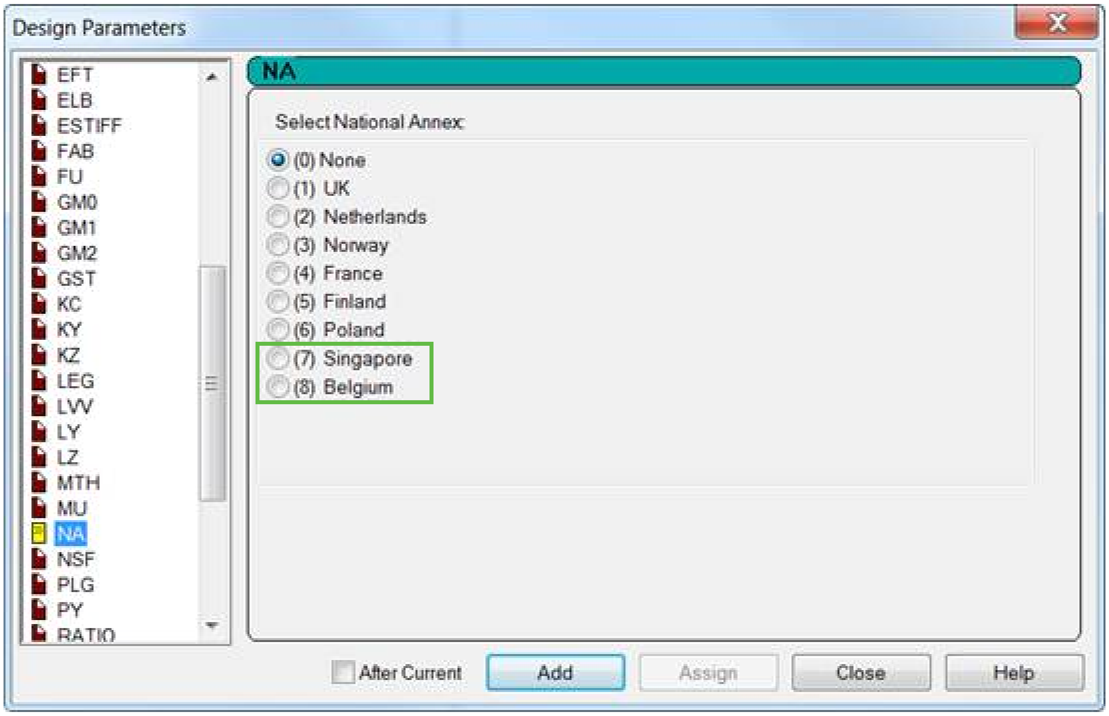
A new surface load has been added to include the self weight of surface elements. This command can be used to calculate and include the weight of surface elements in the analysis of a structure.

Related Links

- *TR.32.9.2 Surface Selfweight Load* (on page 2497)
- *M. To add a surface selfweight load* (on page 841)

AD.2007-08.3.5 Eurocode 3 National Annexes

Two additional country's National Annex to Eurocode 3 have been incorporated into the Steel design module in STAAD.Pro: Singapore and Beglium. As with the other National Annexes to EC-3, this implementation will make use of the NA parameter.



AD.2007-08.3.5.1 Belgian National Annex to Eurocode 3 (EN 1993-1-1:2005)

To specify a design using the Belgian NA to EC3, use the following procedure.

The Belgian National Annex document referred to is "NBN EN 1993-1-1:2005."

When the Belgian National Annex to EC3 is used for design, the output section title is revised to include the Belgian National Annex (National Annex to NBN-EN 1993-1-1). Additionally, the partial safety factors used are included in the output and are as specified in the Belgian NA. The value for C1 and k factors used in the calculation of the elastic critical moment are also included in the report.

Note: For additional information, please refer to D5.D.10 Belgian National Annex to EC3 (on page 1563) and D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) .

1. In the Modeling mode, select the **Design | Steel** tab.
   The **Steel Design - Whole Structure** dialog box opens.
2. In the **Current Code** drop-down menu, select **EN 1993-1-1:2005**.
3. Click **Define Parameters...**.
   The **Design Parameters** dialog box opens.
4. Select the **NA** parameter in the list box.
5. Select the option for **(8) Belgium**.
6. Click **Add**.

   This will insert the following commands into the STAAD input file:

   ```
   CODE EN 1993-1-1:2005
   NA 8
   ```

AD.2007-08.3.5.2 Singaporean National Annex to Eurocode 3 (EN 1993-1-1:2005)

To specify a design using the Belgium NA to EC3, use the following procedure.

The Singaporean National Annex document referred to is "SS EN 1993-1-1:2005."

When the Singaporean National Annex to EC3 is used for design, the output section title is revised to include the Singaporean National Annex (National Annex to SS-EN 1993-1-1). Additionally, the partial safety factors used are included in the output and are as specified in the Singaporean NA. The value for C1 and k factors used in the calculation of the elastic critical moment are also included in the report.

Note: For additional information, please refer to D5.D.9 Singaporean National Annex to EC3 (on page 1556) and D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) .

1. In the Modeling mode, select the **Design | Steel** tab.
   The **Steel Design - Whole Structure** dialog box opens.
2. In the **Current Code** drop-down menu, select **EN 1993-1-1:2005**.
3. Click **Define Parameters...**.
   The **Design Parameters** dialog box opens.
4. Select the **NA** parameter in the list box.
5. Select the option for **(7) Singapore**.
6. Click **Add**.

   This will insert the following commands into the STAAD input file:

   ```
   CODE EN 1993-1-1:2005
   NA 7
   ```

AD.2007-08.3.6 EC3 Slender Circular Hollow Sections

Slender circular hollow (pipe) sections may now be designed per Eurocode 3 (EN 1993-1-6:2007).

Eurocode 3 – Part 1 (EN 1993-1-1:2005) –hereafter EC3-6– states in Cl. 6.2.2.5 (5) that the design of slender circular hollow sections is to be based on the procedure in EN 1993-1-6. EC3 6 deals with the design of shell structures. EC3-6 does not, however, specify additional or modified safety factors. Therefore, the default safety factors from EN 1993-1-1 are used.

Note: You can change these values through the `GM0`, `GM1`, and `GM2` design parameters.

The program checks the plastic and buckling limit states for primary stresses based on the stress design method described in EC3-6.

Refer to D5.C.5.6 Design of Slender pipe sections to EN 1993-1-6 (on page 1497) for details on the methodology and calculations used in this design.

AD.2007-08.3.7 User Defined Section for EC3

The feature to design user-provided table (UPT) general sections has now been introduced steel members designed per Eurocode 3 (EN 1993-1-1:2005). However, rather than assuming that the section will behave like an I section, you are given the option of choosing the 'section-type' he would like to design the member for.

This is achieved through the introduction of a new design parameter, `GST`, that has the following values:

1. I-Section (Default)
2. Single Channel

3. Rectangular Hollow Section
4. Circular Hollow Section
5. Angle Section
6. Tee Section

Unless specified using the GST parameter, a general section will be assumed to be an I- Section.

Note: This parameter will be ignored if assigned to any section other than a General Section.

The design procedure will then account for the section type and proceed with the design as necessary. The output report will also indicate the section type considered for the design of the UPT section. The design output will indicate the section as follows:

```
            *     1 ST   IPE100       (UPT: DESIGNED AS I-SECTION)

                       FAIL     EC-6.3.2 LTB       8.591        1
                       0.00          0.00        -31.25       2.50
 |---------------------------------------------------------------------|
 | CALCULATED CAPACITIES FOR MEMB     1 UNIT - kN,m  SECTION CLASS  1  |
 |MCZ=    9.2 MCY=    2.1 PC=    12.3 PT=   242.1 MB=    3.6 PV=   68.7|
 | BUCKLING  CO-EFFICIENTS C1  AND  K  :    C1 =  1.132    K =  1.000  |
 | PZ=   242.05    FX/PZ =   0.00       MRZ=    9.2      MRY=    2.1   |
 |---------------------------------------------------------------------|
```

Refer to D5.C.6 Design Parameters (on page 1502) for additional information on all EC3 design parameters.

AD.2007-08.4 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the Post Processing modes. These are explained in the following pages.

AD.2007-08.4.1 Eurocode 2:2004 Slab Design

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2007.08.4.2 Changes to STAAD.foundation license

The license for STAAD.foundation V8i (release 5.3) is now included with STAAD.Pro contains the capability for design the following rigid foundation types:

- Isolated
- Combined
- Pile Cap

STAAD.foundation functions as a design module similar to others included with STAAD.Pro.

Contact Bentley Systems for a full license to use all of the design capabilities for STAAD.foundation or to upgrade to STAAD Foundation Advanced V8i, which includes an improved user interface, foundation toolkit wizards, plant foundation types, and FEM analysis for mat foundations.

AD.2007-08.5 Nuclear Related Features

The following new features have been added for the NRC release.

Note: This feature requires STAAD.Pro V8i (SELECTseries 3) NRC (build 20.07.08.22) or higher.

AD.2007-08.5.1 Design per ASME NF 3000-2001

The design per ASME NF 3000-2001 is now available as a new design code option.

Design of members per ASME NF 3000 - 2001 requires the *STAAD Nuclear Design Codes* SELECT Code Pack.

Refer to D1.L.4. ASME NF 3000 - 2001 & 2004 Codes (on page 1338) for additional information.

AD.2007-08.5.2 ASME NF 3000-2001 Service Level Conditions

All editions of the ASME NF 3000 code now can be designed for different service level conditions as defined by that code.

Service Level Conditions are basically the loading conditions for which the plant structure and its components are to be designed. The same primary load can be multiplied by different factors to signify the different service levels. Also the load combinations for various service levels are different and pre-defined by the code.

Each ASME NF 3000 code edition now contains the a new design parameter, `SLR`, which is used to specify the service condition level as defined in the codes. For the case of service level D (failure), three additional new parameters –`KS`, `KV`, and `KBK`– are used to directly specify the service level factors.

Design of members per ASME NF 3000 - 2001 requires the *STAAD Nuclear Design Codes* SELECT Code Pack.

Refer to D1.L.5. ASME NF 3000 Service Level Conditions (on page 1348) for additional information.

AD.2007-08.5.3 TATA Structura Sections

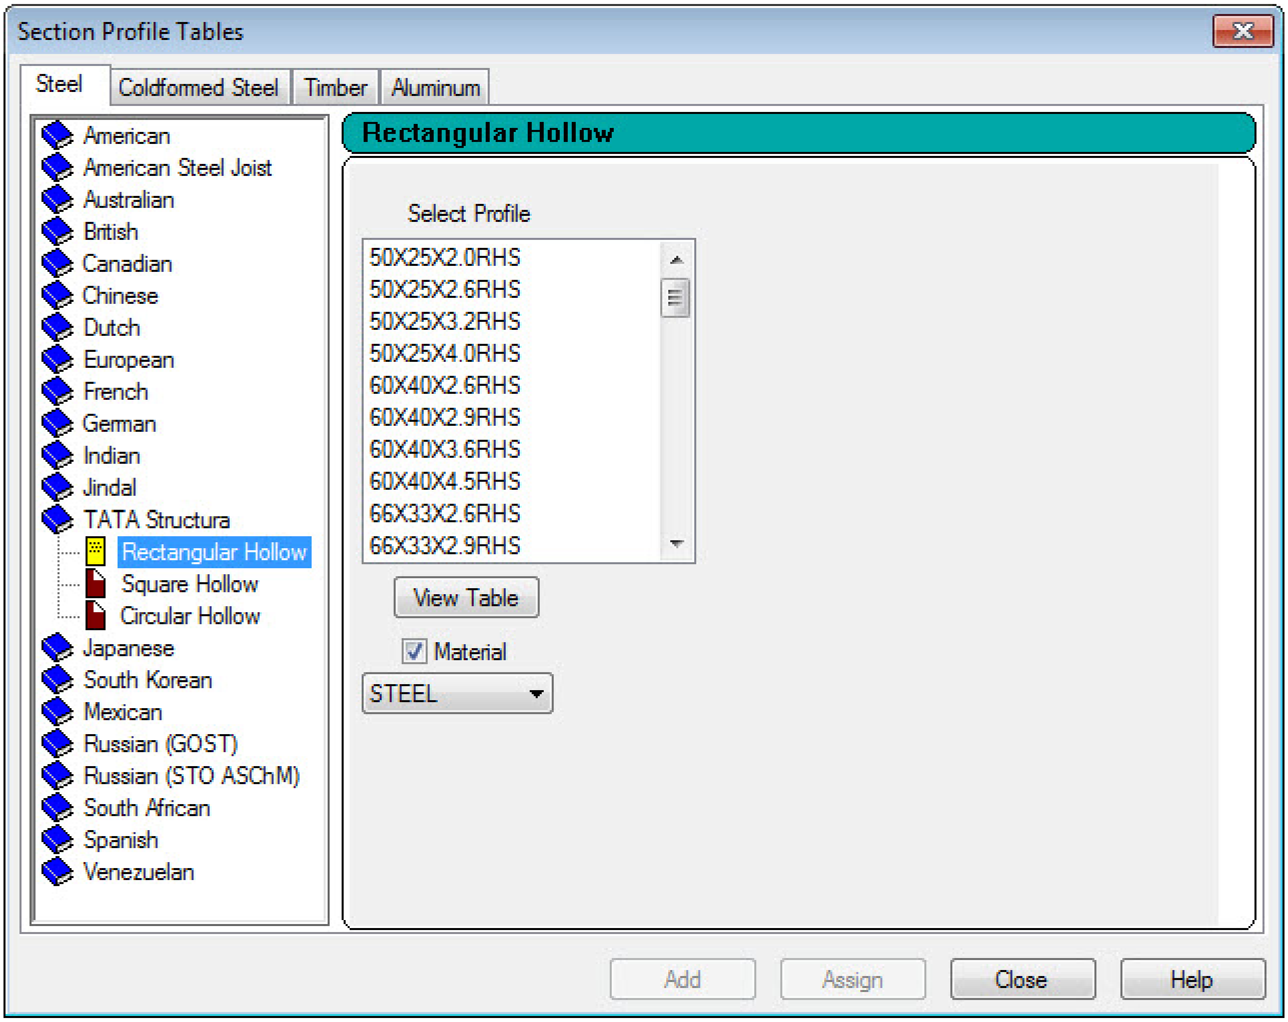
The catalog of available TATA Structura (Indian) hot rolled steel sections has been expanded to include the hollow sections from TATA publications.

Specifying a TATA Structura hollow section

1. Select the **General | Property** page.

   The **Properties - Whole Structure** dialog box opens.
2. In the **Properties - Whole Structure** dialog box, click **Section Database**.

   The **Section Profile Tables** dialog box opens.
3. Select the **Steel** tab.
4. Select one of the tables available in the **TATA Structura** section: Rectangular Hollow, Square Hollow, or Circular Hollow.



5. Select an entry from the **Select Profile** list.
6. Click **Add**.

   The section is now added to the Section tab in the **Properties - Whole Structure** dialog box and can be assigned to members..

V8*i* (SELECTseries 2)

The Software Release Report for STAAD.Pro V8*i* (SELECTseries 2) contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8*i* (SELECTseries 1) (release 20.07.06) This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-07.1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

AD.2007-07.1.1 Academic Licensing

In order to ensure that the next generation of engineer that emerges from the higher education system is up to speed using our applications, Bentley has a policy of providing software to Universities and Colleges at a favorable rate.

Students can now use STAAD.Pro under an Academic License, which is obtained through a SELECT account. Contact your regional engineer or visit Bentley.com to obtain a license.

Note: When using an Academic License, the program window title bar and About window indicate this. Similarly, all output (Analysis files and Reports generated from STAAD.Pro) are marked as "Academic License User."

Caution: The Advanced Analysis Engine is not available when using the program under an Academic Licence.

AD.2007-07.1.2 StructLink and PipeLink Plug-ins

Two plug-ins are available to you when installing STAAD.Pro: StructLink and PipeLink.

- StructLink is a utility used for the bi-direction exchange of data between STAAD.Pro and ProSteel V8i.
- PipeLink is an all new utility used for the exchange of pipe stress model data between STAAD.Pro and AutoPIPE V8i. Refer to AD.2007-07.3.4 AutoPIPE V8i (SELECTseries 2) and PipeLink support (on page 209) for additional the bi-directional data exchange capabilities made available through this utility.

Note: During the installation of STAAD.Pro, select the option to install additional programs and utilities in order to have these two utilities installed.

Refer to the documentation included with these plug-ins for additional information on their use.

AD.2007-07.1.3 Structural Dashboard Integration

Bentley's Structural Dashboard is now integrated into STAAD.Pro V8i.

Bentley's Structural Dashboard V8i is a free utility application which allows you to manage workflows and project files as well as keep up to date with latest products, news, and Be Communities happenings. This program can now be accessed from within STAAD.Pro and will launch whenever STAAD.Pro is started to assist you in managing your entire project workflow.

When STAAD.Pro is first launched after installing Structural Dashboard, a welcome dialog opens to allow you to set the automatic launch option. To launch the program and continue allowing it to launch whenever a Bentley Structural program starts, leave the option selected and click the **OK** button. Otherwise, you can de-select this option before proceeding.

Launch Structural Dashboard on program startup	Set this option to open the Structural Dashboard application whenever STAAD.Pro is opened. **Tip:** This setting can be changed at any time from within the Structural Dashboard program.
Show me this dialog on startup	Set this option to display this dialog whenever STAAD.Pro is opened. **Tip:** This setting can be changed at any time from the Configure Program dialog File Options tab.

To launch Structural Dashboard from STAAD.Pro

1. Select **File** > **Structural Dashboard...**.

   The Bentley Structural Dashboard V8i program opens.

> **Note:** If Structural Dashboard has not been installed, this menu item is inactive. You can download the program from http://www.bentley.com/en-US/Promo/ISM/downloads/.

> **Note:** Refer to Section 2.3.1 of the User Interface Manual for additional help in using the Structural Dashboard with STAAD.Pro.

AD.2007-07.2 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

> **Note:** Items labeled with an asterisk (*) were added in the QA&R release of V8i (SELECTseries 2) (Build 20.07.07.31).

AD.2007-07.2.1 Time History Spectrum Enhancements

New options have been added to the spectrum input for a Time History definition which allow you to output time history input data, a Response Spectrum for a Time History load, or to use frequency-spectrum pairs. These options can be added by modifying the input command file.

Two new output options are available for reporting time history input and synthetic time history ground acceleration data used by the program for a time history load with the spectrum generation option. You can control the amount of output generated (as this can be quite large) as well.

A new option has also been added to allow you to instruct the program to use frequency-spectra pairs in lieu of period-spectra pairs for the time history spectrum input.

Related Links

- *TR.31.4 Definition of Time History Load* (on page 2441)
- *M. To generate output for time history spectrum* (on page 878)
- *M. To use frequency-spectra pairs in a time history load* (on page 878)

AD.2007-07.2.2 Response Spectrum Signed Results and IMR Load Cases

Two methods to produce signed response spectrum results have been added to the STAAD.Pro analysis engine. The Dominant and Sign commands may be used in the input file to produce signed output. Additionally, STAAD.Pro now includes an option to automatically generate new load cases based on a specified number of modes from the response spectrum.

Signed Results

STAAD.Pro can now assign a mathematical sign (positive or negative) to the modal results by one of two means. The first method allows you to select a DOMINANT mode, the sign of which will then be applied to all other modes. The second method will produce signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign.

Individual Modal Response Case Generation

The Individual Modal Response (IMR) load cases are simply the mode shape scaled to the magnitude that the mode has in this spectrum analysis case before it is combined with other modes. If the IMR parameter is entered, then STAAD will create load cases for the first specified number of modes for this response spectrum case (i.e., if five is specified then five load cases are generated, one for each of the first five modes). Each case will be created in a form like any other primary load case.

The results from an IMR case can be viewed graphically or through the print facilities. Each mode can therefore be assessed as to its significance to the results in various portions of the structure. Perhaps one or two modes could be used to design one area/floor and others elsewhere. You can use subsequent load cases with Repeat Load combinations of these scaled modes and the static live and dead loads to form results that are all with internally consistent signs (unlike the usual response spectrum solutions). You can also use the Repeat Load capability to combine the modal applied loads vector with the static loadings and solve statically with P-Delta or tension only.

The modal accelerations are multiplied by the nodal masses to produce equivalent static lateral forces for each modal load case.

Note: When the IMR option is entered for a Spectrum case, then a Perform Analysis & Change must be entered after each such Spectrum case.

Help

To add Signed results to a Response Spectrum

1. Select **Commands** > **Loading** > **Load Commands**.

   or

   Select the General **|** Load & Definition page and then click the **New...** button.

   The Create New Load Items dialog opens.
2. Select the Response Spectra tab.
3. Select the **Code** you wish to use.

   Note: See below for using IMR generation options. All other parameters are same as previous versions.
4. Select the option to use the **Dominant Mode No.** to assign the same sign as the selected mode to all modes.
5. (Optional) Select to provide **Signed** results to

   Note: Selecting this option will not use the Dominant Mode No., but rather will create signed values for all results by comparing the sum of the squares values for positive and negative values to determine the governing sign.
6. Click the **Add** button to add this response spectrum load.

To add Individual Modal Response results to a Response Spectrum

1. Select **Commands** > **Loading** > **Load Commands**.

   or

   Select the General **|** Load & Definition page and then click the **New...** button.

   The Create New Load Items dialog opens.
2. Select the Response Spectra tab.
3. Select the **Code** you wish to use.

   Note: See above for options to add signed results. All other parameters are same as previous versions.

   Note: The Individual Modal Response case generation is not available for SNiP II code response spectra.
4. Select the option to **Generate load cases for ...** to individual modal response load cases.
5. (Optional) Specify the number of modes for which load cases will be generated.

   Note: Selecting this option will not use the Dominant Mode No., but rather will create signed values for all results by comparing the sum of the squares values for positive and negative values to determine the governing sign.
6. (Optional) Specify a beginning load case number for the first primary load case generated from the IMR.
7. Click the **Add** button to add this response spectrum load.

- *M. To add a generic response spectrum* (on page 861)

AD.2007-07.2.3 Design of Class 4 (Slender) Steel Sections per S16-01

An update to the Canadian Steel Design code has been added for the design of Class 4 (slender) steel sections per CAN/CSA-S16-01. Previous versions of STAAD.Pro were capable of designing Section Classes 1, 2, or 3.

The design of slender Class 4 steel sections does not require any different actions or input. The analysis engine will determine if a section meets the criteria for a Class 4 section and then perform the necessary checks, if design checks have been requested for that member.

Methodology

Refer to D4.B.6 Member Resistances (on page 1424) for a detailed description of the methodology used in STAAD.Pro for performing the design of Class 4 sections per S16-01. A verification problem using this feature has also been added to Section 3B.10.

AD.2007-07.2.4 Von Mises Stresses per AIJ 2002 and 2005

Design per AIJ (Japanese) steel design codes has been updated to include checking members in accordance with Von Mises stress criteria in AIJ 2005. This check is a requirement for the design of steel structures in nuclear power plants in Japan.

The von Mises stress equation is calculated when the new `MISES` parameter has been set to a value of 1 (the default value of 0 does *not* check this condition). The calculated forces and moments are combined per the von Mises stress criteria.

To specify a von Mises stress check in an AIJ 2002 or AIJ 2005 design

1. Create a model with steel members.
2. Select either **AIJ 2002** or **AIJ 2005** for the **Current Code** on the **Design | Steel** page.
3. Click the **Define Parameters...** button.

   The Design Parameters dialog opens.
4. Select the **MISES** tab in the parameters list.
5. Select option 1 to instruct STAAD.Pro to perform the von Mises stress check as part of the steel design.
6. Click the **Add** button to add this parameter.
7. Close the Design Parameters dialog.
8. Assign the `MISES` parameter to members as needed, just as you would any other design parameter.

How the von Mises check results are included in the output depends on the level of detail (`TRACK` parameter) selected:

Track 0 or 1	The von Mises stress is reported if this ratio is the critical condition.
Track 2	The value for $f_m = \sqrt{(\sigma_x{}^2 + 3\times\tau_{xy}{}^2)}$ (numerator in the von Mises stress ratio equation) is displayed in the Stresses output category. When the von Mises check ratio is the critical condition, the value of the ratio is reported.
Track 4	Used for deflection checks only. Von Mises checks are not reported.

Methodology

Refer to D9.B.4 Von Mises Stresses Check (on page 1727) or D9.C.10 Von Mises Stresses Check (on page 1742) for a detailed description of the methodology used in STAAD.Pro for performing von Mises stress checks per AIJ 2002 or 2005.

AD.2007-07.2.5 Norsok N-004

The design of tubular steel (European round pipe sections) members per NORSOK N-004 Rev 2, October 2004 has been included in STAAD.Pro. The program will perform the member design for ultimate limit states (and optional deflection checks for serviceability). The tubular joints can also be automatically generated and checked per the code.

The NORSOK code has been added to the steel design code list available in STAAD.Pro. Selecting this code allows you to assign parameters, including defining the water level above the origin (for calculating hydrostatic pressure) or the

Note: N-004 refers to the superseded version of Eurocode 3 (DD ENV 1993-1-1) in several places. In such cases, the corresponding clause from the latest version of EC-3 (EN 1993-1-1:2005) has been used in the STAAD.Pro implementation.

To perform a member design per the NORSOK N-004 code

1. Create a model with steel tubular members.

   Caution: The Norsok code only supports pipe sections. Errors will be presented in sections other than pipe members are used.

2. Select **NORSOK** for the **Current Code** on the **Design | Steel** page.
3. Click the **Define Parameters** button.

   The Design Parameters dialog opens.

4. Specify parameters as required.

   Note: The height of water level above the origin is specified using the HYD parameter. Alternatively, the PSD parameter may be used to define the water pressure.

5. Close the Design Parameters dialog.
6. Assign the torsion-related parameters to members as needed, just as you would any other design parameter.

To perform a joint check per the NORSOK N-004 code

1. Add the `CHECK JOINT` command to a new `PARAMETER` manually in the STAAD.Pro input file using the Editor.
2. Perform an preliminary design by selecting **Analyze** > **Run Analysis...**.

   The program creates an external text file titled `filename_JOINTS.NGo` which contains the automatically generated chord and brace definitions associated with the nodes included in the `CHECK JOINT` command. All joints are classified as Y by default.

3. Open the text file using a text editor program (i.e., Notepad or STAAD Editor).
4. Manually edit the joint classifications as needed.
5. (Optional) Edit the Brace and Chord definitions as needed.

> **Note:** The Brace and Chord members at each joint are assumed based on the relative cross section dimensions. Lengths of Chord and Brace members are taken as the analytical beam member length.

6. Save the text file and the re-analyze the structure

Methodology

Refer to D12.B. Norwegian Codes - Steel Design per NORSOK N-004 (on page 1837) for a detailed description of the methodology used in STAAD.Pro for performing steel tube member design per NORSOK N-004.

AD.2007-07.2.6 EC3 Torsion Design

Design per EC3 [EN 1993-1-1:2005] has been enhanced to include the design of members subject to torsion. You may select to have the program execute basic or detailed torsion stress checks. Torsion design checks can be performed on I-sections, H-Sections, Channel sections, and structural hollow sections (RHS, SHS, CHS).

> **Note:** The default behavior is to neglect torsion. The new `TORSION` parameter must be set to either 1 (basic) or 2 (detailed) to perform torsion design.

To include torsion design for EC3 steel design members

1. Create a model with steel members.
2. Select **EN 1993-1-1:2005** for the **Current Code** on the **Design | Steel** page.
3. Click the **Define Parameters...** button.

   The Design Parameters dialog opens.
4. Select the **TOR**(sion) tab in the parameters list.
5. Select either option 1 (von Mises check excluding warping effects) or option 2 (detailed checks including warping effects) to include design for torsion and click the **Add** button to add this parameter.
6. Specify the loading and support conditions of members subject to torsion using the **CMT** tab in the parameters list and click the **Add** button to add this parameter.
7. (Optional) For the cases of a concentrated torque (CMT = 2,3, or 6) somewhere along the member length (other the default of mid-span), specify the location of the torque using the **ALH** tab in the parameters list and click the **Add** button to add this parameter.
8. (Optional) Specify the effective length of members for torsion using the **EFT** tab in the parameters list and click the **Add** button to add this parameter.
9. Close the Design Parameters dialog.
10. Assign the torsion-related parameters to members as needed, just as you would any other design parameter.

Torsion design in EC3 is given in Cl. 6.2.7 of EN 1993-1-1:2005. Therefore, this clause is used primarily for this implementation.

EN 1993-1-1:2005 does not deal with members subject to the combined effects of torsion and lateral torsional buckling. However, EN 1993-1-6 considers such a condition in Appendix A. Therefore, STAAD.Pro uses Appendix A of EN 1993-1-6 to check for members subject to combined torsion and LTB.

The following clauses from EC3 are then considered:

- Cl. 6.2.7(1)
- Cl. 6.2.7(9)
- Cl. 6.2.7(5)
- EC-3 -6 App A

When torsion design is included (TOR = 1 or 2), then the EC3 design output includes the following sections:

- Basic (TORSION = 1) - The ratio calculated for stress interaction per EC-6.2.7(5) is displayed for each load case, along with the calculated values of axial force, shear in Y and Z, Bending about Y and Z, and torsion.
- Detailed (TORSION = 2) - The additional clauses viz. 6.2.7(1), 6.2.7(9) and EC3-6 A-1 will be included in the output. The stress interaction ratio per each is displayed for each load case, along with the calculated force and moment values used. Additional torsion calculation details are provided as well.

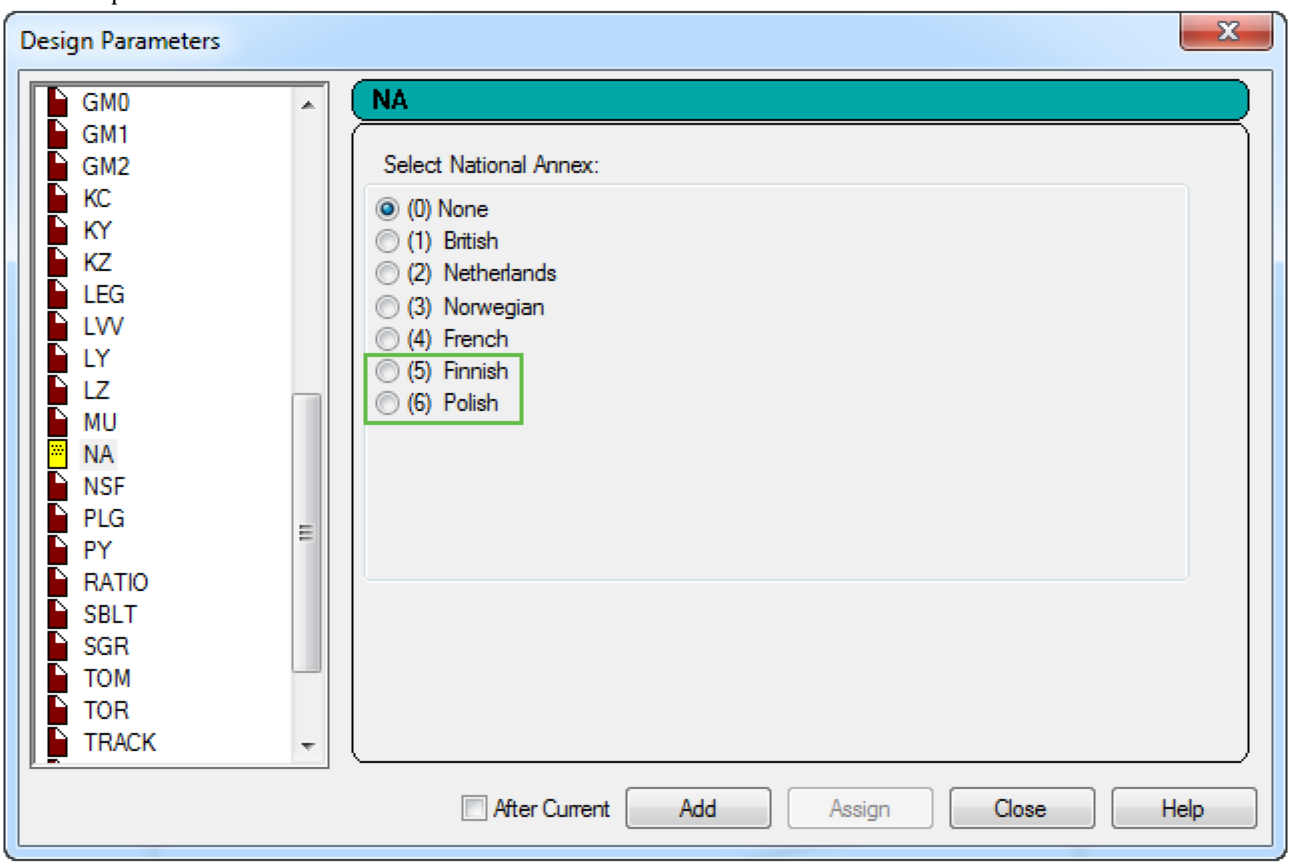
Note: If Torsion design is selected for a member which does not have any torsional moment, a warning is displayed in the output.

Methodology

Refer to D5.C.5.4 Members Subject to Torsion (on page 1488) for a detailed description of the methodology used in STAAD.Pro for performing torsion stress checks per EC3.

AD.2007-07.2.7 Eurocode 3 National Annex

Two additional country's National Annex to Eurocode 3 have been incorporated into the Steel design module in STAAD.Pro: Finland and Poland. As with the other National Annexes to EC-3, this implementation will make use of the NA parameter.



AD.2007-07.2.7.1 Finnish National Annex to Eurocode 3 (EN 1993-1-1:2005)

To Initiate a EC3-Finnish NA Steel Design, use the following procedure.

The Finnish National Annex document referred to is "National Annex to Standard SFS-EN 1993-1-1."

1. In the Modeling mode, click the **Design** > **Steel tab**.
2. In the **Current Code** drop-down menu, select **EN 1993-1-1:2005**.
3. Click the **Define Parameters...** button.
   The **Design Parameters** dialog opens.
4. Select the **NA** parameter in the list box.
5. Select the option for **(5) Finland**.
6. Click the **Add** button.

   This will insert the following commands into the STAAD input file:

   ```
   CODE EN 1993-1-1:2005
   NA 5
   ```

Note: For additional information, please refer to D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) and D5.D. European Codes - National Annexes to Eurocode 3 [EN 1993-1-1:2005] (on page 1516)

When the Finnish National Annex to EC3 is used for design, the output section title is revised to include the Finnish National Annex (National Annex to SFS-EN 1993-1-1). Additionally, the partial safety factors used are included in the output and are as specified in the Finnish NA. The value for C1 and k factors used in the calculation of the elastic critical moment are also included in the report.

AD.2007-07.2.7.2 Polish National Annex to Eurocode 3 (EN 1993-1-1:2005)

To Initiate a EC3-Polish NA Steel Design, use the following procedure.

The Polish National Annex document referred to is "National Annex to Standard PN-EN 1993-1-1".

1. In the Modeling mode, click the **Design** > **Steel tab**.
2. In the **Current Code** drop-down menu, select **EN 1993-1-1:2005**.
3. Click the **Define Parameters...** button.
   The **Design Parameters** dialog opens.
4. Select the **NA** parameter in the list box.
5. Select the option for **(6) Poland**.
6. Select the new **PLG** parameter in the list box.

   Note: This parameter is used to select if additional checks per clause 6.3.3 will be performed for designs using the Polish National Annex.
7. Click the **Add** button.

   This will insert the following commands into the STAAD input file:

   ```
   CODE EN 1993-1-1:2005
   NA 6
   ```

Note: For additional information, please refer to D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) and D5.D. European Codes - National Annexes to Eurocode 3 [EN 1993-1-1:2005] (on page 1516)

When the Polish National Annex to EC3 is used for design, the output section title is revised to include the Polish National Annex (National Annex to PN-EN 1993-1-1). Additionally, the partial safety factors used are included in the output and are as specified in the Polish NA. The value for C1 and k factors used in the calculation of the elastic critical moment are also included in the report.

AD.2007-07.2.8 AS4100 Physical Member Design

The workflow for design steel members per AS 4100:1998 has been updated to incorporate the use of physical members. Physical members are groups composed of a series of analytical beam elements of the same section and which are colinear (analytical beams are the beams used in modeling in STAAD.Pro). Using physical beams allows you to design for the actual conditions of the structure and assign specifications based on the true conditions of a steel member.

Some of the physical member design updates apply to design codes other than AS 4100, such as checks in the STAAD.Pro analysis engine for physical member overlapping and colinearity. These checks were previously made in the graphical interface but now they will checked again in the engine in the event you have manually generated the STAAD.Pro input file.

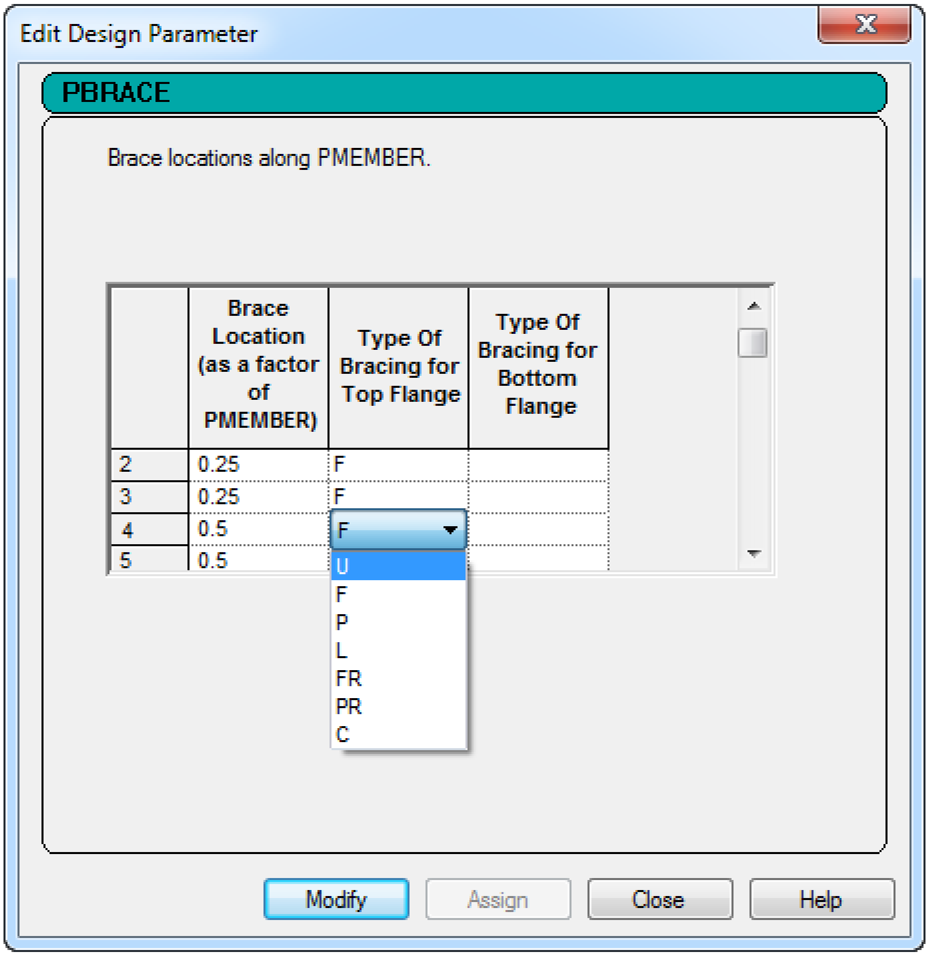
The physical member mode is initiated through the Toggle Physical Member mode tool found in the Steel Design toolbar (which docked on the left hand side of the screen by default). This “mode” is used when modeling the structure and any parameter or specification added while this tool is toggled on will then only be available for physical member groups.

Tip: Command entries in the tree, material properties, and specifications will be designated with “(Physical)” when added in this mode.

Physical members are then formed or selected using the tools in the Steel Design toolbar. Refer to M. Physical Members (on page 663) for additional information.

Physical Member Restraints

A new parameter has been added for AS 4100 physical members to describe the bracing conditions/locations on a physical member. This parameter describes where the restraint is located along the length of the physical member and the type of restraint on the top or bottom flange.



Engine Physical Member Validation

When creating physical members, the STAAD.Pro graphical interface will check to ensure that the analytical members included in a physical member definition are both interconnected and colinear. However, it is not uncommon for input files to be generated outside of the STAAD.Pro graphical environment. Thus, these checks are now performed by the STAAD.Pro Analysis & Design engine again when an analysis is performed. You will be alerted if either condition is not met.

Tip: The analytical members contained in a physical member definition must be colinear (or, all lying in a straight line). Each adjacent analytical member must be within 5° of one another to meet this condition.

Refer to D2.B.8 Design Parameters (on page 1364) for additional information using the new SGR (steel grade) and LHT (load height position) design parameters for steel design per AS4100. Refer to D2.B.12 Physical Member Design (on page 1372) for additional information on using the PBRACE parameter and performing the design of physical members per AS4100.

AD.2007-07.2.9 SNiP 2.23-81 Steel Design

Several minor enhancements have been made to STAAD.Pro regarding steel design per the SNiP 2.23-81 code.

The following corrections and enhancements were made to the SNiP 2.23-81 steel design code implementation in STAAD.Pro:

- PHI and NIU factors messages extensions explaining different design results cases
- Additional bending check for non axial compression/ tension with small eccentricity
- Compressed steel member design by weakened section
- Full Check by combinations envelope for different sections of each steel member. Print of Analysis results for each member section
- Additional parameters for Steel grade by EC3 in EN 10025-2 steel tables
- Correction of other minor bugs and errors

AD.2007-07.2.10 Geometric Nonlinear Analysis Cycle Control

You are now able to limit the analysis cycle using a displacement limit control. These controls can be found on the Analysis/Print Commands dialog Nonlinear Analysis tab or input manually in the input command file.

The displacement limit control allows you to select a nodal displacement degree of freedom be monitored during a geometric nonlinear analysis. A target displacement is set and, if the number of load steps set is two or greater, the analysis will proceed step-by-step until the target displacement is met or exceeded. This provides you with an additional, practical means of limiting the number of steps used in a geometric nonlinear (GNL) analysis.

Related Links

- *TR.37.8 Geometric Nonlinear Analysis* (on page 2654)
- *Nonlinear Analysis tab* (on page 2922)
- *A. To specify a nonlinear analysis* (on page 954)

AD.2007-07.2.11 Jindal Steel Section Database

To add a section from the available JPSL catalog, use the following procedure.

A number of Jindal Power & Steel Limited (JPSL) catalog sections have been added to the section database.

1. Select the **General | Property** page.
2. In the **Properties - Whole Structure** dialog, click **Section Database**.
   The **Section Profile Tables** dialog opens.
3. On the Steel tab, select the **Jindal** entry in the table families list.
4. Select the table, section, and type specification.
5. Click **Add**.

AD.2007-07.2.12* Design per ASME NF 3000 2004 Code

The design of steel sections according to the requirements in the American Society of Mechanical Engineers (ASME) specifications, Rules for the Construction of Nuclear Power Plant Components, Section III – Subsection NF has been implemented per the 2004 edition of this code and the **Design | Steel** page has been updated to allow the design parameters to be defined and assigned.

To perform a steel design per ASME NF 3000 2004

Use the following procedure to specify post analysis steel design code checking requirements for the ASME NF code.

1. Create a model with steel members.

2. Select **ASME NF3000 2004** for the **Current Code** on the **Design | Steel** page.
3. Click **Define Parameters...**.

   The **Design Parameters** dialog opens.
4. Specify parameters as required.
5. Close the **Design Parameters** dialog.
6. Assign parameters to members as needed.
7. Select **Analysis** > **Run Analyze** (or press CTRL+F5).

For more information on the technical requirements of this design code, including the full set of parameters and default values, refer to D1.L.4. ASME NF 3000 - 2001 & 2004 Codes (on page 1338) .

Note: The STAAD Nuclear Code pack is required to perform designs per an ASME NF 3000 code.

AD.2007-07.2.13* Update to ANSI AISC N690 1984 & 1994 Codes

Four new Stress Limit Coefficients (SLC) parameters have been added for designs per ANSI/AISC N690 1984/1994 codes.

These parameters, `SFC`, `SFT`, `SMZ`, and `SMY`, all default to 1.0 and are used to control the interaction equations in Section Q1.6 of the ANSI/AISC N690 1984/1994 codes.

Equations Q1.6-1a, Q1.6-1b, Q1.6-2 and Q1.6-3 of code ANSI/AISC N690 1994 will be rewritten as follows:

- Members subjected to both axial compression and bending stresses are proportioned to satisfy equation Q1.6-1a:

  $$f_a/F_a + C_{my}f_{by}/[(1 - f_a/F'_{ey})F_{by}] + C_{mz}f_{bz}/[(1 - f_a/F'_{ez})F_{bz}] \le 1.0$$

  and Q1.6-1b

  $$f_a/(0.6 F_y) + f_{by}/F_{by} + f_{bz}/F_{bz} \le 1.0$$

  when, $f_a / F_a > 0.15$, as per section Q1.6.1 of the code.
- Otherwise, equation Q1.6-2 must be satisfied:

  $$f_a/F_a + f_{by}/F_{by} + f_{bz}/F_{bz} \le 1.0$$
- Members subjected to both axial tension and bending stress are proportioned to satisfy equation Q 1.6-1b:

  $$f_a/(0.6 F_y) + f_{by}/F_{by} + f_{bz}/F_{bz} \le 1.0$$

Refer to D1.K.2.1 Design Process (on page 1303) for additional information on using the ANSI N690 1984 and 1994 codes.

AD.2007-07.2.14* Load Combination Enhancements

It is now possible to refer to a previously defined load combination within a new load combination. For example, a SRSS combination of individual response spectrum cases can now be referenced in a load combination along with dead load, live load, etc.

There are no changes to the input file syntax. Load combination definitions may now refer to existing load combination numbers along with load case numbers.

Note: There is no limit to the amount of load combination “nesting” which can be done in STAAD.Pro, other than the total limit of load cases and load combinations allowed by the program.

Related Links

- *TR.35 Load Combination Specification* (on page 2616)
- *Define Load Combinations dialog* (on page 2836)
- *M. To define a new load combination* (on page 886)

AD.2007-07.2.15* Enhancement to Maximum Number of Response Spectrum Load Cases

STAAD.Pro now supports up to 50 response spectrum load cases, instead of the previous limit of four.

Refer to TR.32.10.1 Response Spectrum Analysis (on page 2498) for additional information on using Response Spectra.

AD.2007-07.3 Features Affecting Post Processing

Several new features have been added and existing features have been modified in the Post Processing modes. These are explained in the following pages.

AD.2007-07.3.1 RAM Connection V8i (SELECTseries 1) Support

The enhancements included in Bentley's RAM Connection V8i (releases 6 and 7) are now available in STAAD.Pro. This includes new connection types, new codes, and design for seismic loads.

Some of the new features and enhancements include:

- Now compatible with versions of RAM Connection V8i up through release 7.0 (SELECTseries 3).
- British Design Code - Connection design per BS5950-1:2000 (British standard) has been added. This code can now be selected along side AISC codes.
- AISC Seismic Provisions - The seismic provisions of AISC 341-05 have now been added for connections per AISC codes.
- Seismic Frame Management - A new Seismic Frames page has been added to assign the lateral seismic resisting system classification to frames for connection design. This page is also used to add plastic hinge locations to beam members.
- Base Plate Design is now available for AISC (ASD & LRFD) connections. Column base plates are available in the Smart Connections dialog and Column-Brace gusset base plates are available in the Gusset Connections dialog.
- The RAM Material dialog has been expanded to accommodate for various materials from different countries. UK steel, bolt, and weld types have been added, as well as concrete and anchor bolt materials for US base plate design.

  Note: A notification message may be displayed when selecting the RAM Connection mode that you need to provide some additional material properties.
- Several new selection methods have been added to the **Select** > **By Joints** > sub-menu.
- Reports have been enhanced with code references and display of formulas used.

AD.2007-07.3.2 RC Designer

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2007-07.3.2.1 ACI 318 Metric

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2007-07.3.2.2 GB50010

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2007-07.3.2.3 IS456 with Seismic Design per IS13920

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

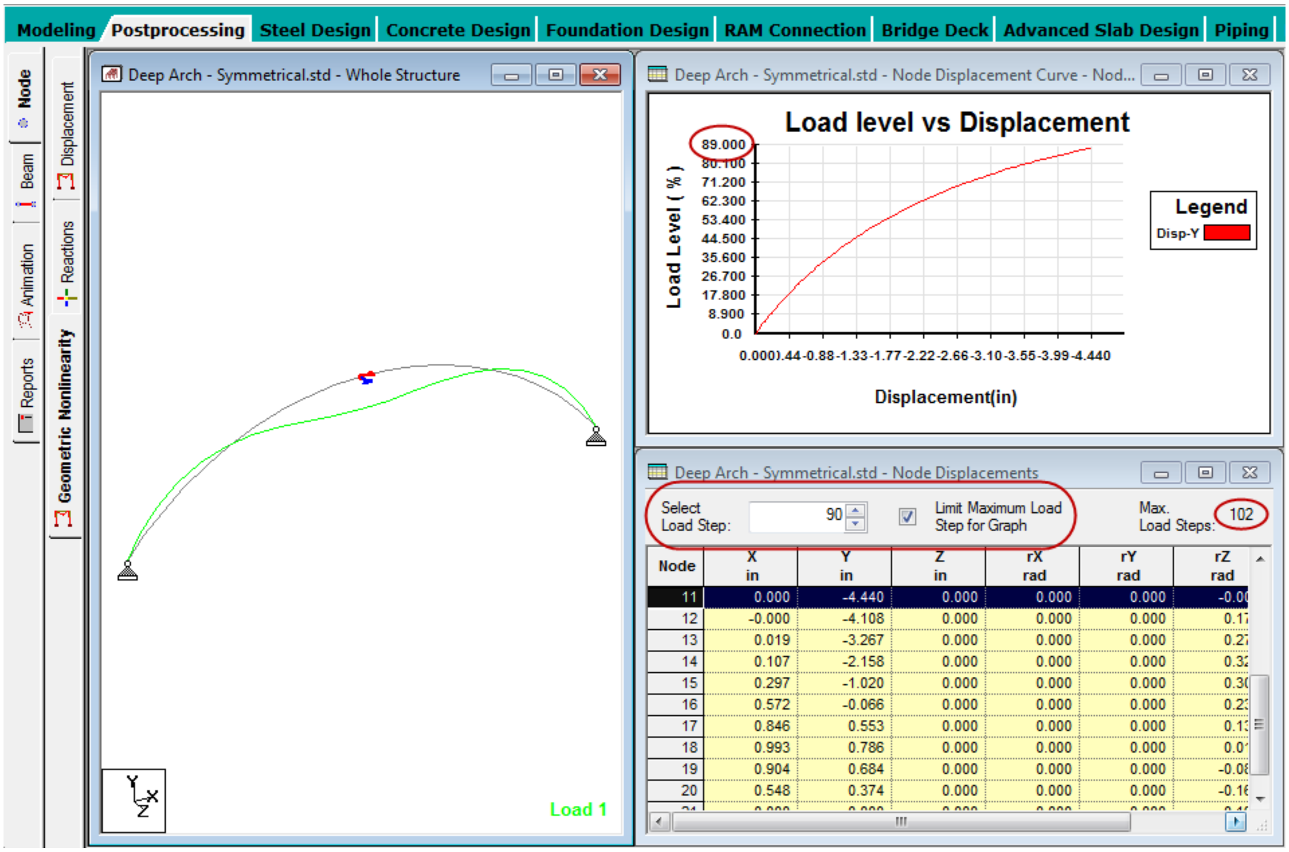
AD.2007-07.3.3 Enhanced Geometric Nonlinear Post Processing

The graphical display of the results of a geometric nonlinear analysis have been improved. The Graphs are now easier to read and a new control has been added to limit the maximum Load Step displayed.

When a structure is analyzed with a geometric nonlinear analysis, the nodal displacements can be viewed by selecting the Node **|** Nonlinearity page in the Post-Processing mode. The Node Displacements Curve has been enhanced and a new control has been added to the Node Displacements table to limit the maximum Load Step plotted.

In the event that a load level is specified which exceeds the non-linear buckling capacity of a structure, the analysis performed by STAAD.Pro will produce exceedingly large post-buckling displacements. This signifies that the load steps in this post-buckling level are beyond the scope of designed performance of the STAAD engine (and likely beyond the load level and effects intended by the engineer). In these cases, the scale of the non-linear load displacement curve was did not adequately display the pre-buckling characteristics due to the very large scale required to display the post-buckling displacements.

Now, in the event of a large post-buckling load, the maximum load level scale of the Load Level vs. Displacement graph can be limited to the currently selected load step by selecting this option on the Node Displacements table, thus allowing you to see the pre-buckling behavior.



AD.2007-07.3.4 AutoPIPE V8*i* (SELECTseries 2) and PipeLink support

STAAD.Pro is now capable of two-way data exchange with AutoPIPE via a new PipeLink utility. Additionally, the tools for transferring loads between the pipe model and the structural model have been enhanced such that you can now select, update, and remove loads to be applied to the structural model.

Note: For details on the updates to Bentley AutoPIPE V8i, refer to the documentation included with that product.

Some of the new features and enhancements include:

- The integration between STAAD.Pro and AutoPIPE has been enhanced to allow bi-directional transfer of data between STAAD.Pro and AutoPIPE. This is accomplished through a new plug-in program called PipeLink, which is used to generate common database files for use in both AutoPIPE and STAAD.Pro. Export Revised Model dialog (on page 2961) back to AutoPIPE is now possible.
- The system now allows pipe models to be imported from a number of databases and these models may all be stored locally. The active model can be selected from the Pipe Model dialog (on page 2962).
- The loading transfer process has been significantly revised. The mappings between the pipe loadings and the Transfer Pipe Reactions to Structure Model dialog (on page 2970) are recorded so that these structure loadings may be revised or removed rather than the previous once-only method. Further, loads can now be modified individually.
- Connections can now be individually selected to transfer moment to the supporting STAAD model structure by selecting the Pipe Supports table (on page 2968) option at each connected Pipe Node.

- The program now connects pipe supports – rather than pipe nodes – to the structure. This allows both node and support labels to be used. This allows additional filters in the Support Connection Wizard (on page 2964) and also allows STAAD.Pro to import multiple supports at a single support node.
- Pipe supports are now graphically displayed with icons which reflect the nature of the pipe support. The display of these icons, along with other pipe model elements, can be controlled through a new tab in the Diagrams dialog Pipe tab (on page 2972).

AD.2007-07.3.5 Transverse IRC Loading in STAAD.Beava

For the specific bridge width, IRC (Indian Road Congress) chapter 6-2000, table 2, clause 207.4 defines the rules to combine the live loads. This new feature allows you to either use these IRC live load rules or use an iterative, custom method. If the IRC rule option is selected, this function uses the appropriate live loads and number of design lanes and the generates all the possible load combinations as stated for this particular bridge width. Otherwise, you can select a specific live load and design lane to generate combinations.

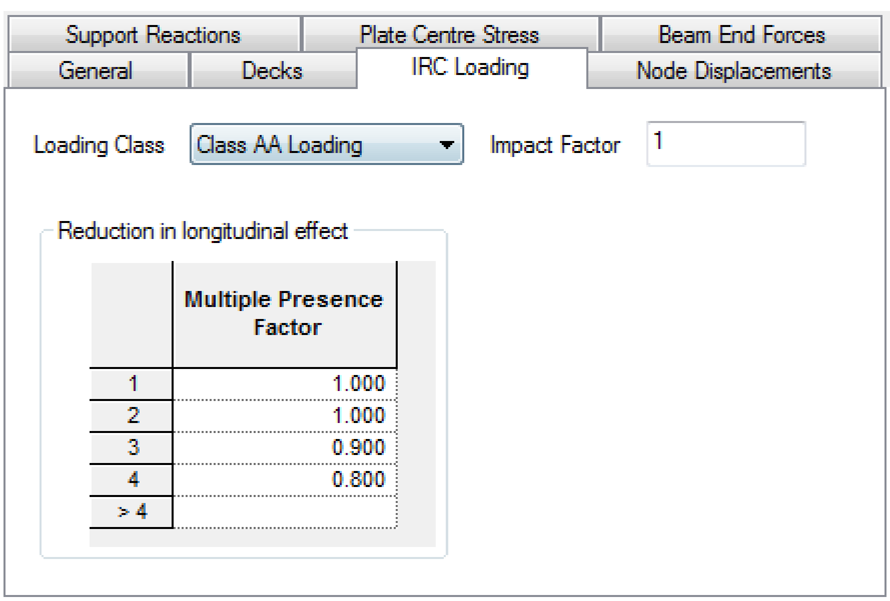
Loading rules per IRC Chapter 6 are applied in much the same way as previous codes. The defined roadway for the selected deck(s) is divided into design lanes and the selected load class is applied to the structure achieve the specified actions.

To specify loading per IRC Chapter 6

1. Open an analyzed bridge model in the Bridge Deck mode.
2. Create Deck and Roadway definitions.
3. Generate influence surfaces for the structure.
4. Select **Loading** > **Run Load Generator...**.

   The Load Generation Parameters dialog General tab opens.
5. Select IRC Chapter 3 for the Design Code and select the appropriate Limit State.

   The <code> tab updates to display IRC Loading.
6. Select the **IRC Loading** tab.



7. Select the appropriate **Loading Class**.

> **Note:** Combinations of the AA, B, and 70R vehicles have been added to the included vehicle definitions. These may be reviewed in the Vehicle Database dialog.

8. (Optional) Specify an impact factor or modify the **Multiple Presence Factors** as needed.
9. Specify the decks for consideration on the Decks tab and the load effects to dictate load placement on the Node Displacements, Support Reactions, Plate Center Stresses, and Beam End Forces tabs.
10. Click the **OK** button.

    The program places the selected loads in design lanes to produce the maximum or minimum effects requested. A text file containing a summary of the generated loads and corresponding effects is opened in a text editor for review.

Related Links

- *IRC Specific Parameters* (on page 2986)

AD.2007-07.3.6 STAAD.foundation V8i Integration

The export of support geometry and reactions to STAAD.foundation V8i can now be initiated from within STAAD.Pro using the Foundation Design mode. This feature is similar to the **Import STAAD.Pro File** capability included in STAAD.foundation.

When selected, the Foundation Mode opens the Foundation page which contains a view of the whole structure and the Foundation Design Options dialog.

From here, you can select to include all supports, you can graphically select supports, or you can specify a list of support numbers for exporting to a STAAD.foundation project. Similarly, the load cases from the analysis are listed for inclusion in the STAAD.foundation project.

> **Tip:** Models containing a large number of supported nodes or load cases may result in slow performance on older computer hardware. Exporting a limited set of data can be used to improve performance in STAAD.foundation in these cases.

Planned future enhancements also include the export of mat foundations modeled in STAAD.Pro for design in STAAD.foundation.

AD.2007-07.3.7 Additional Section Databases in RAM Connection mode

Steel section databases for the following countries are now available for use when design connection in RAM Connection mode:

- Indian
- European
- Japanese
- Australian

> **Note:** Connection design is only performed per the US and British codes available in RAM Connection.

AD.2007-07.4 Additional Features

The following features have yet to undergo testing and are presented "as is."

> **Note:** Items labeled with an asterisk (*) were added in the QA&R release of V8i (SELECTseries 2) (Build 20.07.07.32).

Beta Features

The following features have yet to undergo testing and are presented "as is."

- (None)

AD.2007-07.4.1* Design of Class 4 “Slender” Sections in IS800:2007

The design of slender classified sections (only rolled or welded I sections) per IS:800-2007 has been added to STAAD.Pro.

The IS:800-2007 code does not provide any clear guidelines about what method should be adopted for the design of slender section. The “Flange Only” concept has been adopted where it is assumed that flexure is taken by the flanges alone and the web will resist shear with adequate shear buckling resistance. This means that the flange elements must be non-slender with slender web element to qualify for slender section that can be designed. If any of the flanges become slender, the design will not be performed for Bending and a warning message is displayed.

Refer to D8.A. Indian Codes - Steel Design per IS 800 - 2007 (on page 1607) for additional information on the design procedures used for slender sections for IS800:2007 as well as a verification example problem.

V8*i* (SELECTseries 1)

The Software Release Report for STAAD.Pro contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8i (release 20.07.05) This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-06.1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

AD.2007-06.1.1 CIS/2 Translator Update

The STAAD.Pro tool to import and export models with the CIS/2 translator has been enhanced for the transfer of models into 3D modeling, such as Intergraph SmartPlant® 3D (SP3D).

The CIS/2 (CimSteel Integration Standard, Version 2) allows for the transfer of steel models using a prescribed data standard in the STEP (Part 21) format. These files can contain different models including analysis models.

In previous versions of STAAD.Pro, CIS/2 files could not be imported into an existing STAAD file. The import process has now been updated so that new STAAD input files can be created or existing input files updated from a CIS/2 file.

STAAD.Pro will retain all relevant information generated by SP3D –including the object IDs (GUIDs)– when importing CIS/2 files. Further modeling operation will be done in STAAD.Pro which includes special purpose load generations, analysis, design and member selections and modifications. You may then export out to a CIS/2 STEP file and retain all information inherited from SP3D STEP file and addition/deletion/modification information performed in STAAD.Pro.

Using import and export of STEP files in SP3D, further modification can be made in SP3D and the STAAD.Pro model can be updated its model. Only geometry, member properties, boundary condition information are within the update scope of STAAD.Pro. While updating the STAAD.Pro model, no other information will be considered. This round-trip process can be repeated an unlimited number of times

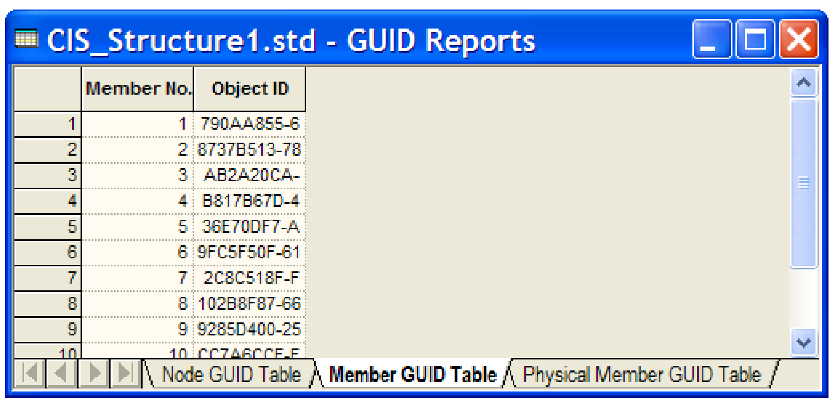
Additionally, two new VBS Macros have been included in the User Tools to aide in the verification of model integrity before and after update operations using the Import dialog. These may be found in the User Tools drop-down menu in the File toolbar or under **Tools** > **User Tools**.

New User Tools (VBS Macros)

Two VBS macro are developed to assist users to confirm the model integrity before and after the update operations.

List Object GUIDs

Opens the GUID Report tables. This is useful to verify that the GUIDs are same as those in SP3D.



CIS/2 Object Update Report Tool

Used to capture model state before an update operation (Create Pre-Update Report) and then same tool can be invoked again after the update process to generate a report showing what exactly has been updated (Create Post-Update Report).

AD.2007-06.2 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

AD.2007-06.2.1 ANSI/AISC N690-1984 Design Code

For steel design, STAAD.Pro compares the actual stresses with the allowable stresses as defined by the *ANSI/ AISC N690-1984: Nuclear Facilities - Steel Safety-Related Structures for Design, Fabrication, and Erection*.

The parameter `CODE AISC N690 1984` is used to initiate code checking per ANSI/AISC N690-1984.

The full details for this code - including parameters, commands, and technical background - are in D1.K.2. ANSI/ AISC N690-1984 Code (on page 1303).

To use the ANSI/AISC N690 1984 code

1. In the modeling mode, select the **Design | Steel** page.
2. Select **AISC N690 1984** in the **Current Code** drop-down list.

AD.2007-06.2.2 Update to Russian Concrete Design

The Russian SNiP concrete design routines have been updated to accommodate new reinforcement and concrete class definitions. In order that these new classes can be assigned to members that are to be designed, the following changes have taken place in the RCL, BCL, and RHS parameters.

Refer to D13.A. Russian Codes - Concrete Design Per SNiP 2.03.01-84* (on page 1866) for additional information.

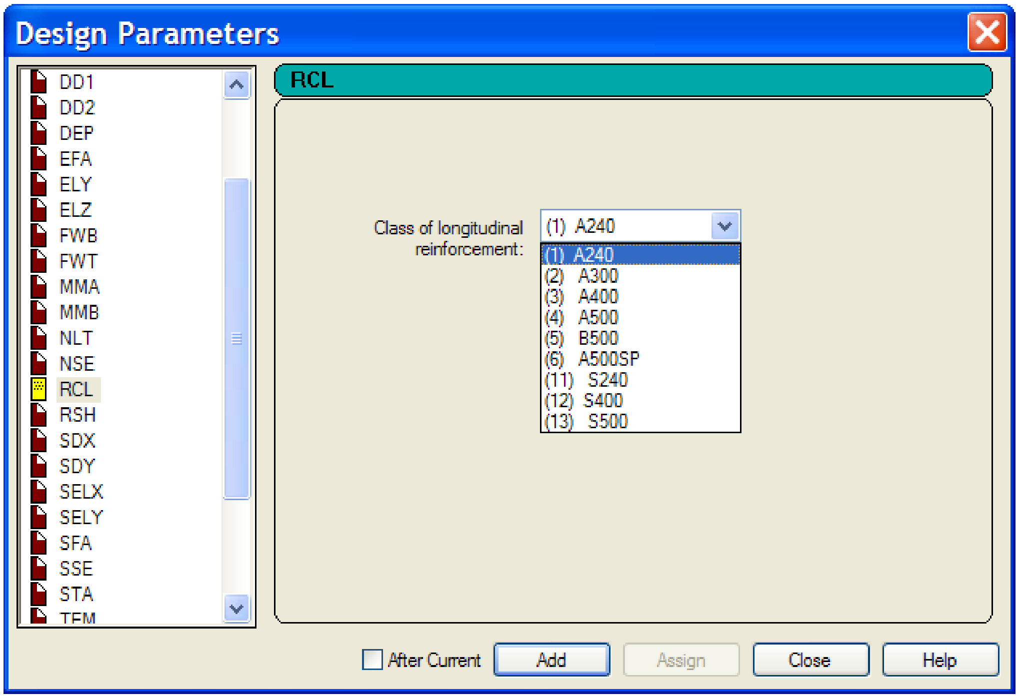
Additionally a few other minor updates have been incorporated to ensure axial tension is ignored in column design and that the provided area of steel in both directions is not less than the minimum.

To select reinforcement or concrete class definitions

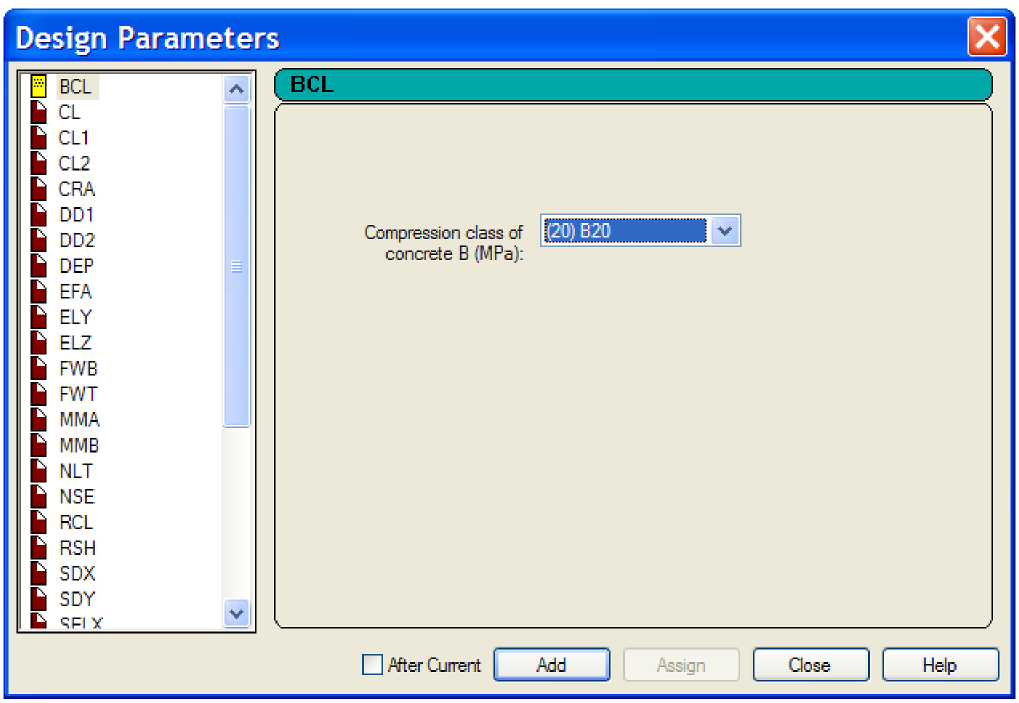
1. In the modeling mode, select the **Design | Concrete** page.

2. Select **SNiP 2.03 01-84** in the **Current Code** drop-down list.
3. Click the **Define Parameters** button below the model outline panel.
4. The **RCL**, **BCL**, and **RSH** parameters have the new definitions available. Refer to D13.A.2 Design Parameters (on page 1867) for additional information.

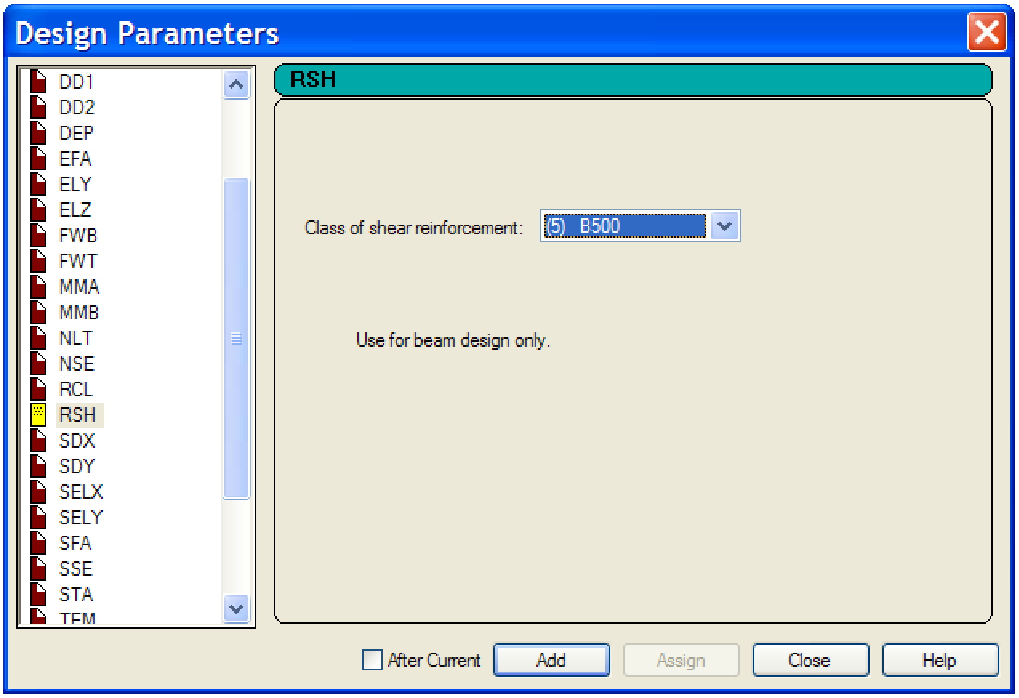
   Reinforcement Class for longitudinal reinforcement (RCL):



Compression class of concrete B (BCL):

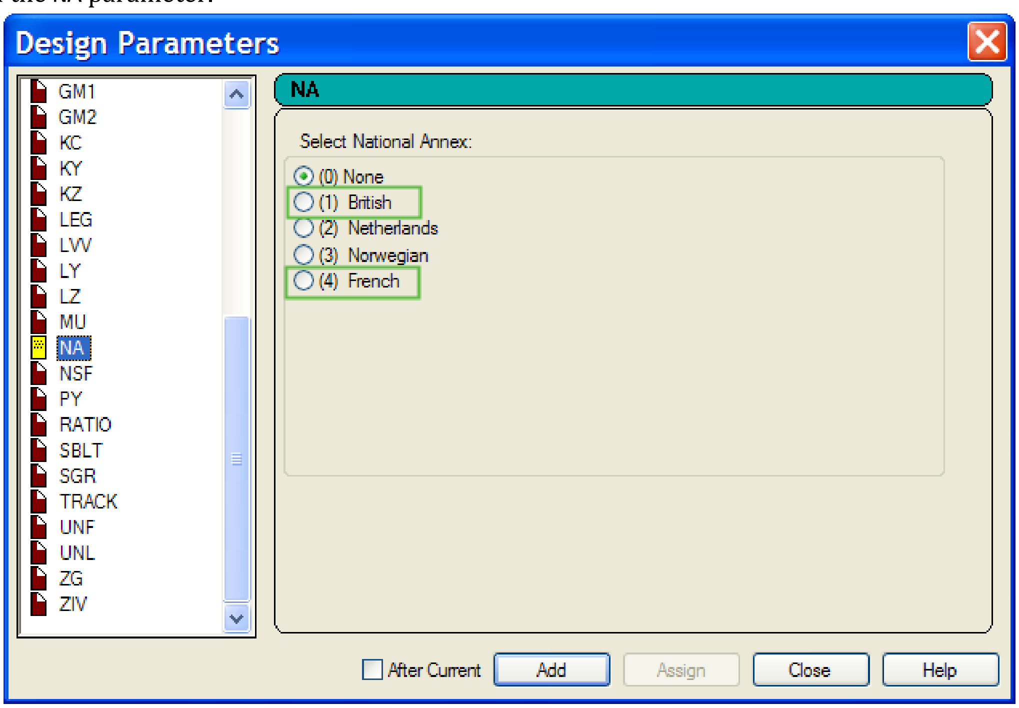


Reinforcement class for shear reinforcement (RSH):



AD.2007-06.2.3 Eurocode 3 National Annex

Two country's National Annex to Eurocode 3 have been incorporated into the Steel design module in STAAD.Pro: United Kingdom and France. As with the other National Annexes to EC-3, this implementation will make use of the NA parameter.



Caution: The GB1 parameter (which, in fact was common to the base EC-3 and was a reminiscent of the previous DD ENV implementation of EC-3) has been removed. Hence any legacy STAAD files that have the GB1 Parameter defined will need to be revised to take out this parameter as it is no longer valid as per the latest EN1993.

AD.2007-06.2.3.1 United Kingdom National Annex to Eurocode 3 (EN 1993-1-1:2005)

To Initiate a EC3-UK NA Steel Design, use the following procedure.

The UK National Annex document referred to is "NA to BS EN 1993-1-1:2005".

1. In the Modeling mode, click the **Design | Steel** page.
2. In the **Current Code** drop-down menu, select **EN 1993-1-1:2005**.
3. Click the **Define Parameters** button.
   The **Design Parameters** dialog opens.
4. Select the **NA** parameter in the list box.
5. Select the option for **(1) United Kingdom**.
6. Click **Add**.

   This will insert the following command into the STAAD input file:

```
CODE EN 1993-1-1:2005
NA 1
```

Note: For additional information, please refer to D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) and D5.D. European Codes - National Annexes to Eurocode 3 [EN 1993-1-1:2005] (on page 1516)

AD.2007-06.2.3.2 French National Annex to Eurocode 3 (EN 1993-1-1:2005)

To Initiate a EC3-French NA Steel Design, use the following procedure.

The French National Annex document referred to is "Annexe Nationale a la NF EN 1993-1-1:2005".

1. In the Modeling mode, click the **Design | Steel** page.
2. In the **Current Code** drop-down menu, select **EN 1993-1-1:2005**.
3. Click the **Define Parameters** button.
   The **Design Parameters** dialog opens.
4. Select the **NA** parameter in the list box.
5. Select the option for **(4) France**.
6. Click **Add**.

   This will insert the following command into the STAAD input file:

```
CODE EN 1993-1-1:2005
NA 4
```

Note: For additional information, please refer to D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) and D5.D. European Codes - National Annexes to Eurocode 3 [EN 1993-1-1:2005] (on page 1516)

AD.2007-06.2.4 Chinese Static Seismic Loading

A simplified base shear method of the seismic load generation for the Chinese GB50011-2001 code has been added to STAAD.Pro V8i.

This set of commands may be used to define and generate static equivalent seismic loads as per Chinese specifications GB50011-2001. This load uses a static equivalent approach, similar to that found in the UBC. Depending on this definition, equivalent lateral loads will be generated in the horizontal direction(s).

- *M. To add a seismic load definition* (on page 857)

AD.2007-06.3 Features Affecting the RAM Connection Design Mode

Several new features have been added and existing features have been modified in the RAM Connection Design Mode. These are explained in the following pages.

Note: Full use of the RAM Connection Mode requires access to a valid RAM Connection license. If you do not possess a license, contact your Bentley account manager to have it added to your SELECT licenses. Without a valid license, only a small subset of the full range of available RAM connections can be utilized.

AD.2007-06.3.1 RAM Connection V8*i* Support

The enhancements included in Bentley's RAM Connection V8*i* (release 5.5) are now available in STAAD.Pro. Additionally, the connection assignment and design process has been streamlined within STAAD.Pro. Now, joints and connections can be automatically assigned for a set of selected members and connection designs can be grouped together. Additionally, when a connection is edited using the RAM Connection pad, those changes will be saved in the STAAD.Pro model design.

Connections are designed in the newly updated RAM Connection Mode by creating “Joints,” from the geometry, section properties and forces resulting from the analysis and assigning a design brief made up of connection templates. A suitable connection design, if one is available, will be reported once you have selected the appropriate connection templates.

In previous releases of STAAD.Pro, you were able to only select and assign a connection to individual joints. Now, any number of joints may be selected and designed. Further, connection design is performed automatically for you once appropriate templates have been selected for the selected joints. These enhancements greatly reduce the time required for connection design in models of all sizes.

Tip: The selected load envelope is now used for all connection designs, instead of per design brief as in previous versions of STAAD.Pro.

AD.2007-06.4 Features Affecting the Piping Mode

STAAD.Pro can utilize the pipe layout and reactions created in the applications ADLPipe or AutoPipe. The pipe model can be imported in the Piping Mode. The following describes the method of using the Piping Mode and features recently added to this mode.

AD.2007-06.4.1 AutoPIPE Integration Enhancements

An enhancement to how pipe/structure connections are assigned has been made to the Piping module. A new Support Connection Wizard is available to allow you to add multiple supports to the entire model or a subset of a model, based on some general parameters.

Note: Pipe-structure links are not part of the undo system. Nodes created at the end of the wizard will be removed by an undo but the links are not changed.

Within the Piping mode, after the pipe model has been loaded, you will be able to call up a modeless connection wizard. The wizard will take you through the following steps:

1. Defining the set of pipe nodes to consider.
2. Defining the set of structural beams to consider.
3. Defining the set of structural nodes to consider.
4. Setting range and tolerance parameters.
5. Previewing and accepting the determined connections.

Potential connections will be determined after step 4 and fully created at the end of step 5.

Potential connections will be determined by finding the closest beams and closest nodes to each pipe node. In the previewing stage the closest five items, along with a “to ground” option, will be available as options to you, sorted by distance.

Parameter Page / Connection Finder

The connection finding routine runs in two parts. First looking at beams (length of perpendicular from beam) and then looking at nodes (straight line length). The five closest found connectable points are saved to be presented on the results page. In order to provide control over the connection finder, several parameters are available to you for editing. The default values of distance-based parameters will depend on the base unit of STAAD.Pro.

General

- Max. Range: double: default 2m / 6’ : Potential connections beyond Max. Range will be discarded.
- Insert nodes into beams at connection points: default true : This parameter effects the connection of the structures rather the point finding algorithm. If set true a new node will be created at each intermediate beam point and the connection made to that rather than to the beam itself. If the algorithm finds new node points within “End Tolerance” of each other then only one new node will be added.

Beam

- End Tolerance : double : default 5cm /2" : To allow for differences in precision and to avoid very short beam breaks this parameter will determine at what distance from the node the perpendicular will be considered to be at the node itself.

- Allow Non-Perpendicular Connection at End Nodes: Boolean : default true: This is only really relevant if the node subset does not explicitly include the nodes at the end of members in the beam subset. If set "true" the beam end nodes will be included in the node search. If set 'false' the end nodes of a given beam will only be considered for connections perpendicular to the beam, unless they have been explicitly added to the node subset.

This page has no effect on structure diagrams. The connection finding routine is run when advancing from this page.

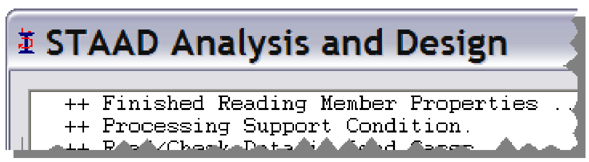
V8*i* (release 20.07.05)

The latest What's New document for STAAD.Pro V8*i* contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8*i* (2007 build 04). This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-05.1 Features Affecting the Analysis and Design Engine

The following section describes the new features have been added to the analysis and design engine and existing features that have been updated or modified.



AD.2007-05.1.1 Geometric Nonlinear Analysis

The range of analysis options has been supplemented with a new solution to account for nonlinear effects of moderate displacement and small strain. This solution holds for where the element distortion is small and small rotations are assumed.

Note: The nonlinear analysis command is available with the Advanced Analysis license.

Related Links

- *TR.37.8 Geometric Nonlinear Analysis* (on page 2654)
- *A. To specify a nonlinear analysis* (on page 954)

AD.2007-05.1.2 IS 800:2007 Steel Design

The Indian Bureau of Standards has released a new version of the design code for the design of steel structures, known as IS 800:2007. This replaces the previous version of the code (also supported in STAAD.Pro), IS 800:1984, which was versified again in 1998. This is a new approach to steel design and is based on the limit state design rather than a stress based design of the old code.

The Steel Design section has been enhanced to include design per IS 800:2007. Both section checking and selection routines are supported.

The design will follow the same process as used by all other steel design codes currently available in STAAD.Pro. The design of each member is controlled through a set of parameters that have been added to the GUI Steel Design Dialog under the title **IS 800:2007**.

The design engine will allow all standard section database sections and User Table sections to be designed.

The design process followed:

1. Check slenderness
2. Check classification
3. Check tension forces
4. Check compression forces
5. Check bending Forces
6. Check interaction

The results will be:

1. output to the `ANL` file
2. available in the member query
3. available in the post processing mode in the Design Results table

Note: *Top and Bottom represent the positive and negative side of the local Y axis (local Z axis if SET Z UP is used).

- *D8.A.4 Design Parameters* (on page 1617)

AD.2007-05.1.3 Eurocode 3 Includes National Annex

A number of countries that have signed up to the replace their current steel design standards with the Eurocode, EN 1993-1-1:2005, known commonly as Eurocode 3, have published their National Annex documents. These documents make small changes to the base document and STAAD.Pro has been updated to incorporate some of these National Annex documents. Currently, the Dutch and Norwegian National Annexes have been added to the STAAD.Pro engine.

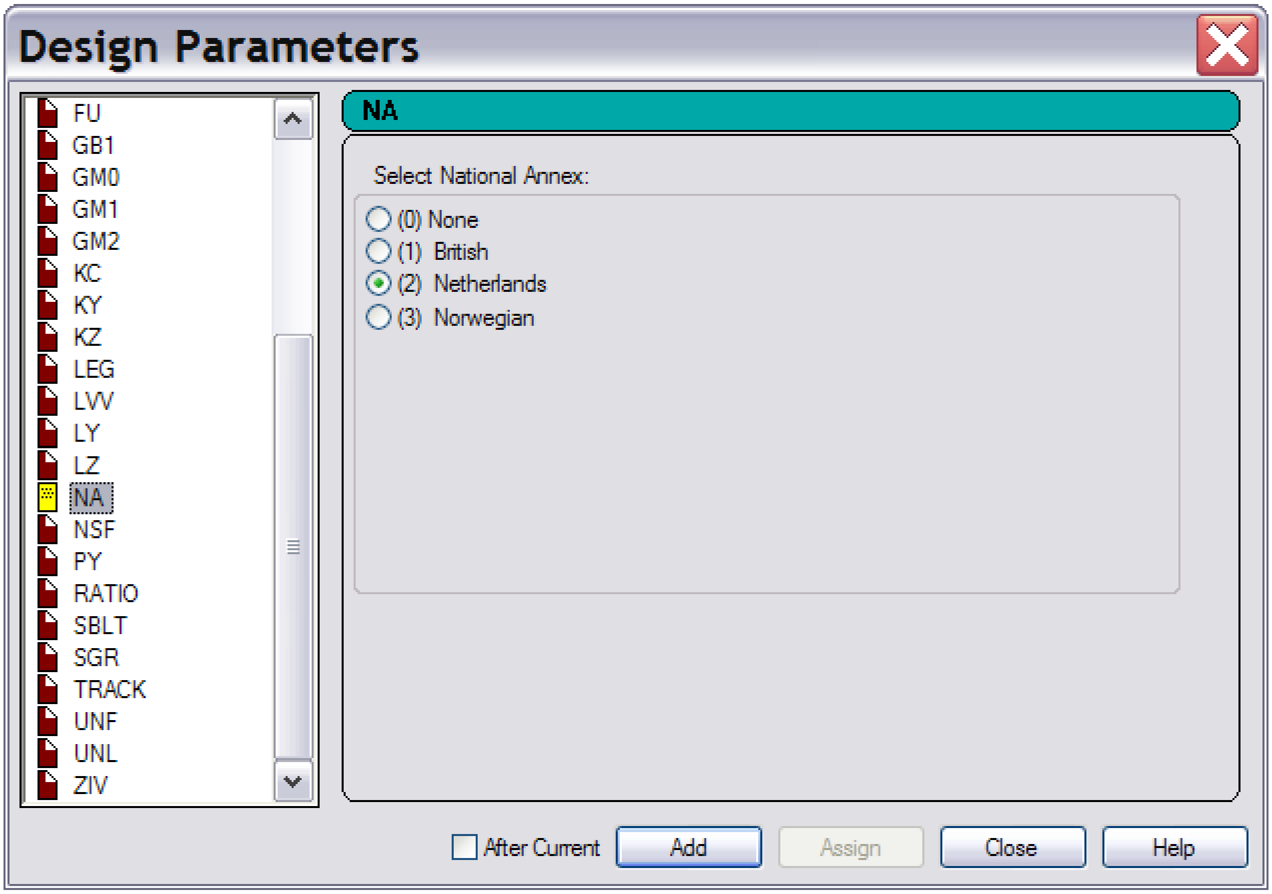
A new parameter, `NA`, that sets the default material gamma factors and any additional changes outlined in the country specific National Annex such as specific equations or methods.

The output file printout has been updated to indicate which National Annex (if any) has been used in a code check / select process. (For all `TRACK` settings)

To specify checks per a National Annex

In order to include additional check specified by a National Annex, do the following:

1. From the Modeling mode **Design | Steel** page, select **EN 1993-1-1:2005** from the current code list.
2. Click **Define Parameters** to launch the Design Parameters dialog.
3. Select the parameter **NA** from the list.



4. Select the radio button for the National Annex you wish to use; or leave as Basic in order to use EC3 without additional checks.
5. Click **Add** to add the NA parameter to the code check.
6. Click **Close** to dismiss the dialog once parameter definitions are complete.

A design performed to the new Eurocode 3 National Annex is displayed in the output file (`*.ANL`) with the following header, in addition to the base EC3 output:

```
ALL UNITS ARE - KN   METE (UNLESS OTHERWISE NOTED)

MEMBER      TABLE        RESULT/   CRITICAL COND/      RATIO/      LOADING/
                           FX            MY              MZ        LOCATION
=======================================================================

  EC-6.2.5       0.723     1      0.0      50.0     0.0    50.0     0.0
  EC-6.2.6-(Y)   0.284     1      0.0      50.0     0.0    50.0     0.0
  EC-6.3.2 LTB   0.757     1      0.0      50.0     0.0    50.0     0.0

  ADDITIONAL CHECKS AS PER NATIONAL ANNEX [NEN-EN 1993-1-1/NB] (units- kN,m):

  EC CLAUSE              NA-CLAUSE         RATIO    LOAD        FX        VY        VZ
  EC-6.2.8-(Y)   NEN-6770-Eq.11.3.1      0.689     1         0.0      50.0      0.0
  EC-6.2.10(Y)   NEN-6770-Eq.11.3.1      0.689     1         0.0      50.0      0.0
  EC-6.2.10(C)   NEN-6770-Eq.11.3-31     0.550     1         0.0      50.0      0.0
   Torsion and deflections have not been considered in the design.
```

Note: The previous, development edition of Eurocode 3 is included as the Code EN3 DD.

AD.2007-05.1.4 Eurocode 8

Eurocode 8: Part 1 [EN 1998-1-1:2004] contains specific requirements and recommendations for building structures that are to be constructed in seismic regions. Essentially, these fundamental requirements have been provided to ensure that the structures can sustain the seismic loads without collapse and also – where required – avoid suffering unacceptable damage and can continue to function after an exposure to a seismic event.

As with all Eurocodes, a National Annex Document should accompany the use of Eurocode 8 in each of the European nations.

AD.2007-05.1.5 AIJ Concrete Design Update

An old version of Japanese concrete code based on the AIJ standard for structural calculation of Reinforced Concrete Structures (1985 edition) was previously implemented in STAAD.Pro batch mode design. Recently, critical errors in the column design and beam design were discovered and corrected. In addition, the AIJ concrete design has been udpated to incorporate the latest AIJ standard for structural calculation of Reinforced Concrete Structures (1991 edition). .

Generally, this implementation will be invisible to you. The 1985 edition of the AIJ has been completely replaced by the 1991 edition for the design of concrete members per the AIJ. The existing commands as described in D9.A. Japanese Codes - Concrete Design per 1991 AIJ (on page 1713) are applicable to the 1991 edition.

AD.2007-05.2 Features Affecting the Concrete Design Mode

An existing feature has been modified in the RC Designer section of the program, also known as the Concrete Design mode. This is explained in the following pages.

AD.2007-05.2.1 RC Designer Member and Envelope Import

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

V8*i* (release 20.07.04)

The Software Release Report for STAAD.Pro V8*i* contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2007 build 03. This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-04.0 New Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

AD.2007-04.0.1 ProjectWise Integration

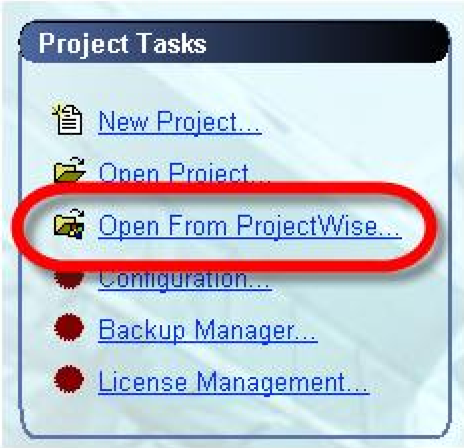
ProjectWise is an engineering project team collaboration system which is used to help teams improve quality, reduce rework, and meet project deadlines. One of the major pieces of functionality provided by ProjectWise is an Integration Server which allows data to be managed and shared across a distributed enterprise.

STAAD.Pro has been enhanced so that the model STD data file can be managed on a ProjectWise server.

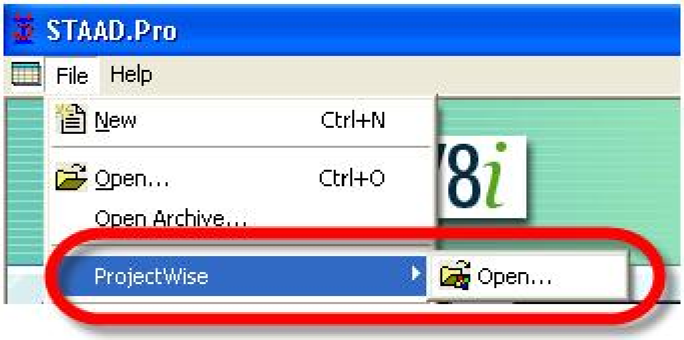
Installation and management of a ProjectWise server is beyond the scope of this document and should be obtained from the ProjectWise installation.

A local ProjectWise client should be installed which allows access to ProjectWise repositories.

When STAAD.Pro is launched, the option to open and check out a STAAD.Pro STD file from a ProjectWise repository is made available from the Project Tasks on the Start Page thus:



This is also available from the File menu while still on the Start Page prior to opening a model:

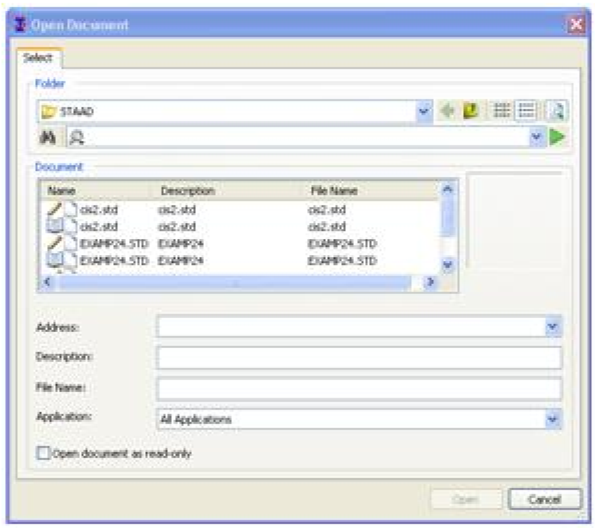


If a suitable ProjectWise client is not installed, then the link on the Start Page is shown as unavailable with a red line through the icon thus:

As authentication is required to access files stored on a ProjectWise repository, a login dialog allows the required details to be entered either with specific user credentials or by using the current windows login credentials thus:

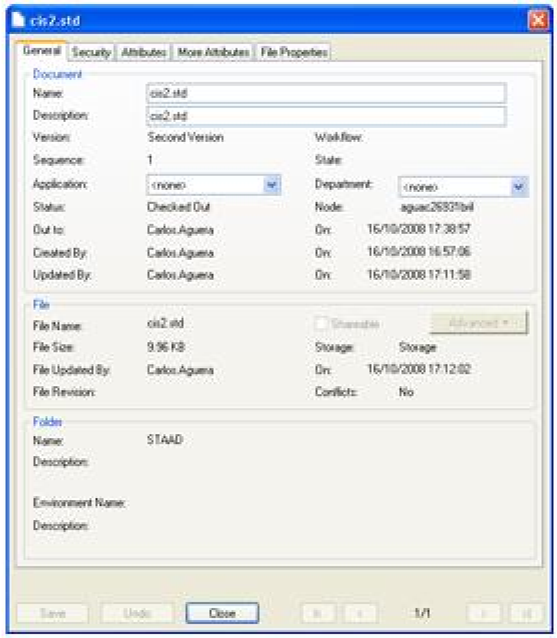
Files that are accessed from a ProjectWise server are “Checked Out” and stored locally during the STAAD.Pro session until the file is closed and then it is returned to the server.

The first time that a successful link to a ProjectWise server is established, a location in which check out files are to be stored locally and additionally, where all the auxiliary data files are stored whist STAAD is running is required. Afterwards and on all future occasions, the ProjectWise open dialog presented is then presented where the repository can be navigated and filtered as defined in the ProjectWise documentation.

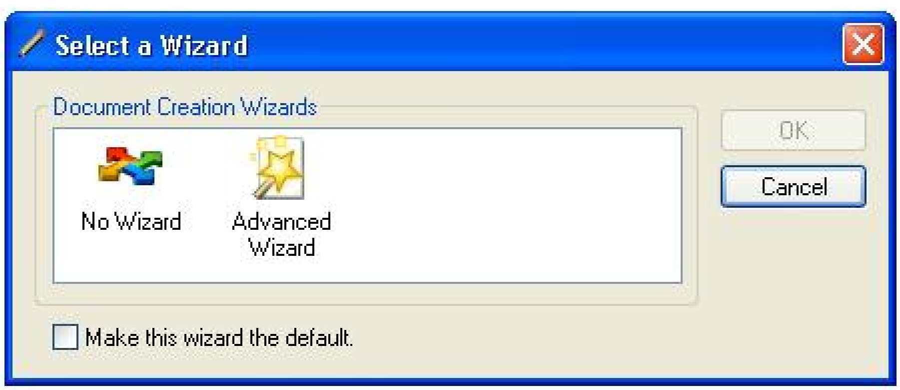


Note the significance of the icons next to the STAAD filenames. These indicate the status of the file such as the current document, checked out to you, or locked as checked out to some other user. Refer to the ProjectWise documentation for a full description of each icon.

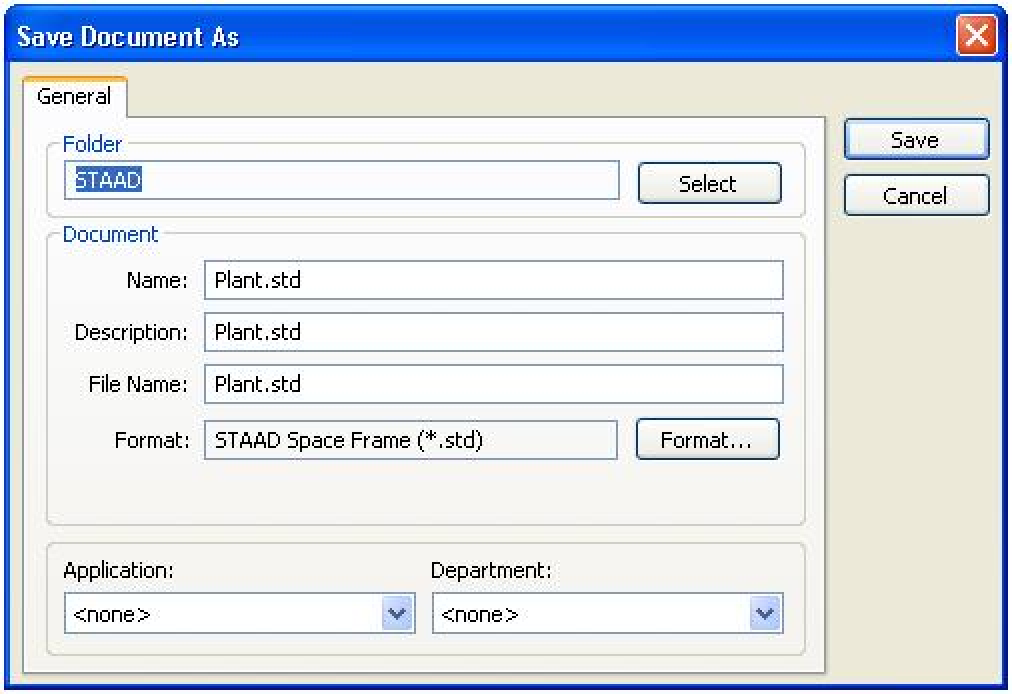
With a file checked out and loaded in STAAD.Pro, it is possible to see the ProjectWise Properties, by selecting the option from the ProjectWise toolbar or File menu:



If working on a STAAD model that has not originated from a ProjectWise server (e.g., starting a new file) and it has been decided that it needs to be added to a repository, then at any time whilst working in the STAAD.Pro environment, clicking on the toolbar option Add to ProjectWise server, or equivalent **File** > **ProjectWise** menu option will launch the following dialog:



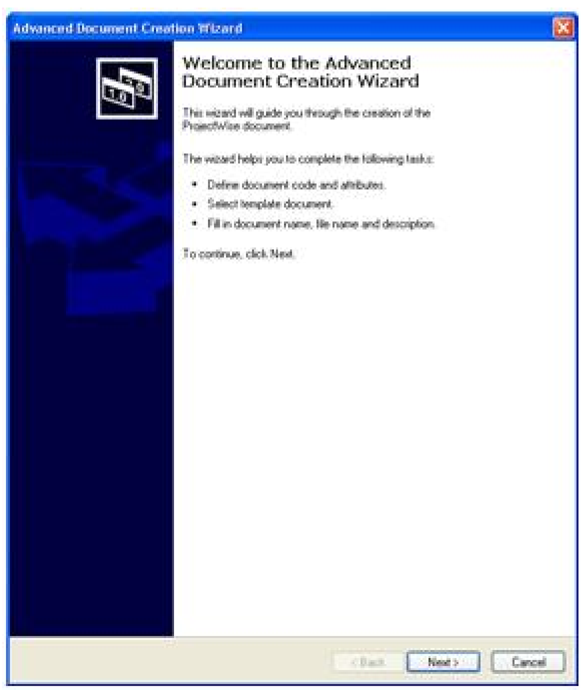
Selecting the option **No Wizard** offers the following dialog into which the file details can be entered.



Clicking on Save, adds this model to the repository, but indicates its status as checked out until the file is closed in STAAD.Pro and the model checked back in.

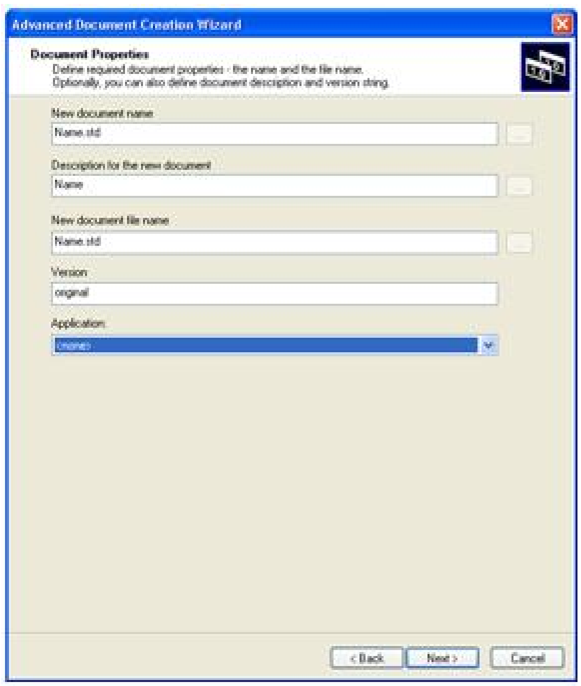
Alternatively, by selecting the **Advanced Wizard** option the data needed to define the ProjectWise data file is presented in the following four steps:

1. Advanced Wizard



2. Select target Folder

3. Document Properties



4. Create the document

Creates the document and marks it as checked out until the file is closed and checked in to the server.

Four integration functionalities have been added. These are:

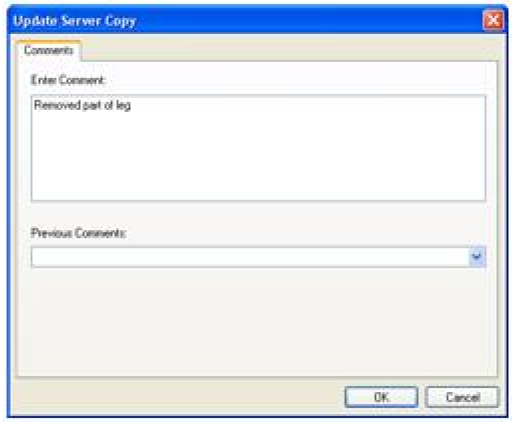
- Open a STAAD model from a ProjectWise repository.
- Save a local STAAD model into a ProjectWise repository.
- Update an existing model from ProjectWise.
- Review model properties (meta-data) which has been opened from a ProjectWise repository.

Note that access to all of these functionalities is available from ProjectWise sub-menu under the general **File** menu described below.

Saving changes of a Checked Out model Back on the Server

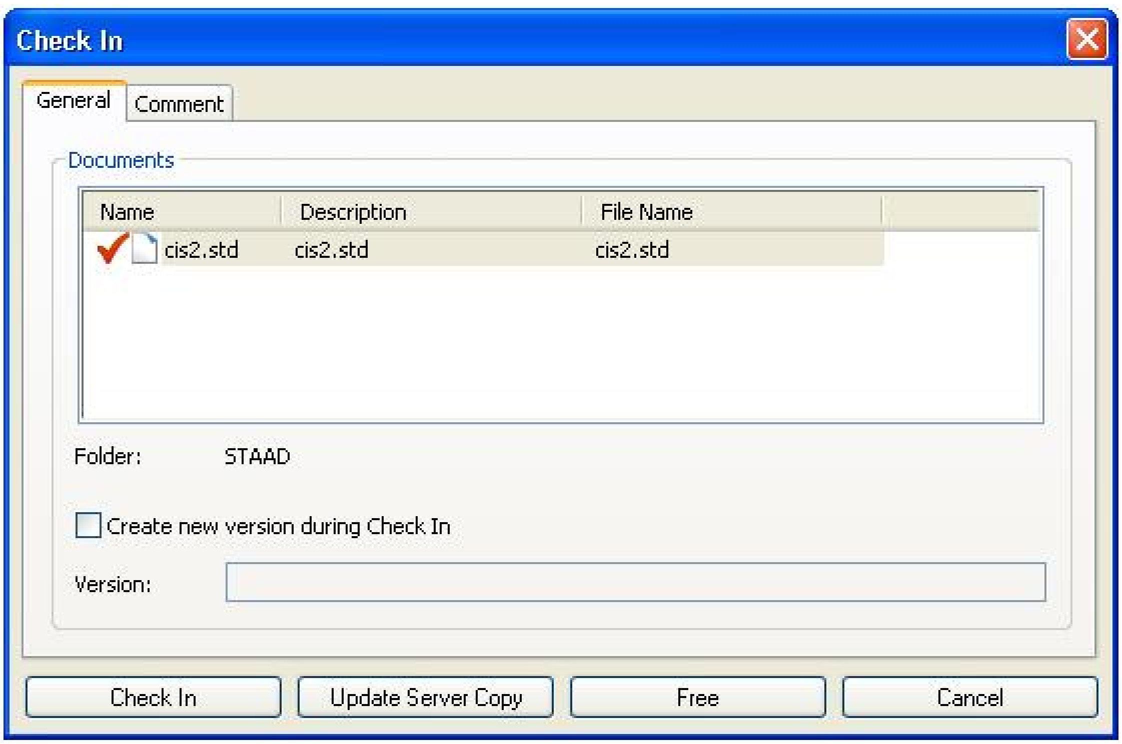
When a model is checked out from a ProjectWise server, selecting Save or Save As, only maintains a local copy of the model. There are two methods available to update a checked out model. Firstly, during a STAAD.Pro session, it is possible at any time to save any changes back on the server by selecting the Update Server Copy icon from the ProjectWise toolbar or from the **File** > **ProjectWise** menu.

First save updates to the file locally. If not, then this will be prompted. Then the following dialog is displayed which allows a comment to be added to this model, thus:



The file remains checked out and can be continued to be worked on.

The second method is automatically generated when a checked out model is closed. This launches the Check In dialog that displays the file(s) that are to be checked in and provides four actions:



Check In This copies the local version of the STAAD model back to the server and releases it so that it is available for others to modify. If the option Create New Version is selected, then a new copy of the file is created on the server which becomes the current version of the model. The status of the checked out model is changed to read only on the server and can be used as a reference to a stage in the development of the model.

Update Server Copy This updates the model on the server with the current local model, but does not change its status which remains as checked out.

Free	This changes the status of the model as checked in which allows other users to take control and check out the model, but does not update the server model. Thus local changes will be discarded
Cancel	This cancels any change to the status of the model or the model itself on the server.

Menu

The commands that drive the ProjectWise integration are defined in the main File menu thus:

File > **ProjectWise**

The Add... command is available when using a locally opened (not checked out from ProjectWise), which allows the current model to be saved into a ProjectWise repository.
The Open… command is available when a suitable ProjectWise client has been installed to allow access to a repository from which to check out a STD file.
The Update Server Copy command is available when working on a checked out file and the changes made on the model can be

Toolbar

A new toolbar named ProjectWise has been added that duplicates the commands from the **File** > **ProjectWise** menu, thus:

Notes

1. For more details on ProjectWise refer to the ProjectWise client installation documentation.
2. This functionality requires access to a version V8i or greater of ProjectWise.

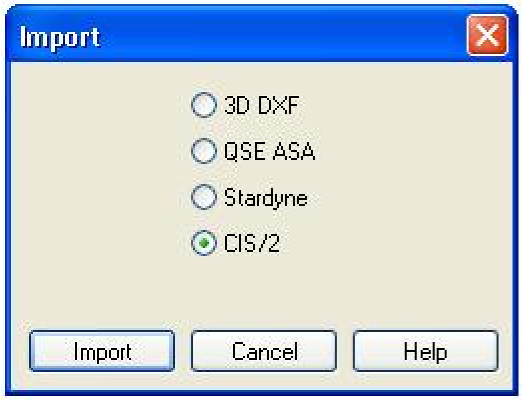
AD.2007-04.0.2 CIS/2 Update

The STAAD.Pro tool to import and export models with the CIS/2 translator has been enhanced to work with international models and transferring models into 3D modeling such as SmartPlant 3D.

The CIS/2 (CimSteel Integration Standard, Version 2) allows for the transfer of steel models using a prescribed data standard in the STEP (Part 21) format. These files can contain different models including analysis models. The STAAD.Pro CIS/2 translator only operates on the analysis model within the file. While STAAD.Pro has supported a wide range of the steel sections that this standard can support, this enhancement allows a far greater range of sections to be imported/exported with this tool.

Import

The CIS/2 import can be initiated after starting a new model and before creating any model data, selecting the menu option, **File** > **Import...**



Selecting the CIS/2 option and clicking on the “Import” button allows selection of a suitable STEP file. This file is a text file and will be similar to the following extract:

```
ISO-10303-21;
HEADER;
/* Generated by software containing ST-Developer
* from STEP Tools, Inc. (www.steptools.com)
*/
FILE_DESCRIPTION(
/* description */ ('CIS2 Export File'),
/* implementation_level */ '2;1');

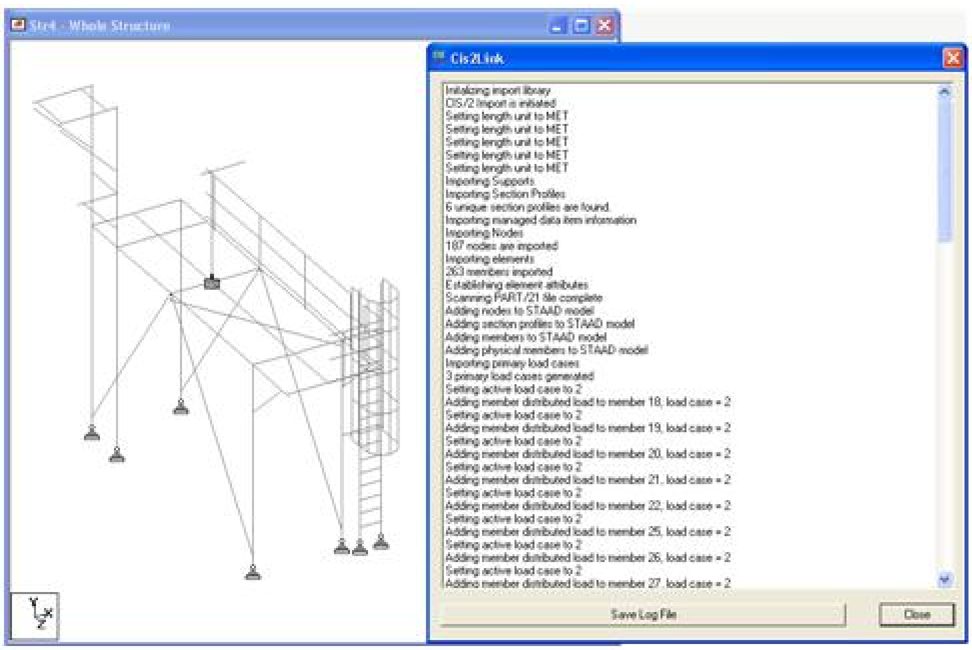
#15=LOAD_ELEMENT_DISTRIBUTED_CURVE_LINE(#265,'Member20UDLLoad1',$,#1090,
```

Once a file has been selected, the data is ready to be imported with the CIS/2 import tool thus:

Clicking the Import button then runs the model import where the CIS/2 file is processed and the analysis model data is extracted to form the STAAD.Pro model.



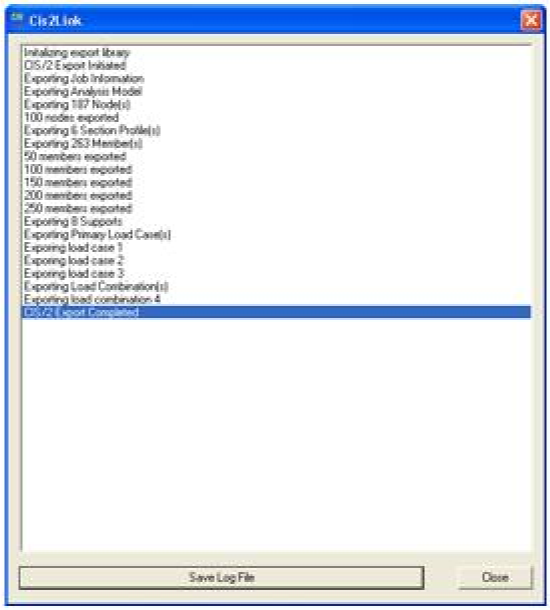
Note that as the CIS/2 file is being processed, a log file which identifies the data that has been utilized in the STAAD model is produced and displayed which can be saved as a text file for future reference.

Export

The CIS/2 Export is available for any model that has been created as an option in the menu item File>Export…

Selecting the CIS/2 option and clicking on the “Export” button allows the definition of a suitable STEP filename and folder to locate it. Once again the CIS/2 tool is presented, this time with an Export Model button at the bottom which when clicked creates the STP file.

Once again, when the export has completed, the user can save the log file which is produced as the model is converted into the STEP format.



Enhancements

The STAAD.Pro CIS/2 import now recognizes sections defined from standard databases such as those defined in Japanese, British, Indian, Australian and European tables.

The import/export has been enhanced to support the ability of STAAD.Pro to create double sections, such as back to back angles and channels or double wide flange sections. Additionally, it now supports the creation of T sections which are defined in STAAD.Pro as a wide flange section that is split at mid height.

Although CIS/2 has been developed for the processing of steel models, the STAAD.Pro translator will now support the transfer of prismatic properties normally associated with concrete sections. This means that sections defined as PRISMATIC in a STAAD.Pro model will be included in exported STP file and can be imported if they exist.

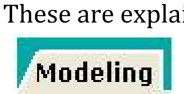
AD.2007-04.1 Features Affecting the Pre-Processor (Modeling Mode)

Several new features have been added and existing features have been modified in the pre-processor section of the program, also known as the Modeling Mode. These are explained in the following pages.



AD.2007-04.1.1 ASME NF Steel Design Codes

The design of steel sections according to the requirements in the American Society of Mechanical Engineers (ASME) specifications, Rules for the Construction of Nuclear Power Plant Components, Section III – Subsection NF has been implemented and the steel design page has been updated to allow the design parameters to be defined and assigned.

The design requirements for the following years have been added:

- 1974
- 1977
- 1989
- 1998

Post analysis steel design code checking requirements for the required ASME NF code can be selected by entering the **Design | Steel** page and setting the ASME code / year in the **Current Code** option in the **Steel Design - Whole Structure** dialog:

The method for selecting design parameters and assigning them to the members to change them from the default values is exactly the same as for all other steel design codes. Additionally, choosing members that are to be checked or selected for maximum utilization follows exactly the same method as for all other steel design codes.

For more information on the technical requirements of this design code, including the full set of parameters and default values, see the new section in the D1.L. American Codes - Steel Design per ASME NF Codes (on page 1310).

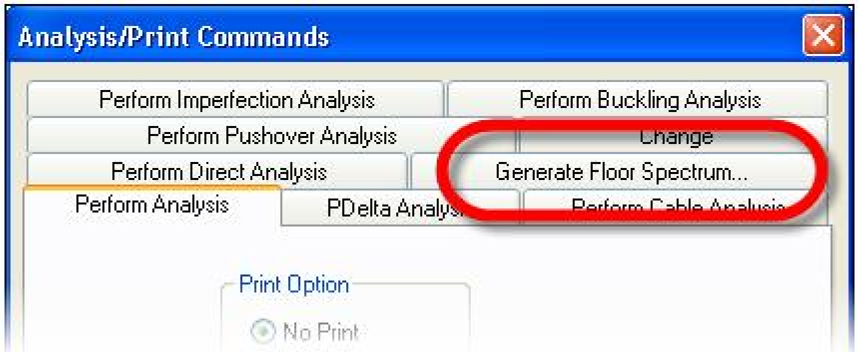
Note: In order to run a design check to any of the ASME NF design codes, then access to a STAAD Nuclear Code pack will be required.

AD.2007-04.1.2 Floor Response Spectrum

A new dynamic feature has been added that allows the extraction of a response spectrum from a collection of nodes that constitute a floor when subjected to a time history loading. This information can then be used in conjunction with equipment that will be supported by these floors and is often required by the equipment manufacturers.

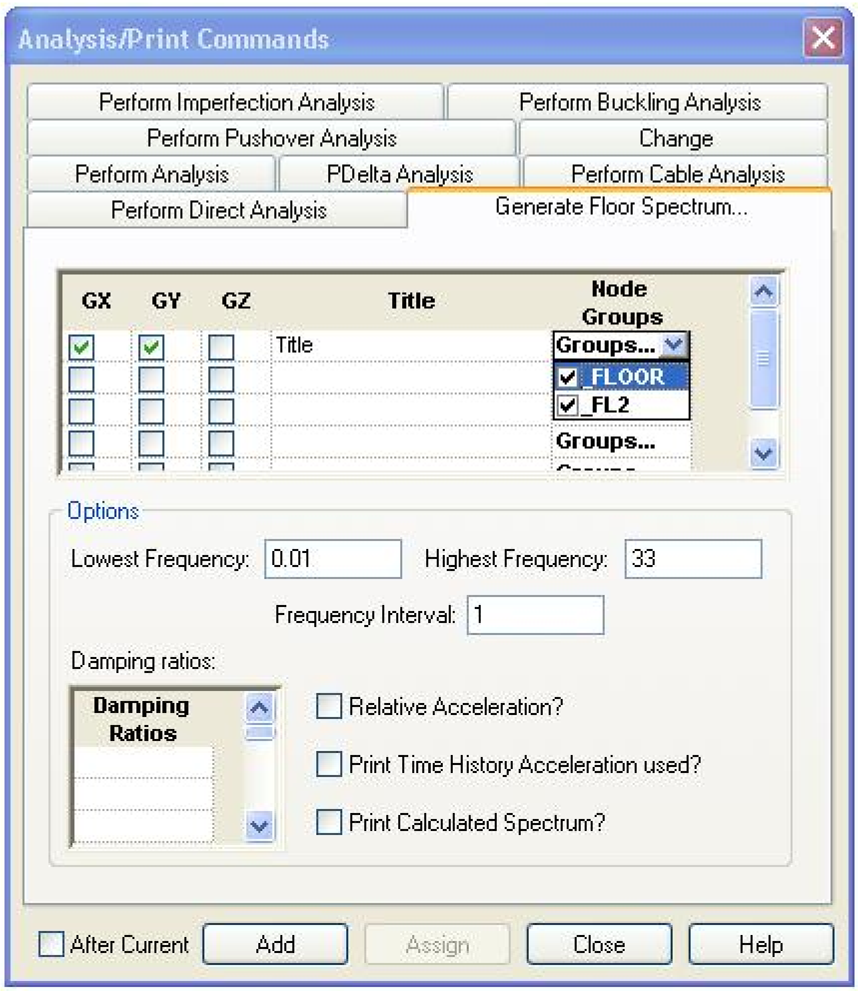
Users will require a license for the advanced analysis module to access this feature.

The required commands (see AD.2007-04.2.3 Floor Response Spectrum (on page 245) for more information) can be entered graphically after adding the analysis command by selecting the new analysis sheet **Generate Floor Spectrum** thus:



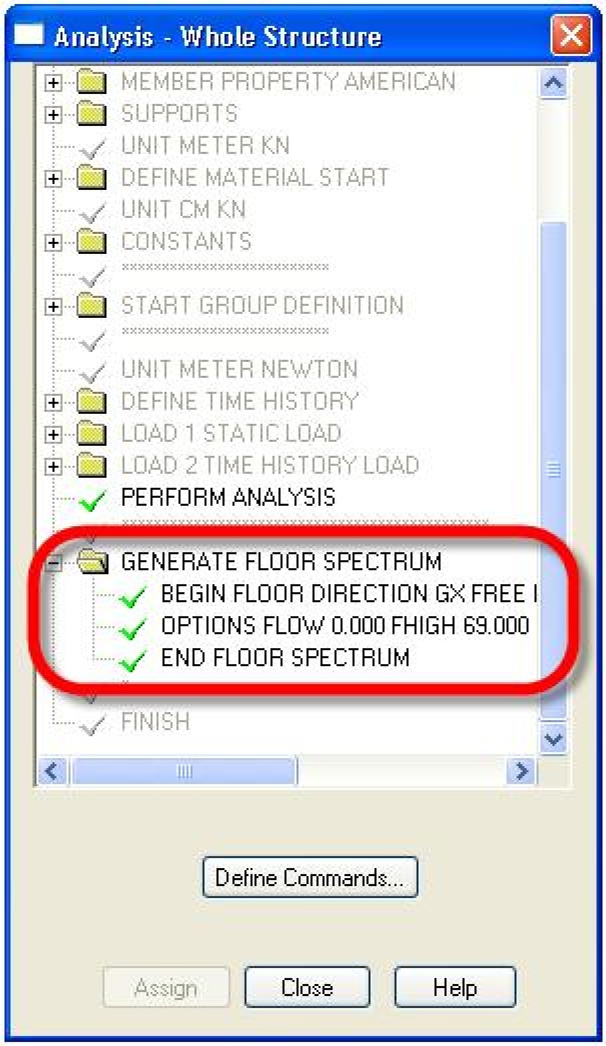
This command should follow immediately the definition of the analysis and will require defined groups of nodes which need to be defined first.

The following displays the layout of this sheet:

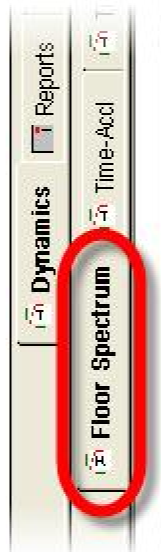


Note: Each line of settings constitutes one floor which can have one or more floor groups assigned. The resulting response spectra will be based on the collective responses of all the nodes in the selected groups.

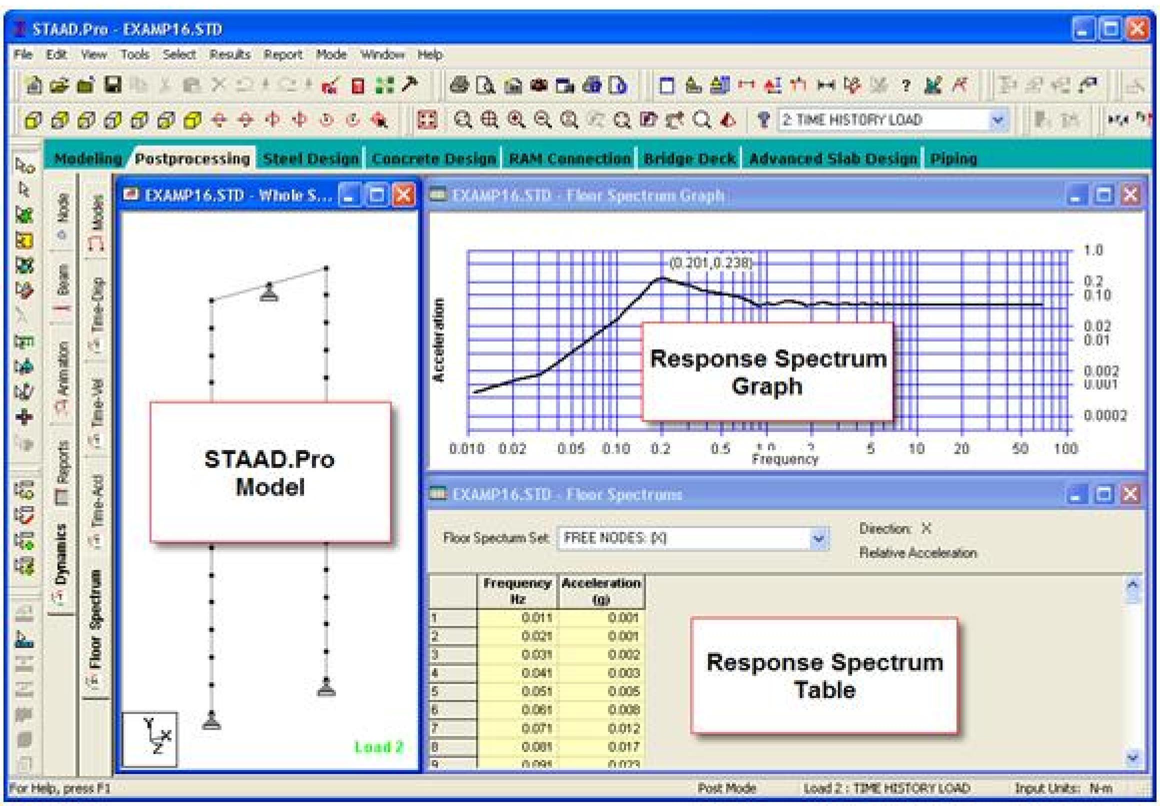
Once the required options have been set, click on the Add button to add the command set to the model which should appear in the Analysis Window thus:



Once the command has been added and the file saved, the analysis can be run which will generate a new sub-page in the Post-Processing Mode in the Dynamics Page called Floor Spectrum:



Entering this page, STAAD.Pro will display the floor spectrum thus:



To change graphs to that of another selection of node groups or damping ratio, then

select the required set from the drop list in the Response Spectrum Table.

The graph is initially set to display the results on a log/log graph. This can be changed to a linear graph by right clicking on the graph and selecting the “Linear Graph” option. Additionally, the calculated points on the graph can be added by again right clicking on the graph and selecting the option ‘Show Points’.

The data that has defined the graph can also be exported to a text file and used in a third party application by right clicking on the graph and selecting the option "Save Data in Text File…"

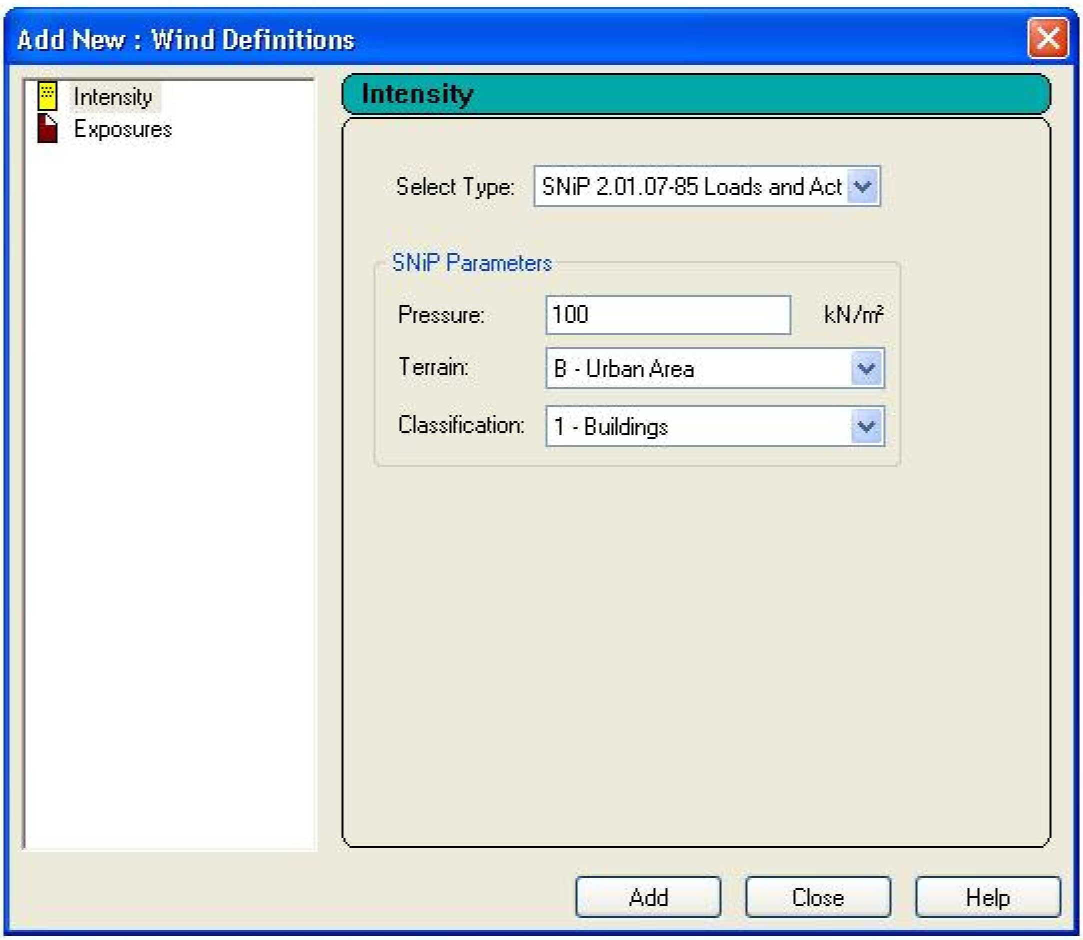
AD.2007-04.1.3 Russian Wind Loading

The wind loading as defined in the design code SNiP 2.01.07–85 "*Loads and Actions*" added in this version of STAAD.Pro can be added graphically to the model by modifications in the Loads Page.

There are two areas where the graphical user interface has been updated:

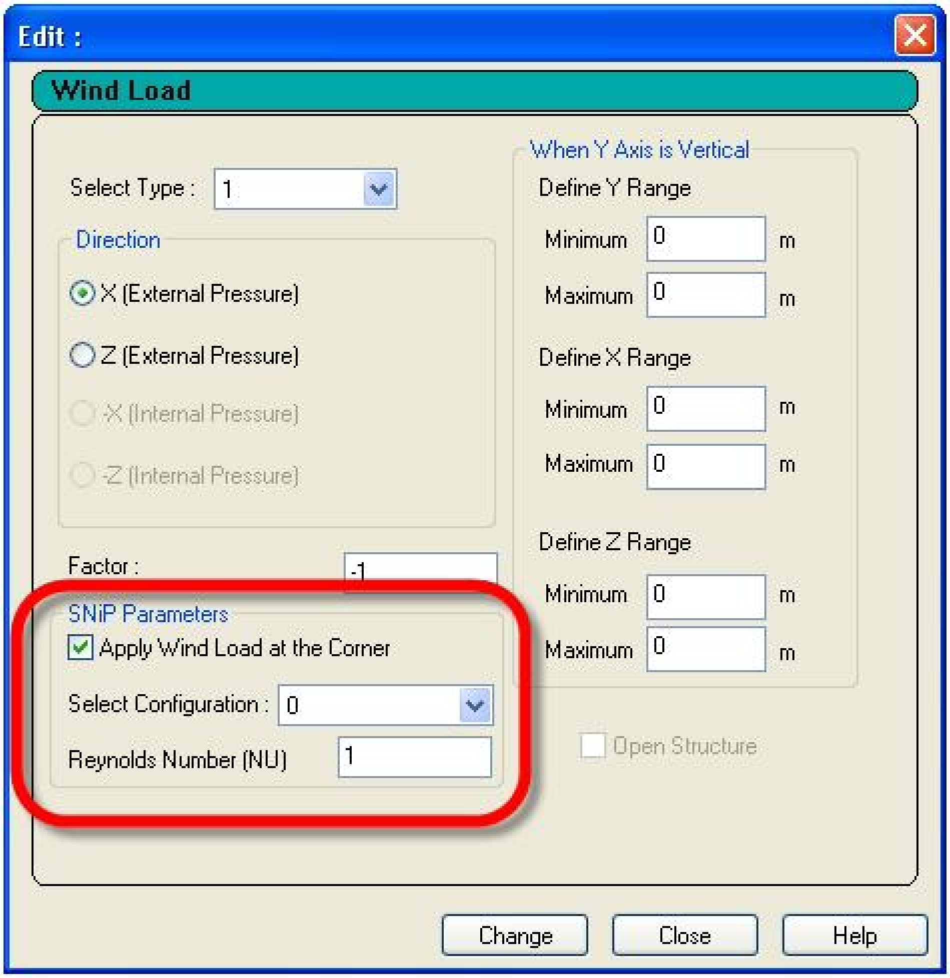
Wind Load Definition dialog

The dialog has been updated to allow the entry of the required parameters for a Russian Wind Load definition thus:-



This will create a definition which can be added to a wind load case.

Wind Load



Note: The first load case which has a Russian Wind Load command added to it will consider all other loads defined in it as the masses to be considered for calculating the dynamic effect which is required by this command.

For technical details of this wind loading see section AD.2007-04.2.2 Russian Wind Loading (on page 244) .

AD.2007-04.1.4 Additional Standard Profile Databases

An additional Australian cold formed database has been provided to complement the cold formed sections databases currently provided.

The following database and tables have been added from OneSteel. Duragal®, Galtube® and Tubeline®

Australian Cold Formed Steel Hollow Sections

Circular Hollow Sections:

- Galtube Plus®, 26.9mm to 76.1mm diameter
- Tubeline, grades C250L0 (AS1163) and 350L0 (AS1163), 26.9mm to 457.0mm

Rectangular Hollow Sections

- Duragal®, grade C450L0 (AS1163), 50x20mm to 150x50mm
- Galtube Plus®, grade C350L0, 50x20mm to 75x25mm
- Tubeline®, grade C350L0 (AS1163), 50x20mm to 250x150mm

Square Hollow Sections

- Duragal®, grade C450L0 (AS1163), 20x20mm to 100x100mm
- Galtube Plus®, grade C350L0, 20x20mm to 65x65mm
- Tubeline®, grade C350L0 (AS1163), 13x13mm to 250x250mm

AD.2007-04.2 Features Affecting the Analysis and Design Engine

The following section describes the new features have been added to the analysis and design engine and existing features that have been updated or modified.

AD.2007-04.2.1 ASME NF

The design of steel sections according to the requirements in the American Society of Mechanical Engineers (ASME) specifications, Rules for the Construction of Nuclear Power Plant Components, Section III – Subsection NF has been implemented and the steel design page has been updated to allow the design parameters to be defined and assigned.

The design requirements for the following years have been added:

- 1974
- 1977
- 1989
- 1998

For the list of parameters and commands including the default values, please refer to the D1.L. American Codes - Steel Design per ASME NF Codes (on page 1310).

For each steel member that is checked, the following checks are performed according to the clauses for that year:

1. Slenderness check
2. Tension
3. Compression
4. Bending (a) About major axis, (b) About major axis
5. Shear
6. Combined Stresses

AD.2007-04.2.2 Russian Wind Loading

The wind loading commands have been enhanced to allow the creation of wind loading as defined in the in Russia by the design code SNiP 2.01.07–85 *Loads and Actions*.

The basic quantity in the wind loading is the characteristic (normative in Russian terminology) wind pressure. The reference wind velocity pressure corresponds to a 10-minute time-averaged velocity pressure at 10-metres height in a flat terrain, based on a 5-year return period. This wind pressure is the static component of the wind load. The total wind pressure consists of static and fluctuating components. If the structure is sufficiently flexible, according to the code provisions, the dynamic structural response to the fluctuating wind component must be taken into account.

The updated wind loading commands automatically perform both the aerodynamic and structural load analysis of vibration-susceptible buildings and structures.

The wind loading commands have been updated to support the wind loading as defined in the Russian design code. This requires the creation of the following commands.

There are three parts to creating a Russian wind load on a STAAD Model.

1. Definition of the wind load requirements
2. Application of the wind load definition within a load case
3. Cut-off frequency or mode shape

Related Links

- *TR.30.1 Cut-Off Frequency, Mode Shapes, or Time* (on page 2344)

- *TR.32.12.3 Generation of Wind Loads* (on page 2603)
- *M. To add a SNiP wind load definition* (on page 847)

AD.2007-04.2.3 Floor Response Spectrum

The following commands have been added in order to allow the response spectrum of floors to be extracted from a time history analysis.

This command is used to specify the calculation of floor and/or joint spectra from time history results.   The Floor Response Spectrum command must immediately follow an analysis command. That analysis can only contain a single time history load case.

Related Links

- *TR.37.10 Floor Spectrum Command* (on page 2657)
- *A. To generate a floor spectrum* (on page 959)

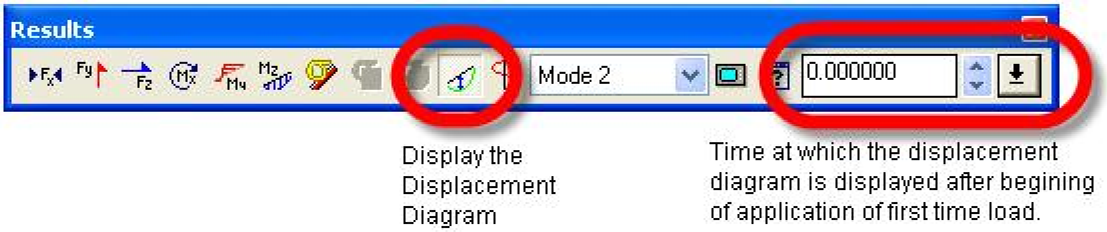
AD.2007-04.3 Features Affecting the Post-Processing (Results Mode)

Several new features have been added and existing features have been modified in the post-processing section of the program, also known as the Results Mode. These are explained in the following pages.

AD.2007-04.3.1 Time History Animation

In order to visualize the displacement that occurs on a model during the application of a time history load, a new toolbar icon has been added which allows the displacement at a specific time instance to be displayed.

The results toolbar has been updated to include a new option which is activated when the displacement diagram icon has been clicked and the current load case contains time history loading:



For a time history load case the displacement that is displayed will be defined by the time instance entered in the above edit box. Alternatively the time can be set from a sliding scale by clicking on the button with the down arrow icon which displays the following option setting:

The slider scale is based on the overall time for which the time history analysis has been performed.

The displacement is produced at the time at which the slider arrow is dragged to and the mouse button released.

If the **Apply Immediately** option is selected, then the application will attempt to render the displacement diagram dynamically as the slider is dragged up and down the scale of time. For large models this may prove to be too demanding on the graphics system and left un-checked which means that the displacement diagram will be produced at the time step at which the slider arrow is released.

Note that the displacement diagram will be set to the scale as defined in the Scales sheet in the **Structure Diagrams** dialog box.

Additionally note that it is possible to view the time v displacement of individual nodes by clicking on the Dynamics>Time-Disp in the post processing mode which is only available for models that include time history.

AD.2007-04.3.2 Enhanced Plate Stress Results

In order to provide additional understanding of stress distribution in finite element models, STAAD.Pro has expanded the sets of results that can be reported for each element both in the Plate Centre Stress Table and graphically using the Plate Stress Contour.

To view the results data of plate elements, enter the Post Processing (Results) Mode, and click on the Plate Contour Page on the left menu.

Plate Centre Stress Table

The new Combined Stresses sheet in the Plate Centre Stress table provides resolved stresses for the top (positive local Z) and bottom (negative local Z axis) surface for each plate element, referred to as the Top Combined Stresses and Bottom Combined Stresses respectively.

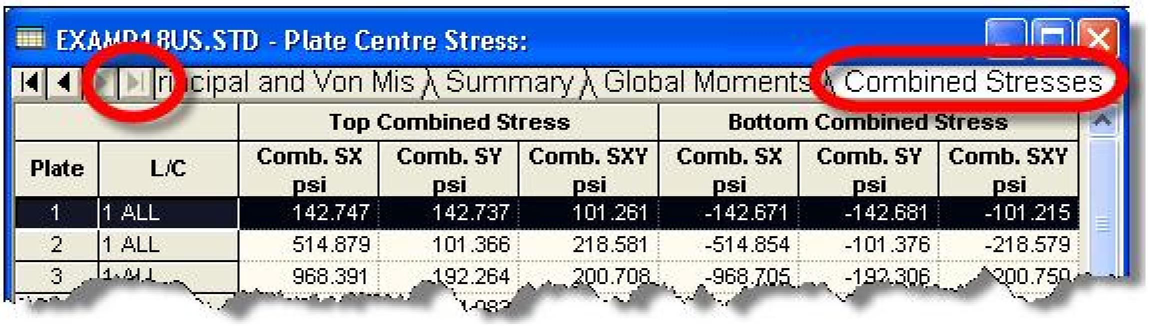


Plate	L/C	Top Combined Stress Comb. SX psi	Comb. SY psi	Comb. SXY psi	Bottom Combined Stress Comb. SX psi	Comb. SY psi	Comb. SXY psi
1	1 ALL	142.747	142.737	101.261	-142.671	-142.681	-101.215
2	1 ALL	514.879	101.366	218.581	-514.854	-101.376	-218.579
3	1 ALL	968.391	192.264	200.708	-968.705	-192.306	200.750

Note that if the sheet title Combined Stresses is not visible on the top of the table, then click on the right arrows displayed on the left of the table header to scroll the table sheets which will display the title.

The combined stresses are calculated thus:

Top:

SX_{top} = SX + MX/S

SY_{top} = SY + MY/S

SXY_{top} = SXY + MXY/S

Bottom:

SX_{bottom} = SX + MX/S

SY_{bottom} = SY + MY/S

SXY_{bottom} = SXY - MXY/S

where

S	=	$t^2/6$ t
t*S*	=	average plate thickness

Plate Stress Contour

The Plate Stress Contour sheet of the Diagrams dialog has been enhanced to allow visualization of these stresses. The six new stress results are available in the Stress Type pull down menu thus:

STAAD.Pro 2007 Release Reports

This section of the Software Release Report contains detailed information on additions and changes that have been implemented in builds of STAAD.Pro 2007 since the release of STAAD.Pro 2006 build 1005. This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

STAAD.Pro 2007 Build 03 Release Report

The Software Release Report for STAAD.Pro 2007 Build 03 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2006 Build 05. This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

STAAD.Pro 2007 Build 02 was a maintenance update and only contained a number of minor updates which are listed in the Revision History text file.

AD.2007-03.0 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

AD.2007-03.0.1 RSS Feed added to the Start Page

The STAAD.Pro Start Page has been updated to include a new section which has been configured to display the most current information about STAAD and Bentley that will be of use to you, such as program updates, seminars, and training courses. This has been done by adding an RSS (Really Simple Syndication) reader on the application front screen.

Each news item is identified with a title which is a link to a website which can be clicked on and will launch your web browser and load that website and a brief summary of the item.

The item is categorized with one of the following five categories:

 Important

 Bentley General

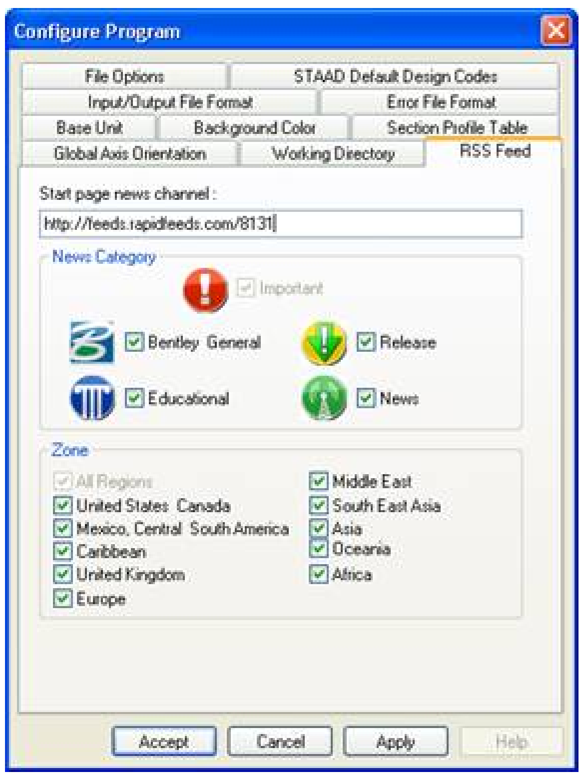
 Release

 Educational

 News

Additionally, each item is marked for specific regions thus:

To configure which messages are displayed and for which region, click on the **Configuration...** link on the Start Page. Select the RSS Feed and click in the categories and regions to remove those that are not required.



Note: Items that have been classed as Important and for All Regions cannot be disabled, but other issues can be by un-checking the boxes next to them

AD.2007-03.1 Features Affecting the Pre-Processor (Modeling Mode)

Several new features have been added and existing features have been modified in the pre-processor section of the program, also known as the Modeling Mode. These are explained in the following pages.

AD.2007-03.1.1 New Meshing Options

The Parametric Models section STAAD.Pro has been enhanced with additional meshing options to provide three methods for creating a finite element mesh. These methods are classified as **Basic**, **Standard**, and **Advanced**.

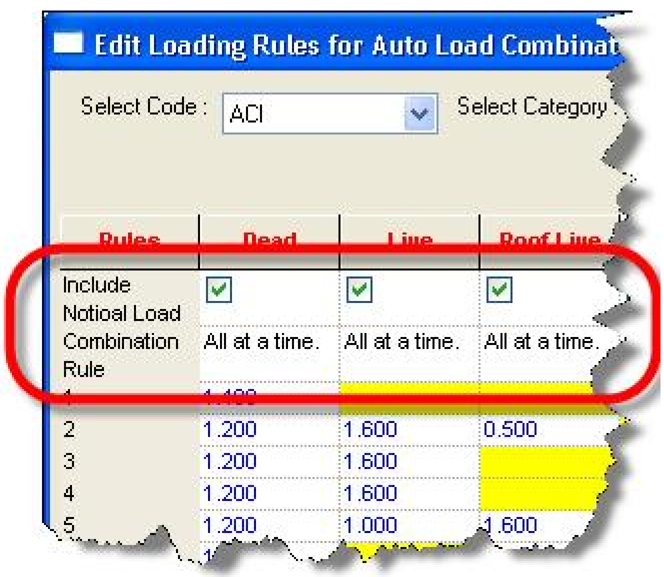
The original content of this topic has been superceeded by content in the main help.

Please refer to the Add Parametric Model dialog (on page 2737) in the User Interface help for current details.

AD.2007-03.1.2 Enhanced Automatic Load Combination Generation

The Automatic load combination generator has been enhanced with two options that define whether notional loads should be included in the combinations and how combinations are created to allow a far greater range of combination conditions to be considered.

The two new options are displayed on the top rows of the dialog box that is opened from the Pre-Processor menu item: **Commands** > **Loading** > **Edit Auto Rules**



Related Links

- *Edit Load Rules for Auto Load Combination Generator dialog* (on page 2875)
- *M. To define automatic load combination rules* (on page 887)

AD.2007-03.1.3 Generation of Primary Load Cases Using Repeat Load Commands

With the large number of combinations that are required by design codes, STAAD.Pro introduced a tool to allow the combinations to be created automatically based on a rule set. This functionality has been enhanced to allow the automatic creation of equivalent combinations, but using primary load cases and the `REPEAT` command.

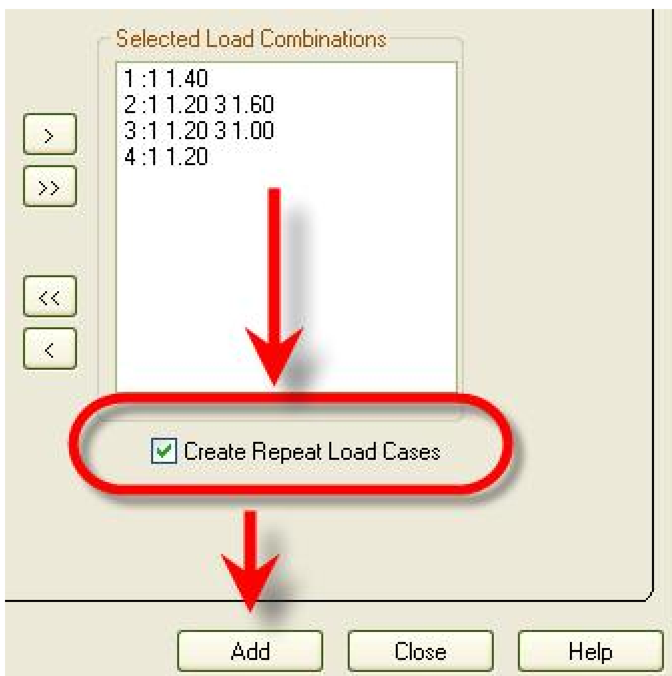
The use of the `COMBINATION` command to obtain results for a collection of load cases that occur together is entirely valid when using first order analysis and models that are not dependent upon the forces in them (such as tension only members or one-way supports). In these cases, the law of superposition allows the results of each load case to be multiplied by a scaling factor and added together. However, for models where this does not apply, such as using a P-DELTA analysis, TENSION ONLY members or ONE-WAY supports, then the law of superposition does not necessarily apply. For this reason, STAAD.Pro has the ability to create primary load cases which replicate the effect of a combination, but in a primary load case. This means that the analysis will solve the load case by using the applied loading rather than simply adding the results. This is achieved in a primary load case by using the `REPEAT` command.

For full details of the `REPEAT` command see TR.32.11 Repeat Load Specification (on page 2595).

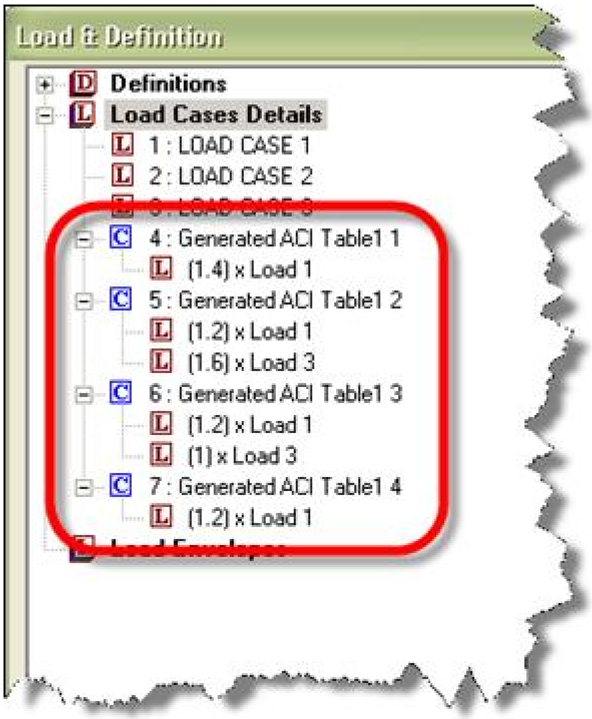
There are three parts to automatically creating primary load cases equivalent to combinations.

1. Define the rules that determine how load case types are to combined
2. Define the individual primary load cases classified with their type
3. Create the combinations.

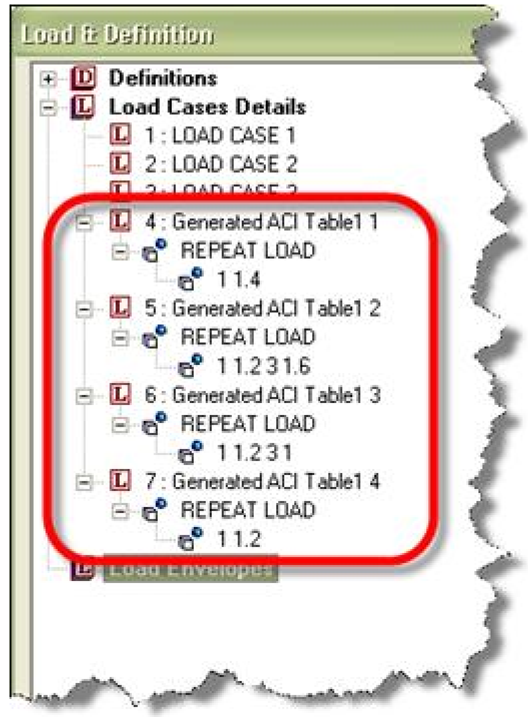
By selecting the option **Create Repeat Load Cases** all the load case combinations in the Selected Load Combinations list will be created into primary load cases:



Note the difference in the **Load & Definition** dialog when comparing a generation of Combination load cases rather than Primary load cases with `REPEAT` commands:



Combination Load Cases



Primary Load Cases with Repeat

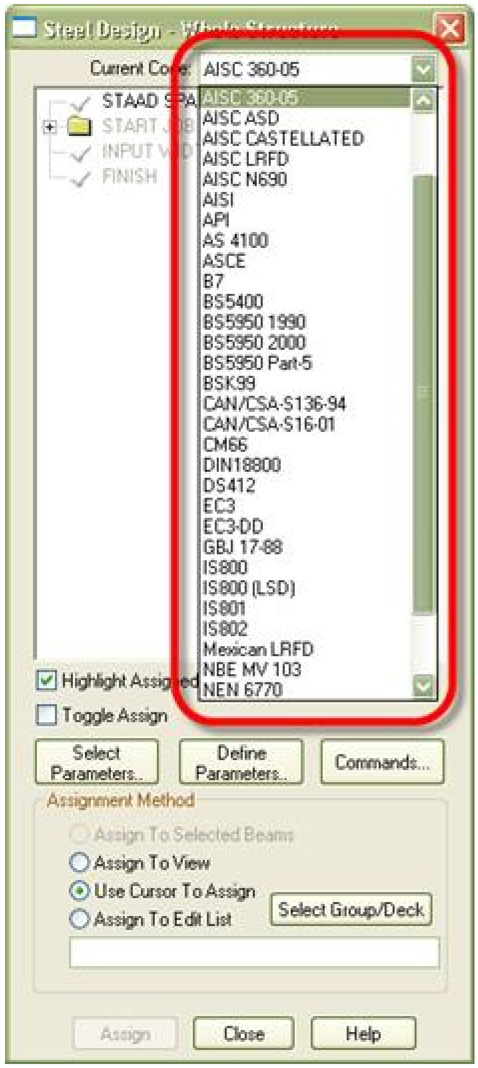
Related Links

- *Edit Load Rules for Auto Load Combination Generator dialog* (on page 2875)
- *M. To define automatic load combination rules* (on page 887)

AD.2007-03.1.4 Design Code List

The list of supported design codes in the design dialog boxes has been updated to represent the actual document rather than the country where this is possible.

The list of codes displayed in the Steel, Concrete, Timber, and Shearwall Design dialog boxes has been updated such as here for the Steel **Design** dialog box:



Note that there is no change to the input or output generated from the design unless noted in the section, AD. 2007-03.2 Features Affecting the Analysis and Design Engine (on page 262).

AD.2007-03.1.5 Additional Standard Profile Databases

An additional Japanese cold formed database has been provided to complement the cold formed sections databases currently provided.

The following database and tables are available.

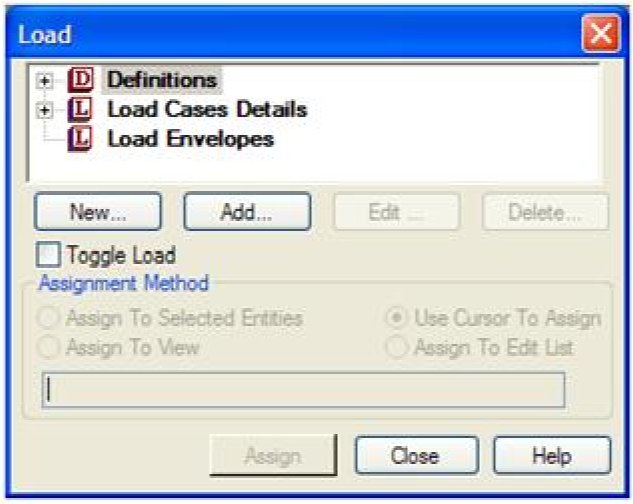
Japanese Cold-Formed Steel

Box Column Press
Box Column Press (Tough)
Box Column Roll

AD.2007-03.1.6 IBC 2006

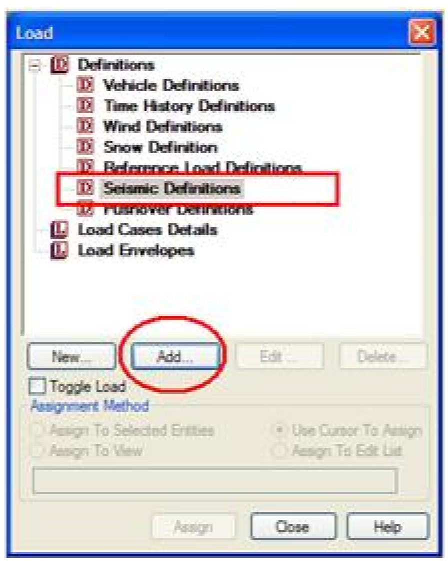
The static equivalent method for performing dynamic analysis as per the IBC 2006 code has been implemented. This follows the principals and methods as in the IBC 2000 and IBC 2003 codes previously implemented.

When the **General | Load** Page is selected, the right hand side of the screen will display the following if no load cases exist in the model.



Definitions contains the options through which one creates the **Define** block of data required to create wind load cases, seismic load cases like IBC and UBC, moving load cases and time history load cases.

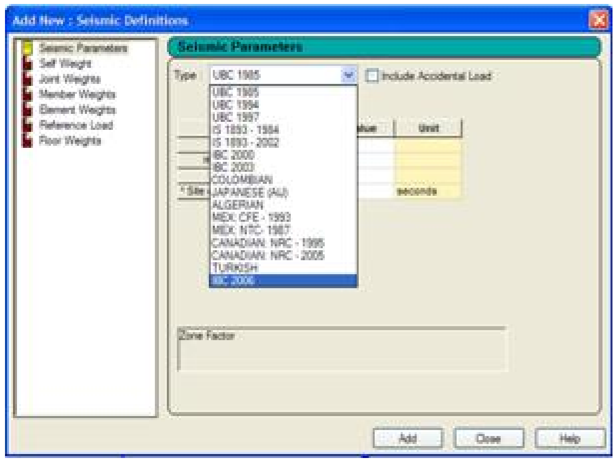
When the tree view is expanded, it will display thus:



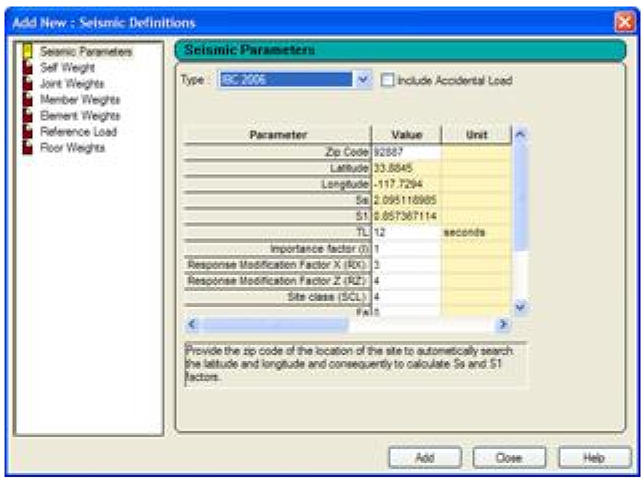
To define the definition of the IBC 2006 select the Seismic Definitions and click on Add. As with other seismic definitions, there are three parts to the exercise,

1. Defining the code and parameters
2. Defining the weights to be considered
3. Include the definition in a primary load case

In the dialog box that is displayed, select **IBC 2006** from the drop-down list.



In this dialog box, the required data is entered into the parameters as described below.

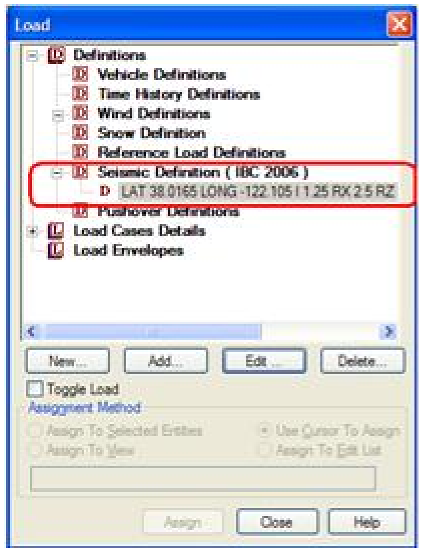


There is an option to **Include Accidental Load**, if this is selected the analysis will include an additional accidental torsion component as described in section 12.8.4.2 of ASCE 7-05.

Refer to the Add New Seismic Definitions dialog (on page 2895) and TR.31.2.14 IBC 2006/2009 Seismic Load Definition (on page 2405) for details.

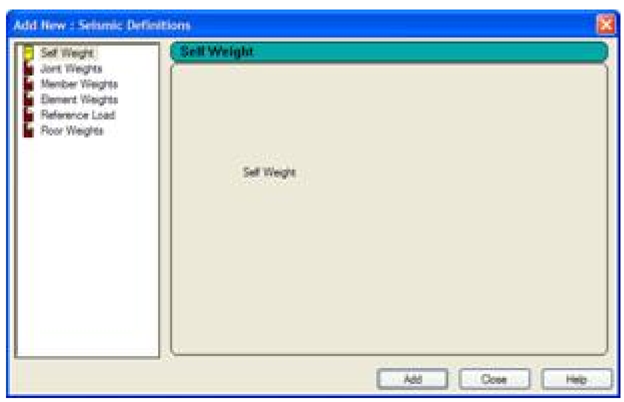
After specifying the values for the parameters, click on the **Add** button.

Note that the **Load** dialog box has been updated with the new command.



As described earlier, the second part of the process is to identify the structural weights that should be considered. These can be added once the defined parameters have been created by clicking on the **Add** button. The dialog box is updated to display the various weights that can be added thus:

Selfweight



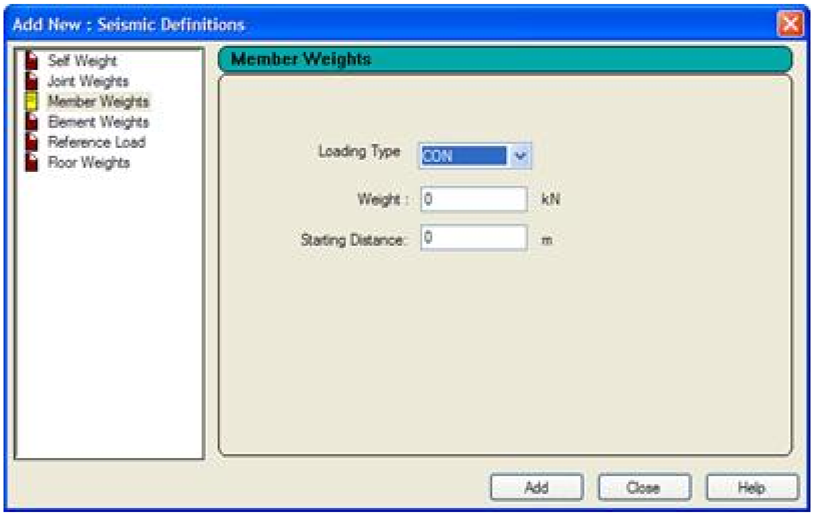
This is the selfweight of the structure.

Joint Weights

These are the concentrated weights acting at one or more joints.

Member Weights

Distributed and concentrated weights acting on member spans are specified through this option. After clicking the Member weight button, the Member weight dialog box appears, as shown below.



Select the **Concentrated** or **Uniform** load type from the **Loading Type** drop-down list. Enter the intensity of the distributed weight or magnitude of the concentrated weight as the case may be, along with the location of the load.

Element Weights

If the structural model consists of plate elements representing entities like floor slabs, the pressure loads on those slabs can be considered for weights calculation for lateral load generation per UBC/IBC/other codes. This is done with the help of the Element Weights option. Its parameters include the magnitude of the uniform pressure, and the elements they are applied on. Since it is a weight, it is a quantity without a sign.

Reference Load

Reference Load cases which are described in AD.2007-1001.1.12 of the STAAD.Pro 2007 Software Release Report can be referred to using this option. Loads which are specified under Reference Loads can be used as weights for IBC.

Floor Weights

In many situations, a user may decide not to include the structural slabs in his/her analytical model. Hence, the model may be solely the skeleton framing system consisting of the beams, columns and bracing members.

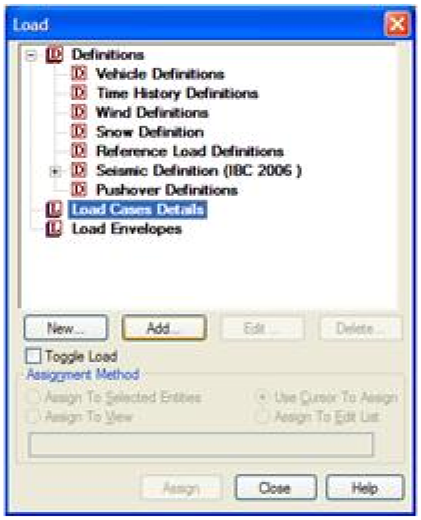
Under these circumstances, the loads which act on the slab can no longer be applied on the structure using the ELEMENT PRESSURE options. This is because there are no elements to represent the slab. So, an alternative is to apply the load using the FLOOR LOAD option. It is described in detail in TR.32.4 Area, One-way, and Floor Load Specifications (on page 2475).

Within a UBC/IBC/other codes definition, the FLOOR WEIGHT is the counterpart for the FLOOR LOAD just as MEMBER WEIGHT is the counterpart for a MEMBER LOAD, and an ELEMENT WEIGHT is the counterpart for an ELEMENT LOAD.

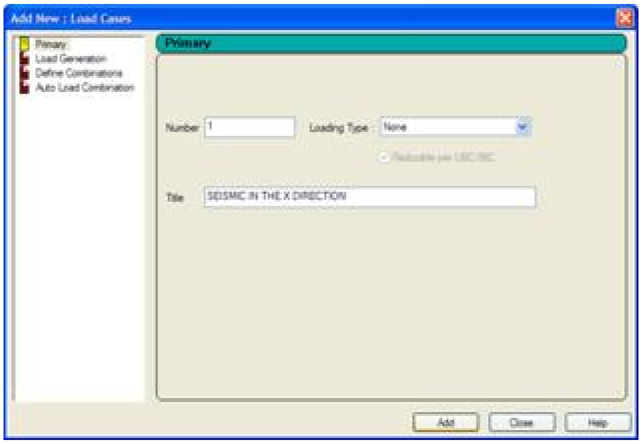
Note: Its parameters are hence very similar to what are found in a normal FLOOR LOAD definition. XRANGE, YRANGE and ZRANGE options allow the user to narrow in on panels at specific regions of the building. The pressure value is provided as a quantity without sign because it is contributing to the overall weight - a numerically positive term.

Once the seismic definition, including weights, has been specified, it should be included in a one or more primary load cases.

Select **Load Cases Details** and click on **Add**.

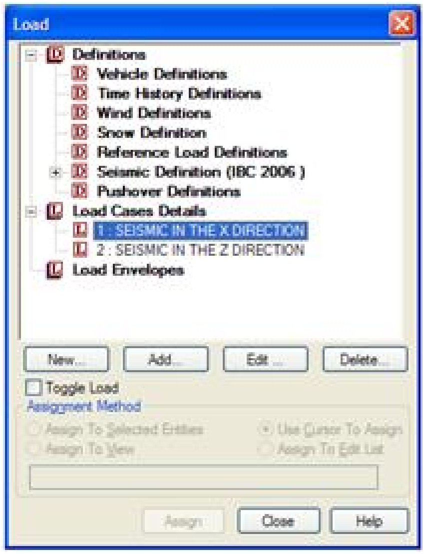


In the dialog box that is displayed, provide a **Title**, select the loading type as ‘seismic’ (although this is not strictly required, just useful for future reference) and click on **Add.**

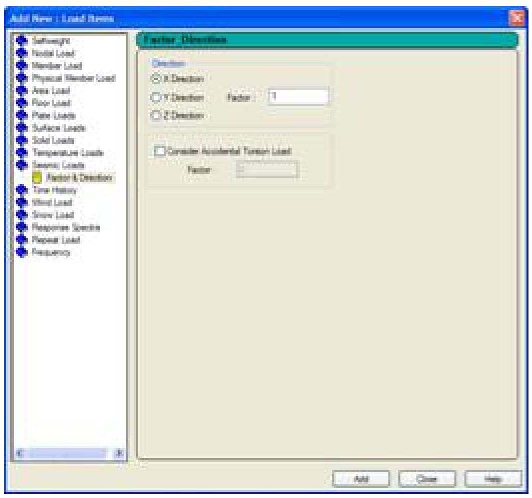


More load cases can be added in this manner.

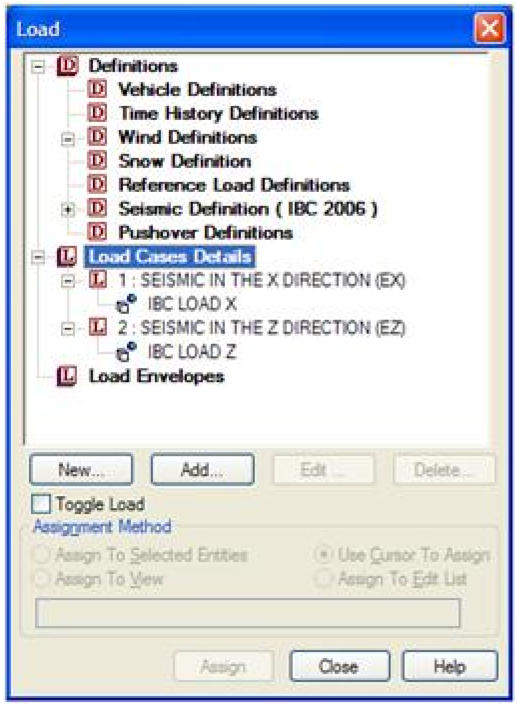
To add load items to our first load case, keep the expression **1: SEISMIC IN THE X DIRECTION** highlighted and click on the **Add** button.



Enter the **Factor**, **Direction**, etc. and click on **Add**.



The **Load** dialog box will display the new load item.



We can continue adding other load items to this load case in a similar fashion.

For more information on other UBC and IBC load definitions, see TR.31.2 Definitions for Static Force Procedures for Seismic Analysis (on page 2349). To find more information about including the seismic loads in a primary load case, see TR.32.12 Generation of Loads (on page 2596).

AD.2007-03.2 Features Affecting the Analysis and Design Engine

The following section describes the new features have been added to the analysis and design engine and existing features that have been updated or modified.

AD.2007-03.2.1 Selfweight Command with a Member List

When considering stage construction, it is occasionally necessary to create load cases which include the effects only of the additional parts of structure. In order to do this the SELFWEIGHT command has been enhanced to allow a member list to be added which will be processed and only selfweight on that list will be considered.

This command may be used to calculate and apply the SELFWEIGHT of the structure for analysis. This allows you to enter body weight of the structural components. In other words, it allows different parts of the structure to be excited with different accelerations.

Refer to TR.32.9 Selfweight (on page 2496) for details on using member lists with the Selfweight command.

Example

```
LOAD 1 DEAD AND LIVE LOAD
SELF WEIGHT X 1.4 LIST 4 TO 10
SELF X 1.0 _PLATEGRP1
SELF
SELF Y -1.4
SELF X 1.4 ALL
SELF WEIGHT Z 1.4 _SOLIDGRP1
SELF Y -1.4 YR 10.5 10.51
SELF Y -1.4 X
```

In above example, the first specification includes factored weight of member (/plate/solid) 4 through 10 along global X direction and the second includes weight of all members (/plates/solids) associated with `group _PLATEGRP1`. The third command includes weight of all structural components towards gravity direction (`SELF WEIGHT Y -1.0`).

`SELFWEIGHT` specification for definition of static method of seismic load generator also is capable of accepting list. Only there is no direction specification for this command.

Similarly, the `SELFWEIGHT` specification when used in a Reference Load is also capable of handling a list.

AD.2007-03.2.2 Direct Analysis

The AISC 360-05 Appendix 7 describes a method of analysis, called Direct Analysis, which accounts for the second order effects resulting from deformation in the structure due to applied loading, imperfections and reduced bending stiffness of members due to the presence of axial load.

This is a non-linear iterative analysis as the stiffness of the members is dependent upon the forces generated by the load. The analysis will iterate, in each step changing the member characteristics until the maximum change in any Tau-b is less than the tau_tolerance, If the maximum change in any Tau-b is less than 100*tau_tolerance *and* the maximum change in any displacement degree of freedom is less than the disp_tolerance; then the solution has converged for this case.

There are two steps involved in setting up a Direct Analysis.

1. Specify the definition with a `DEFINE DIRECT` command.
2. Specify a direct analysis method with the command `PERFORM DIRECT ANALYSIS`

Note: Like all other analysis methods, by specifying the direct analysis parameters and only including a PERFORM ANALYSIS command, will result in only a first order elastic analysis, not a direct analysis to be performed.

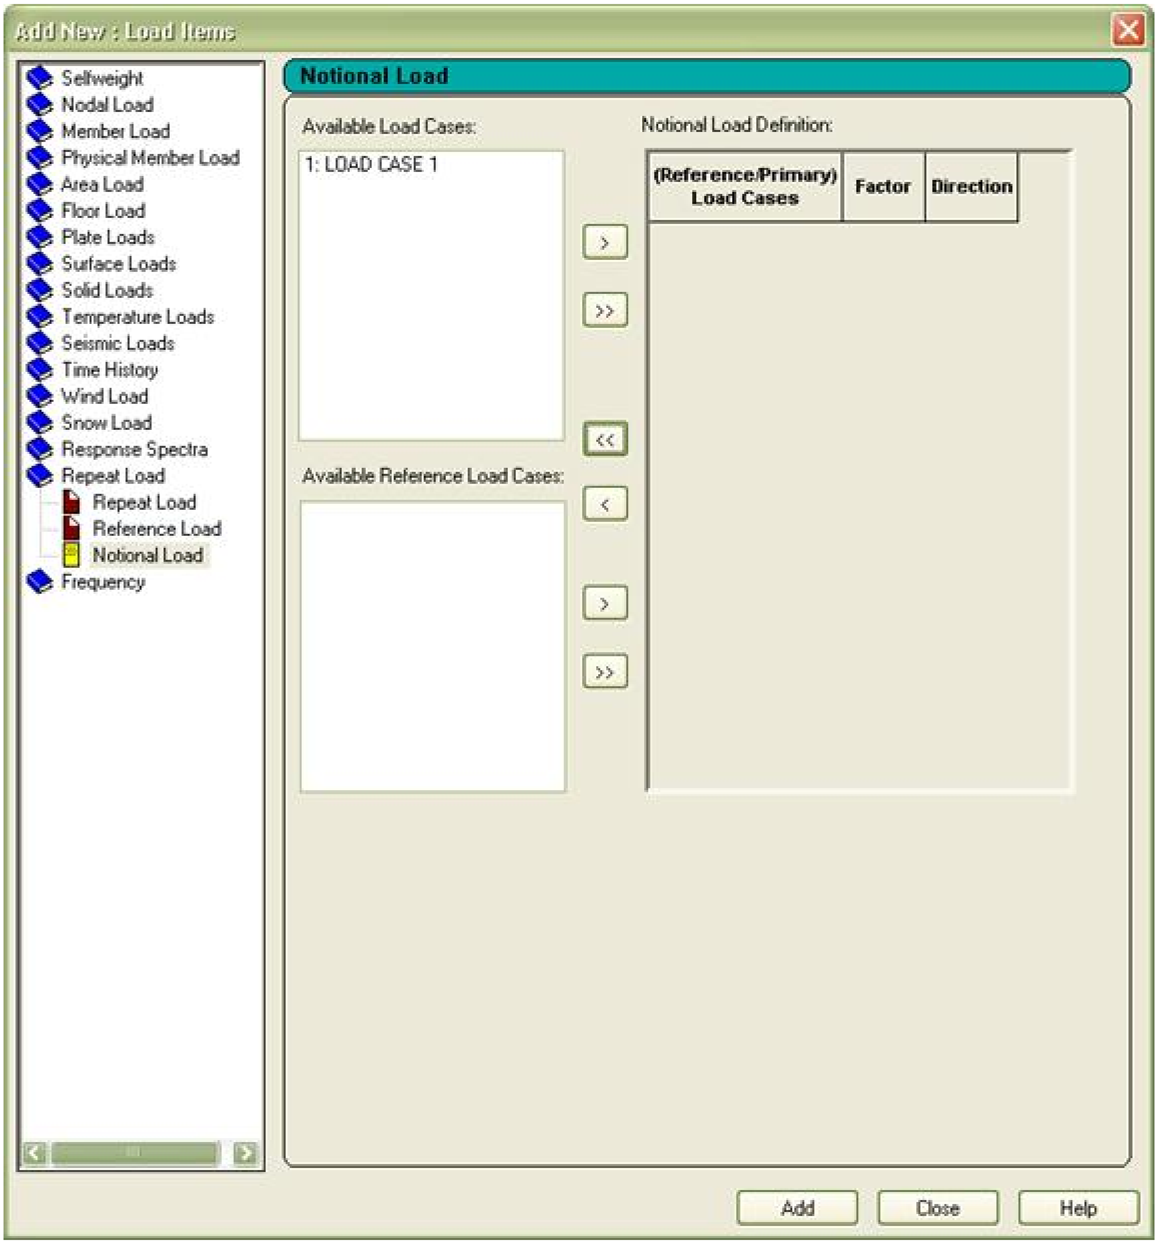
Related Links

- *M. To define direct analysis parameters* (on page 871)
- *A. To specify a direct analysis* (on page 953)

AD.2007-03.2.3 Notional Loads

A number of design codes require that a notional load be considered. Typically this is defined as a percentage of the gravity loads. What has been added to STAAD.Pro is an enhancement on the `REPEAT LOADS` command so that Primary and /or Reference load cases can be selected and a percentage of them can be applied in the appropriate global direction.

The addition of the Notional Loads command in the GUI is as an additional option on the **Repeat Load** option of the New Load Items, thus:



Both Principal and Reference load cases can be selected and moved into the Notional Load Definition where the required factor and direction can be specified.

The notional loads are calculated and applied as joint loads. Note that the actual values of the applied loading are not displayed in the GUI until after the analysis has been performed.

AD.2007-03.2.4 STP Parameter Added to AISC 360-05 Design

The AISC 360-05 design of wide flange depends on whether the section is formed from a rolled process or from plates welded together.

The parameter STP has been added to the list of parameters to indicate whether the section is built up from welded plates or from a rolling process. This is then used to determine the appropriate slenderness ratio as defined in table B44.1 from AISC 360-05. This parameter takes the following values:

1. Rolled Section
2. Built-up section

The default value is 1.0

- *D1.A.6 Design Parameters* (on page 1100)

AD.2007-03.2.5 Updated and Additional Standard Steel Grades in Eurocode 3

The standard steel grades are referenced in the Eurocode 3 have been provided as standard steel grades in order that the appropriate buckling curves can be selected.

The steel grade can be specified using the parameter SGR which accept values of 0 to 5. This translates to the following:

Grade	SGR
S 235	0 (default)
S 275	1
S 355	2
S 450	3
S 460	4

Note: If a user-defined yield stress PY is specified, the buckling curve will still be determined from the SGR setting (i.e., if not specified, it will be based on the default SGR parameter). Therefore, if setting a user PY, this should be *preceded* in the file by the appropriate steel grade command.

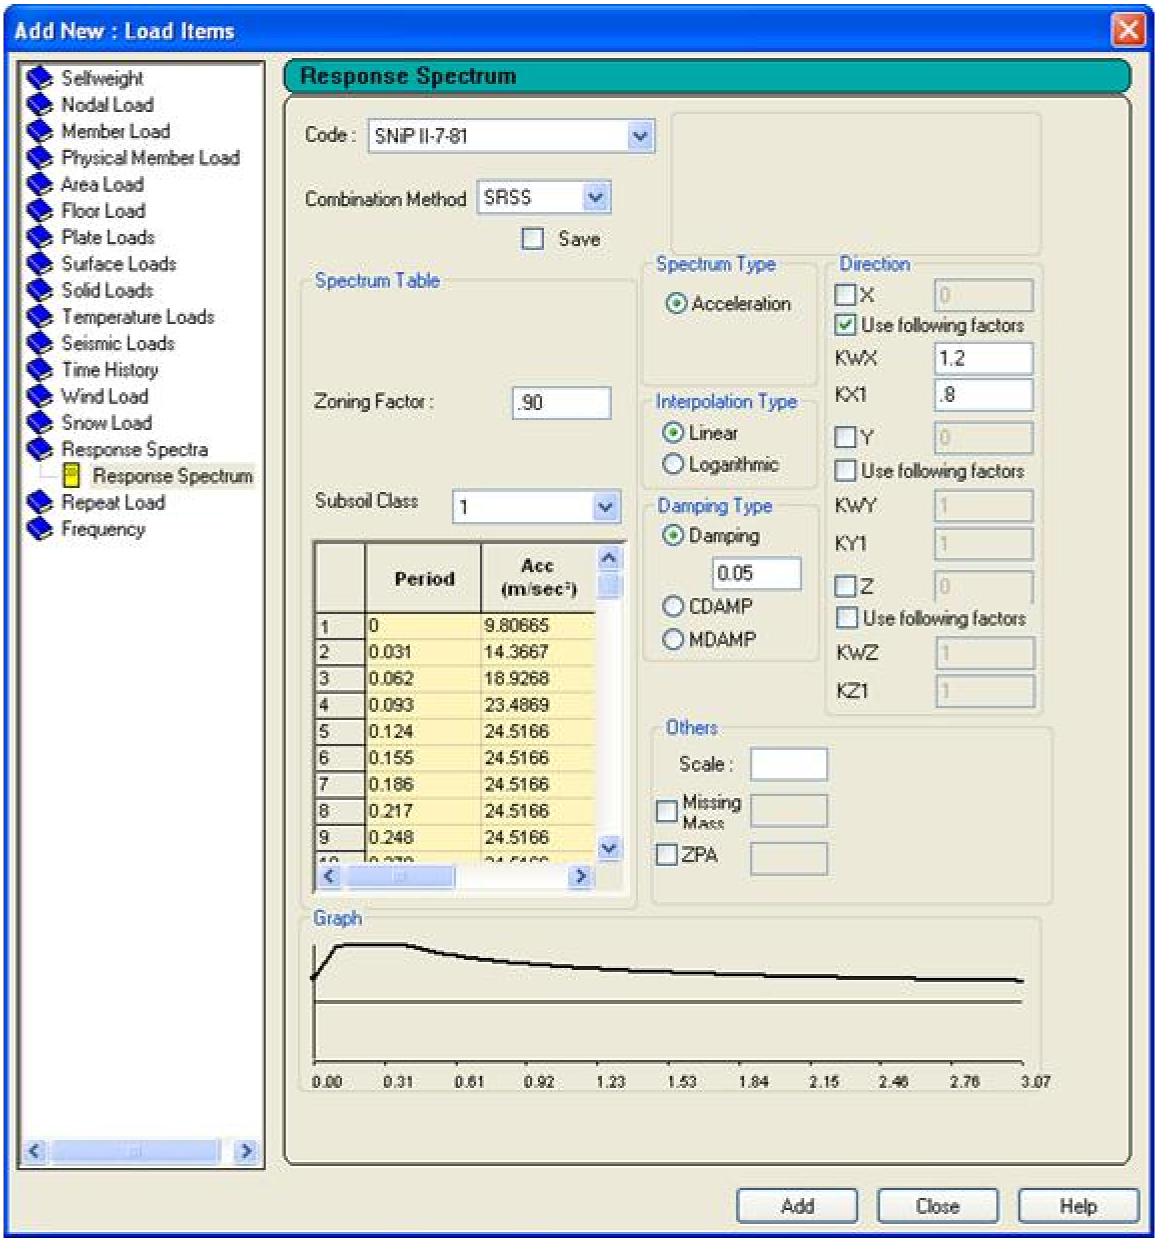
AD.2007-03.2.6 Russian Response Spectrum

The Response Spectrum functionality has been enhanced with the ability to create response spectra as defined in the SNiP II-7-81.

To create a response spectrum as defined in the SNiP code, enter the **General | Load & Definition** Page and create or select the load case which is to be used. Click on the **Add...** button and select the **Response Spectra** option from the left panel.



Enter the required data in the provided fields and click on the Add button to include the command in the selected load case of the data file.

Related Links

- *TR.32.10.1.14 Response Spectrum Specification per SNiP II-7-81* (on page 2584)

AD.2007-03.2.7 Eurocode 3 Updated to Support Design of Slender Box Sections

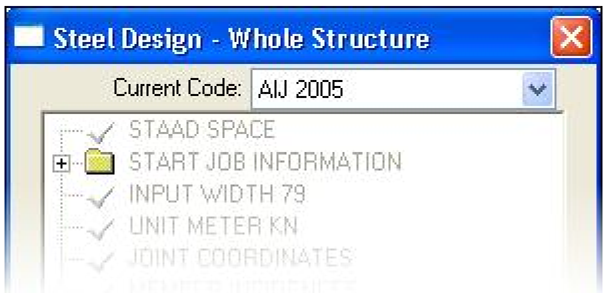
Both the ENV and DD versions of Eurocode 3 steel design need to design box sections that have slender elements.

Members that are specified with steel hollow box section properties that contain slender elements can now be designed to Eurocode 3. Previously, these members would not be designed and result in a warning in the output stipulating that slender members are limited to I section properties only.

AD.2007-03.2.8 AIJ 2005 Steel Design

The AIJ has updated the Japanese steel design code, AIJ 2005. This design code has been implemented and complements the existing Japanese steel design code AIJ 2002. The changes are minor and the code checking process remains the same as the previous AIJ design.

The design parameters are the same and apply as defined for the current AIJ, the only exception, however, is the **Current Code** parameter which must be set to **AIJ 2005.** This setting is available from the GUI list of codes.



Note that a design performed to the new AIJ 2005 standard is displayed in the output file (`*.ANL`) with the following header:

```
                         STAAD.PRO CODE CHECKING - (    AIJ 2005      )

************************************************
```

The equivalent header for a code check (or member selection) to the older standard is displayed thus:

```
STAAD.PRO CODE CHECKING - (    AIJ 2002      )

************************************************
```

AD.2007-1003.2.9 IBC 2006

In AD.2007-03.1.6 IBC 2006 (on page 256), the graphical screens containing the implementation of the seismic loading chapters of the IBC 2006 and ASCE 7-05 codes were described. In this section, the technical details and command syntax for the parameters of that feature are described.

Related Links

- *TR.31.2.14 IBC 2006/2009 Seismic Load Definition* (on page 2405)

AD.2007-03.2.10 IBC 2006 Response Spectrum

This command may be used to specify and apply the `RESPONSE SPECTRUM` loading as per the 2006 edition of the IBC specification “International Building Code (IBC),” for dynamic analysis. The graph of frequency–acceleration pairs are calculated based on the input requirements of the command and as defined in the code.

Related Links

- *TR.32.10.1.10 Response Spectrum Specification per IBC 2006* (on page 2561)

AD.2007-03.3 Features Affecting the Concrete Design Mode

The following section describes the new features have been added to the analysis and design engine and existing features that have been updated or modified.

AD.2007-03.3.1 ACI 2005 Beam, Column, and Slab Design

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2007-1003.3.2 AS 3600 Beam and Column Design

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2007-1003.3.3 EC2 2004 Beam and Column Design

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2007-03.4 Features Affecting the RAM Connection Design Mode

Several new features have been added and existing features have been modified in the RAM Connection Design Mode. These are explained in the following pages.

Full use of the RAM Connection Mode requires access to a valid RAM Connection license. If you do not possess a license, contact your Bentley account manager to have it added to your SELECT licenses. Without a valid license, only a small subset of the full range of available RAM connections can be utilized.

AD.2007-03.4.1 Support of British Sections

To allow models created with British steel sections to be designed with RAM Connection, these sections need to be added to the supported US section database.

The ranges of supported sections are:

US Sections

Wide Flange

W Shape - W
M Shape - M
S Shape - S
HP Shape - HP

Tee

Tees cut from W sections - WT
Tees cut from S sections - ST
Tees cut from M sections - MT

Channel

Channel - C
MC Channel - MC

Angle

Angle - Equal and unequal, L and LU
(Double angle, T2L and T2LU, but with fixed spacing)

Hollow

Tube - TUBE
Pipe - PIPE
HSS Rectangular - HSS_RECT
HSS Round - HSS_RND

Not supported

B Shape
Castellated
Solid Round
Cable

British Sections

Wide Flange

UB Shape - UB
UC Shape - UC
JO Shape - Joist

Tee

Tees cut from UB sections - TUB
Tees cut from UC sections - TUC

Channel

Channel - PFC

Angle

Angle - Equal and unequal, EA and UEA

Hollow

Tube - Rectangular and square, SHS and RHS

Pipe - CHS

Not supported

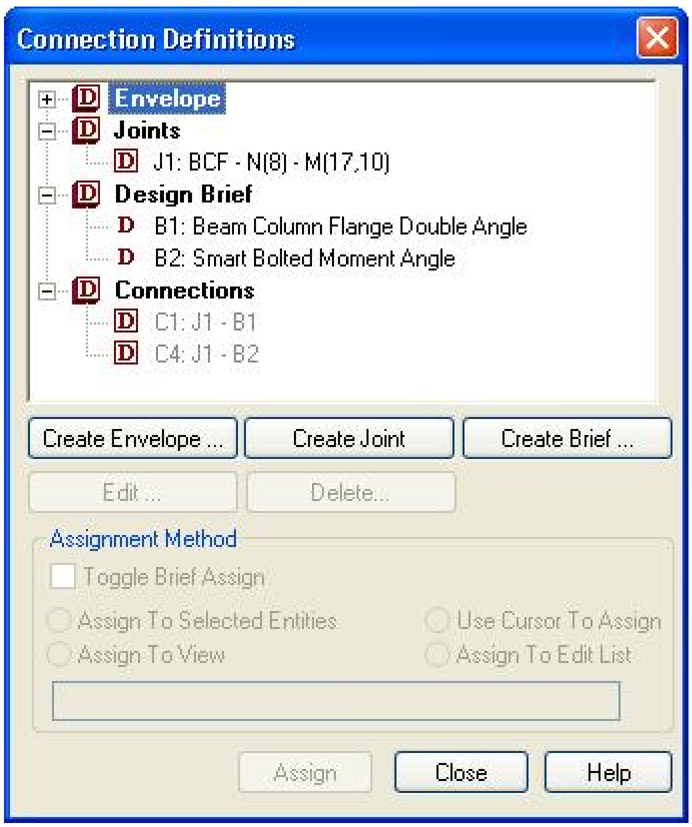
UP Shape

AD.2007-03.4.2 Support of Multiple Connections at a Joint

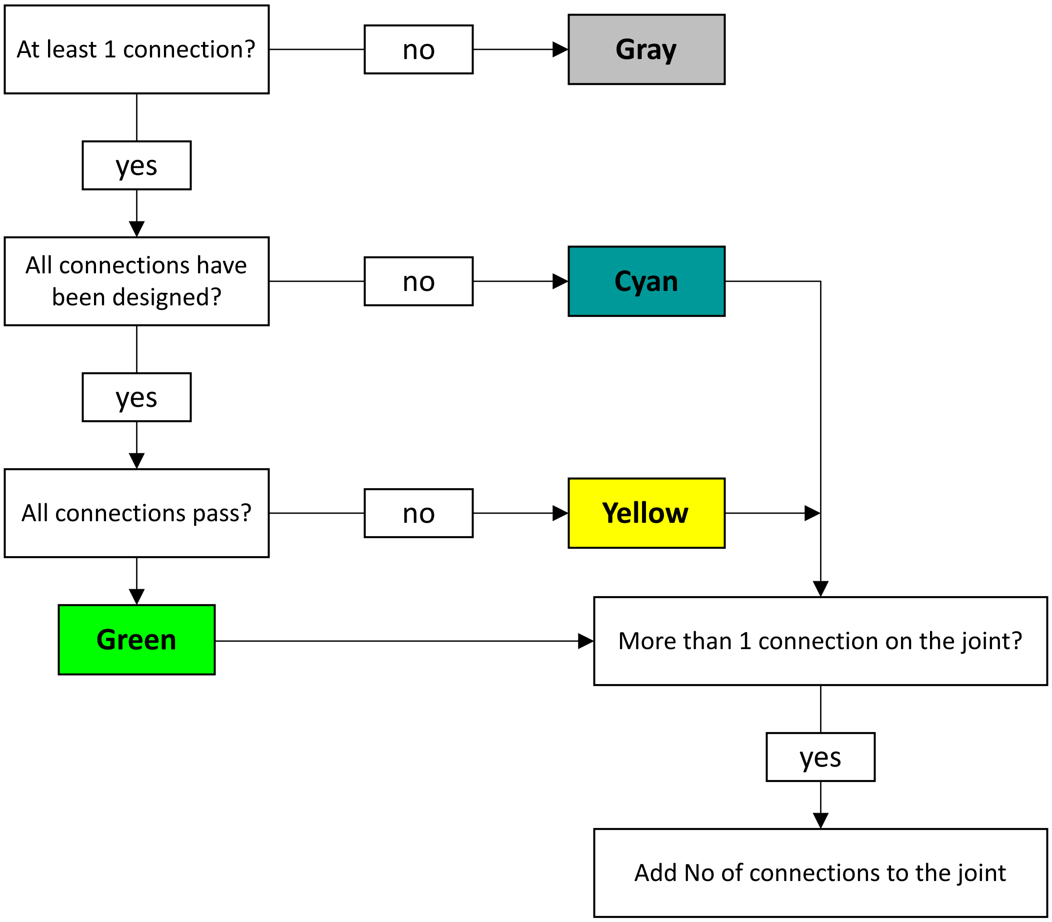
RAM Connection designs separate parts of a connection with different templates such as a Shear Plate Connection and a Moment Connection. Therefore the RAM Connection mode has been enhanced to allow multiple Connections to be assigned to a single joint.

The following is an enhancement of the new feature added in STAAD.Pro 2007 Build 1001. Refer to AD. 2007-1001.5.1 RAM Connection Design Mode.

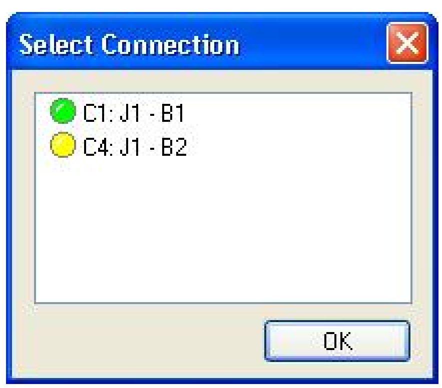
If a design brief is assigned to a joint that already has one assigned, then rather than replacing the existing design brief, an additional connection will be defined.



When multiple connections exist at a joint, the information is displayed such that the colour coding of the connection uses the following logic:



When selecting a joint that has multiple connections associated with it, the following dialog box is displayed that shows the associated connections from which the required connection should be selected:



Note: Each connection is designed and detailed independently

STAAD.Pro 2007 Build 1001 Release Report

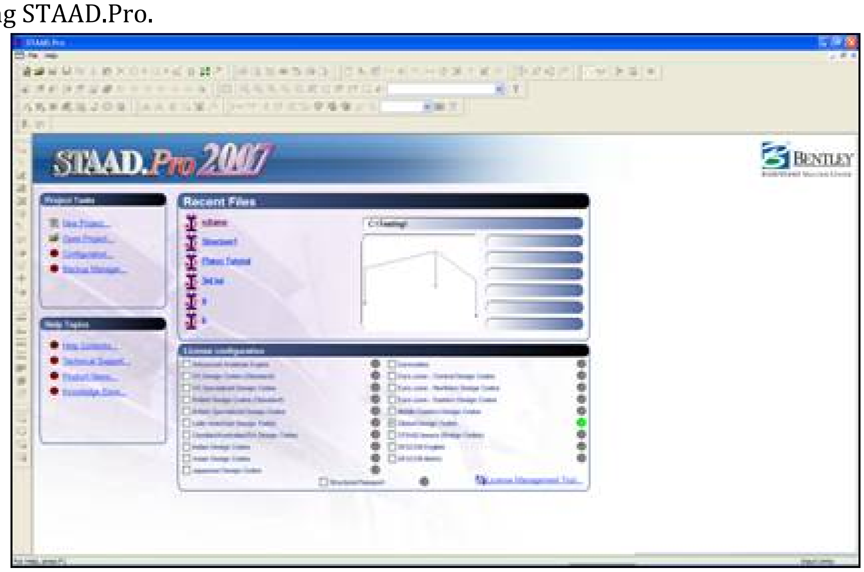
The Software Release Report for STAAD.Pro 2007 Builds 01 + 02 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2006 build 1005. This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-1001.1 Features Affecting the Pre-Processor (Modeling Mode)

Several new features have been added and existing features have been modified in the pre-processor section of the program, also known as the Modeling Mode. These are explained in the following pages.

AD.2007-1001.1.1 New Start Page

STAAD.Pro now includes a start page with access to the functions normally required when first starting STAAD.Pro, including shortcuts for starting a new file, accessing the recently accessed files, launching the help file and configuring STAAD.Pro.



The new Start Page is divided into 4 sections that can be used to achieve the following:

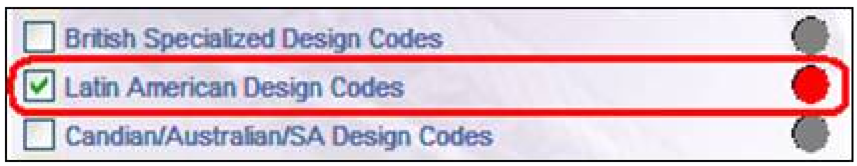
1. **Project Tasks**, to:
   a. Start a New Project using the STAAD.Pro wizard.
   b. Open an existing file using the traditional windows browse dialog enhanced with a model preview window.
   c. Set the program behavior with the Configuration options.
   d. Setup the automatic Backup configuration requirements.
2. **Recent Files** to preview and access the last 6 models opened.
3. **Help Topics**,
   a. Quick access to the online Help document.
   b. Locate the technical support centers and contact details.

c. Find out the latest information on the program online from the Product News link.
d. Access the growing STAAD.Pro online knowledge base.

4. **License Configuration**. To quickly identify which SELECT licenses are being used by the current session of STAAD.Pro, they are displayed and color coded on the Start Page thus:
   - If the license is available it is marked with a green circle thus:

   - Licenses that have not been selected are marked with a grey circle thus:

   - If the selected license can not be obtained or is not available from the server will be shown with a red circle, thus:



Additional configuration of the Bentley SELECT license, such as specifying the server name and activation key, can be viewed and set using Bentley License Management Tool which can be accessed from the link at the bottom right of the License Configuration section.

AD.2007-1001.1.2 Enhanced Grid Tool

The Snap/Grid Node tools have been enhanced to

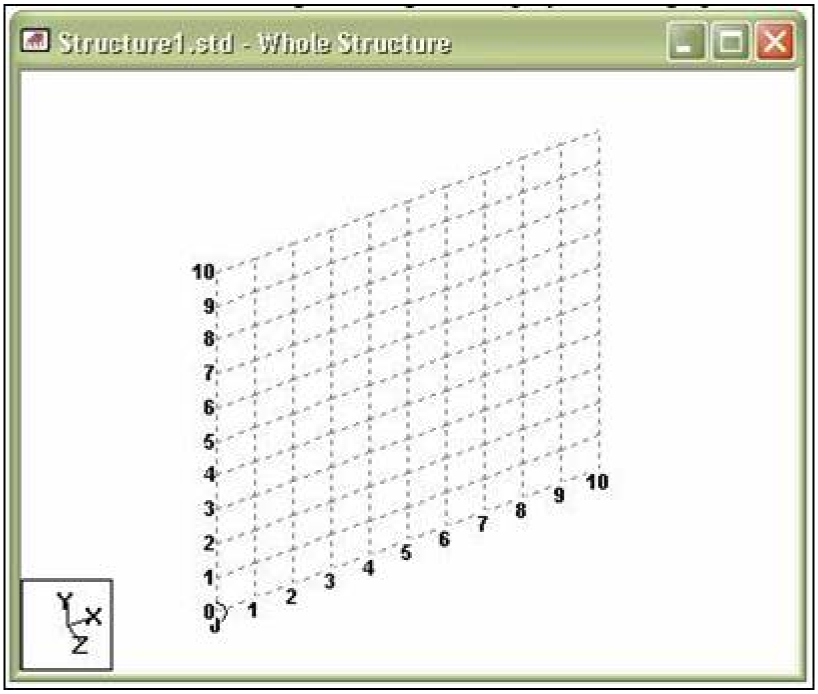
1. Allow multiple different grids to be created.
2. Import a DXF file and use it as a template.
3. Import grid files created in another STAAD.Pro model

Beams, plates (both triangular and quadrilateral) and 8 noded solid elements can be generated using the appropriate Snap/Grid Node tool.

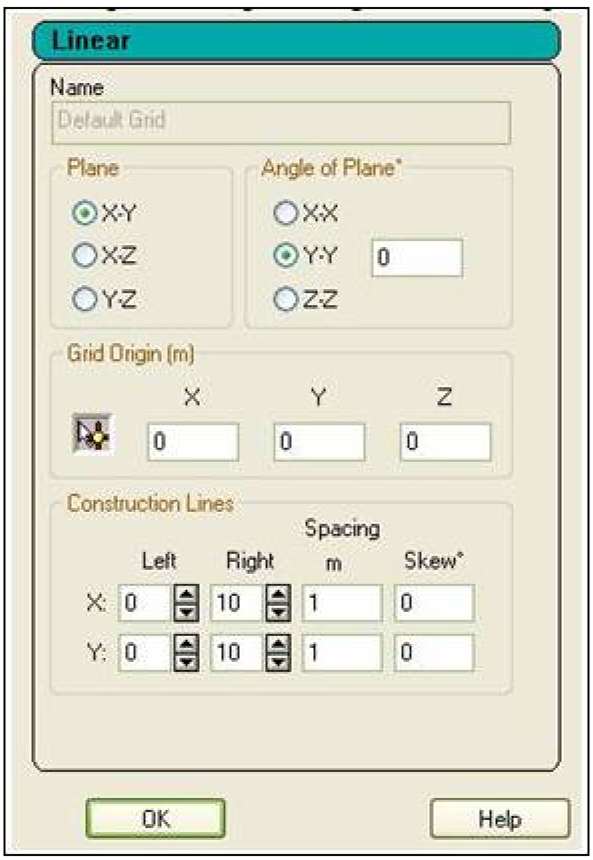
When this function is launched, the following dialog is opened which will include a Default Grid. This grid will be of type ‘Linear’, there are also options to create Radial, Irregular and imported DXF grids which will be described later.

As new grids are added or modified, the information is stored in the STAAD.Pro data folder with a GRD extension that allows other STAAD files to re-use these defined grids.

The effect of the current grid settings are displayed in the graphics window, thus:

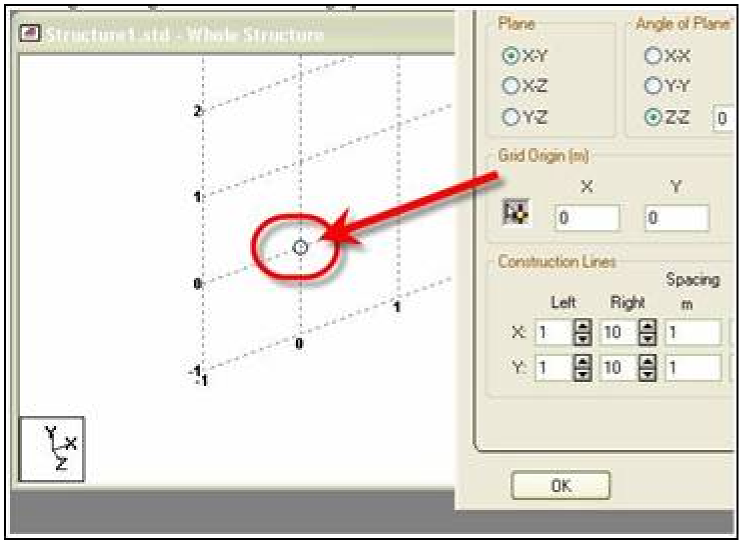


To change the settings of this grid click on the **Edit** button to display the current grid properties, e.g.:



The current plane of the grid is set by selecting the required option. This can be rotated about one of the global planes by selecting the axis of rotation and setting the angle.

The origin of the grid is marked on the graphics with a small circle:



The location of the origin, specified in global co-ordinates, can either be defined explicitly in the given X, Y and Z co-ordinates, or it can be set to the co-ordinates of an existing node by clicking on the icon,  (the cursor changes to ) and then on the node itself in the graphical window. Note that at this point the origin co-ordinate is updated.

The construction lines are used to specify how many gridlines are created either side of the origin, the spacing between the gridlines and if there should be a skew in degrees along either axis.

Click on the **OK** button to accept these settings.

Additional grids can be defined by clicking on the [Create…] button. Three different types of standard grid can be created:

- Linear
- Radial
- Irregular

The type of grid required should be selected from the drop list of types available at the top of the property sheet.

Each new grid should be identified with a unique name for future reference. The functionality for each type of grid is thus:

Linear

The Default Grid defined above is a Linear Grid and thus see above for the settings of a Linear Grid.

Radial

The settings for a Radial grid are defined in the following window:

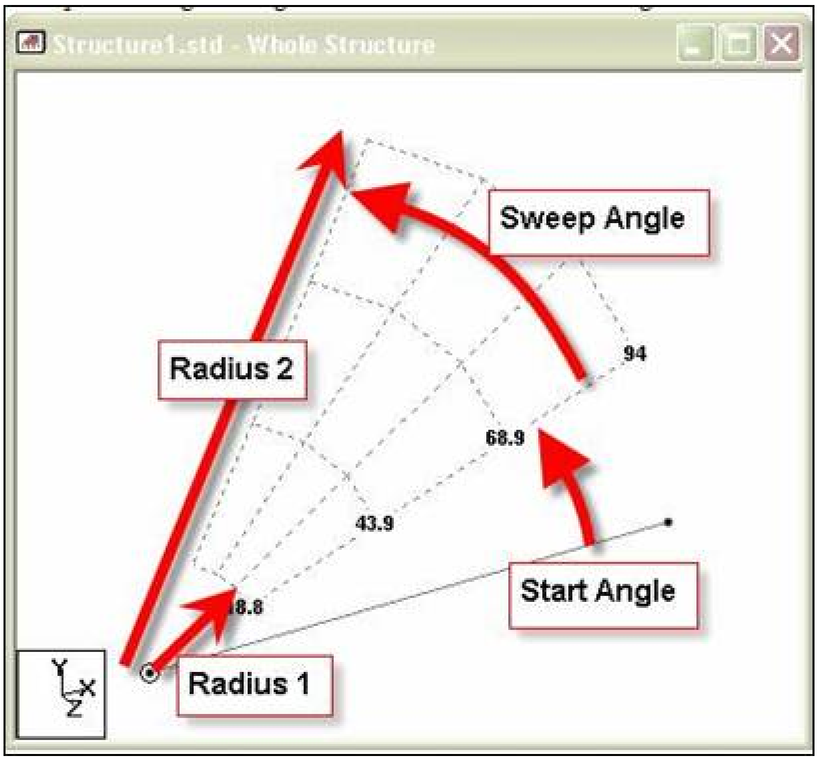
Modeling

The Plane, Angle of Plane and Grid origin options are as for the Linear (or Default Grid).

The construction lines options

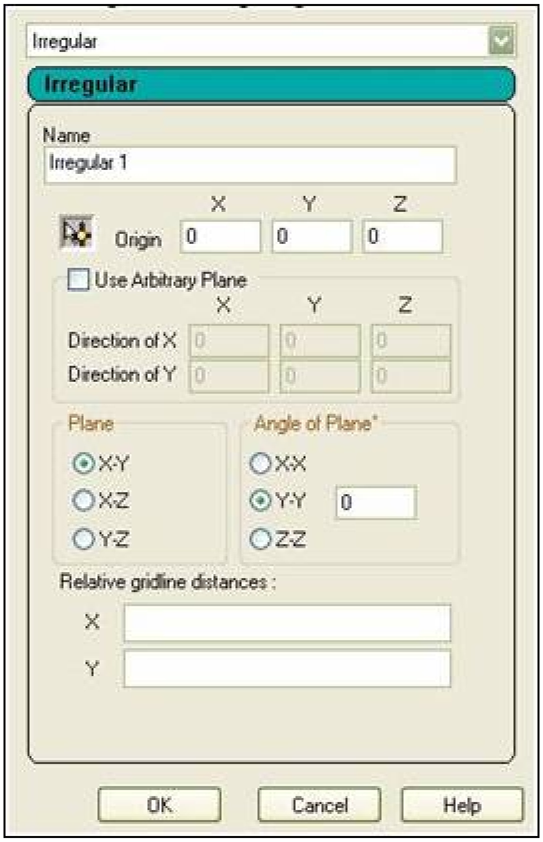
Start Angle, is the angle in degrees about the orthogonal axis to the plane from the axis first referred to in the definition of the plane. For examle, if the selected plane is X-Y, then the angle is measured about the Z axis (using the right hand rule) from the axis parallel to the X axis.

Sweep is the angle in degrees measured from the start angle which is divided into the selected number of Bays, thus:



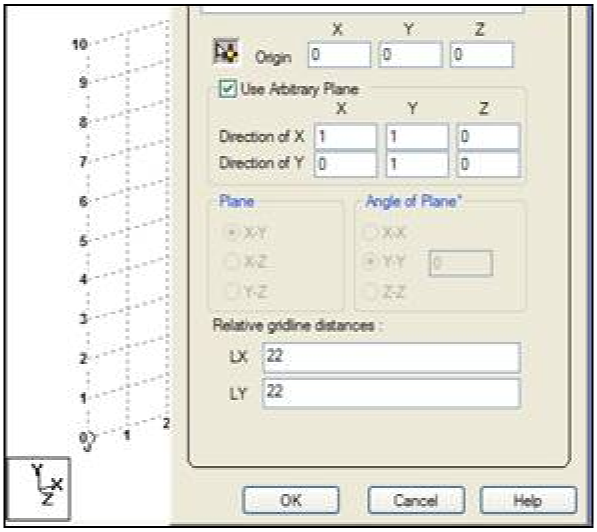
Irregular

The settings for an Irregular grid are defined in the following window:



The origin is set as described above for both Regular and Radial grids.

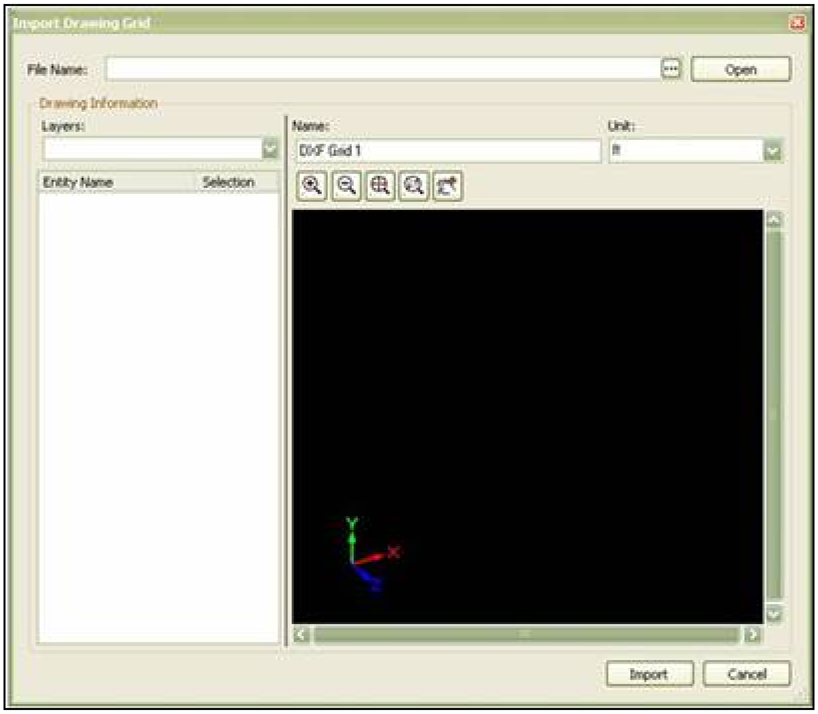
The plane of the grid can either be set in one of the global planes X-Y, X-Z or Y-Z and rotated about one of the global axes. This method is identical to that described for the Regular or Radial Grids. Alternatively, the directions of the two axes can be specified as relative co-ordinates from the origin:



The gridlines are defined by the distance to the next gridline and the numbers separated with a space.

There are two import options that can be selected that can allow either DXF files or grids defined in another STAAD.Pro model (all but the default will be imported).

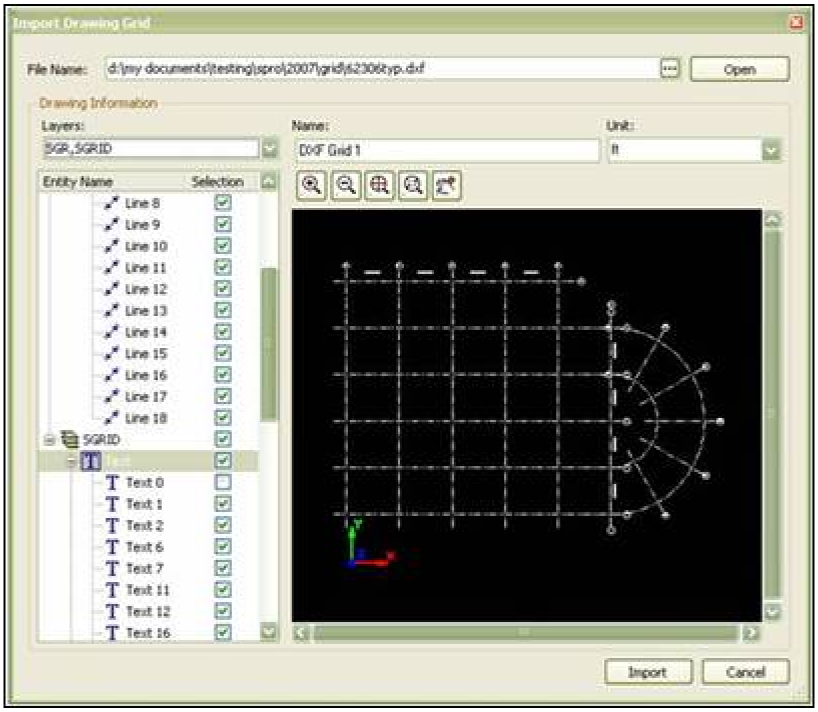
The option to import a DXF file will open the following dialog:



To select a DXF file click on the **[...]** button and navigate to the required file.

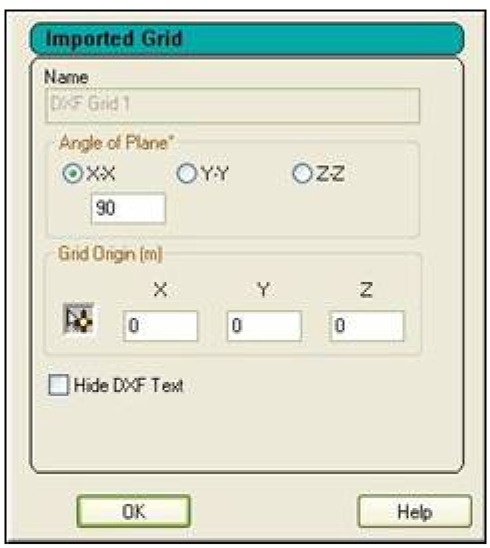
The file will be opened and displayed in the preview window. Individual layers can be turned on and off from the Layers droplist. The individual entities in the selected layers are displayed and can be toggled on or off for import.

By clicking on an entity in the graphical window, the entity is highlighted in the table so that it can be turned off if required.

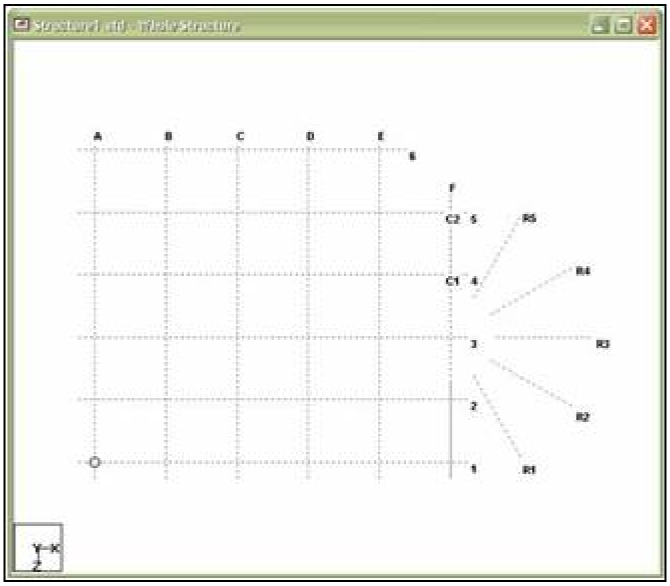


With the required entities selected, a suitable reference name supplied and unit selected, click on the **Import** button.

The data will be imported in the plane in which it was defined in the original DXF. However, if required this can be rotated about any of the global axes. Also, the origin of the grid can be located at any 3D co-ordinate.



The option to Hide DXF text can be used to toggle the display of grid labels if they start clashing with the rest of the model. The grid is displayed thus (Note curved lines are currently not imported):



The DXF grid operates as the other forms of grid in that when the **Snap Node/...** button is clicked, nodes can be created at the ends and intersections of grid lines.

The second import option is to Import Grids previously defined in another STAAD.Pro model. Selecting this option opens a browse dialog box to identify a GRD file created by the Snap Node Grid tool. Note that GRD files are only created by STAAD.Pro 2007 (or later).

Icons on the **Geometry** toolbar are:

 **Snap/Node Beam**

 **Snap/Node Triangular Plate**

 **Snap/Node Quadrilateral Plate**

AD.2007-1001.1.3 Fly-out Toolbars

The amount of screen space occupied by a number of toolbar icons has been recovered by collapsing a number of similar icons into a single icon.

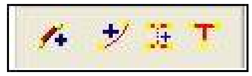
The active icon can be changed by holding down the left mouse button when clicking on the button. Icons that have this property are identified with a black triangle in their lower right corner:

There are four Geometry Toolbar icons that have this propery:

- Add Beam
- Add Plate
- Add Solid

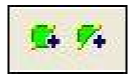
- Snap Node Grid

The **Add Beam** icon supports four commands:



- Add Beam from Node to Node
- Add Curved Beam
- Add Beam Between Mid Points
- Add Beam Using Perpendicular Intersection

The **Add Plate** icon supports two commands:

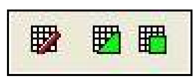


- Add Quadrilateral Plate
- Add Triangular Plate

The **Add Solid** icon supports five commands:

- Add 8 Noded Solid
- Add 7 Noded Solid
- Add 6 Noded Solid
- Add 5 Noded Solid
- Add 4 Noded Solid

The **Snap Node Grid** icon supports three icons:



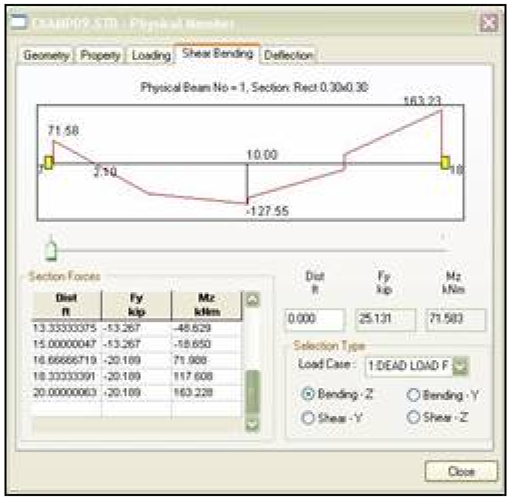
- Snap Node Beam
- Snap Node Quadrilateral Plate
- Snap Node Triangular Plate

AD.2007-1001.1.4 Physical Member Query

The addition of the Physical Member to the range of objects supported by STAAD.Pro requires that there is access to a query tool to get information about the Physical Member.

To access information on a Physical Member, use the **Physical Member Selection** Tool  to highlight the required object and then select the menu option: **Tools** > **Query** > **Physical Member**

to highlight the required object and then select the menu option:



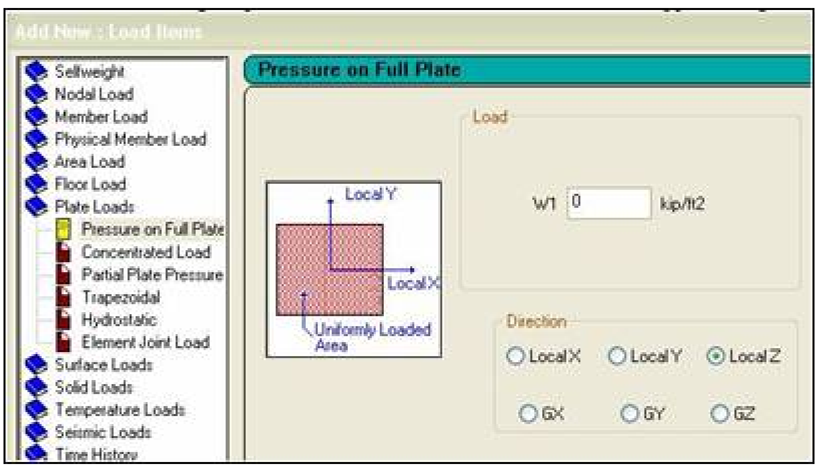
This dialog box can also be accessed from

- Double clicking on a physical member with the **Physical Member Cursor**
- Selecting the physical member, right-clicking and selecting **Properties...** from the pop up menu.

AD.2007-1001.1.5 In-Plane Area Loads on Plates

STAAD.Pro can now apply plate loads in the local X and Y directions to represent in plane friction loads.

As shown in the next figure, pressure on the full element can now be applied along local X and Y axes.



Thus a -2 kip/ft^2 load applied to an element that is 3 ft^2 will result in -6 kips being applied in the plane of the element.

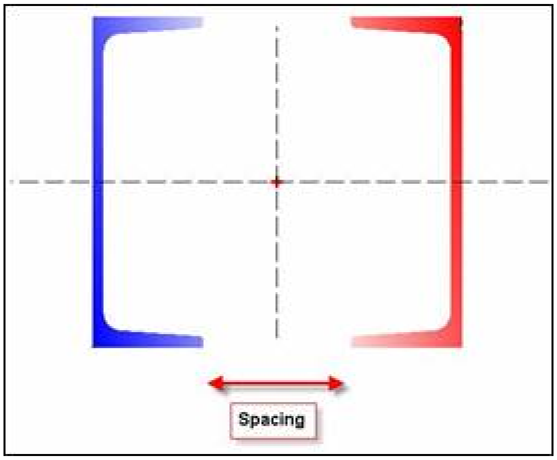
This applies only to Pressure on Full Plate.

Related Links

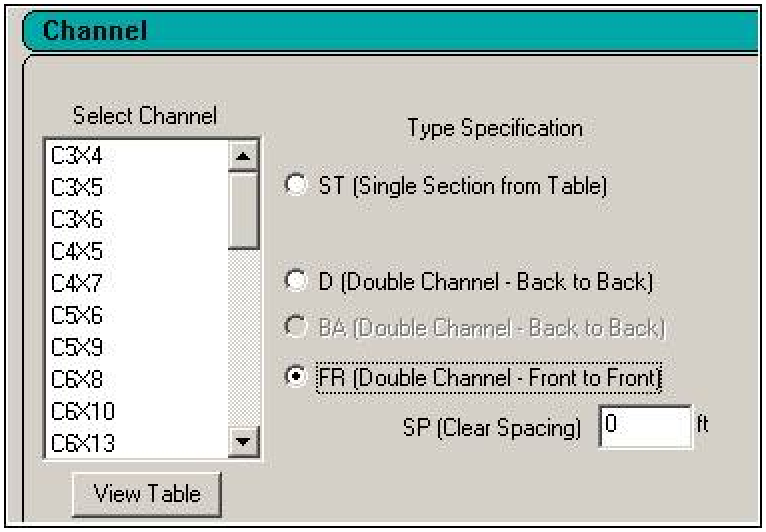
- *TR.32.4.1 Area Load Specification* (on page 2476)

AD.2007-1001.1.6 Front-to-Front Channels

STAAD.Pro has been enhanced to support the definition of steel channel sections being defined in an arrangement with the toes pointing to each other with a given spacing.



Front to front channel steel sections can be defined in the Properties dialog box by selecting the required channel section and choosing the **FR (Double Channel – Front to Front)** option and any spacing required between the channels.



The command that appears in the STAAD.Pro STD data file is:

```
<Member List> TABLE FR C4X5 SP 0.5
```

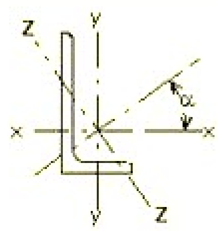
Note: The SP parameter is optional, but if it is not set, the section will *not* be assumed to be a closed box for torsional calculations.

AD.2007-1001.1.7 Automatic Property Calculations for User-Provided Table Angle Sections

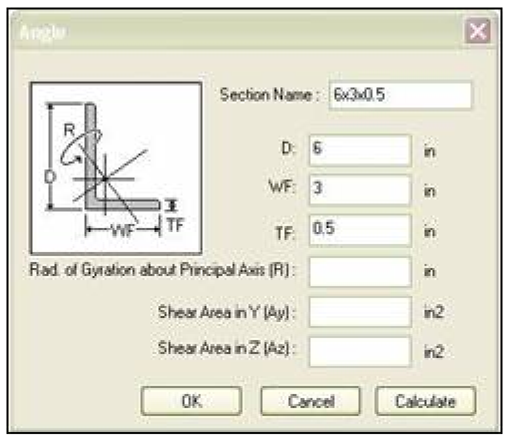
User-Provided Tables (UPTs) of Angle sections require section properties that can now be calculated when the section dimensions have been defined.

Angle Section UPTs require the following data to be entered for each section:

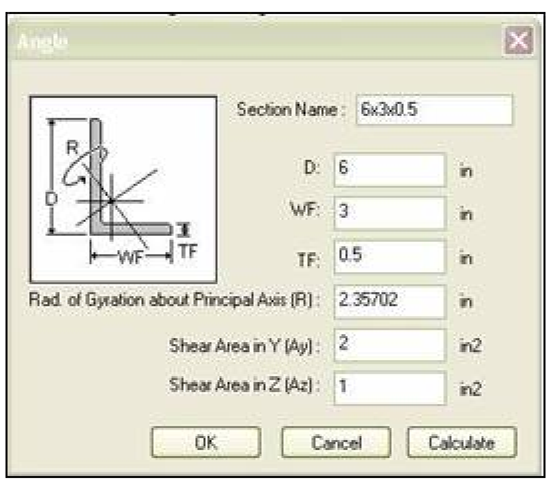
1. **D, Depth of angle**
2. **WF, Width of angle**
3. **TF, Thickness of flanges**
4. R, radius of gyration about principal axis, shown as r(Z-Z) in the AISC manual (see below). This must not be set to zero.
5. AY, Shear area long Y axis
6. AZ, Shear area along Z axis



Define the dimensions of the angle (shown in bold above):



Then click on the **Calculate** button to have STAAD.Pro calculate the remaining properties provided:



Note: When these sections are added to a STAAD.Pro model, the angle will be oriented such that the Z-Z axis as defined in the AISC manual will align with the local Z axis.

AD.2007-1001.1.8 Consolidation of Multiple Property References

When a STAAD file has a number of references of the same property, there is now a tool to consolidate all these properties into a single command.

STAAD models that have the same property defined multiple times can be consolidated by clicking on the new menu item, **Tools** > **Merge Properties**.

A warning is given and thus an opportunity to cancel the property collation if not required or selected by mistake.

All instances of a given section property will be collated into a single property reference.

Notes:

- Properties references with differing additional parameters will not be collated.
- Properties references with differing assigned material properties will not be collated.

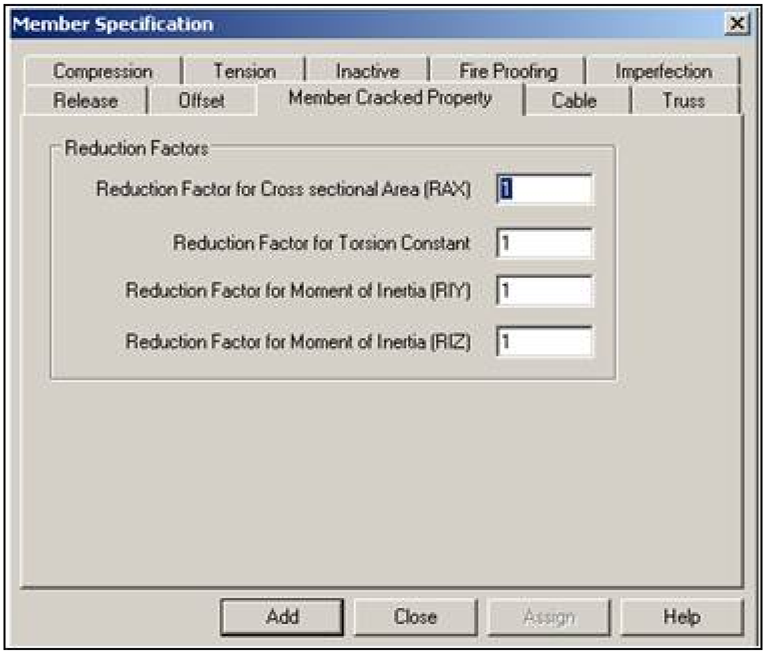
AD.2007-1001.1.9 Section Property Reduction in Analysis to Account for Cracking

Concrete design specifications recommend the use of cracked section properties for the analysis and design of concrete sections. Though the methodology to handle cracked section properties is non-linear in nature, i.e. the section capacities should be checked and modified depending upon the section forces the section is handling. The model should then be re-analyzed with modified reduced section properties and redesigned. This iteration should be continued until the forces in all sections designed are below the allowable limit of ultimate strength.

In STAAD.Pro this approach has been simplified as per the recommendations in the ACI-318: 2005 standard which suggests a user input of reduction factors for the individual members. Section 10.11.1 of ACI-318 has provided a list of suggested reduction factors of section properties dependent upon the nature of stresses the member is subjected to.

An additional sheet has been added to the Beam Specifications dialog to allow the reduction of section properties for analysis to be created and assigned. The method is identical to that for creating any other beam specification.

The Specifications dialog can be accessed from the **General | Specifications Page** in the Modeling Mode:



The reduction factor should be a fraction of unity; hence a factor of 0.5 defined for RAX will reduce a defined cross sectional area of 0.5 ft^2 to 0.25 ft^2.

The format of the command that is generated in the STAAD.Pro STD file is:

```
MEMBER CRACKED
<Member List> REDUCTION { RAX | RIX | RIY | RIZ} factor
```

Multiple factors can be assigned on the same line

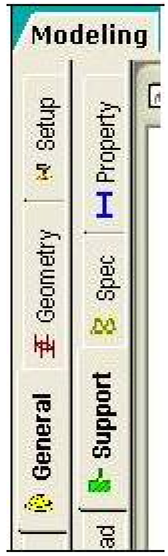
Note: The reduction factor is considered only for analysis but not for design.

AD.2007-1001.1.10 Tension/Compression-Only Spring Support

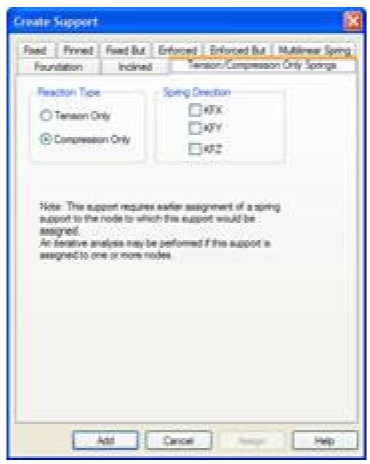
STAAD.Pro can now graphically define spring supports that are to allow tension only or compression only forces.

The Tension/Compression Only Support command is created from the **Supports** dialog box.

The **Supports** dialog can be accessed from the **General | Support** page in the Modeling mode.



Click on the **Create** button and select the **Tension/Compression Only Spring** sheet thus



The selection of Reaction Type indicates that if, after any of the cycles of analysis, the direction of the force in the spring is of the wrong 'type', then the support will be removed from that direction and a new analysis performed.

Reaction Type	Tension Only	Compression Only
Support will remain if the reaction is	- ve	+ ve
Support will be removed and a new analysis flagged if the reaction is	+ ve	- ve

This support definition should be either 'added' to the Supports dialog (by clicking on the **Add** button) or assigned to the currently selected nodes (by clicking on the **Assign** button) that have previously been assigned with spring supports. If the support is not assigned as it is created, it can be assigned later from the Support dialog. However, note that if it is not assigned to at least one spring support when STAAD.Pro is closed, then the definition will not be saved in the STD file.

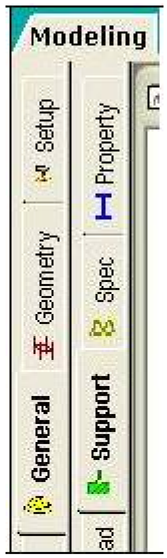
AD.2007-1001.1.11 Enhanced Elastic Mat Plate Mat Options

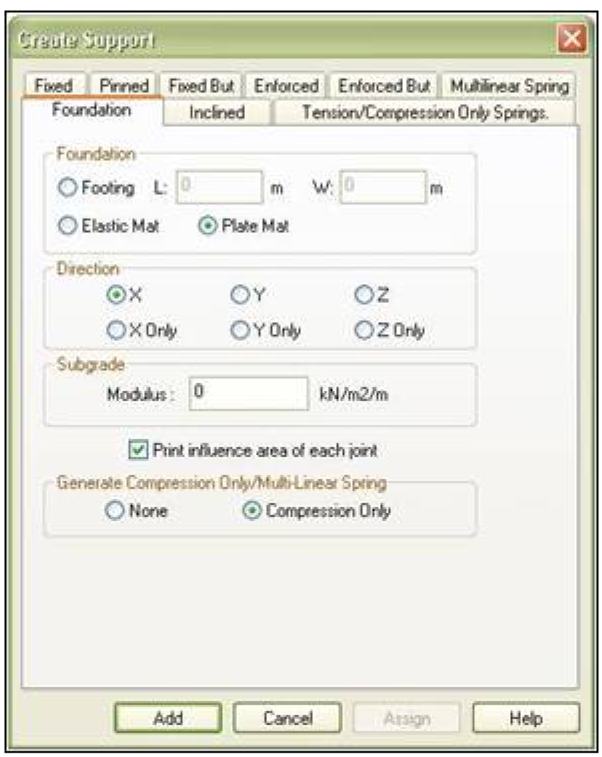
The Elastic Mat and Plate Mat commands can be set to behave as compression only springs and include the influence area that each node has been subjected to in the ANL output file.

In order to allow Elastic Mat and Plate Mat commands to perform as compression only supports to model lift of support situations, the command has been enhanced with an additional parameter which can be set graphically from the command definition.

The Elastic Mat and Plate Mat commands are created from the Foundation sheet in the **Supports** dialog box.

The **Supports** dialog can be accessed from the **General | Support** page in the Modeling mode.





When the Compression Only option is set, then if after any of the cycles of analysis, the force at a node included in the command range (in the elastic mat range or used to define a plate in the plate mat range) is found to be tensile (i.e., negative reaction), then the load case is marked for a re-analysis with that support removed.

There is also a new option to include in the output file, the area that has been used in the calculation of the spring stiffness of each joint used when defining a Plate Mat or Elastic Mat command.

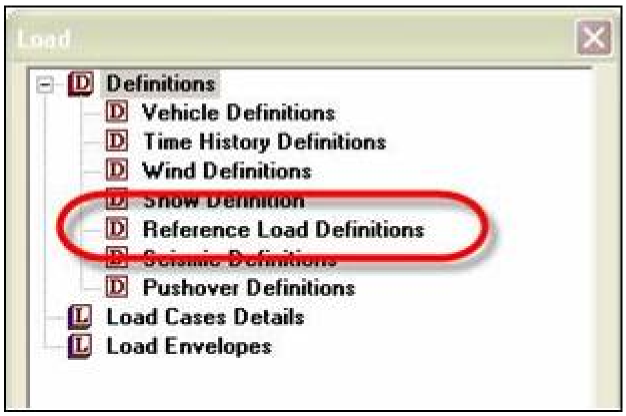
Related Links

- *TR.27.3 Automatic Spring Support Generator for Foundations* (on page 2319)

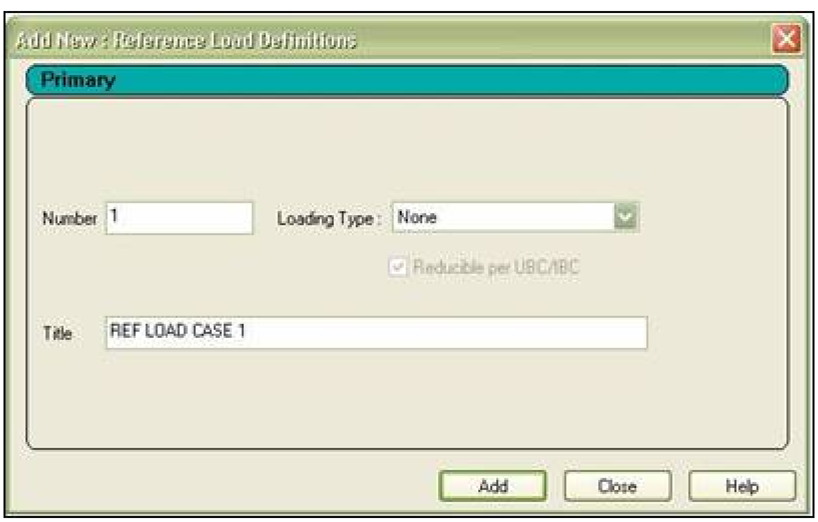
AD.2007-1001.1.12 Reference Load Cases

Large models can include multiple load cases which do not require analysis in their own right and are simply the building blocks for inclusion in primary load cases. This is similar to a `REPEAT LOAD` command, but has the added benefit of not being solved in its own right.

A reference load case is listed in the Load dialog box of the General Load Page of the modeling mode. A Reference load case is listed in the Definitions section of the data file and displayed thus:

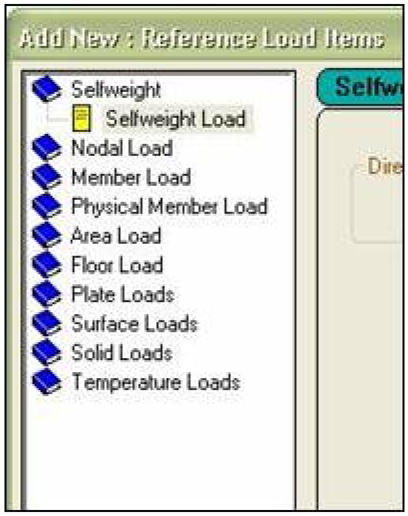


To add a new Reference load case, highlight the **Reference Load Definitions** in the **Load** dialog and click on the **Add** button. Provide the title for the load case and number (however, similar to that of creating Primary load cases, the next available reference load case number. Note that these reference load case numbers can be the same as a primary or combination load case number (however a combination load case number cannot be the same as a primary load case number).



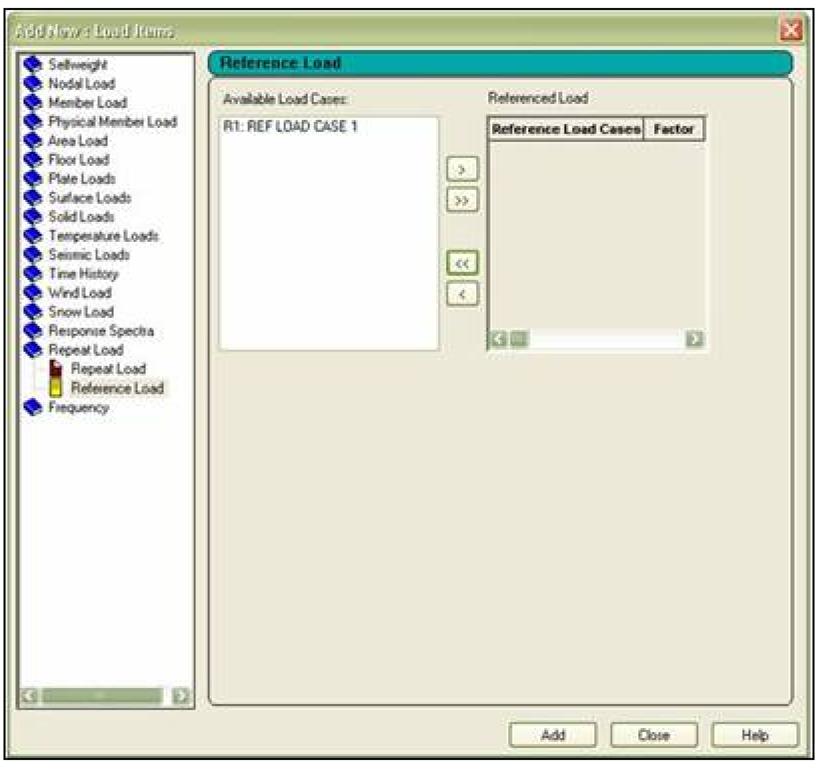
The Reference load case names are shown in the **Load** dialog box. Load items should then be added to this load case in exactly the same way as adding load items into a primary load case.

Select the Reference load case and click on the **Add** button to display all the load items that can be added to this load case, thus:



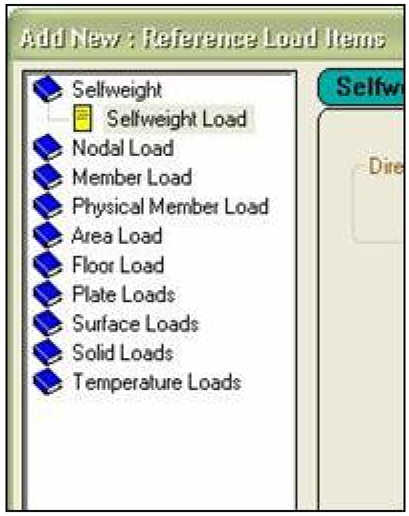
To be analyzed, the loads defined in a Reference load case must be added to one or more Primary load cases. This is done by selecting the required primary load case and clicking on the **Add** button.

Select the load item **Repeat Load** > **Reference Load**:



Select the required defined Reference load cases and click on the **[>]** button to select them for inclusion in the current load case. The **>>** button will select all defined Reference Load cases.

These are added with a factor of 1.0, however, each can be modified with its own specific multiplication factor:



The format of the definition of a Reference Load (i) in the data file is thus:

```
DEFINE REFERENCE LOADS
LOAD R(i) LOADTYPE (type)  TITLE REF LOAD CASE 1
(Load items)
…
END DEFINE REFERENCE LOADS
```

The format of a reference to a Reference Load in a primary load (j) case is thus:

```
LOAD (j) LOADTYPE (type) TITLE LOAD CASE 1
REFERENCE LOAD
R(i) 1.0
…
```

Related Links

- *Repeat Load tab* (on page 2863)

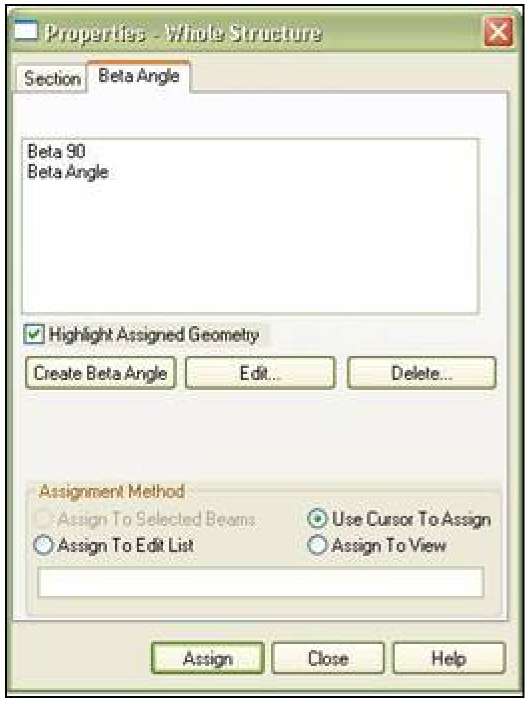
- *M. To create a reference load* (on page 893)

AD.2007-1001.1.13 Enhanced Beta Angle Definition and Assignment

Assigning beta angles on members has been improved visually by displaying the commands that are stored in the STAAD data file, making them easier to manage.

Beta angle definitions are created and listed in the Beta Angle sheet of the Property dialog box. Each new command is listed in the dialog as shown below and can be assigned using the assignment methods commonly used throughout STAAD.Pro:



The creation of beta angle commands includes three options:

1. Define specific angle to rotate the beams about their local X axis.
2. Specify the command 'Angle'(*)
3. Specify the command 'RAngle' (*)

(*) The Angle and RAngle commands are specifically for equal and unequal angle sections. All sections are aligned with their principal axes aligned with the global axes, however, angle sections are often required to align their flanges with the global axes. By assigning either the Angle or RAngle command, the section will be rotated to align the flanges. For more information, see TR.26.2 Specifying Constants for Members and Elements (on page 2305).

Related Links

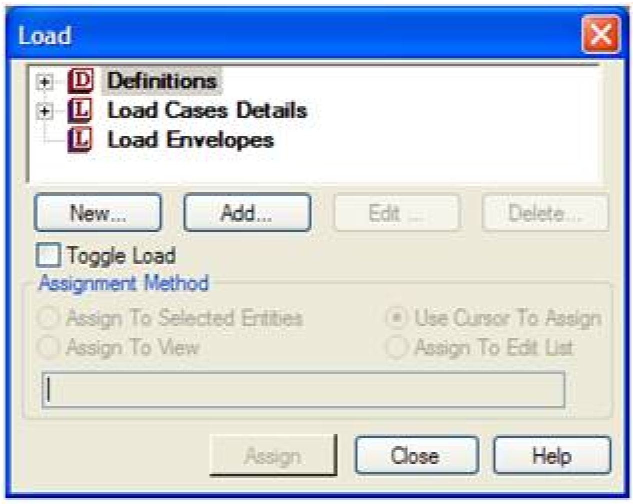
- *TR.26.2 Specifying Constants for Members and Elements* (on page 2305)

AD.2007-1001.1.14 IBC 2006 Equivelant Lateral Force Procedure

The static equivalent method for performing dynamic analysis per the IBC 2006 code has been implemented in STAAD.Pro 2007 Build 02.

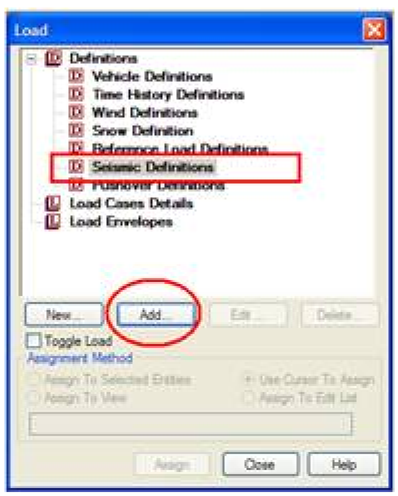
This option can be accessed from the **General | Load** page as explained below.

When the **General | Load** Page is selected, the right hand side of the screen will display the following if no load cases exist in the model.



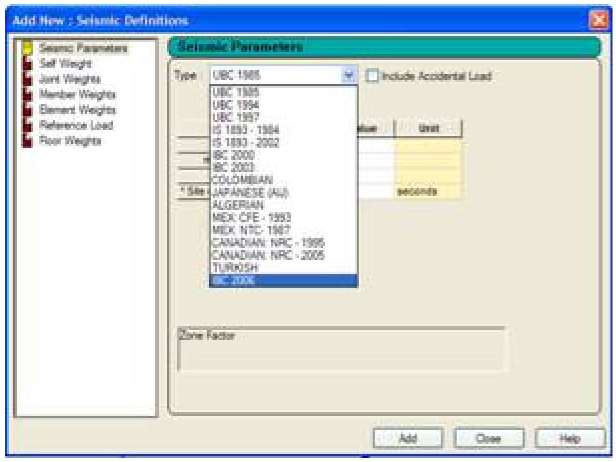
Definitions contains the options through which one creates the “Define” block of data required to create wind load cases, seismic load cases like IBC and UBC, moving load cases and time history load cases.

When the tree view is expanded, it will look as shown below.

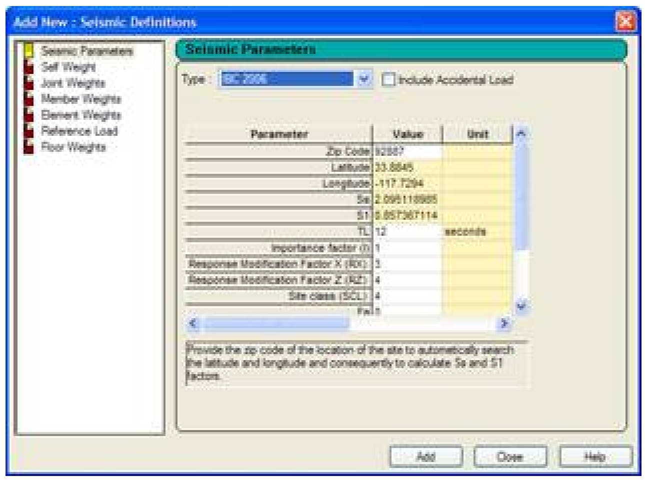


Select Seismic Definitions and click on **Add.**

In the dialog box that comes up, select IBC 2006 from the drop-down list.



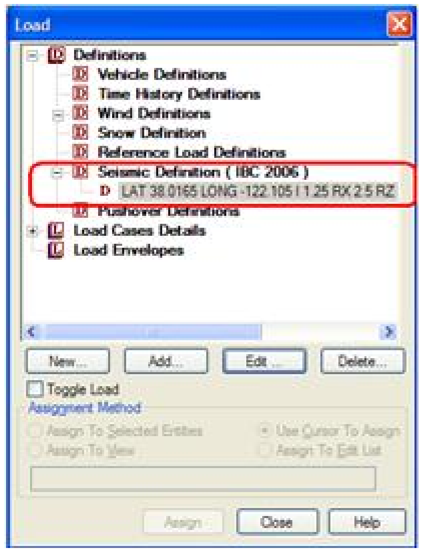
In this dialog box, we can specify the various parameters as described below.



Include Accidental Torsion	Check this box to calculate the accidental torsion component described in section 12.8.4.2 of ASCE 7-05.
Parameter	The various parameters for the IBC 2006 code, such as the Occupancy Importance factor IE, Response modification factors RX and RZ, spectral response accelerations SDS, SD1 and S1, etc., are described in detail in TR.31.2.14 IBC 2006/2009 Seismic Load Definition (on page 2405).

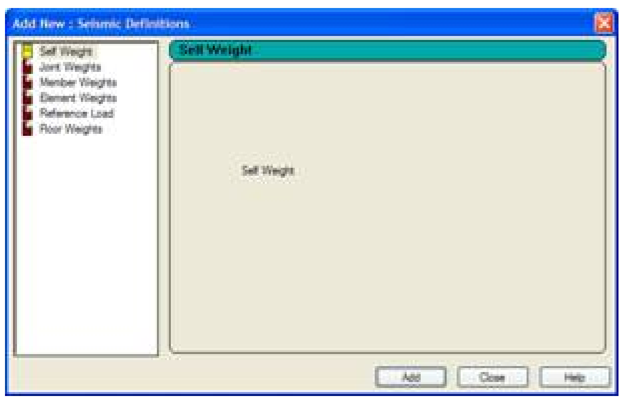
After specifying the values for the parameters, click on the **Add** button.

We will see that the Load dialog box has now been updated.



Next, we should define the structural weights for calculating Base Shear.

After highlighting the expression **LAT 38.0165……**, click on **Add**. A new dialog box titled **Add New Seismic Definitions** will come up.



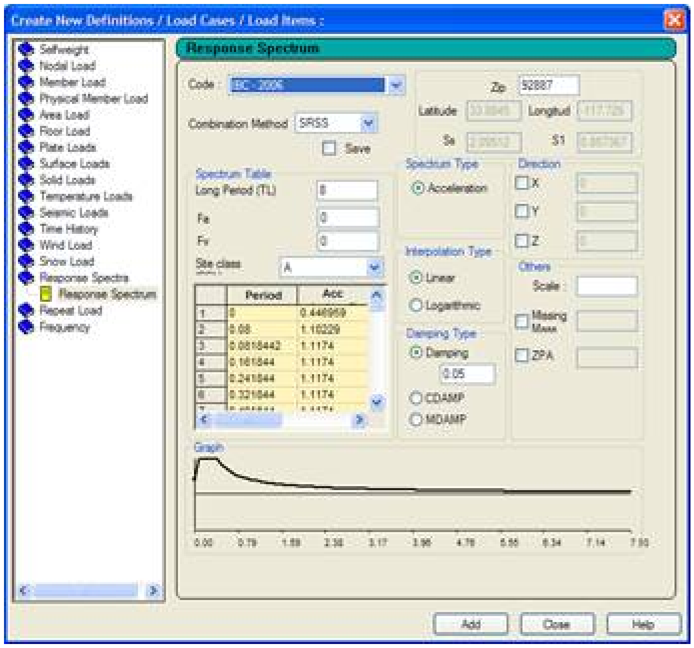
Related Links

- *M. To add a seismic load definition* (on page 857)

AD.2007-1001.1.15 IBC 2006 Response Spectrum Specification GUI

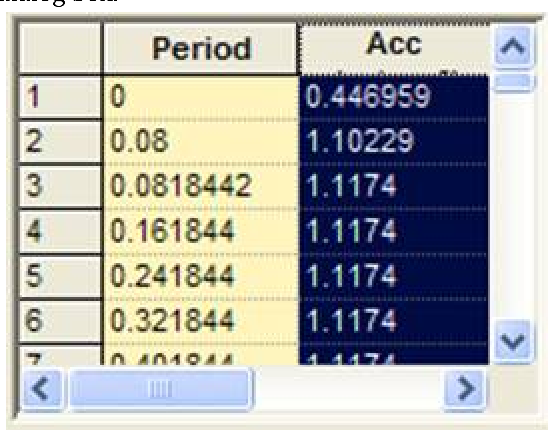
This tab allows the user to apply response spectrum loads on the structure.

This option can also be accessed from the **General | Load** page.



Period vs. Acceleration

Provide the values of period (seconds) and corresponding acceleration (current length units/sec^2) or displacement (current length unit). Spectrum pairs should be provided in ascending value of period. As we provide the curve points, the program displays the curve at the bottom of the dialog box.



Related Links

- *M. To add an IBC 2006 response spectrum* (on page 866)

AD.2007-1001.2 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

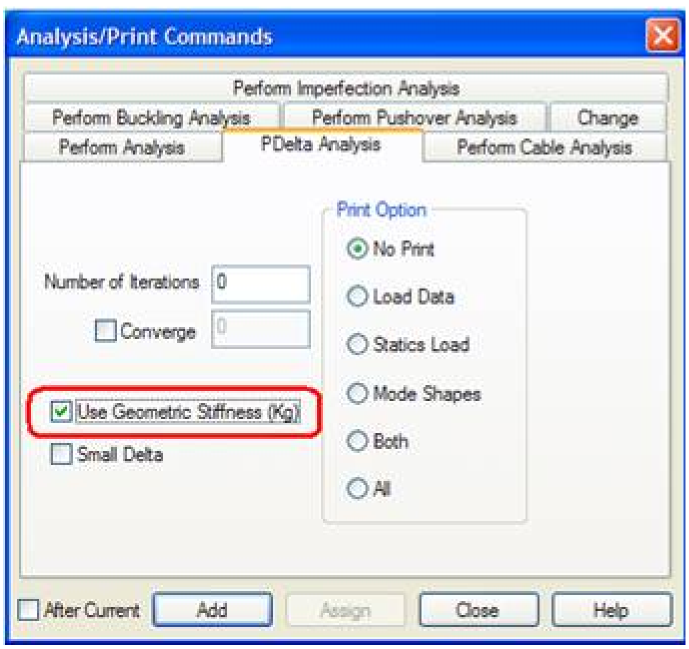
AD.2007-1001.2.1 P-Delta Analysis Including Stiffening Effect of the KG Matrix

The P-Delta analysis capability has been enhanced with the option of including the stress stiffening effect of the Kg matrix into the member / plate stiffness.

A regular STAAD P-Delta Analysis performs a first order linear analysis and obtains a set of joint forces from member/plates based on the large P-Delta effect. These forces are added to the original load vector. A second analysis is then performed on this updated load vector (5 to 10 iterations will usually be sufficient).

In the new P-Delta KG Analysis, that is, with the Kg option selected, the effect of the axial stress after the first analysis is used to modify the stiffness of the member/plates. A second analysis is then performed using the original load vector. Large & small P-Delta effects are always included (1 or 2 iterations will usually be sufficient).

The KG option is activated by selecting the option on the P-Delta Analysis dialog thus:



Related Links

- *A. To specify a P-Delta analysis* (on page 952)

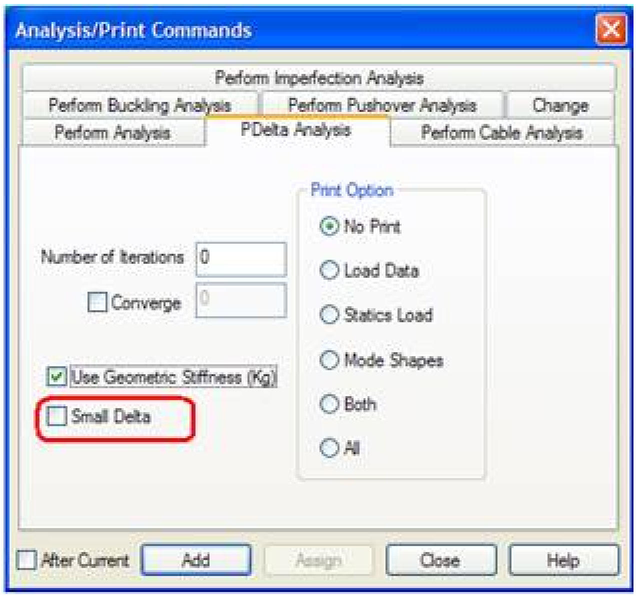
AD.2007-1001.2.2 P-Delta Analysis Including Small Delta

A regular STAAD P-Delta Analysis can now account for the small P-Delta effect whilst performing a P-Delta analysis

Without the Small Delta option, i.e. a regular STAAD P-Delta analysis, STAAD performs a first order linear analysis and obtains a set of joint forces, from members/plates based on the large P-Delta effect, which are then added to the original load vector. A second analysis is then performed on this updated load vector.

With the Small Delta option selected, both the large & small P-Delta effects are included in calculating the end forces, (5 to 10 iterations will usually be sufficient).

The option is activated by selecting the option on the P-Delta Analysis dialog thus:



Related Links

- *A. To specify a P-Delta analysis* (on page 952)

AD.2007-1001.2.3 Buckling Load Analysis

STAAD.Pro can now identify the factor by which the loads in the selected load case should be increased (or decreased if less than 1) such that Euler buckling would occur.

Two methods have been introduced to do buckling analysis. One method is introduced in the standard solver, the other in the advanced solver, as described below.

Related Links

- *A. To specify buckling analysis* (on page 957)

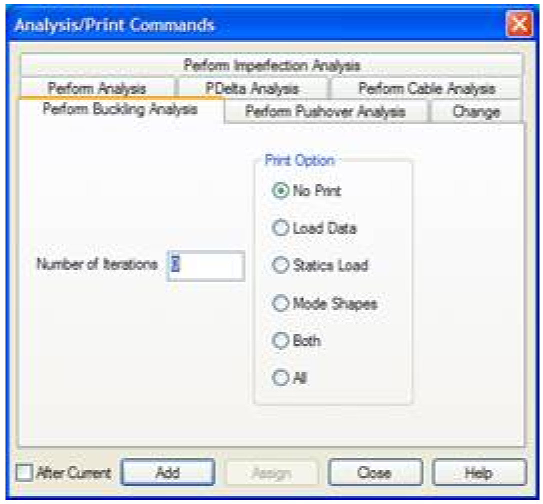
AD.2007-1001.2.3.1 Buckling Analysis Using the Basic Solver

Note: The Basic solver is deprecated as of STAAD.Pro CONNECT Edition V22 Update 4 (v22.04).

AD.2007-1001.2.3.2 Buckling Analysis Using the Advanced Solver

This buckling method is automatically activated if an Advanced Analysis license is available. When using the Advanced Solver, the corresponding “buckling modes” are included in the output file.

The option is activated using the new option in the **Analysis/Print** dialog thus:

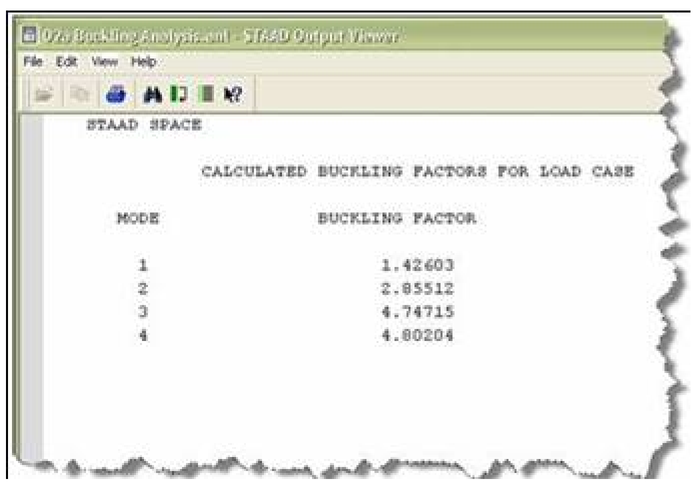


The program performs a P-Delta analysis including Kg Stiffening (geometric stiffness of members and plates) due to large and small P-Delta effects.

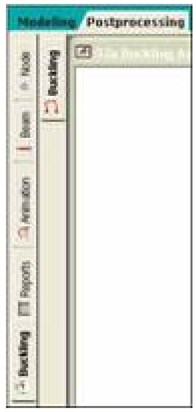
The eigensolution,

$$| [K] - BF [Kg] | = 0$$

is solved for the buckling factors and buckled mode shapes. The first 4 buckling factors and buckled shapes are calculated and included in the output file:



The buckling modes and shapes are available to be viewed in the Post Processing Mode in a new Buckling Page.



This page includes both a Buckling Factors table:

02a Buckling Analysis.std...

Mode	Buckling Factor
1	1.426
2	2.855
3	4.747
4	4.802

and a Buckling Modes table:

02a Buckling Analysis.std - Buckling Modes:

Node	Mode	X	Y	Z	rX	rY	rZ
1	1	0.000	0.000	0.000	0.000	0.000	0.000
	2	0.000	0.000	0.000	0.000	0.000	0.000
	3	0.000	0.000	0.000	0.000	0.000	0.000
	4	0.000	0.000	0.000	0.000	0.000	0.000
2	1	0.006	0.001	0.964	0.000	-0.000	-0.000
	2	0.001	0.001	-0.002	0.000	0.000	-0.000
	3	0.000	0.000	-0.000	0.000	-0.000	-0.000
	4	0.004	0.000	-0.008	0.000	-0.000	-0.000
3	1	0.006	0.000	0.985	0.000	-0.000	-0.000
	2	0.001	0.001	-0.009	0.000	0.000	-0.000
	3	0.000	-0.000	0.001	0.000	-0.000	-0.000
	4	0.004	-0.002	-0.002	-0.000	-0.000	-0.000
4	1	0.000	0.000	0.000	0.000	0.000	0.000
	2	0.000	0.000	0.000	0.000	0.000	0.000
	3	0.000	0.000	0.000	0.000	0.000	0.000

Only the primary load case just prior to the `PERFORM BUCKLING` command is used. The number of iterations entered is ignored. The buckling factor result is reported in the output file and in post processing.

AD.2007-1001.2.4 Modal Analysis Including Stress Stiffening Effect of KG Matrix

STAAD.Pro can include the stress stiffening effect (geometric stiffness) based on the axial member forces/plate in-plane stresses from a selected load case when calculating the modes & frequencies of a structure.

Position the selected load case from which the axial stresses are to be used to modify the stiffness matrix, such that it is the last static case before the dynamic case which is in turn immediately followed by a `PDELTA KG` command.

The dynamic load case should contain mass data followed by one of the following:

a. A `MODAL CALCULATION REQUESTED` command.
b. A response spectrum definition, i.e., set of `SPECTRUM` command data.
c. A reference to a time history definition, i.e., include `TIME LOAD` commands.
d. Valid Steady State data.

Example

```
...
LOAD 1 LOADTYPE None TITLE LOAD CASE 1
******* This is static loading case from which the “axial stress” is
******* used to compute the stress stiffening effects (P-Delta)
******* This case will be solved as a PDelta case with large & small
******* P-Delta effects
SELFWEIGHT Y -1.0
JOINT LOAD
2 3 6 7 9 TO 12 FY -3
LOAD 2 LOADTYPE None TITLE LOAD CASE 2
******* Enter masses in weight units
SELFWEIGHT X 1
SELFWEIGHT Y 1
SELFWEIGHT Z 1
JOINT LOAD
2 3 6 7 9 TO 12 FX 10 FY 10 FZ 10
******* Declare this to be a modes/freq analysis
******* Note that dynamic cases use the factored matrix from the last *******
load case; which is a (K+Kg) case
MODAL CALCULATION REQUESTED
PDELTA KG ANALYSIS
```

AD.2007-1001.2.5 Enhanced Control/Dependent Command Processing

The internal processing of any Control/Dependent command has been enhanced to allow an automatic bandwidth reduction to take place.

The analysis engine now performs a bandwidth reduction on files that include Control/Dependent commands which must occur in the input file after the definition of supports. In previous versions of STAAD.Pro, for the bandwidth reduction to take place, the data of Control/Dependent would need to be repeated before the support definitions. This requirement is now no longer required.

Note: Control / Dependent was formerly referred to as master / slave.

Related Links

- *TR.28.1 Control/Dependent Specification* (on page 2327)

AD.2007-1001.2.6 Advanced Solver

A new substantially faster analysis engine has been produced which can provide solutions of large structures in a fraction of the time currently required by the standard STAAD engine. The Advanced Solver generally uses less disk and memory as well.

The Advanced solver is a new addition to the STAAD Analysis Engine which can be used for solving both static and dynamic problems. It is part of the STAAD engine with no special command required to run it.

The engine can operate in two modes: *in-core* and *out-of-core*. The in-core solver will be used for models with under 20,000 joints and the out-of-core solver for models over 20,000 joints. In most situations, the in-core mode will provide the quickest solution, but where there is insufficient memory available, then the engine will use the out-of-core mode. Again, selection of the mode is automatically chosen by the analysis, but can be overridden using the `SET STAR` command.

The full set of overrides for the advanced engine is:

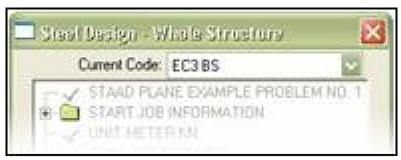
`SET STAR 3` – default
`SET STAR 4` – use out-of-core solver regardless of size

AD.2007-1001.2.7 Eurocode 3:2005

The latest UK release of *Eurocode 3: Design of steel structures – part 1-1: General Rules and rules for buildings* has been implemented.

This code is an update to our current Eurocode 3. The changes are minor and the code checking process remains the same as the previous Eurocode 3 design.

The design parameters are the same and apply as defined for the current Eurocode 3, the only exception, however, is the 'Code' parameter which must be set to 'EC3 BS'. This setting is available form the GUI list of codes.



Note that a design performed to the new Eurocode 3 standard is displayed in the output file (`*.ANL`) with the following header:

```
                       STAAD.PRO CODE CHECKING - (BS EN 1993-1-1:2005)
  **************************

 PROGRAM CODE REVISION V1.1 BS_EC3_2005/1
```

The equivalent header for a code check (or member selection) to the older standard is displayed thus:

```
              STAAD.PRO CODE CHECKING - (DD ENV)
  ***********************

  PROGRAM CODE REVISION V1.14_EC3_94/1
```

AD.2007-1001.2.8 IBC 2006 Equivalent Lateral Force Procedure – Syntax for the Command File

In AD.2007-1001.1.14 IBC 2006 Equivelant Lateral Force Procedure (on page 294), the graphical screens containing the implementation of the seismic loading chapters of the IBC 2006 and ASCE 7-05 codes were presented.

Related Links

- *M. To add a seismic load definition* (on page 857)

AD.2007-1001.2.9 Response Spectrum Specification in Accordance with IBC 2006 - Syntax for the Command File

This command may be used to specify and apply the `RESPONSE SPECTRUM` loading as per the 2006 edition of the ICC specification “International Building Code (IBC),” for dynamic analysis. The graph of frequency–acceleration pairs are calculated based on the input requirements of the command and as defined in the code.

Related Links

- *TR.32.10.1.10 Response Spectrum Specification per IBC 2006* (on page 2561)
- *M. To add an IBC 2006 response spectrum* (on page 866)

AD.2007-1001.3 Features Affecting the Post-Processor (Results Mode)

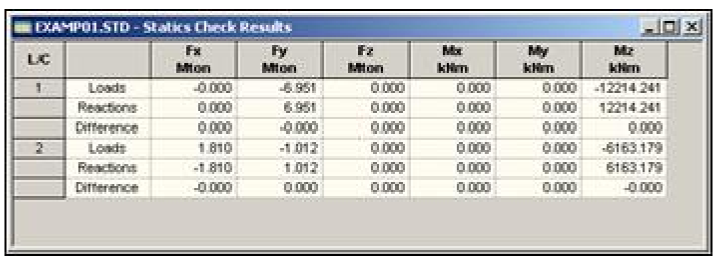
A new feature has been added to the post-processor section of the program, also known as the Results Mode. It is explained in the following pages.

AD.2007-1001.3.1 Statics Check Table

The equilibrium check that has been available in the output file is now automatically included in the Post Processing Mode.

The **Node | Reactions** Page has been enhanced with a new table that displays the results of an equilibrium check. This is the same information that in the past would have been only available by including a `PRINT STATICS CHECK` in the perform analysis command.

The **Statics Check Results** table can be accessed from the **Nodes | Reactions** page in the Post-Processing mode.



EXAMP01.STD - Statics Check Results

L/C		Fx Mton	Fy Mton	Fz Mton	Mx kNm	My kNm	Mz kNm
1	Loads	-0.000	-6.951	0.000	0.000	0.000	-12214.241
	Reactions	0.000	6.951	0.000	0.000	0.000	12214.241
	Difference	0.000	-0.000	0.000	0.000	0.000	0.000
2	Loads	1.810	-1.012	0.000	0.000	0.000	-6163.179
	Reactions	-1.810	1.012	0.000	0.000	0.000	6163.179
	Difference	-0.000	0.000	0.000	0.000	0.000	-0.000

AD.2007-1001.4 Features Affecting the Concrete Design Mode

The enhancement made in the RC Designer section of the program, also known as the Concrete Mode, is explained in the following pages.

AD.2007-1001.4.1 Beam and Column Designs to the Russian Concrete Code SP52

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2007-1001.5 Features Affecting the Connection Design Mode

A new mode has been added that allows quick design of connections using the RAM Connection application. This is displayed on the Modes toolbar with the above icon.

Full use of the RAM Connection Mode requires access to a valid RAM Connection license. If you do not possess a license, contact your Bentley account manager to have it added to your SELECT licenses. Without a valid license, only a small subset of the full range of available RAM connections can be utilized.

AD.2007-1001.5.1 RAM Connection Design Mode

There is now a new mode in STAAD.Pro to dynamically link structural model data, including section properties and analysis results, to the RAM Connection application to check connection designs for code compliance. The resulting data and diagrams of the connection can also be included in the User Report.

Connections are designed in the RAM Connection Mode by creating 'Joints', from the geometry, section properties and forces resulting from the analysis and assigning a 'Design Brief' of connection templates from which a suitable connection, where available, is reported.

Refer to the D. Connection Design workflow (on page 1014) for current details on this feature.

AD.2007-1001.6 Features Affecting the Piping Mode

Several new features have been added and existing features have been modified in the pre-processor section of the program, also known as the Piping Mode. These are explained in the following pages.

AD.2007-1001.6.1 Persistency of Pipe Models

When a pipe model is loaded in the Piping Mode, the location of the data is retained along with the connections defined in the Supports Page. Thus, if STAAD.Pro is closed and re-opened, it is no longer necessary to redefine the pipe model or the support relationships.

This feature is an enhancement of the functionality of the Piping Mode.

STAAD.Pro 2006 Release Reports

The Software Release Report for STAAD.Pro 2006 contains detailed information on additions and changes that have been implemented since the final build of STAAD.Pro 2005. This document should be read in conjunction with all other STAAD.Pro manuals.

STAAD.Pro 2006 Build 1004 Release Report

The Software Release Report for STAAD.Pro 2006 Build 1004 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2006 build 1002. This document should be read in conjunction with all other STAAD.Pro help.

AD.2006-1004.1 Features Affecting the Pre-Processor (Modeling Mode)

Several new features have been added and existing features have been modified in the pre-processor section of the program, also known as the Modelling Mode. These are explained in the following pages.

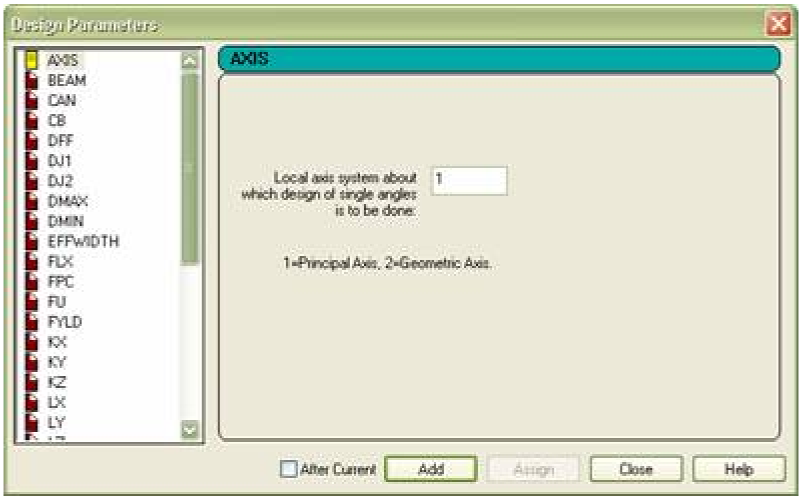
AD.2006-1004.1.1 New AISC Unified Code

A new steel design code module has been added to STAAD.Pro, which allows steel beam sections to be designed to the rules defined in AISC specification, *Specification for Steel Buildings*, March 9 2005, ANSI/AISC 360-05. This is also referred to as the AISC Unified Code. The GUI has been updated to allow you to enter the design information for this new design code.

To perform a design of steel sections to the AISC Unified Code, a design parameter block containing the command `CODE AISC UNIFIED` followed by the command to perform a `CODE CHECK` or `MEMBER SELECTION` must be added to the STAAD.Pro data file.

The GUI has been updated by adding **AISC UNIFIED** in the Steel Design dialog:

When this design code option is selected, clicking on the **Define Parameters** button at the base of the dialog box will in turn open the Design Parameters dialog that will allow parameters to be added or added and assigned to specific steel members.



Note: Design to this module is only possible if your security allows design to US design codes.

Related Links

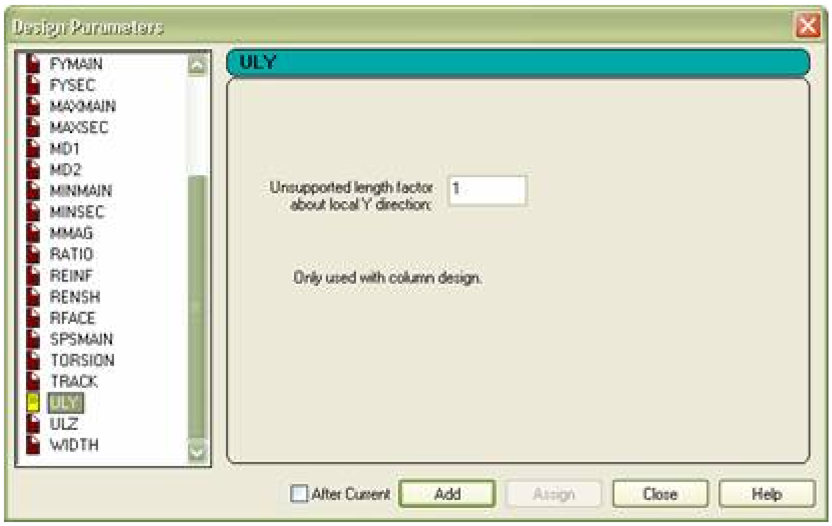
- *D1.A. American Codes - Steel Design per AISC 360 Unified Specification* (on page 1086)

AD.2006-1004.1.2 Update Indian IS 456 Concrete Code

Two new parameters have been added to the IS 456 design code to assist in the design of concrete columns. ULY and ULZ are used to define the ratio of unsupported to actual column length about the local Y and Z axes.

To include the design parameters for a IS456 design check, click on the Design, Concrete Page, and select IS456 from the drop-down list in the concrete design dialog.

When this design code option is selected, clicking on the **Define Parameters** button at the base of the dialog box will in turn open the Design Parameters dialog that will allow parameters to be added or added and assigned to specific steel members.



The definition of the parameters and their default values are as defined below:

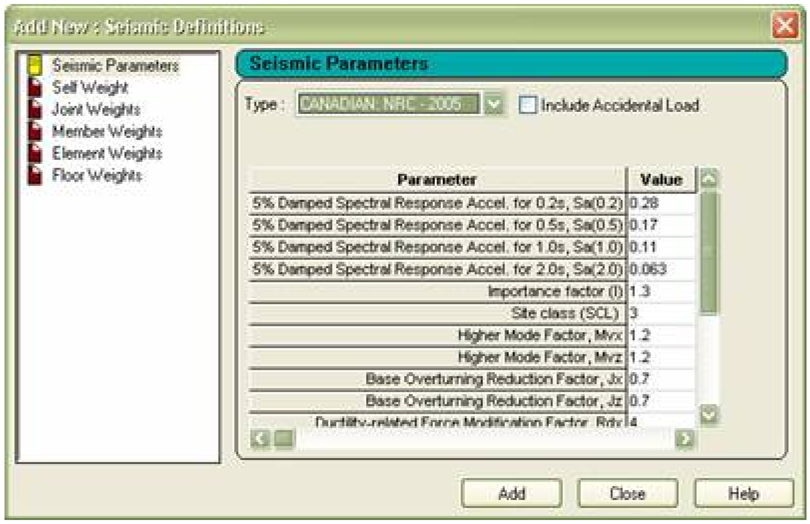
Parameter	Default Value	Description
ULY	1.0	Ratio of unsupported length to actual length of column about minor axis.
ULZ	1.0	Ratio of unsupported length to actual length of column about major axis.

AD.2006-1004.1.3 New NRC 2005 Seismic Code

A new seismic definition module has been added to the STAAD.Pro Loading Definitions.
This is to provide the user a tool to calculate and distribute the equivalent static loads produced by an earthquake that should be considered in a building as defined in the 'National Building Code of Canada 2005 – Volume 1', Section 4.1.8. This is also known as the NRC 2005 Seismic provisions.

This option has been added to be in addition to the previously available 1995 version of the code.

The NRC 2005 seismic provisions can be added using the **Seismic Definitions** dialog from the Definitions option in the main Load dialog box and selecting **CANADIAN NRC – 2005** from the type pull-down list.



Once all the required values for the parameters have been defined, then clicking on the **Add** button will add the data to the model such that it is ready to be used in seismic load cases.

For full details of the command structure for the NRC 2005 parameters see TR.31.2.3 Canadian Seismic Code (NRC) – 2005 Volume 1 (on page 2358).

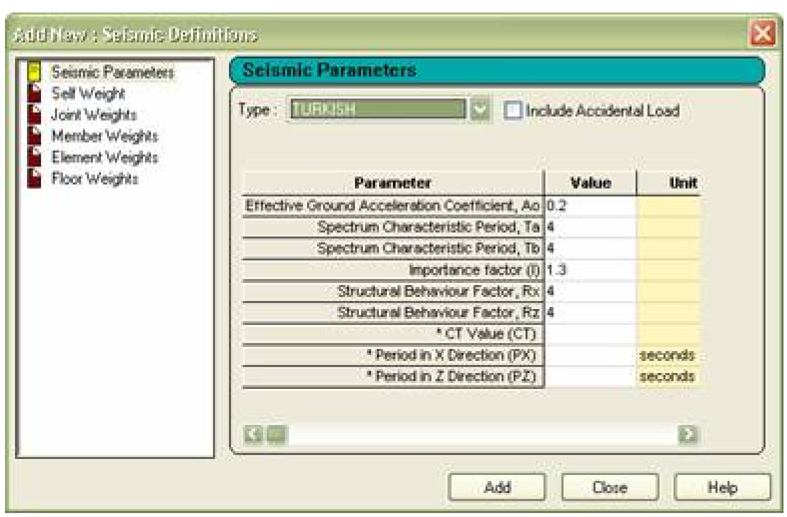
Related Links

- *TR.31.2.3 Canadian Seismic Code (NRC) – 2005 Volume 1* (on page 2358)

AD.2006-1004.1.4 New Turkish Seismic Code

A new seismic definition module has been added to the STAAD.Pro Loading Definitions. This is to provide the user a tool to calculate and distribute the equivalent static loads produced by an earthquake that should be considered in a building as defined in the '*Specifications for Structures to be Built in Disaster Areas. Part III – Earthquake Disaster Prevention. Amended on 2.7.1998, Official Gazette No. 23390 (English Translation)*'. This is referred to as the Turkish Seismic Provisions.

The Turkish seismic provisions can be added using the Seismic Definitions dialog from the Definitions option in the main Load dialog box and selecting **TURKISH** from the type pull-down list.



Once all the required values for the parameters have been defined, then clicking on the **Add** button will add the data to the model such that it is ready to be used in seismic load cases.

For full details of the Turkish seismic load command structure see TR.31.2.21 Turkish Seismic Code (on page 2426).

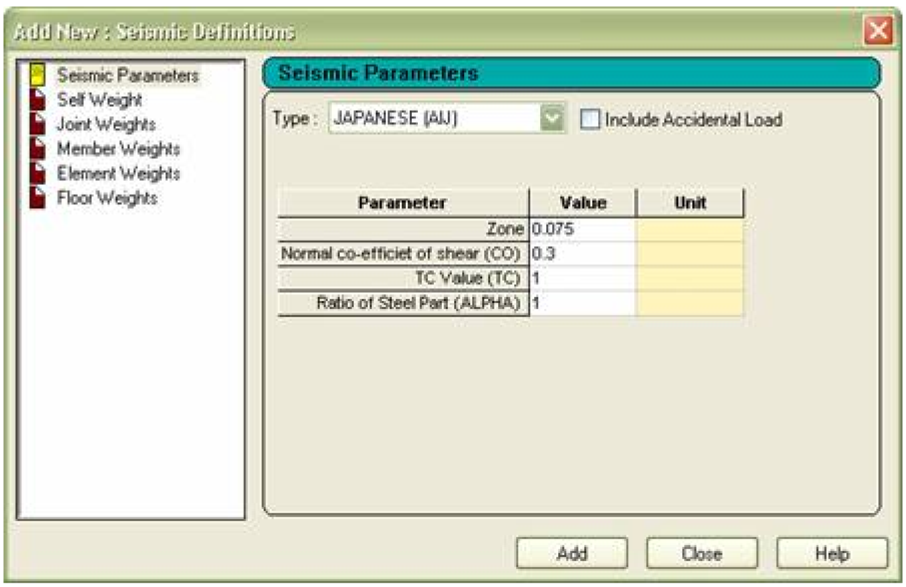
Related Links

- *TR.31.2.21 Turkish Seismic Code* (on page 2426)

AD.2006-1004.1.5 Update Japanese Seismic Definition

The current version of the Japanese Seismic Loading Definition has been enhanced to allow the user to specify a value of 'α (alpha)' which is the ratio of frame height to the overall building height which previously been set to 0.8 and not possible for the user to change.

The Japanese seismic provisions can be added using the Seismic Definitions dialog from the Definitions option in the main Load dialog box and selecting **Japanese (AIJ)** from the Type pull-down list.



Once all the required values for the parameters have been defined, then clicking on the **Add** button will add the data to the model such that it is ready to be used in seismic load cases.

Note: The implementation of the Japanese Seismic Definition is as per Article 88 in the 'Building Codes Enforcement Ordinance 2006.'

For full details of the Japanese seismic load command structure see TR.31.2.18 Japanese Seismic Load (on page 2418).

Related Links

- *TR.31.2.18 Japanese Seismic Load* (on page 2418)

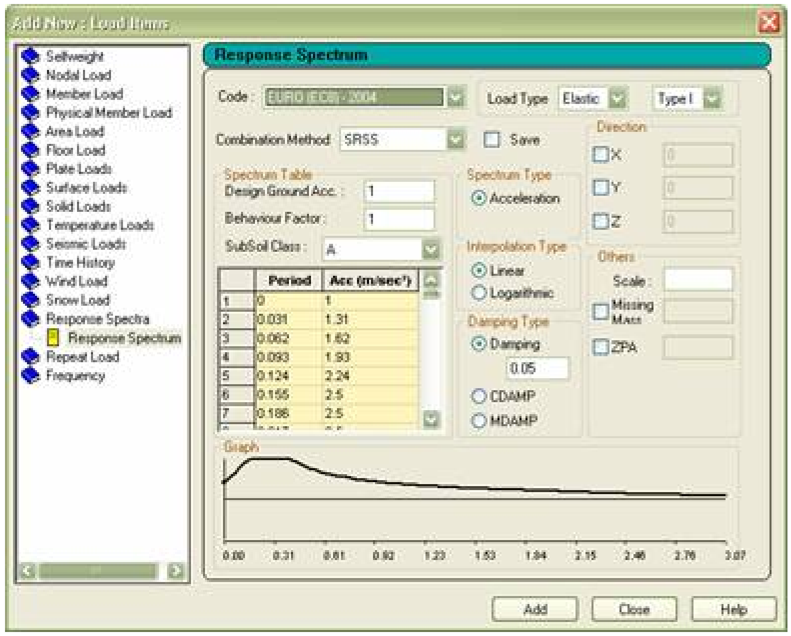
AD.2006-1004.1.6 New Eurocode 8 Response Spectrum

A new response spectrum specification has been added to STAAD.Pro, 'Eurocode 8. Design of structures for earthquake resistance'. General rules, seismic actions and rules for buildings', BS EN 1998-1:2004.

The provisions for Eurocode 8- 2004 have been added to the **Response Spectrum** dialog box.

Enter the General, Loads Page of the Modelling Mode, and select the load case in the **Load** dialog box. Select the required load case name from the Load Case Details group and click on the **Add** button.

In the dialog box that is displayed, select the **Response Spectra** option from the list of items on the left and select the code **Euro (EC8)-2004** to display the following:



Select the required parameters such as the Load Type and Combination Method and the direction that the spectrum is to be defined and click on the **Add** button to add the command to the input file.

Note: This is response spectrum definition has been provided in addition to the ENV 1998-1-1:1994 version of the code that was previously implemented. The older version of the code is still available, although recommended for comparison purposes only.

For a full description of both implemented versions of the Eurocode 8 Response Spectrum command structure, see TR.32.10.1.5 Response Spectrum Specification per Eurocode 8 2004 (on page 2525).

Related Links

- *TR.32.10.1.5 Response Spectrum Specification per Eurocode 8 2004* (on page 2525)
- *M. To add an EC8 response spectrum* (on page 867)

AD.2006-1004.1.7 Update IS 1893 Dialog to Support Command Structure

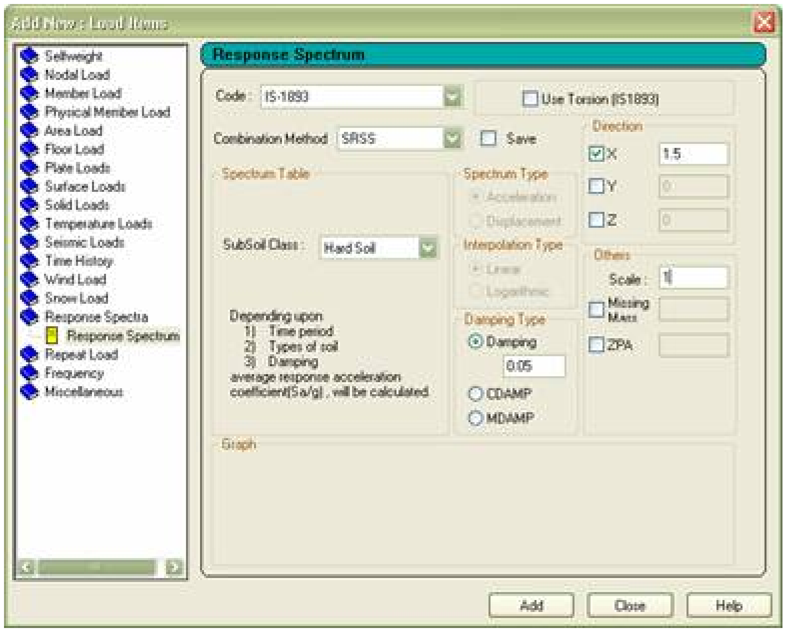
The **Response Spectrum** dialog for defining a Response Spectrum to be calculated as per the IS-1893 code by the analysis engine has been enhanced so that it reflects the input requirements of this command.

Enter the **General | Loads** Page of the Modelling Mode and select the load case in the **Load** dialog box. Select the required load case name from the Load Case Details group and click on the **Add** button.

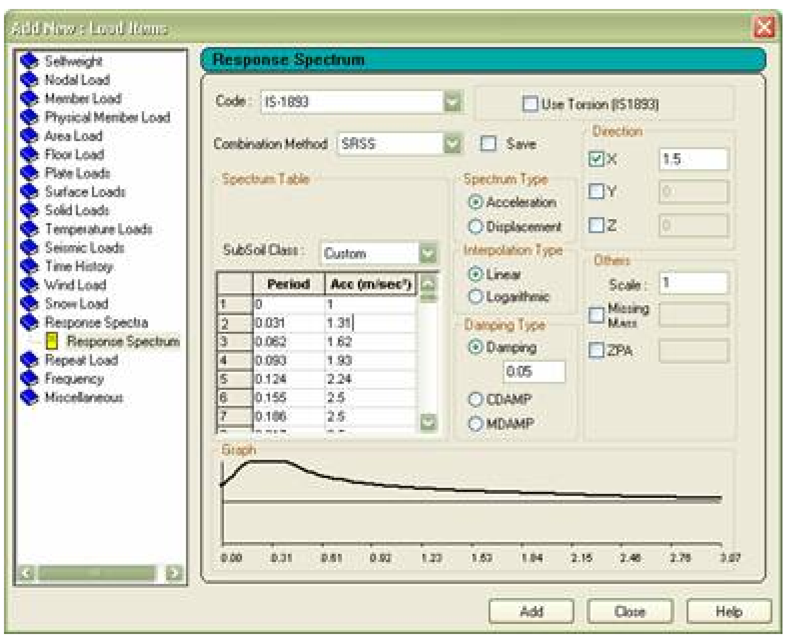
In the dialog box that is displayed, select the **Response Spectra** option from the list of items on the left and select the code **IS-1893**. There are essentially 2 methods that can be employed to define the response spectrum:

a. Select a SubSoil Class
b. Define a Custom Reponse Graph

This choice is made from the **SubSoil Class** in the Spectrum Table. If a defined class is selected, then the Response Spectrum Graph is automatically defined and specified during the analysis, however the following dialog is presented to allow other options to be set:



However, if a custom Response Spectrum Graph is required and selected from the SubSoil drop list, then the various points on the graph of period/acceleration or period/displacement must be entered, thus:



For a full description of the scope of the IS-1893 Response Spectrum command, refer to TR.32.10.1.7 Response Spectrum Specification per IS: 1893 (Part 1)-2002 (on page 2534).

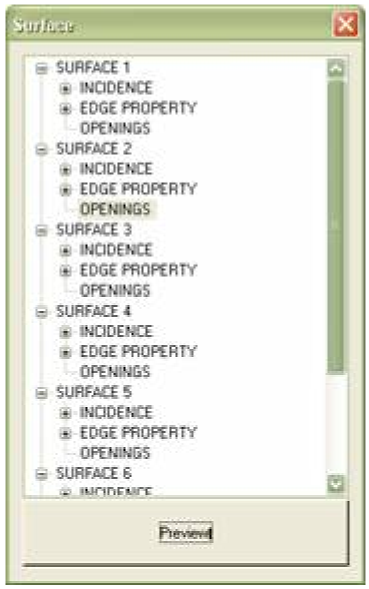
Related Links

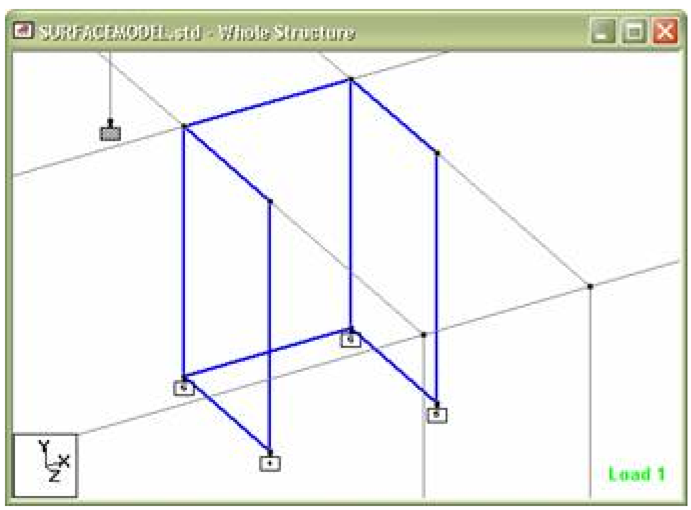
- *TR.32.10.1.7 Response Spectrum Specification per IS: 1893 (Part 1)-2002* (on page 2534)
- *M. To add an IS 1893 response spectrum* (on page 864)

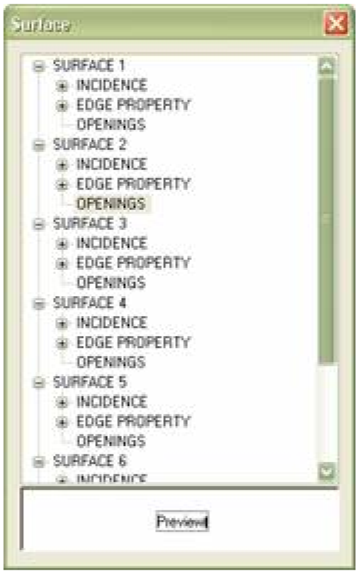
AD.2006-1004.1.8 Preview of Surface Element Meshes

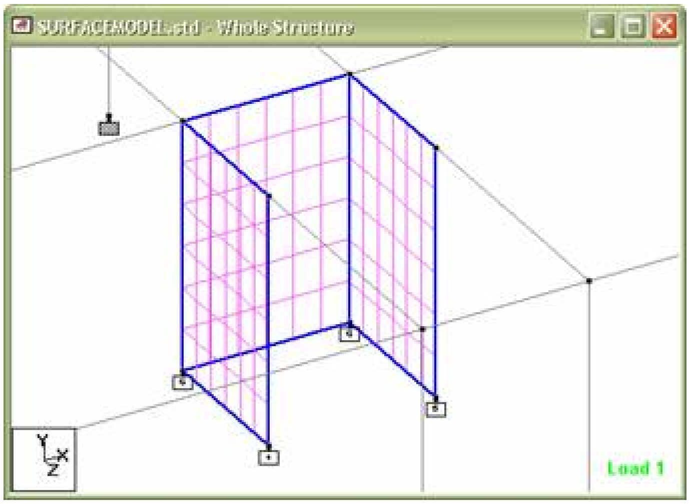
Models that contain large numbers of surfaces, or have complex geometrical requirements can result in extensive analyses which may be un-necessary if appropriate settings are applied to the surface. In order to the mesh that will be generated during the analysis, the option to 'Preview' the surface meshes has been added.

After creating one or more surface elements, go to the Geometry, Surface Page which will display the **Surface** dialog. By clicking on the **Preview** button at the base of the dialog, the mesh that will be generated by the defined parameters will be displayed thus:









AD.2006-1004.1.9 Key File Option Added to Configuration Settings

The output file has the option to list all the key files that were used with the analysis including the date of the principal files. However, this can produce unwanted extra printout data and thus an option to specify whether or not this is to be used has been set in the Configuration Settings.

To access the File Configuration Settings, start STAAD.Pro, but close any open file or the New Wizard if it is open. Click on the menu option, **File** > **Configure** to open the **Configuration Settings** dialog and click on the sheet **Input/Output File Format**, thus:

To include the key file information in the output file, set the option **Add key file information to output**.

If the option is set, the output file contains information similar to the following at the end of the file.

```
EXAMPLE PROBLEM NO. 1                                       -- PAGE NO.   18

    Information about the key files in the current distribution

    Modification Date   CRC     Size (Bytes)        File Name

------------------------------------------------------------------------------
-----------

    10/26/2006      0x3cc1      13266944        SProStaad.exe

    10/25/2006      0x1cc0      05836800        SProStaadStl.exe

    09/19/2003      0x2fc0      00081970        CMesh.dll

    10/25/2006      0x4601      02486272        dbSectionInterface.dll

    …
```

Note: If the general case is that the Key Information is displayed, it can be tuned off in a particular analysis if the data file contains the command `SET NOFILE`.

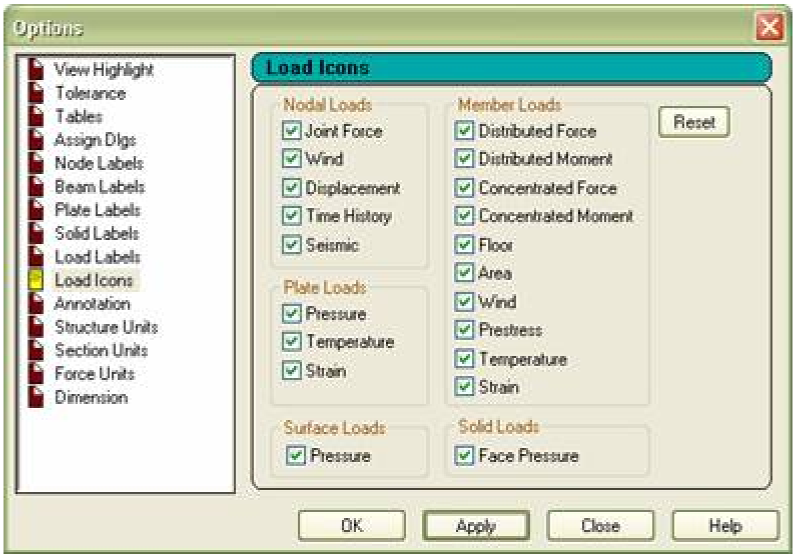
- *GS. Application Configuration dialog* (on page 59)

AD.2006-1004.1.10 Load Icons Display Option

Certain models have large numbers of loads defined in any given load case. It is now possible to select which 'types' of load are displayed when the load case data is displayed.

To select which load items are displayed when the load is displayed, select the Options from the menu item **View** > **Options** and select **Load Icons** thus:



To return to the default of displaying all load types, click on the button **Reset**.

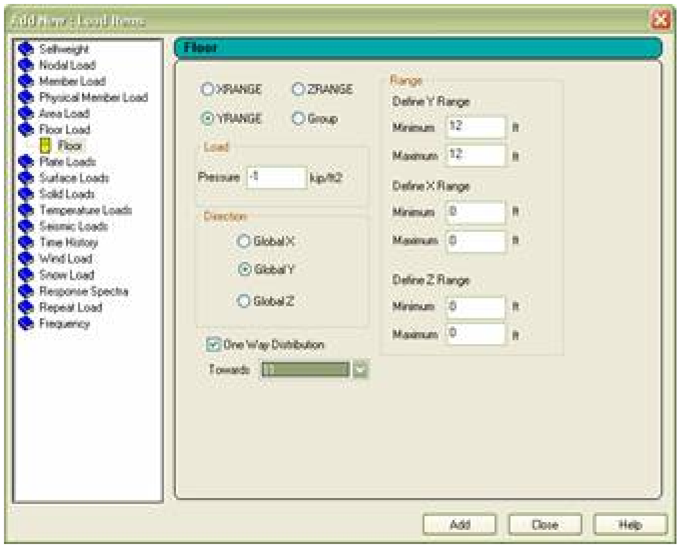
AD.2006-1004.1.11 Update Oneway Loading

The `ONEWAY` command has been enhanced with the option to define the direction in which the load is spanning by selecting a member in the loaded zone onto which the load is to be directed.

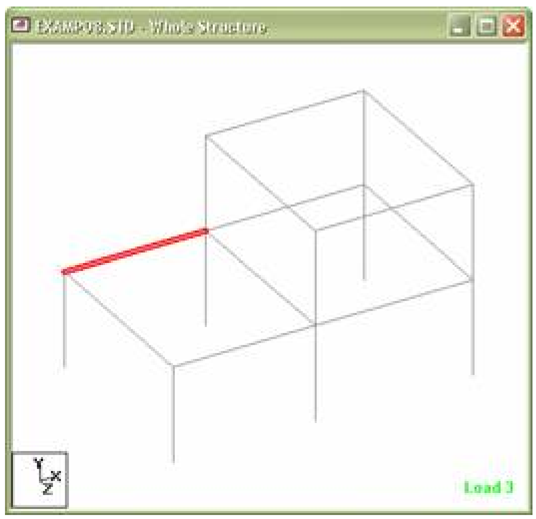
Enter the **General | Loading** Page and create or select the required load case.

Click on the **Add** button on the Load dialog box.

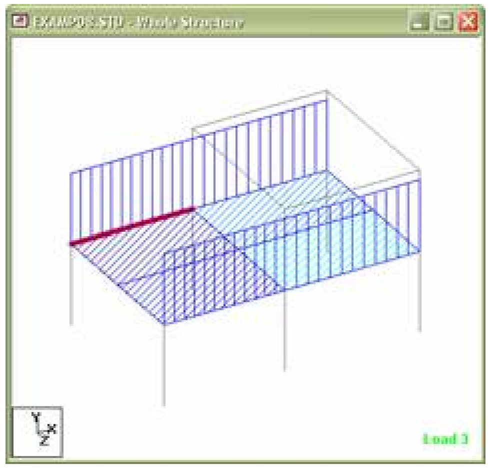
From the options on the left, select the **Floor Load** option and enter the Floor load in the normal way defining the direction, Load intensity and range. This defines a two way spanning system, to indicate a one-way span, click on the **One Way Distribution** option. This will then span in the shorter direction. However, now a beam number can be selected from the **Towards** drop list which is populate with the beams that exist in the defined range. As shown blow:



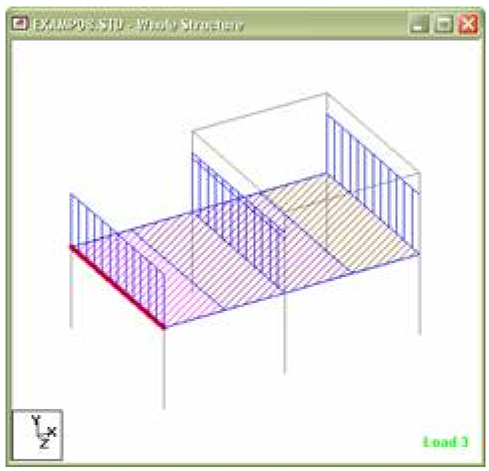
The selected beam is highlighted on the structure so that the spanning direction can be confirmed, thus:



Once the command is created, the load and contributing areas can be displayed by highlighting the command in the Load dialog box, thus:



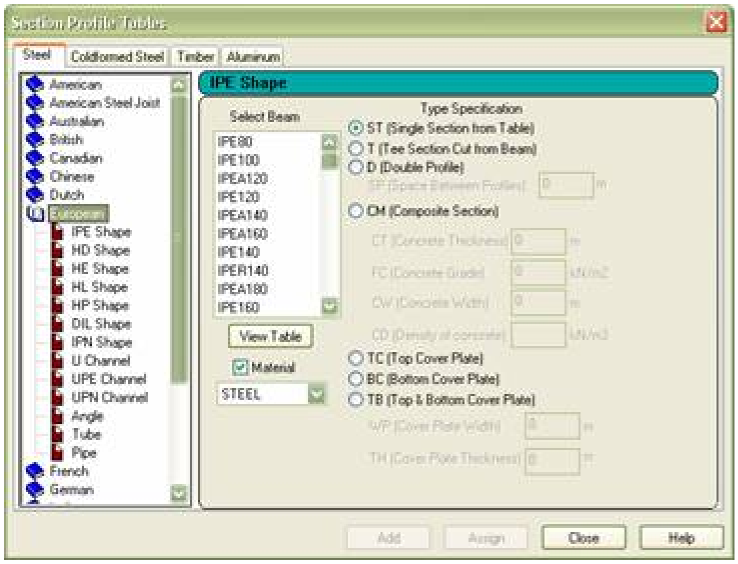
By changing the beam number that defines the direction that the load is towards, the change in the loading can be viewed, thus:



AD.2006-1004.1.12 Additional Standard European Steel Section Types

Additional steel section shapes produced by European Steel manufactures have been added to the standard steel database libraries. Section shapes, HD, HL, UPE have been added.

Click on the **General | Property** page and on the **Properties** dialog box, click on the **Section Database** button to view steel section databases available. Click on the **European** label to view the section types that are now available.



AD.2006-1004.2 Features Affecting the Analysis and Design Engine

The following section describes the new features have been added to the analysis and design engine and existing features that have been updated or modified.

AD.2006-1004.2.1 AISC Unified Code

A new steel design code module has been added to STAAD.Pro, which allows steel beam sections to be designed to the rules defined in AISC specification, *Specification for Steel Buildings*, March 9 2005, ANSI/AISC 360-05. This is also referred to as the AISC Unified Code. The GUI has been updated to allow you to enter the design information for this new design code.

Related Links

- *D1.A. American Codes - Steel Design per AISC 360 Unified Specification* (on page 1086)

AD.2006-1004.2.2 ACI 2005

The ACI concrete design module has been updated to support the current 2005 version of the ACI code, ACI 318-05.

When performing the concrete design using the parameter CODE ACI 2005, the design will be performed according to the requirements of the American Concrete Institute document, 'Building Code Requirements for Structural Concrete (ACI 318-05)'. If it is required to perform the design to the older versions of the code, specifically, the 1999 or 2002 version of the code, then the commands:

```
CODE ACI 1999
```

or

```
CODE ACI 2002
```

The commands `CODE ACI` or `CODE ACI 2005` will set the program ready to perform the design to ACI 2005 when it encounters the commands `DESIGN BEAM`..., `DESIGN COLUMN`... or `DESIGN ELEMENT`....

For more information on the refer to the updated [D1.F. American Codes - Concrete Design per ACI 318](#) (on page 1198).

AD.2006-1004.2.3 Enhancement of Indian Concrete Design

Two new parameters have been added to the Indian concrete design code, IS 456.

ULY and ULZ which are the unsupported lengths in the local Y and Z directions. These commands have been added to assist in the calculation of the minimum eccentricities.

Related Links

- *D8.E. Indian Codes - Concrete Design per IS 456* (on page 1669)

AD.2006-1004.3 Features Affecting the Post Procesing (Results) Mode

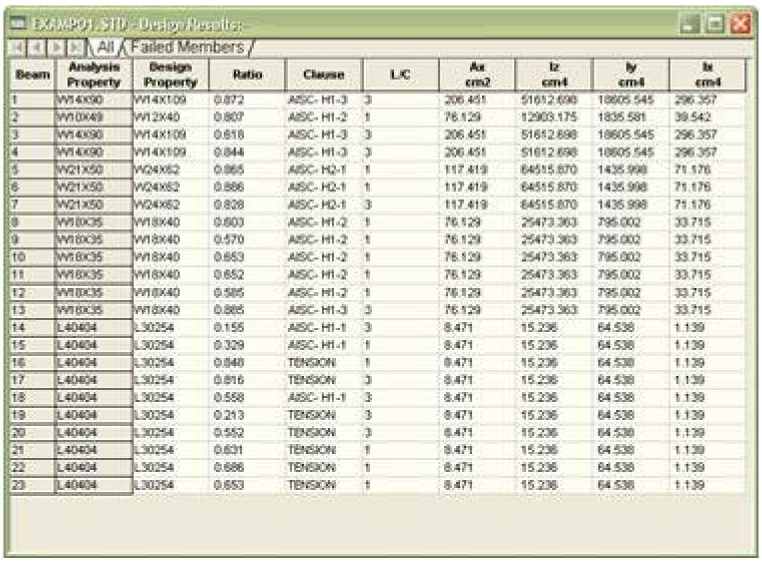
Several new features have been added and existing features have been modified in the Steel Designer section of the program, also known as the Steel Designer Mode. These are explained in the following pages.

AD.2006-1004.3.1 Unity Check Page Update

The Design Results table has been updated so that not only can the maximum utilisation ratio be displayed, but also the governing clause and combination. The superfluous section dimension information has been removed.

Additionally, the table can be sorted by design ratio.

Perform an analysis and design and enter the Post Processing Mode. To view the **Design Results** table, click on the **Beam | Unity Check** Page. The table is displayed on the right of the window:



Beam	Analysis Property	Design Property	Ratio	Clause	L/C	Ax cm2	Iz cm4	Iy cm4	Ix cm4
1	W14X90	W14X109	0.872	AISC- H1-3	3	206.451	51612.698	18605.545	296.357
2	W10X49	W12X40	0.807	AISC- H1-2	1	76.129	12903.175	1835.581	39.542
3	W14X90	W14X109	0.618	AISC- H1-3	3	206.451	51612.698	18605.545	296.357
4	W14X90	W14X109	0.844	AISC- H1-3	3	206.451	51612.698	18605.545	296.357
5	W21X50	W24X62	0.865	AISC- H2-1	1	117.419	64515.870	1435.998	71.176
6	W21X50	W24X62	0.886	AISC- H2-1	1	117.419	64515.870	1435.998	71.176
7	W21X50	W24X62	0.828	AISC- H2-1	3	117.419	64515.870	1435.998	71.176
8	W18X35	W18X40	0.603	AISC- H1-2	1	76.129	25473.363	795.002	33.715
9	W18X35	W18X40	0.570	AISC- H1-2	1	76.129	25473.363	795.002	33.715
10	W18X35	W18X40	0.653	AISC- H1-2	1	76.129	25473.363	795.002	33.715
11	W18X35	W18X40	0.652	AISC- H1-2	1	76.129	25473.363	795.002	33.715
12	W18X35	W18X40	0.585	AISC- H1-2	1	76.129	25473.363	795.002	33.715
13	W18X35	W18X40	0.885	AISC- H1-3	3	76.129	25473.363	795.002	33.715
14	L40404	L30254	0.155	AISC- H1-1	3	8.471	15.236	64.538	1.139
15	L40404	L30254	0.329	AISC- H1-1	1	8.471	15.236	64.538	1.139
16	L40404	L30254	0.848	TENSION	1	8.471	15.236	64.538	1.139
17	L40404	L30254	0.816	TENSION	3	8.471	15.236	64.538	1.139
18	L40404	L30254	0.558	AISC- H1-1	3	8.471	15.236	64.538	1.139
19	L40404	L30254	0.213	TENSION	3	8.471	15.236	64.538	1.139
20	L40404	L30254	0.552	TENSION	3	8.471	15.236	64.538	1.139
21	L40404	L30254	0.631	TENSION	1	8.471	15.236	64.538	1.139
22	L40404	L30254	0.686	TENSION	1	8.471	15.236	64.538	1.139
23	L40404	L30254	0.653	TENSION	1	8.471	15.236	64.538	1.139

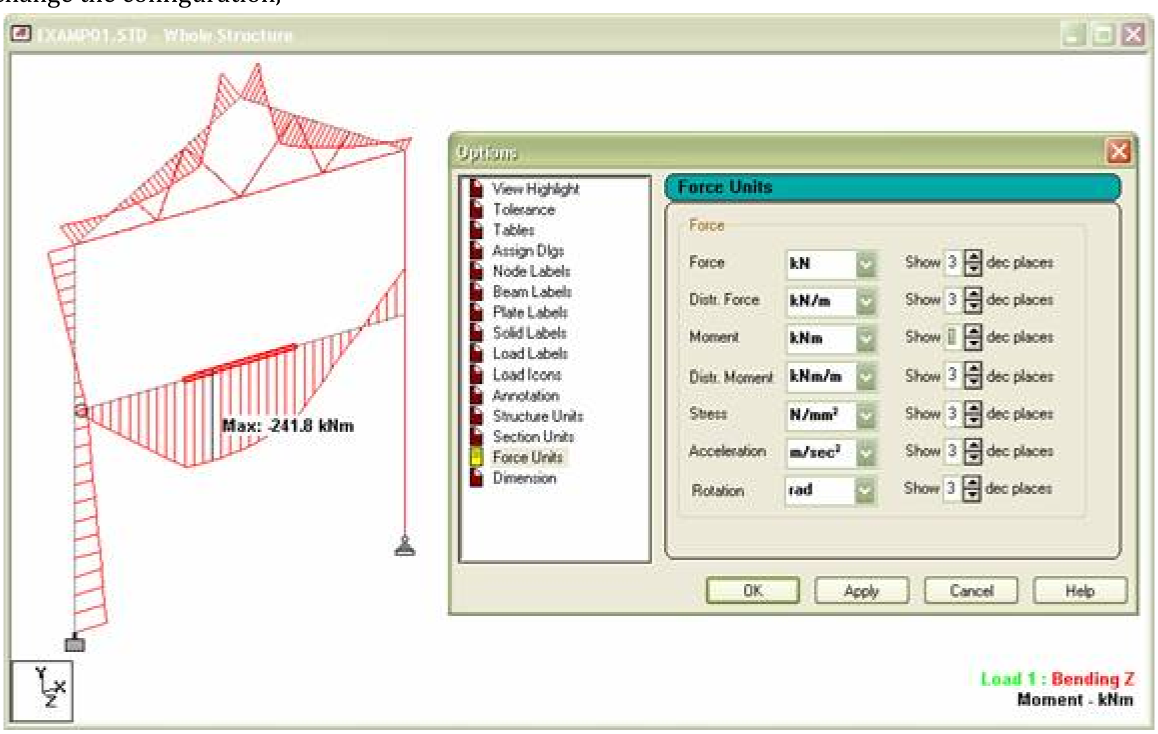
To sort the table by ratio, click on the **Ratio** column heading. To return to the un-sorted list, click on the **Beam** column heading.

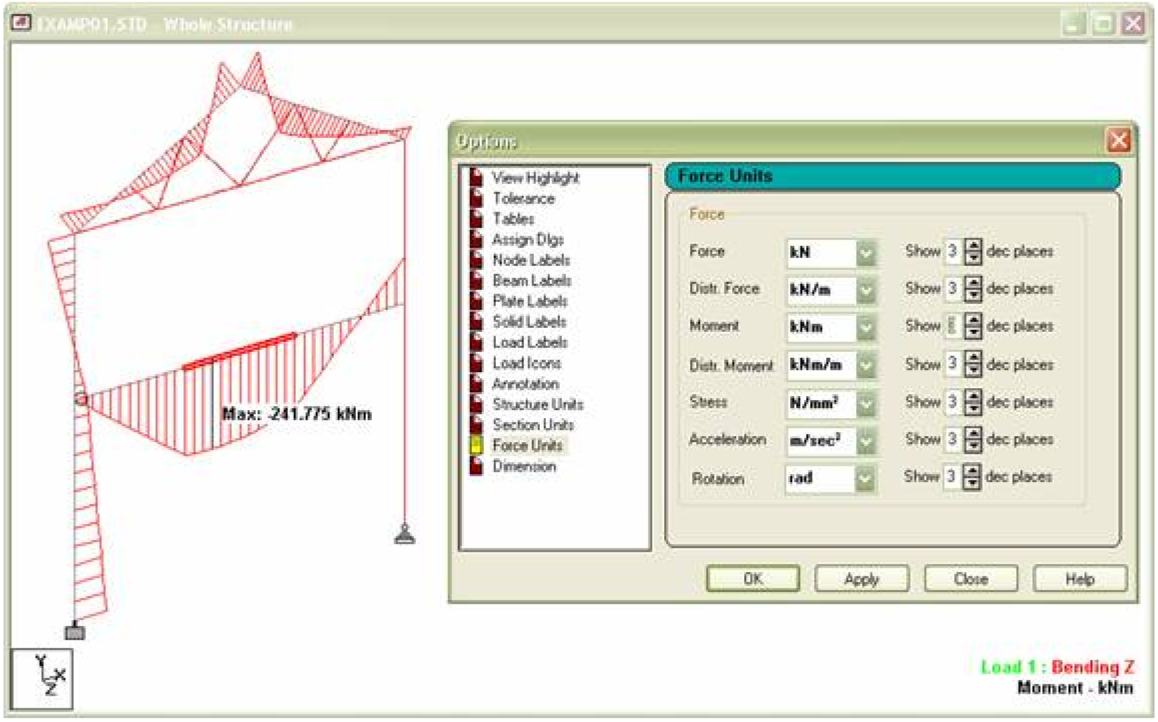
AD.2006-1004.3.2 View Value Annotation Enhanced

The annotation of forces and displacements has been enhanced to allow the number of decimal places viewed on the diagrams to be configured.

1. Open a model with analysis results or run an analysis to obtain a set of valid analysis results.
2. Enter the Post Processing mode and click on the **Beam | Forces** Page to display the bending moment on the graphic view of the structure.
3. Click on the menu item **Results** > **View Value...** to annotate the bending moment diagram and define the items that are required to be annotated in the **Ranges** sheet, the list of items to be annotated such as **Maximum Bending Moments**.

4. To change the configuration,





AD.2006-1004.4 Features Affecting the Concrete Design Mode

Several new features have been added and existing features have been modified in the RC Designer section of the program, also known as the Concrete Design Mode. These are explained in the following pages.

AD.2006-1004.4.1 Bentley Rebar Export from RC Designer

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2006-1004.4.2 Addition of Amendments 1,2, and 3 to the BS 8110 Modules

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2006-1004.5 Features Affecting the Piping Mode

STAAD.Pro can utilise the pipe layout and reactions created in the applications ADLPipe or AutoPipe. The pipe model can be imported in the Piping Mode. The following describes the method of using the Piping Mode and features recently added to this mode.

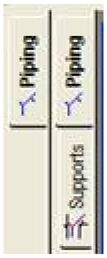
AD.2006-1004.5.1 Update of Importing Piping Models

The import stage of the Piping Mode has been enhanced by allowing the user to better relate the co-ordinate systems used by the two models, the structural model and the piping model. There are two issues that are addressed:

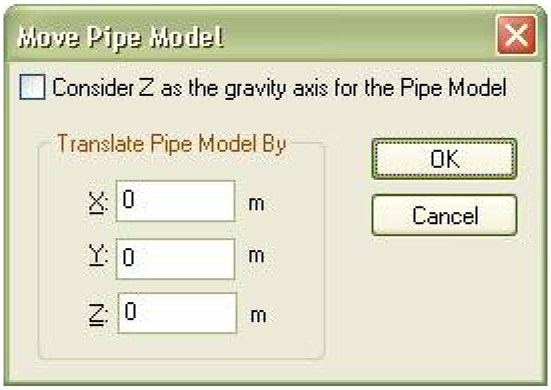
a. Locating the origin
b. Allowance for Y or Z axis as vertical in the piping model

Enter the Piping Mode by either selecting the menu option **Mode** > **Piping** or from the Mode Bar thus:

This displays the principal page and two sub pages available in this mode thus:



To select a pipe model to import, click on the **Open File…** button in the Information dialog box and navigate to the folder that has the required ADLPIPE or AutoPipe (`*.ADI`) model. Select the required file and click on the **Open** button. The following dialog is then displayed:



This allows the direction that was used as vertical in the pipe model system to be identified by clicking the option **Consider Z as the gravity axis for the Pipe Model** if required. Additionally, the X, Y, and Z values allows the origin of the pipe model to be placed at a different location than the origin of the STAAD.Pro structure.

Refer to the M. Piping workflow (on page 902) in the User Interface help

AD.2006-1004.5.2 Pipes Support by Member

Supports defined in the piping model may not have corresponding nodes defined in the STAAD.Pro model. Therefore the pipe support function has been enhanced to allow members to be selected so that the support load will be transferred as a member load rather than node load.

Enter the Piping Supports page. Select the menu item 'Support>Support Node'. Using the Pipe Support cursor, select the pipe support node then click on the supporting member.

Note: For a member to be valid as a pipe support beam, then a line from the pipe support node, that is perpendicular to the support beam, must lie between the start and end nodes of that beam.

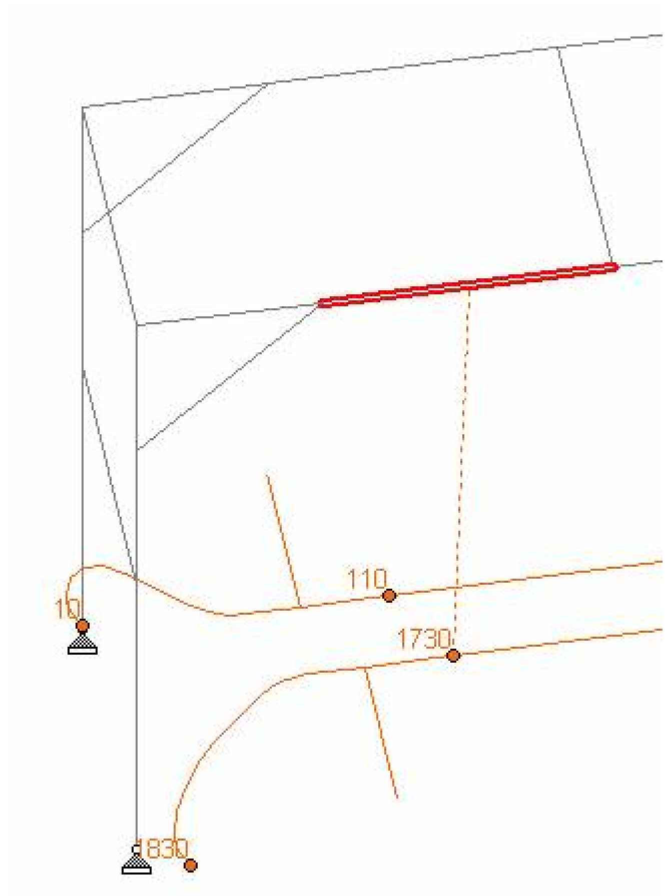


Figure 11: A pipe support node is supported by the highlighted beam

AD.2006-1004.6 Additional STAAD.Pro 2006 Build 1004 Features

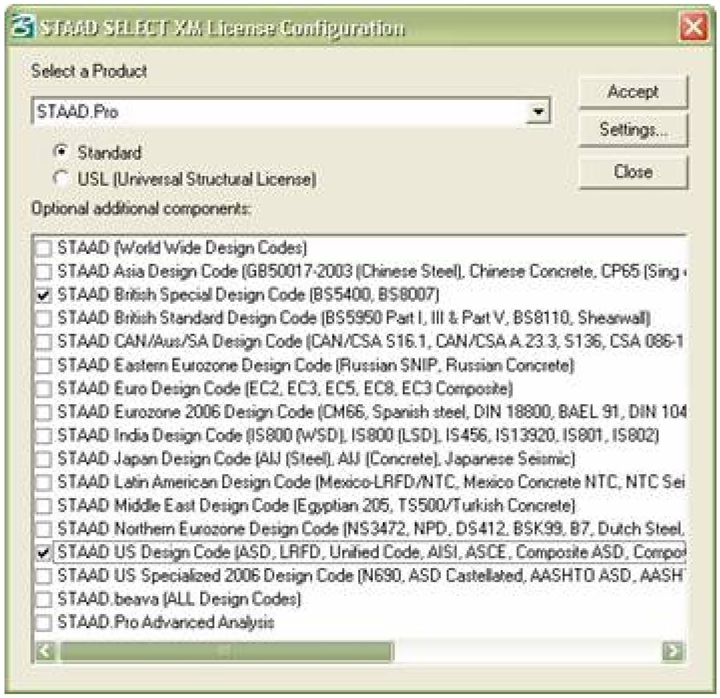
The following pages outline the additional features that have been added to STAAD.Pro in this version.

AD.2006-1004.6.1 Modifications of the SELECT XM Security System

With the SELECT security system, STAAD.Pro can be configured to use either a **STAAD.Pro** license or a **Universal Structural License** (USL), which can also be used to access other structural products in the Bentley portfolio. However, to perform a design, the USL needs to be configured along to specify which design code packs are to be accessed during the operation of STAAD.Pro. Additionally, once the configuration of the STAAD.Pro SELECT license has been established, it is now possible to review the current settings and update it as required.

To review and/or update the current STAAD SELECT security configuration, click on the Start menu item: **Start** > **Programs** > **STAAD.Pro 2006** > **Select License Tools** > **STAAD SELECT Configuration**

1. Select STAAD.Pro from the Product drop list.
2. Select whether a Standard or USL license should be obtained to run STAAD.Pro.
3. Select which code packs should also be obtained when STAAD.Pro is run.



Notes:

1. This configures what licenses are to be obtained. This does not confirm that those features are available. To confirm what features are available, click **Settings**. This launches the **License Management Tool** which displays the list of products and licences available on the currently defined SELECT XM server and those that are currently 'Checked Out' onto the local machine.
2. If a feature or design code requires a specific license during a session of STAAD.Pro, then it is important to check that the license for that feature is available using the License Management Tool and setting the STAAD SELECT XM License Configuration to obtain that license as STAAD.Pro starts.

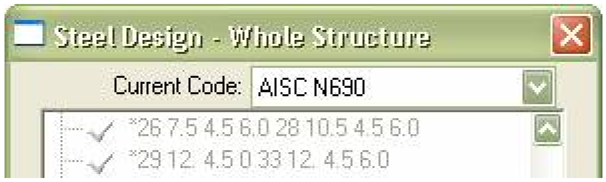
For a complete description of the SELECT security system, please refer to the *Quickstart & Troubleshooting Guide* (`STAAD.Pro_InstallGuide_en.pdf`) document distributed with the installation setup.

AD.2006-1004.6.2 AISC N690

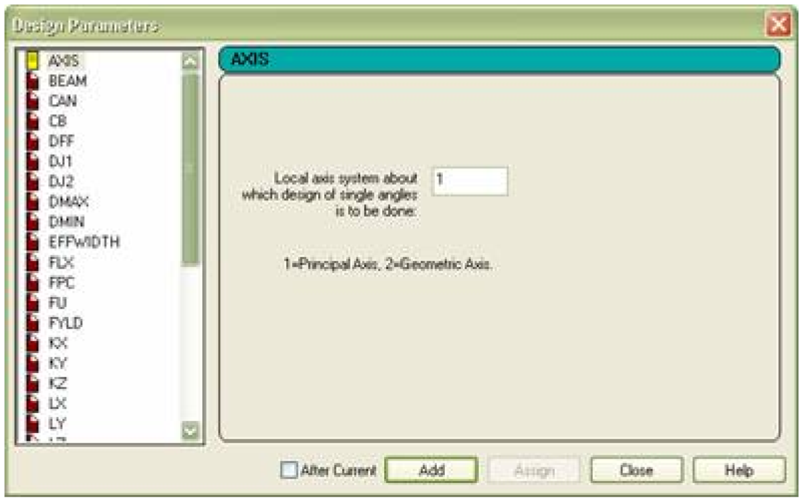
In addition to the standard ASD design method, STAAD.Pro can perform a design to incorporate the design requirements of *Supplement No. 1 to the Specification of the Design, Fabrication and Erection of Steel Safety-Related Structures for Nuclear Facilities* ANSI/AISC N690 – 1994s1. This additional code has been added to the **Steel Design** dialog.

To perform a design of steel sections to the AISC N690, a design parameter block containing the command `CODE AISC N690` followed by the command to perform a `CODE CHECK` or `MEMBER SELECTION` must be added to the STAAD.Pro data file.

The GUI has been updated by adding **AISC N690** in the **Steel Design** dialog:



When this design code option is selected, clicking on the **Define Parameters...** button at the base of the dialog box will in turn open the **Design Parameters** dialog that will allow parameters to be added or added and assigned to specific steel members.



For a full explanation of the features of the design engine see D1.K. American Codes - Steel Design per ANSI/AISC N690 Design Codes (on page 1296).

Note: Design to this module is only possible if your security allows design to US Specialised design codes.

STAAD.Pro 2006 Build 1002 Release Report

The Software Release Report for STAAD.Pro 2006 Build 1002 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2006 build 1001. This document should be read in conjunction with all other STAAD.Pro help, including the Revision History document.

AD.2006-1002.1 Features Affecting the Pre-Processor (Modeling Mode)

Several new features have been added and existing features have been modified in the pre-processor section of the program, also known as the Modeling Mode. These are explained in the following pages.

AD.2006-1002.1.1 Automatic calculation of the Response Spectrum as per IBC

STAAD.Pro previously allowed response spectra to be defined by the user, or calculated as per the Indian IS 1893 or Eurocode EC8.
The graphical user interface (GUI) has been enhanced so that it can now automatically generate a response spectrum as per the guidelines of the IBC/ASCE code

(*). This new feature saves users the time and effort involved in establishing the 1 second and short period accelerations indicated in the IBC/ASCE maps and then converting them into spectral data based on the equations provided in the code.

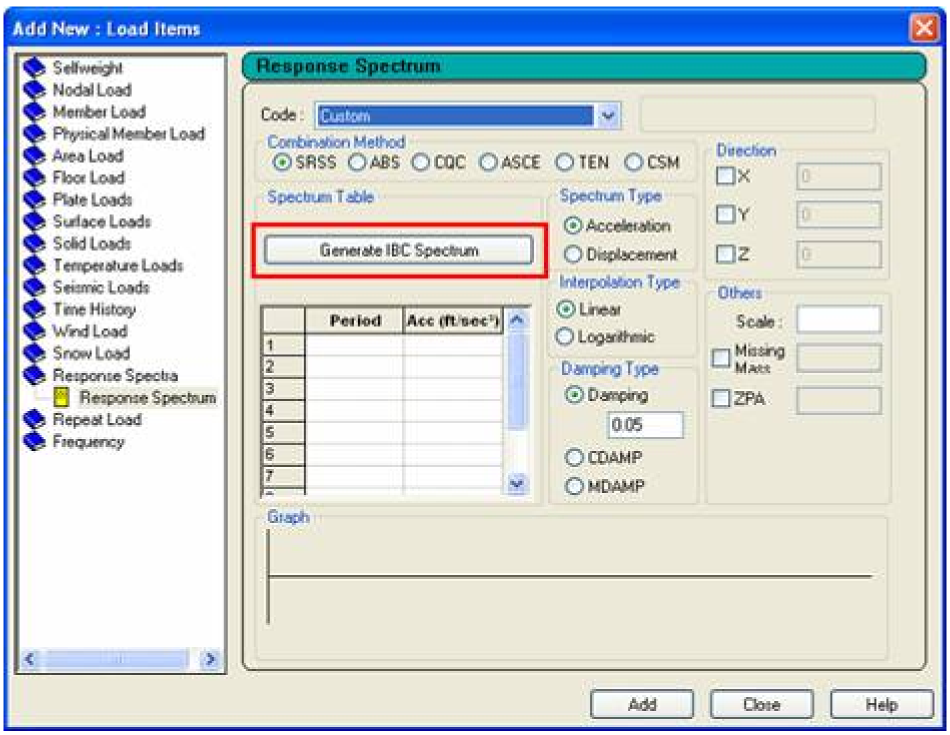
The user enters the latitude and longitude (or select a US zip code), STAAD.Pro then establishes the site coefficients, S1 and SS. The user then selects the appropriate site class (A-F) and with this information, STAAD.Pro calculates the MCE spectral acceleration and design spectral acceleration as per sections 11.4.3 and 11.4.4 of the ASCE7-05 code. Finally the design response spectrum will be generated based on section 11.4.5 of the ASCE7-05 code.

Note: There is no change to the input command structure.

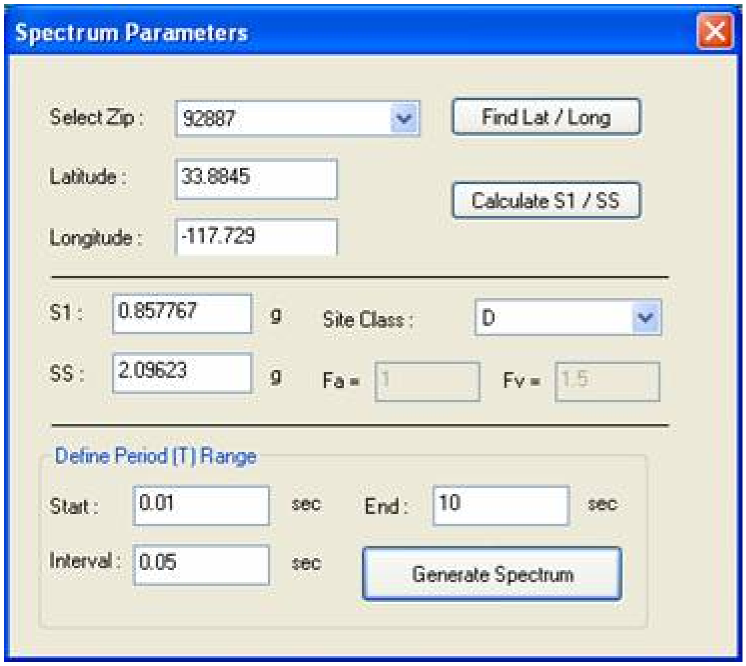
Description

Go to the **General | Load** page and in the **Load** dialog box, open the **Load Case Details** and select the appropriate primary load case with the masses (defined as load items) defined or create a new primary load case and add the masses, if required. Click on the **Add** button which will bring up the **Add New: Load Items** dialog box. Select the **Response Spectrum** option from the list on the left.

With the code option set to **Custom**, a **Generate IBC Spectrum** button will now be available as shown thus



Click on the **Generate IBC Spectrum** button to open the **Spectrum Parameters** dialog box thus



Refer to Spectrum Parameters dialog (on page 2862) for details on the input fields in this dialog.

To complete the generation of the IBC response spectrum pairs, click on the **Close** button. The completion of the Response Spectrum command continues as for all other Custom defined Response Spectrum commands. Note that the details of the spectrum Period, Acceleration pairs are displayed in the Response Spectrum window, but cannot be modified at this time.

For more details on the Response Spectrum loading command, refer to TR.32.10.1.1 Response Spectrum Specification - Custom (on page 2499).

Related Links

- *M. To add an IBC 2000 response spectrum* (on page 862)

AD.2006-1002.1.2 Enhancement to Physical Member Query Window

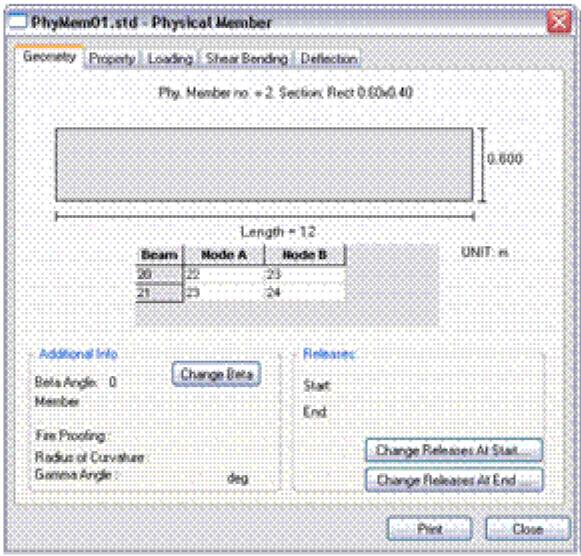
With the enhancement of the physical Member in the Pre-Processing Mode, the Query dialog box obtained when a physical member is double clicked.

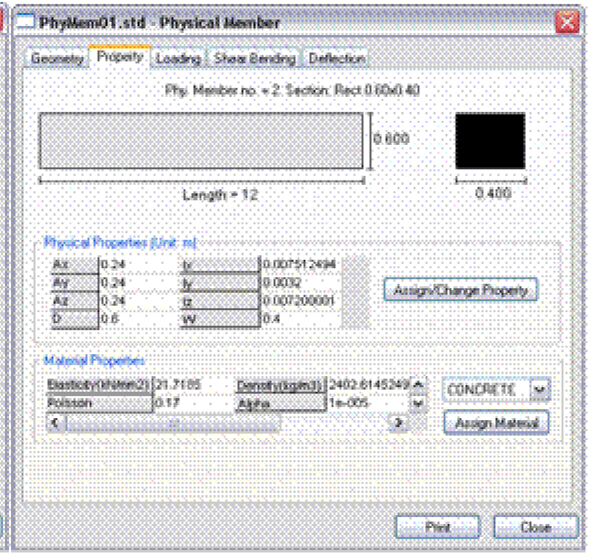
Select a Physical Member by using the Physical Member cursor,  and double-click on that to view the **Physical Member Query** dialog box.

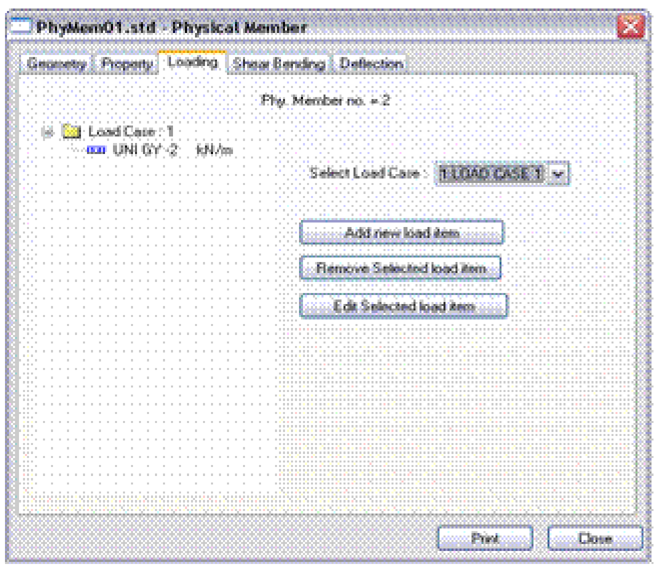
Pre-Processing Information

Prior to any analysis being performed, the physical member information available is displayed in the following three sheets **Geometry**, **Property**, and **Loading**.

All those common physical member attributes, assigned to that particular physical member (i.e., to all the analytical members comprising that physical member) are displayed in these information fields, as shown below:







Post Processing Information

If an analysis has been performed and there are results available, the following post processing results are made available in two additional sheets **Shear Bending**, to view the Shear Force diagram, Bending Moment Diagram, and **Deflection** to display deflected shape information.

Note: The design of Physical Members is only performed in the Steel Design Mode and note the batch method in the current version of STAAD.Pro.

Related Links

- *Physical Member dialog* (on page 3053)

AD.2006-1002.1.3 AAHSTO (LRFD) Design Code

The STAAD.Pro analysis and design engine has been enhanced with the addition of a new design code, AASHTO (LRFD). The Graphical User Interface (GUI) has been updated to allow the design parameters to be entered and applied as required.

Go to the **Design | Steel** page and in the **Steel Design** dialog box, select the option **AASHTO (LRFD)** from the Current Code drop-list. Click on the button **Select Parameters** to display the parameters available to be used with this design code. With all parameters displayed in the right Selected Parameters' panel, close the dialog box. Click on the **Define Parameters** to set the values for the parameters which can be added or assigned to selected members.

Click on the **Commands** button to add or assign the commands to the file to instruct a check or selection of sections based on the parameter settings.

The AASHTO design parameters listed in previous versions of STAAD.Pro as **AASHTO** in the Current Code drop-list of the **Steel Design** dialog box, have been renamed as 'AASHTO (ASD)

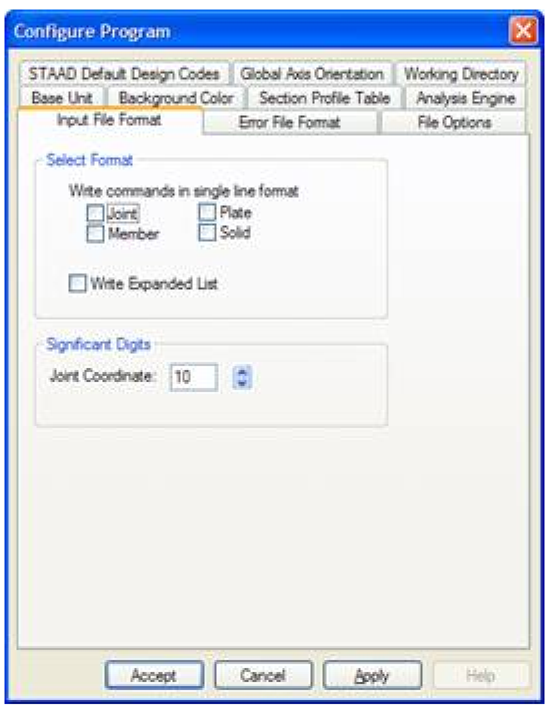
Note that access to design codes is controlled by your licence agreement and security settings. Not all users have access to all design codes. If this code is unavailable, see your STAAD.Pro supplier to obtain the updates needed to activate this or any other design code.

AD.2006-1002.1.4 Node Precision

A number of models require a higher than usual precision on the node co-ordinates that are used by the analysis engine.

With STAAD.Pro running, but without having any structural model loaded, select **File** > **Configure**.

In the resulting dialog, click on the **Input File Format** sheet, there is a new section Significant Digits which allows the required value to be set



Related Links

- *GS. Application Configuration dialog* (on page 59)

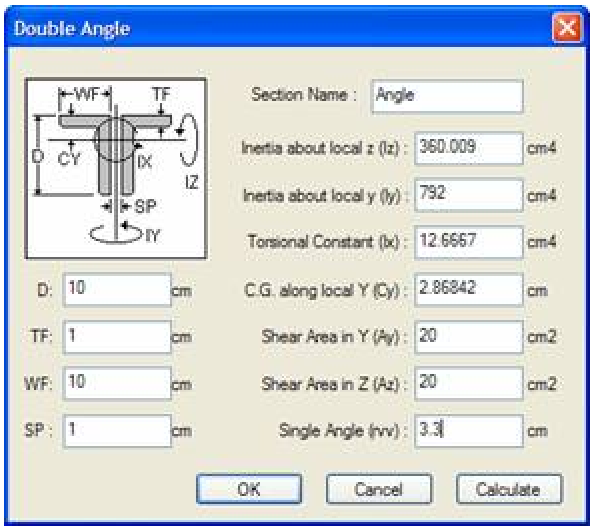
AD.2006-1002.1.5 User Steel Table - Double Angles

To design a beam that has been defined as a Double Angle from a User table, then an 11th parameter must be provided in the section parameters which defines the RVV value. The GUI has been enhanced to support this additional parameter.

Description

Select **Tools** > **Create User Table**.

Start a new table which is of type **DOUBLE ANGLE** and click on the **Add New Property** button which will display the following dialog which allows the value of Rvv to be included in the section property definition.



Related Links

- *TR.19.4 Double Angle* (on page 2248)

AD.2006-1002.2 Features Affecting the Analysis and Design Engine

The following section describes the new features have been added to the analysis and design engine and existing features that have been updated or modified.

AD.2006-1002.2.1 AASHTO Design Code

The STAAD.Pro analysis and design engine has been enhanced with the addition of a new design code, AASHTO (LRFD).

AD.2006-1002.2.2 Updated Parameters on Indian IS 1893 Static Seismic Loading Command

The static equivalent method for creating loads as per the Indian seismic code, IS 1893 has been enhanced with the option for checking soft stories.

Related Links

- *TR.31.2.10 IS:1893 (Part 1) 2002 & Part 4 (2005) Codes - Lateral Seismic Load* (on page 2387)

AD.2006-1002.2.3 Updated Parameters on Indian IS 1893 Response Spectrum Command

The method for creating a response spectrum to the Indian seismic code, IS 1893 has been enhanced with the option for checking soft stories and documentation on the torsion option added.
Related Links

- *TR.32.10.1.7 Response Spectrum Specification per IS: 1893 (Part 1)-2002* (on page 2534)

AD.2006-1002.3 Features Affecting the Steel Design Mode

Several new features have been added and existing features have been modified in the Steel Designer section of the program, also known as the Steel Designer Mode. These are explained in the following pages.

AD.2006-1002.3.1 Access to Physical Members Created in Pre-Processing Mode

Physical members can be created in the Pre-Processor mode and their definition stored in the STAAD.Pro input file (`*.STD`). Physical members that have been created in the Pre-Processing Mode are now available in the Steel Designer Post Processing Mode. Previous versions of STAAD.Pro would require these members being re-defined in the Steel Designer Mode.

Create Physical Members as defined in the manual AD.2006.1.1 Physical Member Interface (on page 333). Perform an analysis and enter the Steel Designer Mode. Go to the Member Design | Member Setup Page, and note that the members that were created in the Pre-Processing Mode are ready to be utilised in the Steel Designer Mode.

AD.2006-1002.4 Features Affecting the Concrete Design Mode

Several new features have been added and existing features have been modified in the RC Designer section of the program, also known as the Concrete Design Mode. These are explained in the following pages.

AD.2006-1002.4.1 DXF Output of Beam and Column Designs

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2006-1002.5 Features Affecting the Advanced Slab Design Mode

The Mode previously known as the ADAPT Slab design has been redefined as the Advanced Slab Design and has been enhanced to support integration with RAM Concept.

Note: Beginning with STAAD.Pro CONNECT Edition, direct export to ADAPT-Builder® has been deprecated.

AD.2006-1002.5.1 Advance Slab Design Mode

Refer to the D. Advanced Slab Design (on page 1073) of the User Interaface help for details.

AD.2006-1002.6 Features Affecting the Piping Mode

STAAD.Pro can utilise the pipe layout and reactions created in the applications ADLPipe or AutoPipe. The pipe model can be imported in the Piping Mode. The following describes the method of using the Piping Mode and features recently added to this mode.

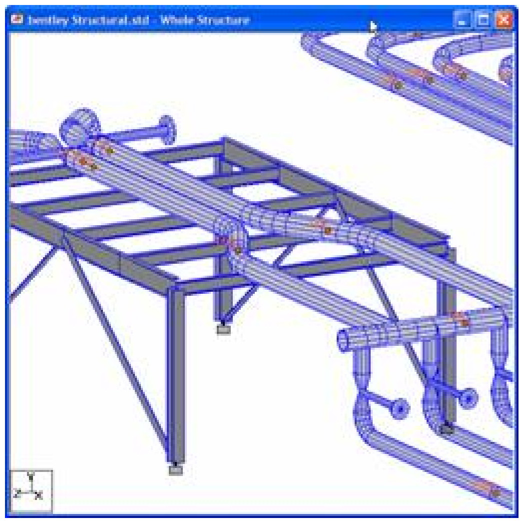
AD.2006-1002.6.1 Piping Mode

Refer to the M. Piping workflow (on page 902) in the User Interface help

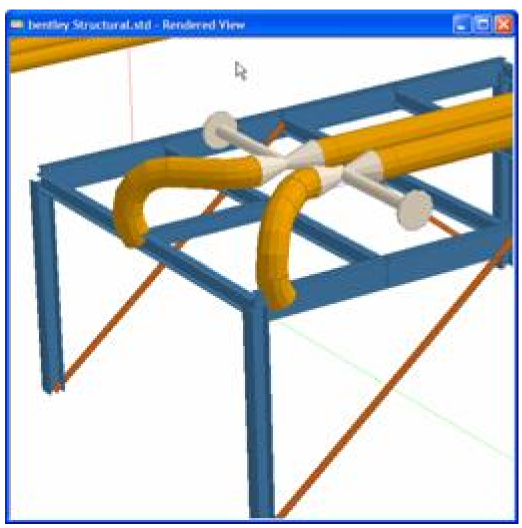
AD.2006-1002.6.2 3D Rendered View of Piping Model

In order to perform quick, visual clash detections, the 3D properties of the piping model have been added to the 3D section view and Rendered 3D View.

To view the solid 3D shapes in the graphical window, select the menu option, View > Structure Diagrams… This opens the Diagrams dialog in the Structures sheet. In the 3D Sections group, select the option 'Full Sections' to display a solid 3D shape of the structure model and piping arrangement, thus:



To view a rendered 3D view of the structural model with the piping arrangement, select the menu option, View > 3D Rendering… This creates a new window and displays a 3D perspective view of the model and piping thus:



Note: The piping model is only displayed in the Piping Mode.

AD.2006-1002.7 Additional STAAD.Pro 2006 Build 1002 Features

The following pages outline the additional features that have been added to STAAD.Pro in this version.

AD.2006-1002.7.1 Modifications in REI Security System

For details on the current security system for STAAD.Pro, please refer to the *STAAD.Pro Installation Guide* (`STAAD.Pro_InstallGuide_en.pdf`).

AD.2006-1002.7.2 Online Help

In order to assist the user operate STAAD.Pro, a number of context sensitive links have been added to the GUI such that clicking on a **Help** button or pressing the **<F1>** key will go directly to an appropriate help topic within the online documentation.

STAAD.Pro 2006 Build 1001 Release Report

The Software Release Report for STAAD.Pro 2006 Build 1001 contains detailed information on additions and changes that have been implemented since the final build of STAAD.Pro 2005. This document should be read in conjunction with all other STAAD.Pro help.

AD.2006.1 Features Affecting the Pre-Processor

Several new features have been added and existing features have been modified in the pre-processor section of the program. They are explained in the following pages.

AD.2006.1.1 Physical Member Interface

STAAD.Pro will allow grouping analytical predefined members into physical members using a special member group `PMEMBER`. `PMEMBER` defines a group of analytical collinear members, with same cross section and material property.

To model using PMEMBER, one needs to model regular analytical members and the start grouping those together.

While creating a PMEMBER, the following are the pre-requisites,

- Existence of the analytical members in the member-list.
- Selected members should be interconnected.
- The selected individual members are collinear.
- Local axis of the individual members comprising the physical member should be identical (i.e., x, y and z are respectively parallel and in same sense).
- A member in one Physical Member Group should not occur in any other Physical Member Group.

Related Links

- *TR.16.2 Physical Members* (on page 2238)

General Format

PMEMBER can be created either in modeling mode or Steel-Designer mode. Modeling mode and Steel-Designer mode physical members will be labeled as M and D, respectively. Modeling mode PMEMBER will allow variable cross-sections. Steel-Designer mode will allow importing PMEMBER-s created in modeling mode.

General Format

Following STAAD commands related to PMEMBER are implemented.

```
DEFINE PMEMBER
PMEMBER PROPERTY
PMEMBER CONSTANT
PMEMBER LOAD
PRINT PMEMBER FORCE
```

To define a Physical Member, the following command is used after the MEMBER INCIDENCE Command:

```
DEFINE PMEMBER
member list PMEMBER pmember-no
```

Example

```
 JOINT COORDINATE
1 0 0 0 6 10.0 0 0
MEMBER INCIDENCE
1 1 2 5
DEFINE PMEMBER
1 TO 5 PMEMB 1
```

To define the member property of a Physical Member, the following command is used:

```
PMEMBER PROPERTY
pmember-list PRIS …
```

The Physical Member supports all types of member properties available in STAAD.

If multiple definitions of member properties for a particular analytical member is encountered (e.g. analytical member properties is defined twice, once via PMEMBER PROP command and again via MEMBER PROP command, then MEMBER PROP command will override PMEMBER PROP definition.

To define the Material constants of a Physical Member, the following command is used:

```
PMEMBER CONSTANT
E  CONCRETE pmember-list
DEN CONCRETE pmember-list
…
```

Any member, which is a part of any PMEMNER is not allowed to be assigned constants explicitly.

Note: Loads are applied directly to PMembers using the PMEMBER LOAD command. See “PMember Load Specification” for details.

After the analysis, the Post Analysis results of a PMEMBER can be seen by using the following command:

```
PRINT PMEMBER FORCE
```

This command will produce member forces for all the analytical members in the group.

Graphical User Interface for Physical Member

The following steps are to be followed for creation of a Physical Member

Post-Processing Features Related to Physical Members

In the post processing results, to view the Shear Force diagram, Bending Moment Diagram and Deflected shape, use the member query dialog box.

Select a Physical Member by using the Physical Member cursor, and double-click on that to view the member query dialog box.

Design of Physical Members

In the current version of STAAD.Pro, the design of a Physical Member is not handled.

To Create a Physical Member

Make a frame model in STAAD.Pro, comprising of two or more consecutive beams.

1. Select two or more colinear, interconnected beams in th emodel.

   Refer the pre-requisites of the analytical members for details.
2. Either:

   Select the **Form Member** tool in the **Physical Member** toolbar

   or

   Right-click and select **Form Member** from the pop-up context menu.

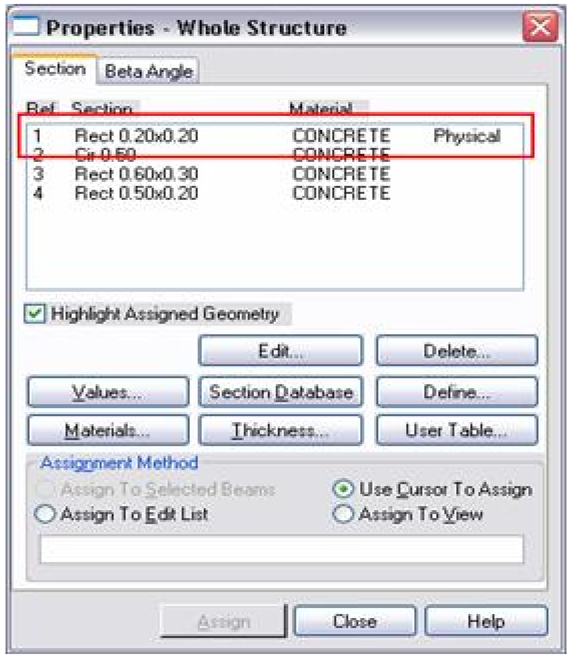
The details of the formed Physical Member can be seen in the **General | Physical Member** page at the right pane of the window.

To assign properties to a physical member

You must first create one or more physical member properties and then these can be assigned to physical members.

1. Select the **General | Property** page.
2. Select the **Toggle Physical Member mode** tool in the **Physical Member** toolbar.
3. Create a physical property:
   a. In the **Properties - Whole Structure** dialog, click **Define**.
      The **Propety** dialog opens.
   b. Select a property class and define the required property parameters.
   c. Click **Add**.

   A new property is added to the list in the **Properties - Whole Structure** dialog. This property is marked as “Physical”.



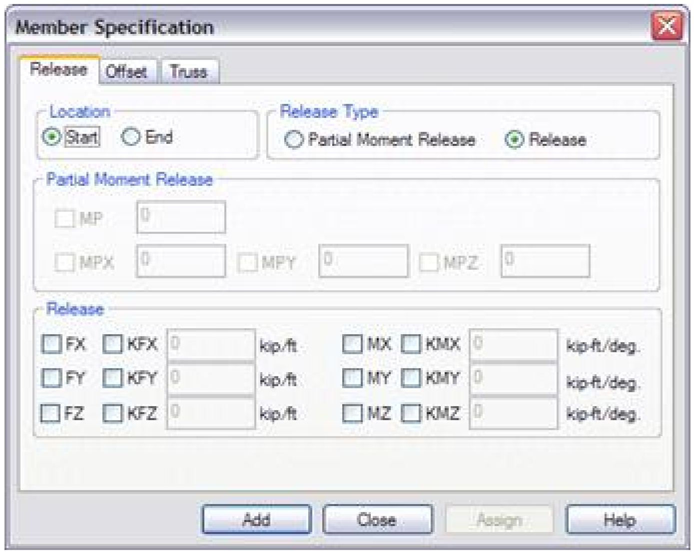
4. Assign this property to the physical member.

Note: For a Physical Member whose physical member property is already assigned, the individual analytical members in that Physical member will adopt the same member property that of the physical member. However, in case, where the analytical member property is assigned to any member in that physical member, then this analytical member property will supersede physical member property.

To assign specifications to a physical member

Only the Release, Offset, and Truss member specifications are available for physical members.

1. Select the **General | Spec** page.
2. Select the **Toggle Physical Member mode** tool in the **Physical Member** toolbar.
3. Create the member specification:
   a. Click **Beam** in the **Specifications - Whole Structure** dialog.
   The **Member Specification** dialog opens.



b. Select the dialog tab corresponding to the specificaiton type you want to add.
c. For Release or Offset specifications, specify the parameters to define the specificaiton.
d. Click **Add**.

A new specification is added to the list in the **Specifications - Whole Structure** dialog. Release and Offset specifications are marked as "Physical" where as Truss specifications are labeled **PMEMBER TRUSS**.

4. Assign this specification to the physical member.

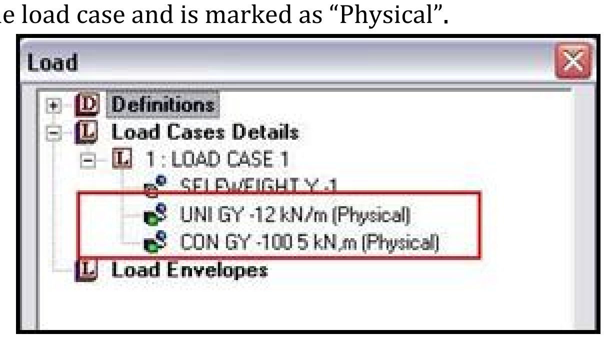
Note: For a Physical Member whose physical member specification is already assigned, the individual analytical members in that Physical member will adopt the same member specification that of the physical member. However, in case, where the analytical member specification is assigned to any member in that physical member, then this analytical member specification will supersede physical member specification.

To assign loads to a physical member

1. Select the **General | Load & Definition** page.
2. Select a load case in the **Load & Definition** dialog and click **Add**.

   Physical member loads can be assigned to a new or existing load case.

   The **Add New : Load Items** dialog opens.
3. Select the **Physical Member Loads** tab.
4. Specify the load item paramters for a load type and click **Add**.
   The load item is added to the load case and is marked as "Physical".



5. Assign the physical load items to physical members.

Note: For a Physical Member whose physical member Load is already assigned, the individual analytical members in that Physical member will adopt the member loads internally depending on the physical member load. However, in case, where the analytical member Load is assigned to any member in that physical member, then this analytical member Load will superimpose on the physical member Load.

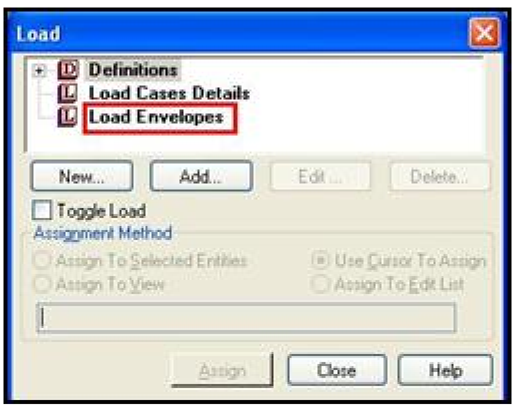
AD.2006.1.2 Load Envelopes

Load page will allow creation of Envelopes that can be saved as part of the STAAD input file. The user will be able to define multiple load envelopes each consisting of groups of predefined load cases. These envelopes can latter be used for post-processing. For example post analysis results may be viewed for a selected load envelope. As far as the STAAD engine is concerned, ENVELOP command will translate in to a LOAD LIST command.

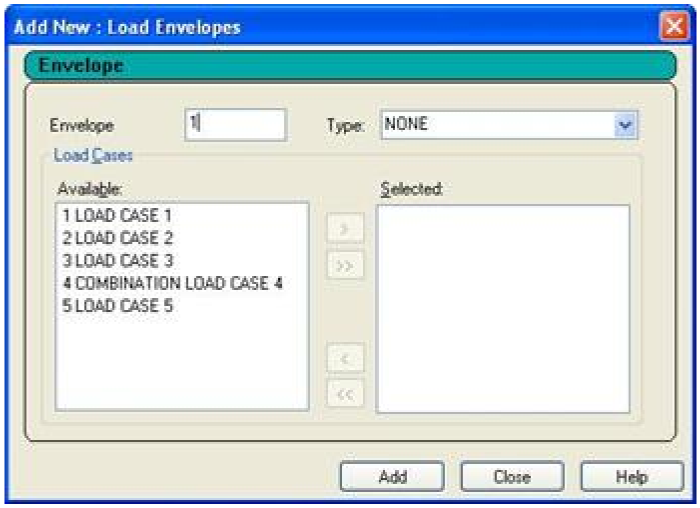
The envelope can be tagged with optional key words to specify qualitative nature of the load or load combination cases included in the envelop definition. Based on the nature of the load cases in the envelope, the users can define appropriate design parameters for each envelope. For example, for design under wind load condition, most of the design codes allow increase of allowable stresses. Design routine can increase the allowable stress used in interaction equation, when it does the design for the envelope. Another application of this feature can be to specify separate load groups for serviceability check, working stress and limit state checks.

Description

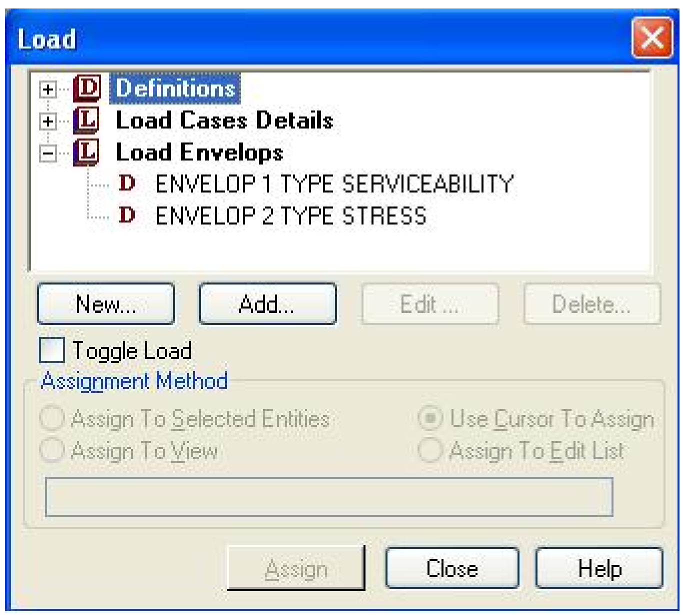
The option for defining **Load Envelopes** appears within the **Load** dialog box in the **General | Load** page as shown in the next figure.



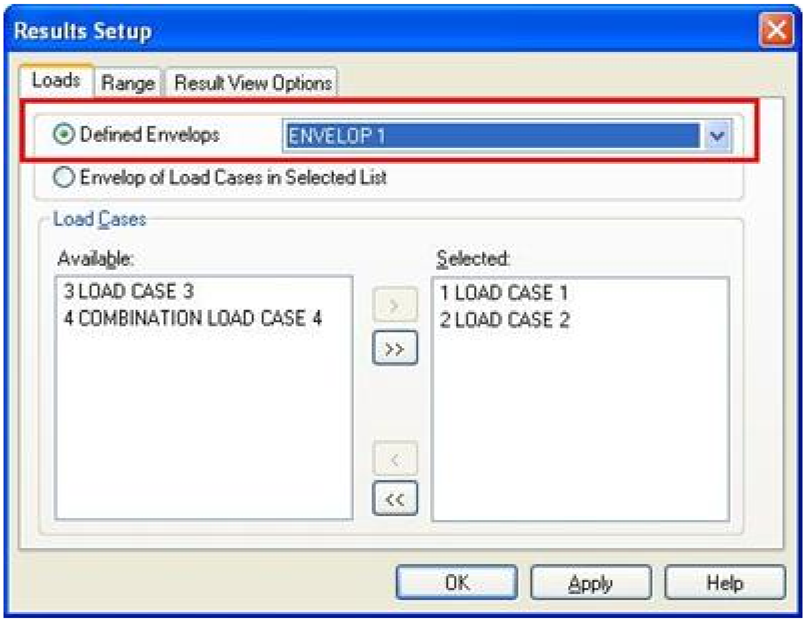
To define an envelope, select the Load Envelopes and click on the Add button and the Add New : Load Envelopes dialog box will come up as shown in the next figure.



The Envelope will be identified by the number that appears in the Envelope edit box. One can select an appropriate type for the load envelope like stress, serviceability etc. depending on the nature of the loads selected for the envelope. All the predefined primary load cases and combination cases will appear inside the **Available** window. One can now select one or more of these cases, bring them to the **Selected** window on the right hand side and click on the **Add** button to create the envelope. Once an envelope is created, it will be displayed in the **Load** dialog box as shown in the next figure.



In the post processing mode, the **Results Setup** dialog box will include option for selecting **Defined Envelopes** for the purpose of displaying results as shown in the next figure. Once an envelope is selected the corresponding loads can be seen within the **Selected** window.



General Format

The load envelope commands are written in the STAAD input file as shown below.

```
DEFINE ENVELOP
load-case-list ENVELOP # TYPE { NONE | STRESS | SERVICEABILITY | COLUMN | CONNECTION |
STRENGTH }
END DEFINE ENVELOP
```

Example

```
DEFINE ENVELOP
1 2 ENVELOP 1 TYPE SERVICEABILITY
3 5 ENVELOP 2 TYPE STRESS
END DEFINE ENVELOP
```

The first line within DEFINE ENVELOPE command means that load cases numbered 1 and 2 make up the serviceability type load envelope 1. Similarly load cases 3 and 5 define the stress type load envelope 2.

To print out the support reactions corresponding to load envelope 1, that includes load cases 1 and 2, the following commands will be defined in the input file

```
 LOAD LIST ENV 1
PRINT SUPPORT REACTIONS
```

If ENV keyword is encountered, the list will be interpreted as list of envelopes rather than a list of load cases.

Note: Please refer to the example file `Load_envelopes.std`, which is available under the different country folders.

AD.2006.1.3 Persistency of Parametric Mesh Model in STAAD Input File

In the past, once the parametric mesh model was merged with the base model, no information about the parametric mesh was retained by STAAD. So, if any modification was required at a later stage, the parametric mesh had to be created afresh. Parametric model feature has now been enhanced and multiple parametric mesh models can now be saved as part of the STAAD model. This would allow the users the flexibility to come back to the saved mesh models at any time and make modifications to it like adding an opening or adding a density line.

The parametric mesh model data is now saved as part of the STAAD input file. Special tag based commands has been introduced to support saving of parametric mesh models as part of the STAAD input file as shown below.

```
2072 1114 1113 1160; 2073 1045 1160 1113;

AD.2006.1.4 Persistency of Parameters User to Generate ASCE Wind Load in STAAD Input File

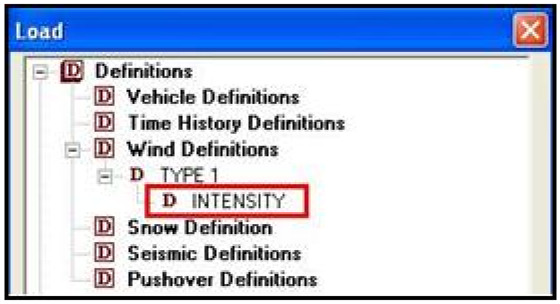
In the past, once the wind load as per the ASCE-7 code was generated automatically using the wind load generator, no information about the parameters was retained by STAAD. So, there was no way to check the parameters, based on which the generation was done. Moreover, if any modification was required at a later stage, all the parameters had to be defined afresh. Automatic wind load generation feature has now been enhanced and the parameters can now be saved as part of the STAAD.Pro model.

Special tag based commands has now been introduced to support saving of ASCE parameters as part of the STAAD input file as shown below.

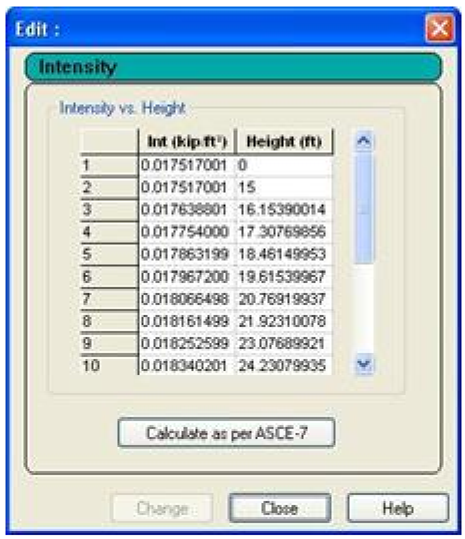
```
DEFINE WIND LOAD
   TYPE 1
   INT 0.017517 0.017517 0.0176388 0.017754 0.0178632 -0.0179672 0.0180665 0.0181615
0.0182526 0.0183402  0.018506 -0.0184246 0.0185846 0.0186607 0.0187345 -
   HEIG 0 15 16.1539 17.3077 18.4615 19.6154 20.7692 21.9231 -23.0769 24.2308 25.3846
26.5385 27.6923 28.8462 30
   <! STAAD PRO GENERATED DATA DO NOT MODIFY !!!
   ASCE-7-2002:PARAMS 85.000 MPH 0 2 2 0 0.000 FT 0.000 FT -0.000 FT 1 1 30.000 FT
```

```
80.000 FT 60.000 FT 2.000 0.010 0 -
   0 0 0 0 0.982 1.000 1.150 0.850 0 0 0 0 0.631 0.800 0.550
   !> END GENERATED DATA BLOCK
```

When a user goes back to the Load page and goes to **Definitions | Wind Definitions** page and double clicks on the **Intensity** as shown in the next figure,



the intensity versus height data shows up as shown below.



One can now click on the **Calculate as per ASCE-7** button and the parameters that were initially defined are going to appear in the resulting dialog boxes.

Note: Please refer to the example file `ASCE_WIND_load_generation.std`, which is available under various country folders.

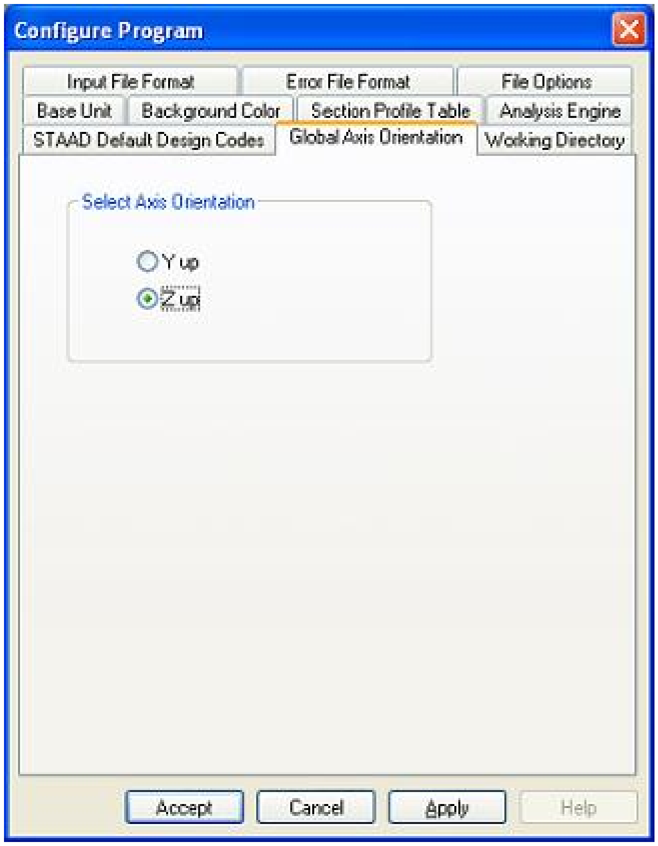
AD.2006.1.5 Enhancement of Z UP System

Earlier, when geometry created using a CAD software that used Z axis as the vertical axis, had to be imported into STAAD.Pro, the users had to reorient the model to make the Y axis the vertical axis before getting the model into STAAD.Pro. This was necessary because a number of STAAD.Pro load generation commands did not work when the Z axis was defined as the vertical axis. In STAAD.Pro 2006 these limitations has been addressed. All the load generations are going to work with the Z axis up coordinate system.

The default coordinate system for a model can be set by going to **File** > **Configure**. The **Configure** option is only available when no STAAD model is open. If a STAAD model is open, one has to click on **File** > **Close** to close the file first.

The **Configure Program** dialog comes up as shown in the next figure.



The **Z up** option can then be selected and applied to the model. This would set the Z axis to be the vertical axis instead of the default Y axis. Subsequently all modeling, analysis and postprocessing items would be based on this coordinate system.

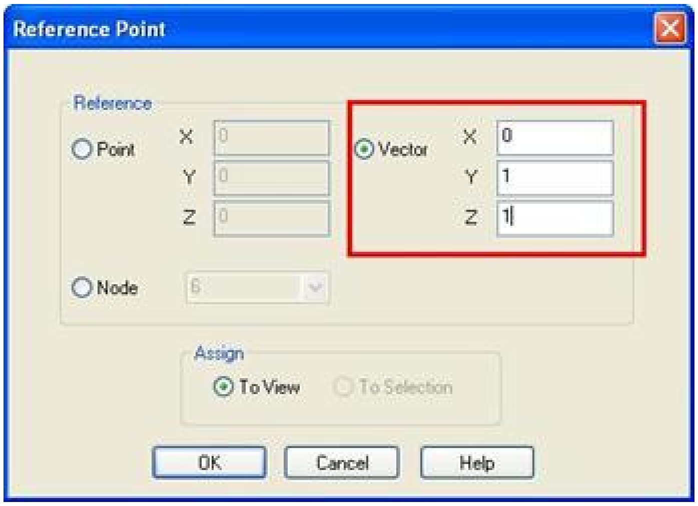
AD.2006.1.6 Specification of Member Orientation Using Reference Vector

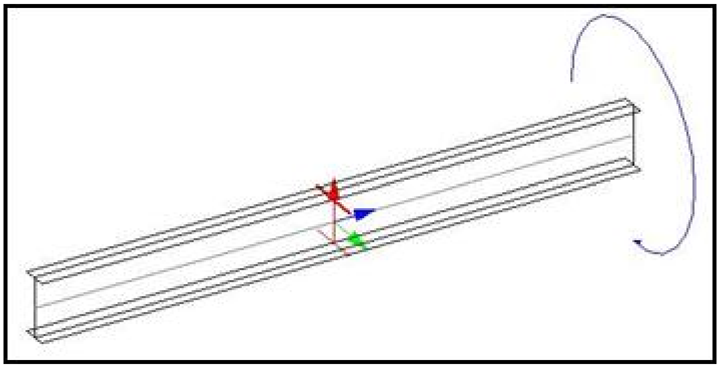
This feature will allow users to orient members by specifying a direction vector. Beta angles will be calculated by the software by itself based on the direction vector specification. The new reference vector will be defined with respect to the local coordinates of the member. This is going to make the task of orienting members much easier.

To access the feature go to **Commands** > **Geometric Constants** > **Member Reference Point**.

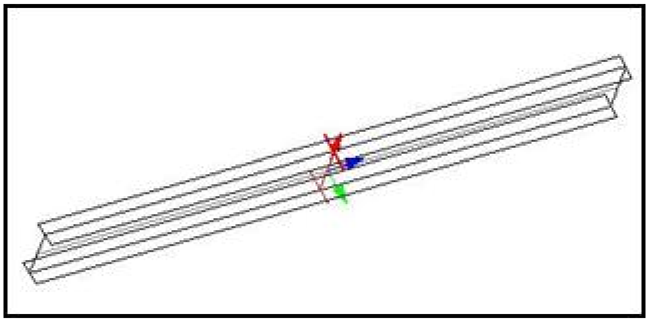
The **Reference Point** dialog box comes up where the vector for the reference axis can be specified as shown in the following figure. The local Y axis for the member is going to oriented along the vector. This X, Y, Z values are going to be based on the local axis system of the member.



The feature is explained in the next section with an example. Let us consider the beam shown in the next figure. The requirement is to rotate the cross section about the axis of the member in the direction as shown, such that the angle of rotation is governed by a slope of 1 horizontal to 2 vertical.



1. Select **Commands** > **Geometric Constants** > **Member Reference Point**. The **Reference Point** dialog opens.
2. Select the **Vector** option and specify the reference vector so that it is oriented as per the required slope.
3. Click **OK**. The member is rotated to the referenc vector.



The member gets oriented correctly without the user having to take the trouble of calculating the beta angle. In the STAAD input file, the following command lines get written.

```
CONSTANTS
REFVECTOR 0 2 1 ALL
```

Beta angle for the member can be easily figured out by simply double clicking on the member that brings up the **Beam** dialog box as shown next. The correct beta angle of 26.5651 is automatically calculated by STAAD.Pro based on the reference vector specification.

- *TR.26.2 Specifying Constants for Members and Elements* (on page 2305)
- *M. To align a member to a reference point* (on page 801)

AD.2006.1.7 Single File Archive to Save All STAAD Input & Ouput Files

Based on user configurations, file open and save dialogs will allow user to select .stz (std archive) files. The archive will be expanded to TEMP folder or user configurable working folder. All input/output will be created at that location.

While exiting the program/session, all of those files will be archived again under same name and copied to original source folder.

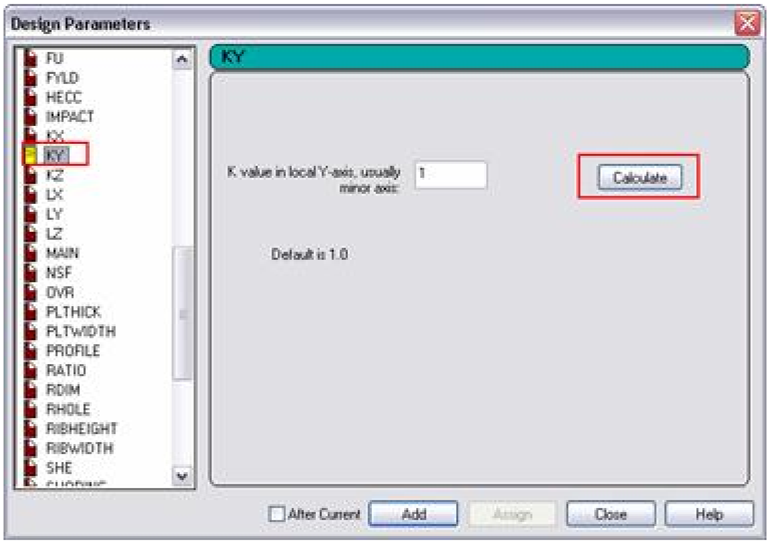
Archive related commands can be found on the **File** menu.

AD.2006.1.8 Auto Calculation of Effective Length Factors of Members as per AISC Code

STAAD.Pro has a new feature to auto-calculate the Effective Length Factors (KY, KZ etc), for the members to be designed as per AISC-ASD Code.

To make use of this feature, the user needs to go to the **Design | Steel** page. Select the Country Code as **AISC ASD**. Select the member for which the Effective Length Factors are to be calculated. Click on the **Define Parameters** button and select the parameter **KY** or **KZ**.

The following dialog box will appear.



The only difference from the previous version of STAAD.Pro is the addition of the **Calculate** button as marked in the figure.

On clicking the **Calculate** button, the program will ask whether the braced or un-braced effective length of the selected member is required.

After getting confirmation from the user, the program will calculate and display the value of the Effective Length Factor in the Edit box.

Now, click on the **Assign** button to associate this value of the respective Effective Length Factor with the selected member.

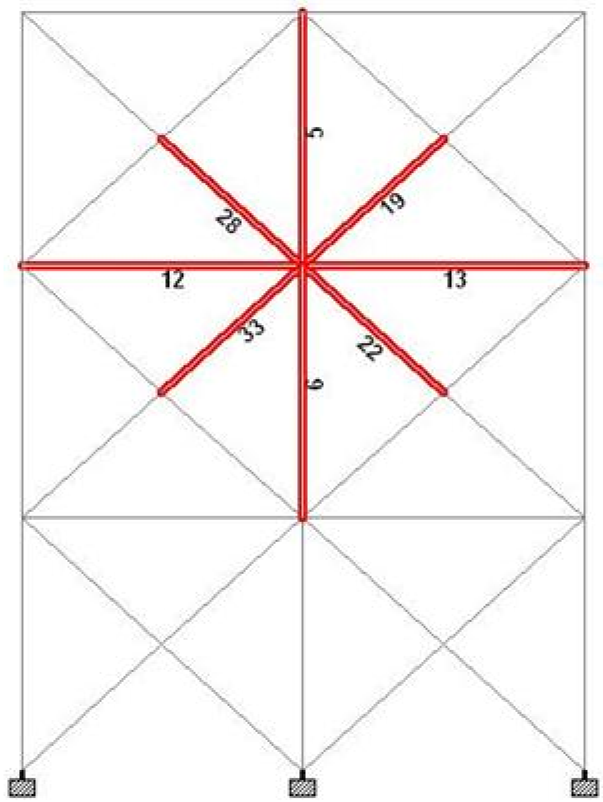
Note: The calculation of the effective length factors are done as per a paper titled *Compression Members* presented by George Tsiatas.

AD.2006.2 Features affecting the Post-Processor (Results Mode)

Several new features have been added and existing features have been modified in the post-processor section of the program. They are explained in the following pages.

AD.2006.2.1 Generation of Transfer Force Report for Connection Design

STAAD.Pro can now calculate the “Transfer force” or “pass through force” that can be used for connection design. This feature is based on a paper on the subject by Dr. William. A. Thornton. Refer to the next figure which shows beams and bracing members connected to either side of the column.

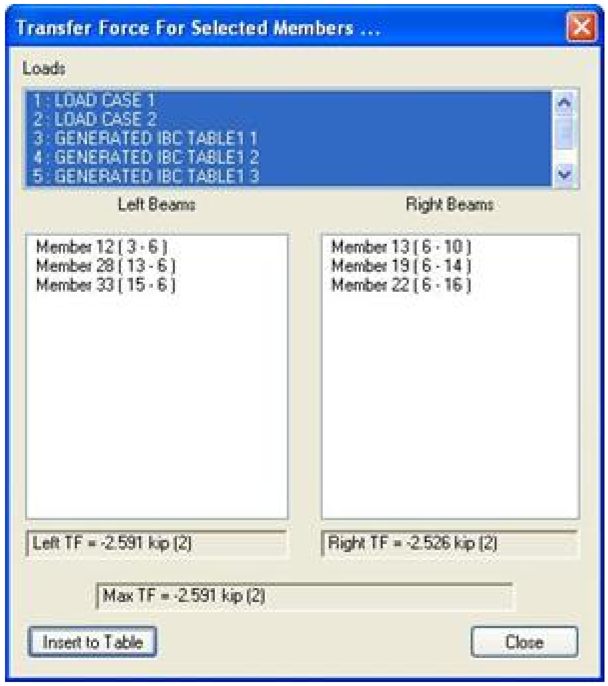


Transfer force is simply the maximum net horizontal force that gets transferred from the one side of the column to the other through the connection. So STAAD.Pro checks the forces in the members framing into each side of the column and finds out the resultant horizontal force for either side. Typically the resultant forces on the two sides would not be equal as some amount of force will be taken up by the column in shear. The greater of the two resultants is reported by STAAD.Pro as the transfer force. The option to determine transfer force automatically, will save engineers considerable time and effort as in most cases, they have to report the transfer forces in the design drawings. The transfer force feature only works for a beam column bracing system lying in a vertical plane.

Description

Go to the Post processing mode by selecting **Mode | Postprocessing** or by clicking on the **Postprocessing** tab above the graphics window. Select all the members that frame into any connection as shown in the previous figure. Then select **Report** > **Column Transfer**.

A dialog box titled **Transfer Force for Selected Members** comes up as shown in the next figure. The **Loads** box displays the load cases that has been considered to calculate the transfer force. By default all load cases are considered but one can exclude a few of them by simply clicking on the load case within the **Loads** box. The boxes **Left Beams** and **Right Beams** list all the members on the respective sides of the column along with their incidences. The boxes **Left TF** and **Right TF** shows the resultant horizontal force from either side. **Max TF** reports the transfer force.



Click on the **Insert to Table** button and a table will be generated containing all the transfer force information as shown in the next figure.

TrasnferForces.std - Transfer Force Report : 6

	Cmn Node	Left Memb	Right Memb	Selected Ld	Left TF kip	Load	Right TF kip	Load	Max TF kip	Load
1	6	12	13	1	-2.591290	2	-2.526045	2	-2.591290	2
2		28	19	2						
3		33	22	3						
4				4						
5				5						
6				6						

Transfer Force Table

The transfer force information can also be included as part of a report by selecting **File** > **Report Setup** or by selecting the **Report Setup** tool  which will open the **Report Setup** dialog box as shown in the next figure.

By default, the **Transfer Force Report** appears in the selected list of items within the dialog box. A report with the transfer force data can then be generated as shown next.

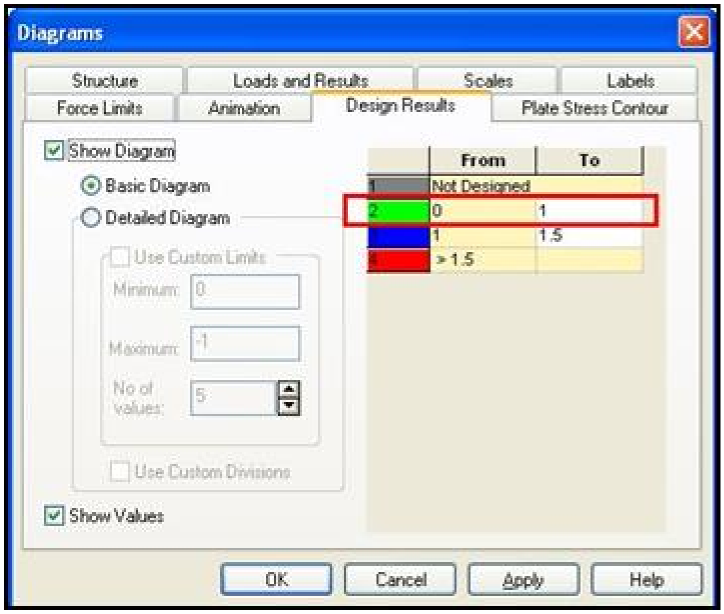
AD.2006.2.2 Customizable Color to Display Unity / Check Utilization Ratio

View steel design results.

Default color for display of passed members was black. It has now been changed to green. The colors representing the various ranges for utilization ratios can be set by the user.



AD.2006.2.3 Enhancement to Steel Designer BS 5950 Calculation Sheets

The design calculation sheets of a steel section that has been designed with a BS 5950-1:2000 design brief has been modified with the following enhancements.

1. The terminology for elastic and plastic sections updated to use same terminology as in the design code.
2. A summary has been added at the end of the calculation sheet.
3. The section classification summary has been improved.
4. The reported dimensions of the section in the 'Compression Flange Buckling Check' have been improved.
5. The status for various checks has been re-titled.
6. Details of check to 4.8.3.3.1 added when required.
7. There are improved details of the clauses 4.8.2., 4.8.3. and Annex I1 calculations.
8. The 4.3.6. Lateral Torsional Buckling Check has been enhanced.
9. Additional detailed calculations for axially loaded members have been added to the document.
10. A number of spelling issues have been addressed.

AD.2006.3 Features affecting Analysis and Design

Several new features have been added and existing features have been modified in the analysis and design section of the program. They are explained in the following pages.

AD.2006.3.1 Pushover Analysis

This is a set of procedures to implement a Pushover Analysis as defined in the document FEMA 356:2000.

STAAD Pushover analysis in STAAD is a static, non-linear procedure in accordance with FEMA 356 specification. Basically, in this method, the magnitude of the lateral push load is increased progressively according to a predefined loading pattern until either loading or the deflection reaches the described level.

Please refer to M. Pushover Loads (on page 881) for details on using this feature.

Note: Refer to the example files `ExampPush01.std`, `ExampPush02.std`, `ExampPush03.std`, and `ExampPush04.std` in the folder `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Pushover\`.

AD.2006.3.2 Steady State Analysis

Please refer to TR.37.6 Steady State and Harmonic Analysis (on page 2632) for details.

Note: Also refer to the example files `SVM33.std`, `SVM32.std`, `SS-beam2.std`, `SS-beam3.std`, `Exam07.std`, and `Exam14b.std` in the folder `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\SteadyState\`.

AD.2006.4 Features affecting the RC Designer Mode

Several new features have been added and existing features have been modified in the RC Designer mode of the program. They are explained in the following pages.

Refer to the RC Designer Manual for full details. Note that references made here are for sections in the RC Designer Manual.

AD.2006.4.1 Slab Design to BS 8110

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2006.4.2 BAEL Beam Design Enhancement

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2006.4.3 French GUI

Recent changes to the program's language facilities have depricated these changes.

AD.2006.4.4 DIN 1045-1 Beam and Column Design

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2006.4.5 Use of Generated Load Cases

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2006.4.6 Use of Primary Load Cases in Column Designs

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2006.4.7 BS8110 Beams Torsion Check Added

Note: The legacy Concrete Design workflow (included in V8i and earlier as the RC Designer application) has been deprecated in favor of the Advanced Concrete Design workflow using RCDC.

AD.2006.5 Additional STAAD.Pro 2006 Features

The additional enhancements made to STAAD.Pro 2006 are explained in the following pages.

AD.2006.5.1 STAAD.Pro Language Application

Recent changes to the program's language facilities have depricated these changes.

AD.2006.5.2 Section Wizard databases

Section Wizard Section Builder module and FreeSketch modules make use of defined standard steel databases. 3 new additional databases have been added and 3 have been updated.

New Additional Databases

INDIAN.PRF - Indian
JAPANESE.PRF - Japanese
SAFRICA.PRF - South African

Updated Databases

BRITISH1.PRF – UK Corus
DIN.PRF - German
USA.PRF - ASTM

Note, all other databases are unchanged.

AD.2006.6 Features Added in STAAD.Pro 2005 Previously Undocumented

The following pages explain features that have been introduced into STAAD.Pro but were not fully documented in previous Release Reports.

AD.2006.5.1 DESCON, Advanced Connection Design Mode

Recent changes to the program's language facilities have depricated these changes.

RAM Connection is now the supported facility for steel connection design in STAAD.Pro.

AD.2006.5.2 ADAPT Slab Design Mode

Recent changes to the program's language facilities have depricated these changes.

Refer to the User Interface help for use with the D. Advanced Slab Design (on page 1073).

Note: Beginning with STAAD.Pro CONNECT Edition, direct export to ADAPT-Builder® has been deprecated.

AD.2006.6.3 BS5950 Part 5 - Cold Formed Steel Design

Refer to D3.E. British Codes - Design per British Cold Formed Steel Code (on page 1405) for details.

AD.2006.6.4 EC4 Timber Design

Refer to D5.E. European Codes - Timber Design Per EC 5: Part 1-1 (on page 1582) for details.

AD.2006.6.5 Canadian Timber Design

Refer to D4.D. Canadian Codes - Timber Design per CAN/CSA-086-01 (on page 1439) for details.

AD.2006.6.6 South African Steel Design

Refer to D14.B. South African Codes - Steel Design per SANS10162-1:1993 (on page 1954) for details.

AD.2006.6.7 South African Concrete Design

Refer to D14.A. South African Codes - Concrete Design per SABS-0100-1 (on page 1949) for details.

AD.2006.6.8 EC8 Earthquake Loading

Refer to TR.32.10.1.4 Response Spectrum Specification per Eurocode 8 1994 (on page 2520) for details.

AD.2006.6.9 Additional Kingspan Cold Formed Steel Database

Refer to TR.20 Member Property Specification (on page 2255) for details.

AD.2006.6.10 Imperfection Analysis

Refer to TR.26.6 Member Imperfection Information (on page 2313) for details.

AD.2006.6.11 Tapered Steel Design Added to BS 5950

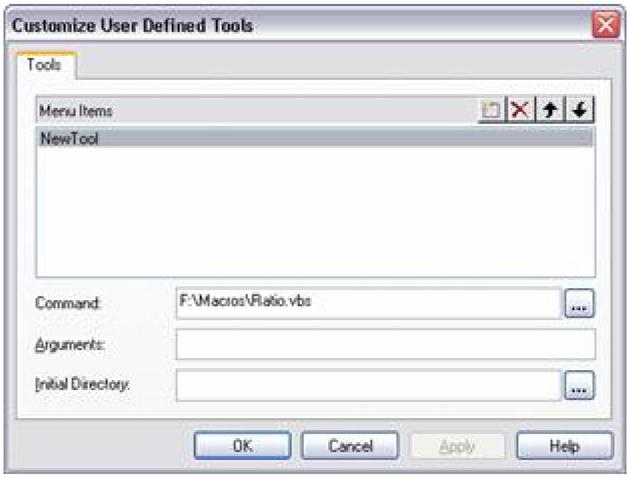
Refer to D3.B. British Codes - Steel Design per BS5950:2000 (on page 1378) for details.

AD.2006.6.12 User Tools

The users can utilize their own customized tools, in form of VBS Macro, to operate on STAAD.Pro models.

The procedure of associating a user tool in STAAD.Pro is furnished below:

1. Run STAAD.Pro and Open an input file.
2. Select **Tools** > **Configure User Tools**.
   The **Customzie User Defined Tools** dialog opens.



3. In the **Menu-Items**, add a name of the Tool, and in the **Command**, locate the Tool (VBS Macro) using the browser. Click **OK** to confirm.
4. Now the Tool name will appear in **Tools** > **User Tools** and also by selecting the Tools tool. 
5. To Run the Tool (Macro), click on the Tool name in any of the places as described in step 4.

Related Links

- *OS. To add the macro to the list of user tools* (on page 7040)

STAAD.Pro 2005 Release Report

This Software Release Report for STAAD.Pro Version 2005 contains detailed information on the additions and enhancements made to the program since the final build of STAAD.Pro 2004.

AD.2005.1 Features affecting the Pre-Processor

Several new features have been added and existing features have been modified in the pre-processor section of the program. They are explained in the following pages.

AD.2005.1.1 Generation of Wind Pressure profile per ASCE 7-02

STAAD.Pro is now capable of generating the wind pressure profile for a structure in accordance with the ASCE-7-02 code. The pressure profile is the table of values of wind intensity versus height above ground.

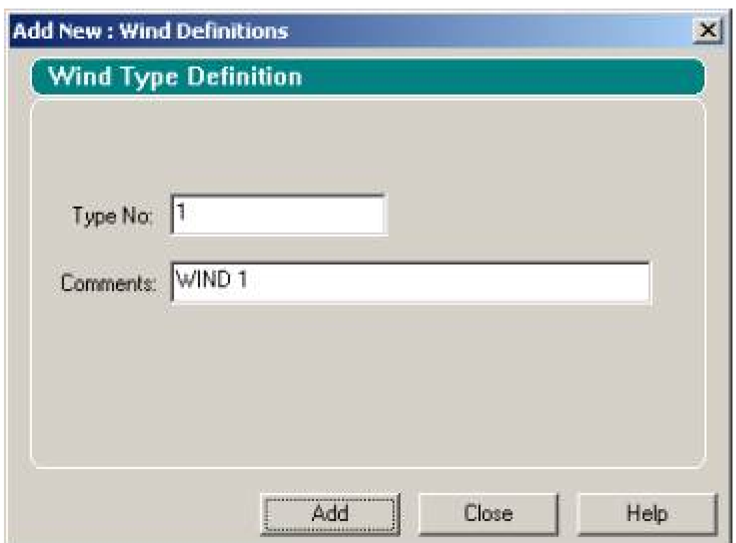
The calculated pressure may then be applied on the structure to compute loads on members using the program's built-in wind load generation algorithm for the closed as well as open-lattice type structures.

Description

The steps required to generate the wind pressure profile are as follows:

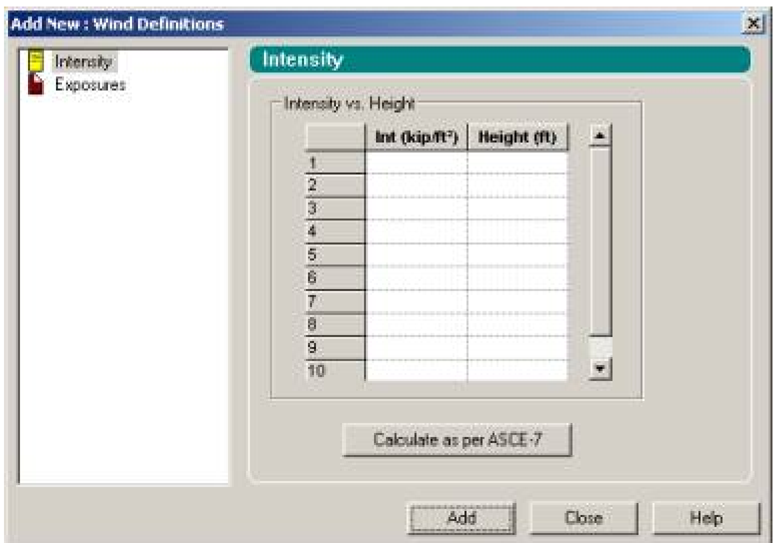
In the **General | Load** page (from the vertical tabs on the left-hand side), go to the Load dialog box on the right and select **Wind Definitions** as shown in the next figure.

Click on the **Add** button to instantiate the **Add New Wind Definitions** dialog box shown in the next figure. Enter the **Type No.** which denotes a number by which the wind load type will be identified. Multiple wind types can be created in the same model. Click on the **Add** button within this dialog box and then click on **Close**.



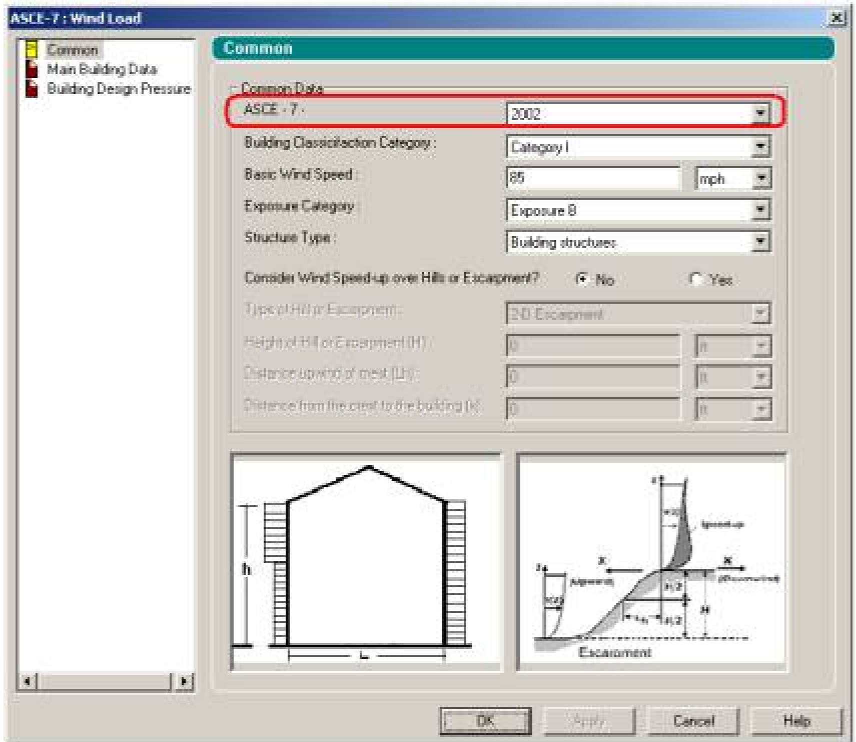
The newly created TYPE 1 wind definition will appear underneath Wind Definitions in the **Load** dialog box as shown below.

Select the TYPE 1 name in the tree control and click on the Add button. The dialog box shown below will prompt for the pressure profile (intensity) for this wind definition.



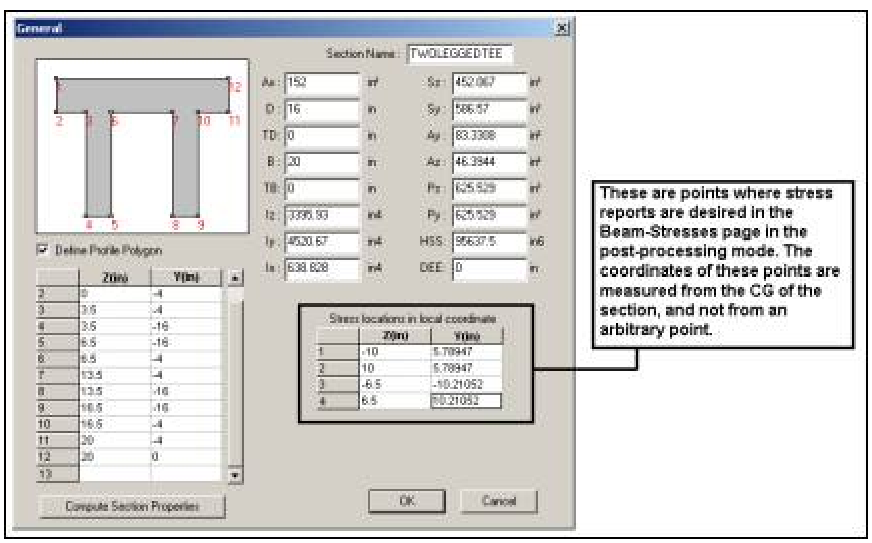
As we said earlier, the pressure profile is the table of wind intensity versus height above ground. If we know that, that information can be typed into the box above. But, our goal is to calculate that. Hence, we click on the button **Calculate as per ASCE-7**.

The ASCE-7: Wind Load dialog box shown below will appear.



The options shown in the dialog box are explained below:

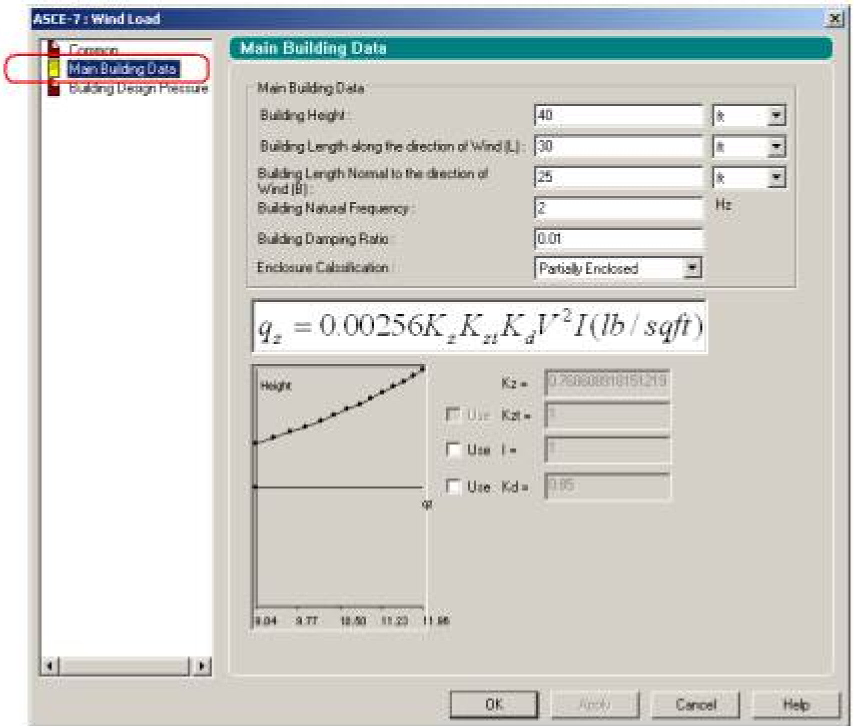
Common Data



ASCE - 7 -	Depending on which version of the code to use, choose either 1995 or 2002.
Building classification category	Building classification category as obtained from Table 1-1 in SEI/ASCE 7-02. Category can be I, II, III or IV
Basic Wind Speed	Basic Wind Speed as described in section 6.5.4 of the SEI/ASCE 7-02 code.

Exposure Category	Exposure category as described in section 6.5.6.3 of the SEI/ASCE 7-02 code.
Structure Type	Select the type of structure that best fits the model from the available choices: • Building structures • Chimneys, Tanks and similar structures • Solid Signs • Open Signs • Latticed Framework • Trussed tower The associated input pages will change depending on the selection of the type of structure.
Consider Wind speed-up over hill or escarpment	If there are isolated hills and escarpments that constitute abrupt changes in the general topography, the increase in speed can be considered as per section 6.5.7 in the SEI/ASCE 7-02 code. Select 'Yes' to consider wind speed-up over a hill or an escarpment and 'No' to ignore it.
Type of Hill or Escarpment	Select the type of hill, ridge or escarpment on which the structure is located, based on figure 6-4 of the SEI/ASCE 7-02 code. The options available are 2-D Escarpment, 2-D Ridge and 3-D Axisymmetric Hill.
Height of Hill or Escarpment (H)	Specify the height of the hill or escarpment relative to the upwind terrain (H in Figure 6-4 of the SEI /ASCE-7-02 code).
Distance upwind of crest (L_h)	Specify the distance upwind of crest to where the difference in general elevation is half the height of the hill or escarpment (L_h in Figure 6-4 of the SEI/ASCE-7-02 code).
Distance from the crest to the building (x)	Specify the distance from the crest to the building site. A negative value signifies that the distance is in the downwind direction (X in Figure 6-4 of the SEI/ ASCE-7-02 code).

Main Building Data



Building Height	The height above ground to the highest point on the roof surface.
Building Length along the direction of Wind (L)	Length of building measured along the direction of wind
Building Length Normal to the direction of Wind (B)	Length of building measured normal to the direction of wind
Building Natural Frequency	Specify the natural frequency of the building to calculate Gust Effect Factor.
Building Damping Ratio	Specify the damping ratio to calculate Gust Effect Factor.
Building Damping Ratio	Specify the damping ratio to calculate Gust Effect Factor.
Enclosure Classification	Classify the building as open building, partially enclosed or enclosed as per the provisions of section 6.2 of SEI/ASCE-7-02.
Kz	Velocity pressure exposure coefficient that is calculated by STAAD.Pro as per Table 6-3 of the SEI/ASCE-7-02 code.
Kzt	When wind speedup is considered, Kzt is calculated as per Eq 6-4 of the SEI/ASCE-7-02 code. Users can modify the value by checking the Use box and providing the required value in the edit box for Kzt.
I	Importance Factor I is considered as per section 6.2 of the SEI/ASCE-7-02 code. Users can enter their own value by checking the Use box and typing the required value in the edit box for I.

Kd	Wind directionality factor is calculated as per Table 6-4 of the SEI/ASCE-7-02 code. Users can modify the value by checking the Use box and typing the required value in the edit box for Kd.

The list of parameters explained earlier corresponds to the structure type called “Building Structures”. When structure type is varied, some of those parameters change. Those parameters that are different are explained below for each type of structure.

Structure type: Chimney, Tank, and similar Structures

Height (H)	Height of the structure as defined by the term ‘h’ in Figure 6-19 of the SEI/ASCE 7-02 code.
Least Horizontal Dimension (W)	Smaller of the plan dimensions. In case the cross section of the structure in plan is circular, the diameter needs to be specified.
Horizontal Cross-Section Type	This is the cross section of the structure in plan as defined in Figure 6-19 of the SEI/ASCE 7-02 code. The available options include square with wind being normal to face or acting along the diagonal, hexagonal, octagonal and round.
Depth of protruding elements such as ribs and spoilers (D’)	For round type cross sections, depth of protruding elements need to be defined which is a measure of the surface roughness as indicated in Figure 6-19 of the SEI/ASCE 7-02 code.
C_f	Force coefficient that is calculated by STAAD.Pro as per Figure 6-19 of the SEI/ASCE 7-02 code. The parameter is used for calculation of design pressure. If desired, users can enter their own value for C_f by checking the **Use** box and typing the required value in the appropriate edit box.

Structure type: Solid Signs

Height (H)	Height of the structure which is used for calculating the height to width ratio as defined by the term ‘n’ in Figure 6-20 of the SEI/ASCE 7-02 code.
Horizontal Dimension of Sign (M)	Horizontal dimension of the solid sign
Vertical Dimension of Sign (N)	Vertical dimension of the solid sign. If the sign is at the ground level, the height (H) and vertical dimension (N) should both be specified the same value.
C_f	Force coefficient that is calculated by STAAD.Pro as per Figure 6-20 of the SEI/ASCE 7-02 code. The parameter is used for calculation of design pressure. If desired, users can enter their own value for C_f by checking the **Use** box and typing the required value in the appropriate edit box.

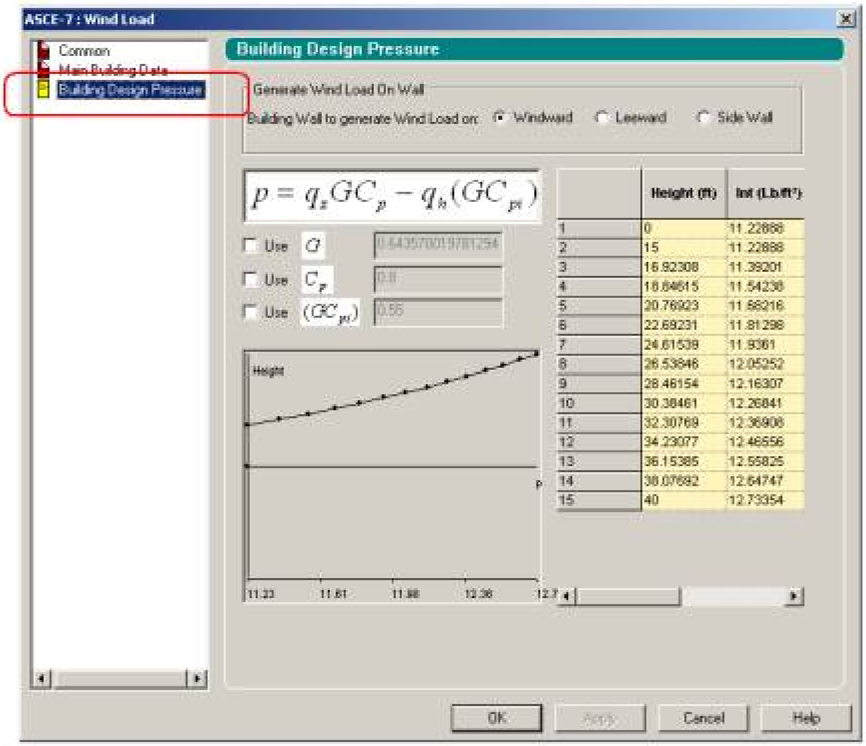
Structure type: Open Signs / Lattice Frame Work

Ratio of Solid Area to Gross Area	Ratio of solid area to gross area as indicated by the term e in Figure 6-21of the SEI/ASCE 7-02 code.
Orientation of the members exposed to wind	The type of member surfaces which are exposed to wind. Select flat-sided members or rounded members in Figure 6-21 of the SEI/ASCE 7-02 code.
Diameter of typical round member	Diameter for round members as defined by the term ‘D’ in Figure 6-21 of the SEI/ASCE 7-02 code.

Structure type: Trussed Tower

Horizontal Cross Section	The type of cross section of the tower in plan as defined in Figure 6-22 of the SEI/ASCE 7-02 code. The available options include square and triangle.

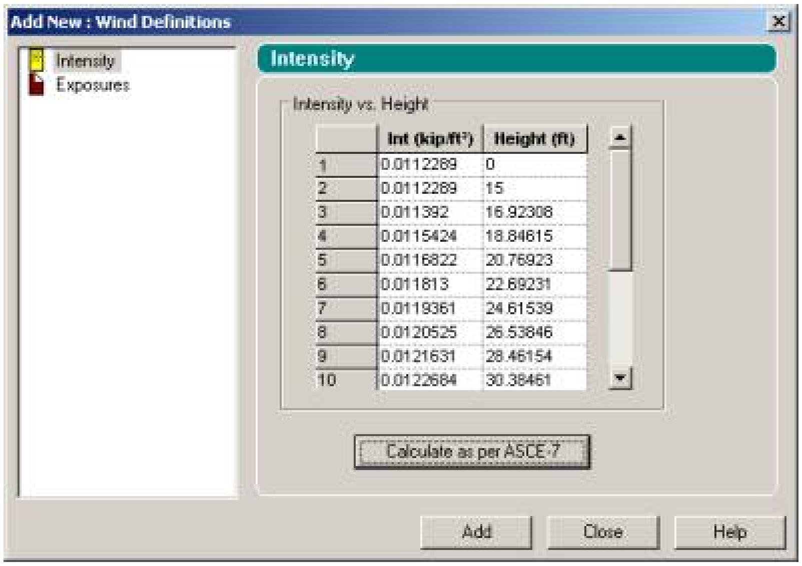
Building Design Pressure



Building Wall to generate Wind Load on:

Windward	To generate the design wind pressure for the windward side, choose this option. The pressure will be calculated as per Equation 6-23 of the SEI/ASCE-7-02 code. The relevant equation is also displayed in the box just beneath the radio buttons.
Leeward	To generate the design wind pressure for the leeward side, choose this option. The pressure will be calculated as per Equation 6-23 of the SEI/ASCE-7-02 code. The relevant equation will be displayed in the box just beneath the radio buttons.
Side Wall	To generate the design wind pressure for the side wall, choose this option. As before, the pressure will be calculated as per Equation 6-23 of the SEI/ASCE-7-02 code. The relevant equation will be displayed in the box just beneath the radio buttons.
G	Gust effect factor calculated as per section 6.5.8 of the SEI/ASCE-7-02 code. Users can modify the value by checking the Use box and typing the required value in the edit box for G.
Cp	External pressure coefficient. The product of external pressure coefficient & gust effect factor is considered as per Figures 6-11 through 6-17 of the SEI/ASCE-7-02 code. Users can modify the value of Cp by checking the Use box and typing the required value in the edit box for Cp.
GCpi	Internal pressure Coefficients as per Figure 6-5 of the SEI/ASCE-7-02 code. Users can modify the value by checking the Use box and typing the required value in the edit box for GCpi.

The table on the right displays the intensities at various heights. Click on OK to arrive at the dialog box shown below.



Click on **Add** to add the load definition.

The defined wind loading can then be applied to the structure following the same procedure as in prior versions of the program. For details on the command syntax for generation of wind loads, refer to section 5.32.12: Generation of Loads from the STAAD Technical Reference Manual and example problem 15 in the Examples manual.

Note: The option we encountered earlier regarding the windward side, leeward side and side walls tells us that the pressure profile for each of those has to be individually determined under a unique type number. Thus, generating the profile for the 3 sides of the building constitutes 3 separate steps and thus, 3 separate types. Each type can then be applied with one load case or separate load cases and then applied in the relevant direction with the appropriate direction factor. Examples illustrating wind load generation can be found in the examples manual.

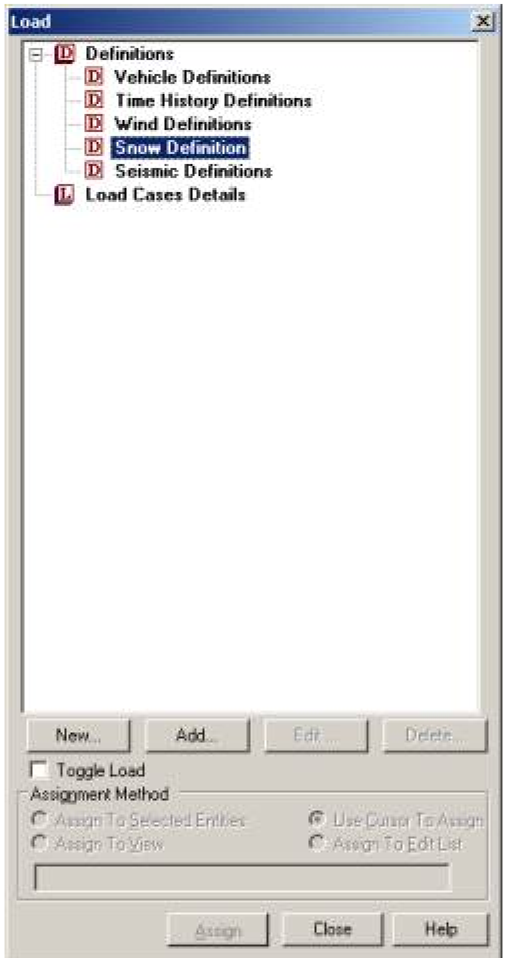
AD.2005.1.2 Generation of Snow Load Per SEI-ASCE 7-02

STAAD.Pro is now capable of generating snow loading on a structure in accordance with the provisions of the ASCE-7-02 code. The feature is currently implemented for structures with flat or sloping roofs. Snow load generation for members of open lattice structures like electrical transmission towers is currently not part of this facility. Hence, the feature is based on panel areas, not the exposed width of individual members.

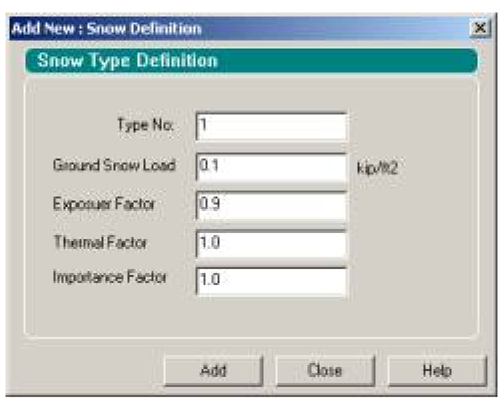
There are two parts to the command specification for snow load generation.

Part I

In this step, we define the parameters. In the **General | Load** page (from the vertical tabs on the left-hand side), go to the **Load** dialog box on the right and select **Snow Definition** as shown in the next figure.



Click on the **Add** button to instantiate the **Add New: Snow Definition** dialog box shown below. The **Type No.** is an integer value (1, 2, 3, etc.) which denotes a number by which the snow load type will be identified. Multiple snow load types can be created in the same model.

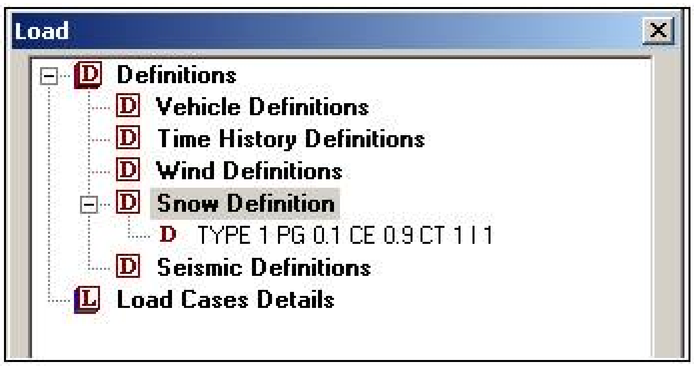


The fields in the above dialog box are:

Ground Snow Load	The pressure or, weight per unit area, to be used for the calculation of the design snow load. Use a negative value to indicate loading acting towards the roof (upwards) as per section 7.2 of SEI/ASCE 7-02.
Exposure Factor	Exposure factor as per Table 7-2 of the SEI/ASCE-7-02 code. It is dependent upon the type of exposure of the roof (fully exposed/partially exposed/sheltered) and the terrain category, as defined in section 6.5.6 of the code.
Thermal Factor	Thermal factor as per Table 7-3 of the SEI/ASCE-7-02 code. It is dependent upon the thermal condition.
Importance Factor	Importance factor as per Table 7-4 of the SEI/ASCE-7-02 code. This value depends on the category the structure belongs to, as per section 1.5 and Table 1-1 of the code.

Click on the Add button within the dialog box and then click on Close.

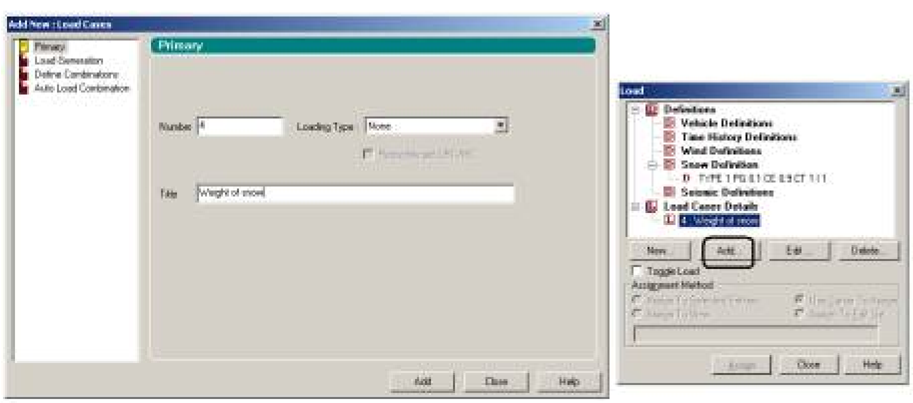
The newly created data will appear underneath Snow Definition in the Load dialog box as shown below.



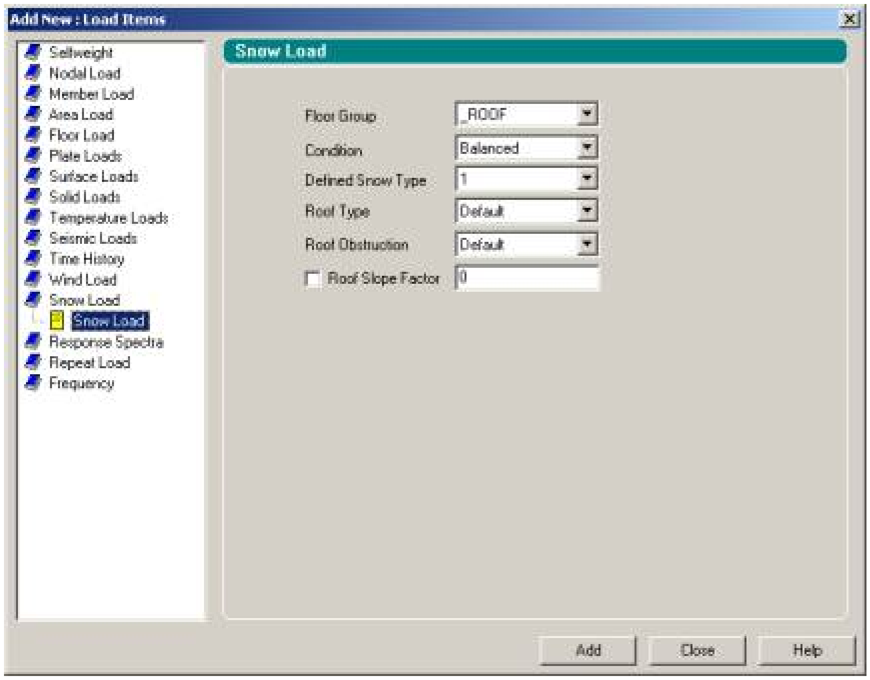
The members for which the snow load has to be generated have to be clustered together into FLOOR GROUPs. That is because, as we saw at the beginning of this section, the load generation is based on panel areas, not the exposed width of individual members. For details on creation of groups, refer to section 5.16 of the STAAD.Pro Technical Reference manual, and AD.2004.11 of the Software Release report for STAAD.Pro 2004.

Part II

Create a new primary load case. After the load case number and load title have been specified, click on Add.



Select it in the Load dialog box and click on the Add button to bring up the Add New: Load Items dialog box as shown below.



Select **Snow load** from the available list of load types. Various options corresponding to data required for snow load generation will appear on the right hand side, as shown in the figure above. The options are explained as follows:

Floor Group Select the floor group on which the snow load is to be applied.

Condition Specify whether the load is “” or “Unbalanced”. These terms are described in section 7.6, and figures 7.3 and 7.5 of ASCE 7-02.

Define Snow Type Select the snow load type number. This is the number specified against the **Type No.** field while creating the snow load definition in Part I described earlier in this section.

Roof Type Specify the roof type from the available choices:

- Default (if the roof type is not Mono, Hipped or Gable, it is referred to as Default)
- Mono (see mono-sloped roof shown in figure 6-6 of the code)
- Hipped (see figures 6-3 and 6-6 of the code)
- Gable (see figures 6-3 and 6-6 of the code)

These choices are described in section … of ASCE 7-02.

Roof Obstruction Specify whether the roof is “obstructed” or “unobstructed”. This also is a term described in section … of ASCE 7-02.

Roof Slope Factor For sloped roofs, the roof slope factor is described in section 7.4 of the SEI/ASCE-7-02. A value of 0 indicates that the roof is horizontal.

Click on **Add** to complete the data input for Part II. The snow load command will appear underneath the snow load case in the **Load** dialog box as shown below.

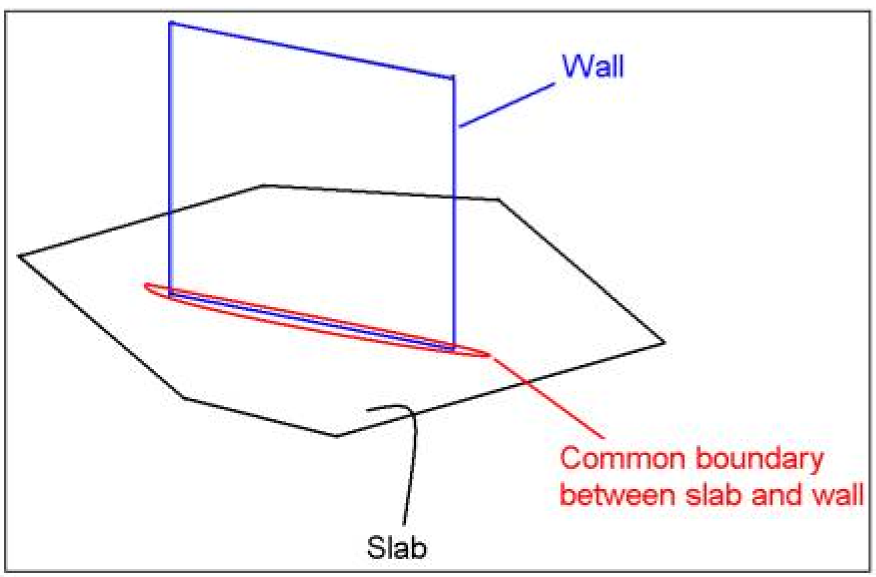
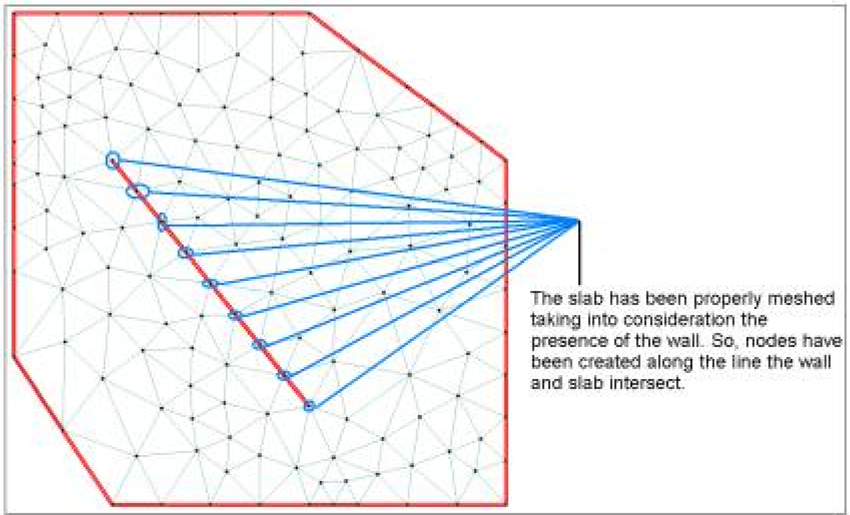
AD.2005.1.3 Wall-slab Interface Considerations in Finite Element Meshing

In the plate element mesh generation for a panel type of entity like a wall or slab, STAAD.Pro now provides a facility for the consideration of boundary conditions at the interface of the panel and any other panel on whose surface one of its edge lies.

To illustrate the problem that one faces if the facility did not exist, consider the wall and slab shown in the figure below:



The Parametric Models facility may be used to mesh the slab, and use the wall boundary as a density line, resulting in the following mesh for the slab.



If the wall is to be meshed subsequently, the nodes along its common boundary with the slab, as shown in the above figure, must automatically be "control points" in the wall meshing process. There was no simple way to do this until now.

Related Links

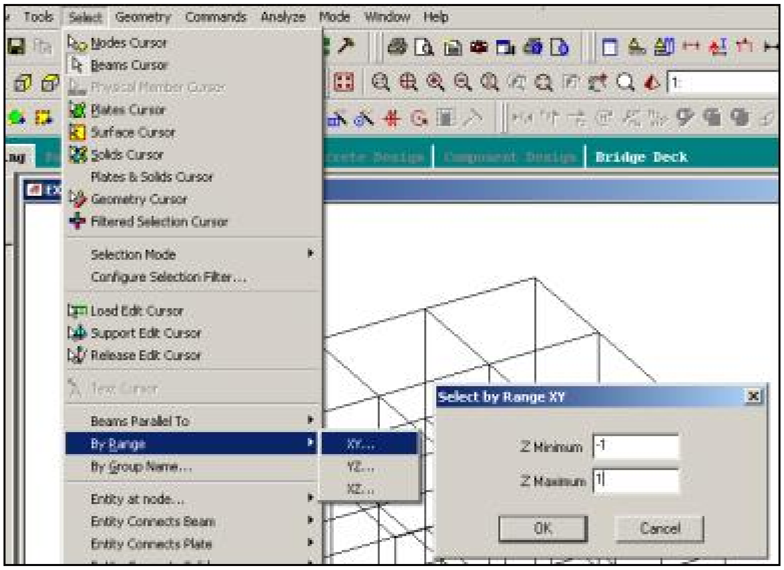
AD.2005.1.4 Enhancements to Renumbering of Entities

The capabilities of the program in renumbering entities such as joints, members, plates, etc. have been enhanced. In the past, only a limited amount of control was available in the manner in which renumbering was to be done. The current enhancements enable a user to set multiple criteria and assign them an order of priority.

Description

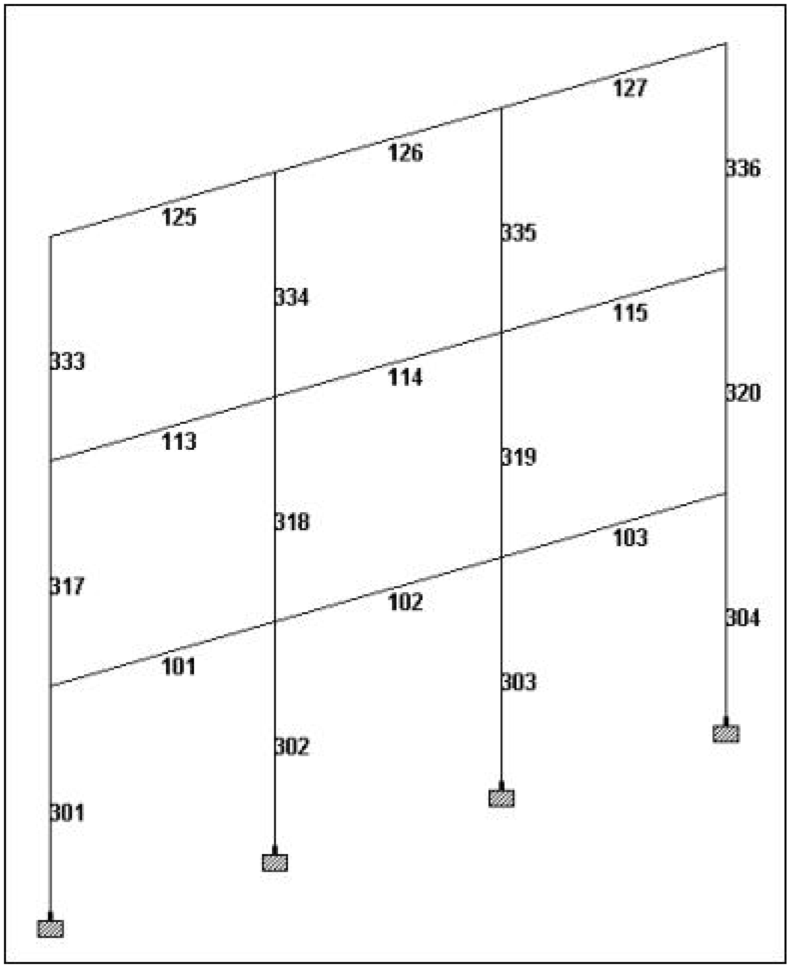
We will use example problem 14 in the US examples folder to illustrate this. We will renumber the columns of one frame of this multi-story building. If you do not wish to modify the file supplied with the program, you may make a copy of the file before you start this exercise.

After opening the model, go to **Select** > **By Range** > **XY** > , and set the **minimum** and **maximum** Z coordinate values to `-1` ft and `1` ft respectively.

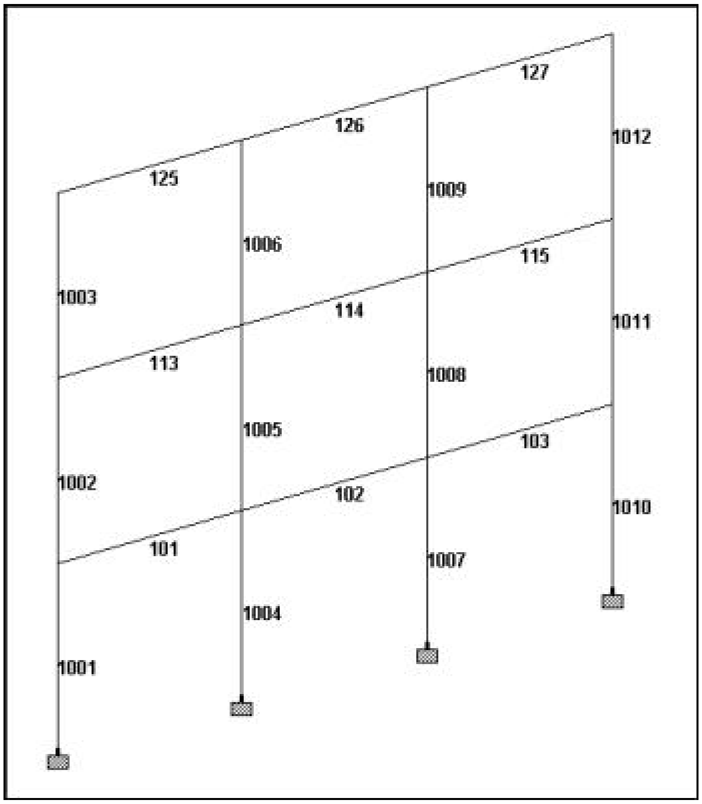


The members at the rear of the structure will be highlighted. Select **View** > **New View** > **Display the view in the active window** > .

Switch on the beam numbers and we get the following.

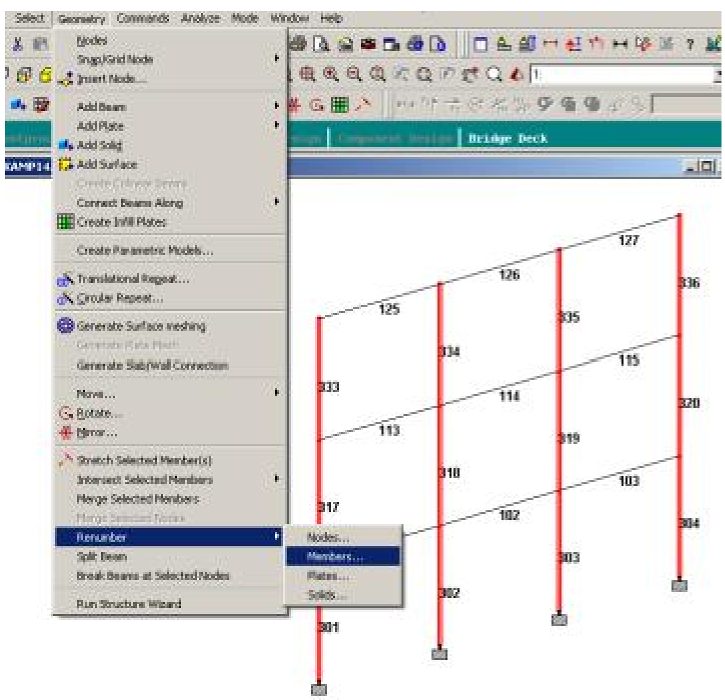


Our goal is to renumber the columns in such a manner that we will have the following once the renumbering is complete.

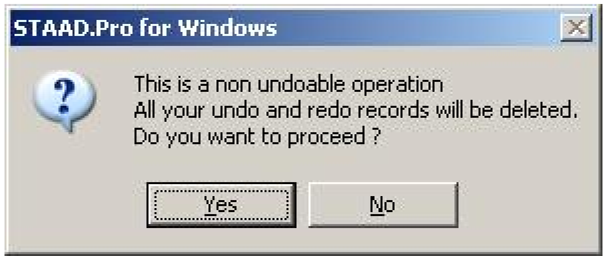


To accomplish that, do the following:

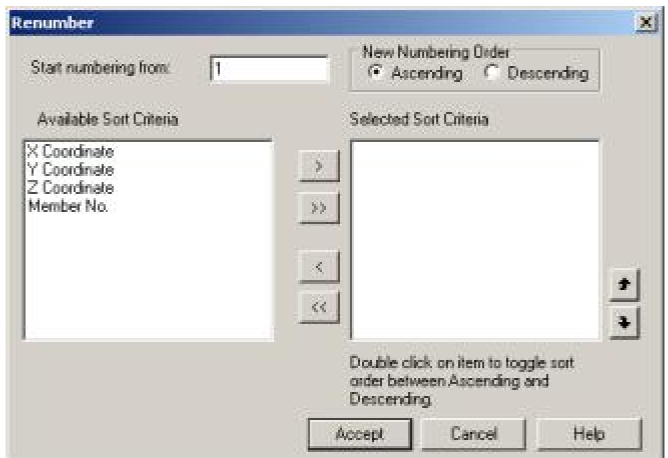
Select **Select** > **Beams Parallel to** > **Y**. The columns will be highlighted. Select **Geometry** > **Renumber** > **Members**.



The following message will be displayed.



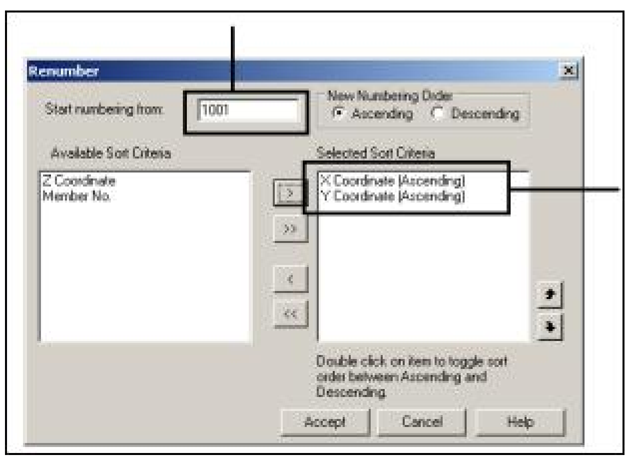
Choose **Yes**, and the **Renumber** dialog box will appear.



It is apparent from the earlier figure that if we set the renumbering criteria to be based on X coordinate first and Y coordinate next, the program will internally create the following sequence for renumbering:

301, 317, 333, 302, 318, 334, 303, 319, 335, 304, 320, 336

So, the settings for the dialog box should be as follows:



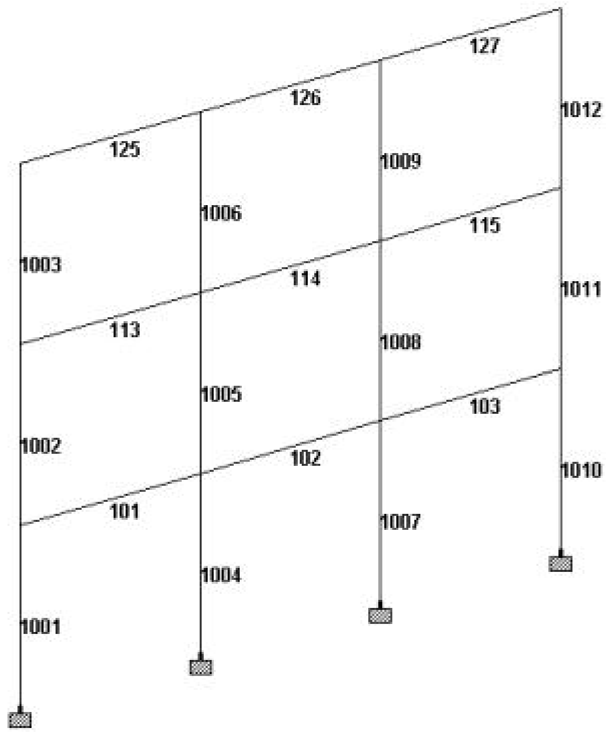
Start numbering from = `1001`

Select Sort Criteria = **X Coordinate (Ascending)**, **Y Coordinate (Ascending)**

Click on **Accept**.

A message indicating the successful completion of the operation will appear.

Subsequently, the following view will appear on the drawing.



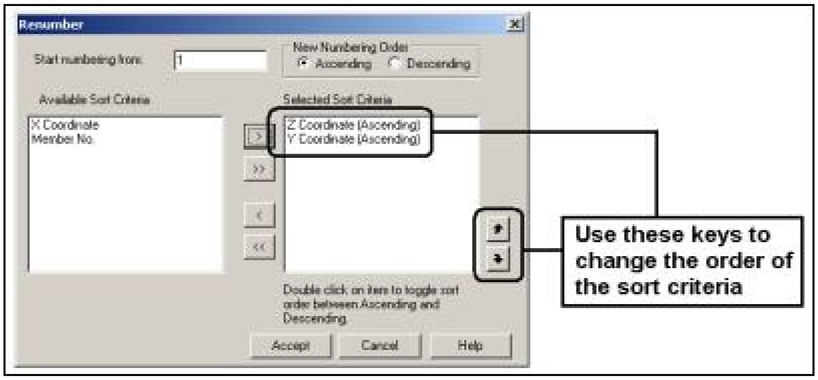
In past versions, 4 separate renumbering operations, each involving one line of columns, would have been required to achieve the same thing.

It is also worth noting that if the user wishes to renumber all the columns of all the frames in sequence, the Z coordinate can be included as a third criteria for sorting.

Notes

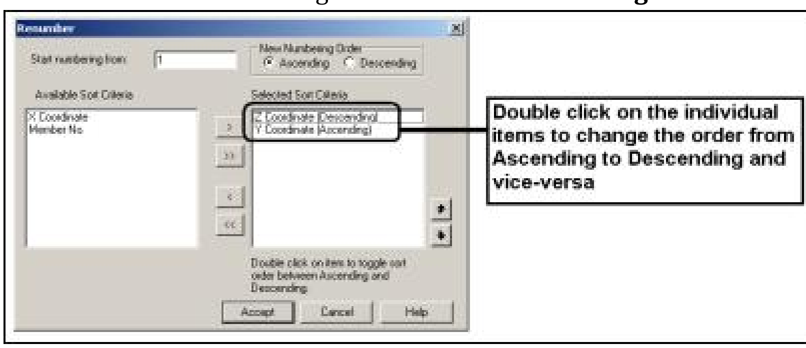
1. The order of importance of the sort criteria can be changed by clicking on the Up and the Down arrow keys as shown below.

Use these keys to change the order of the sort criteria



2. For the individual criteria, if you wish to change the order from Ascending to Descending or vice versa, double click on the item in the list as shown. For example, if you want the extreme right columns to have a lower number than the extreme left, set the criteria for X coordinate to Descending.

   Double-click on the individual items to change the order from **Ascending** to **Descending** and vice-versa.



3. If you want the entity to be numbered in the descending order instead of ascending order (as in 99, 98, 97, 96, …. , etc.), choose the appropriate button shown in the next figure.

   Click here to set the numbering sequence to **Ascending** or **Descending**.

AD.2005.1.5 Property Calculator for User Table General Sections

The user table section type called General has been enhanced in the following manner:

a. The shape of the section can be defined in terms of coordinates of the corner points of its cross section outline

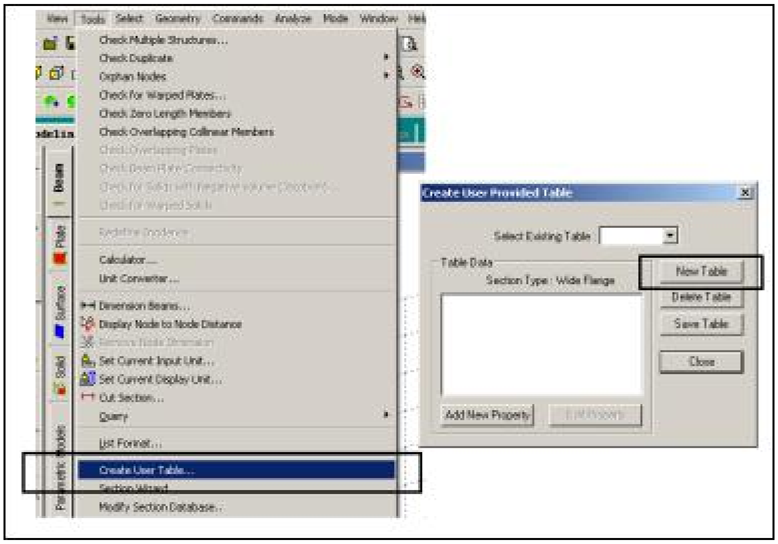
b. A section property calculator built into that dialog box enables the values to be calculated instantaneously. Any values the user wishes to override can be changed by typing over them.

c. Points can be defined at which stresses are to be reported in the Beam-Stresses page of the post-processing mode.

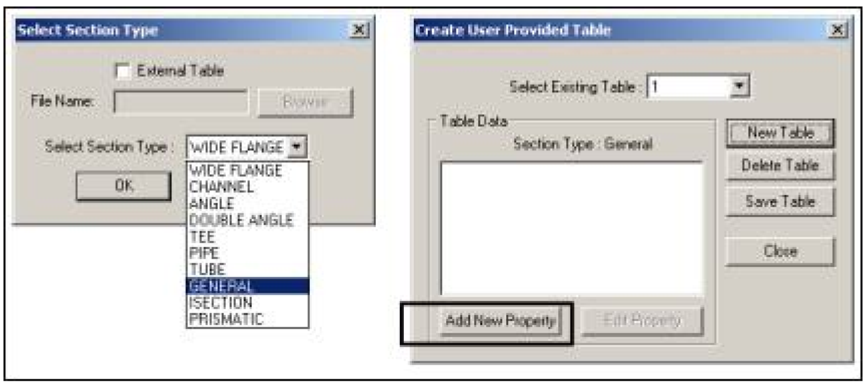
Description

Select **Tools** > **Set Current Input Units** > , and choose the length unit in which to specify the dimensions of the cross section. Let us choose inches for this exercise.

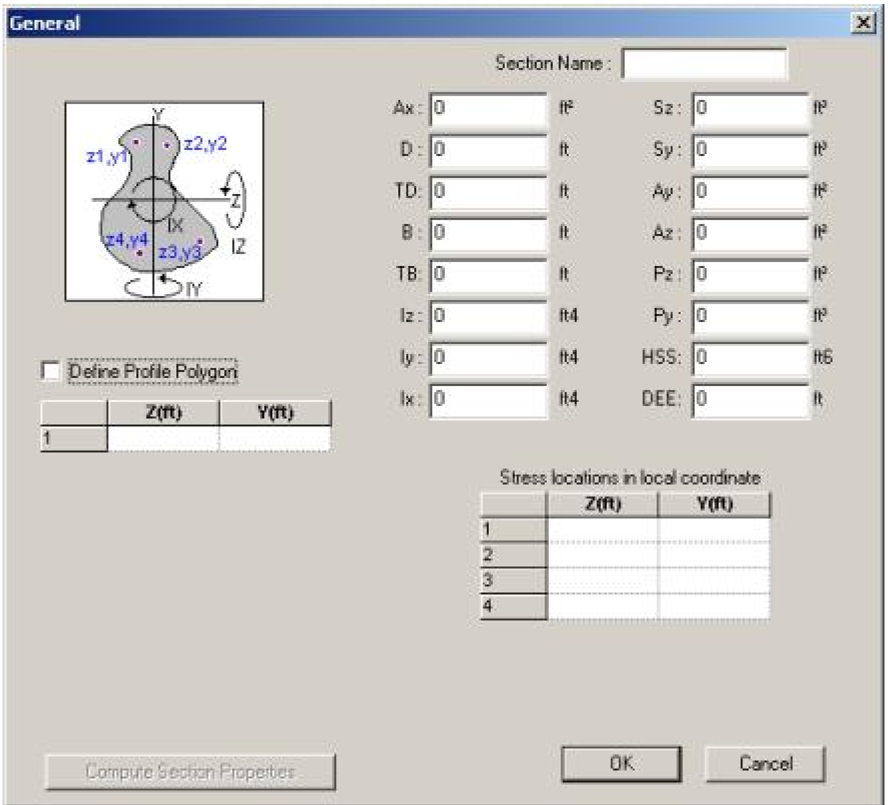
Next, select **Tools** > **Create User Table.** In the **Create User Provided Table** dialog box, click on **New Table.**



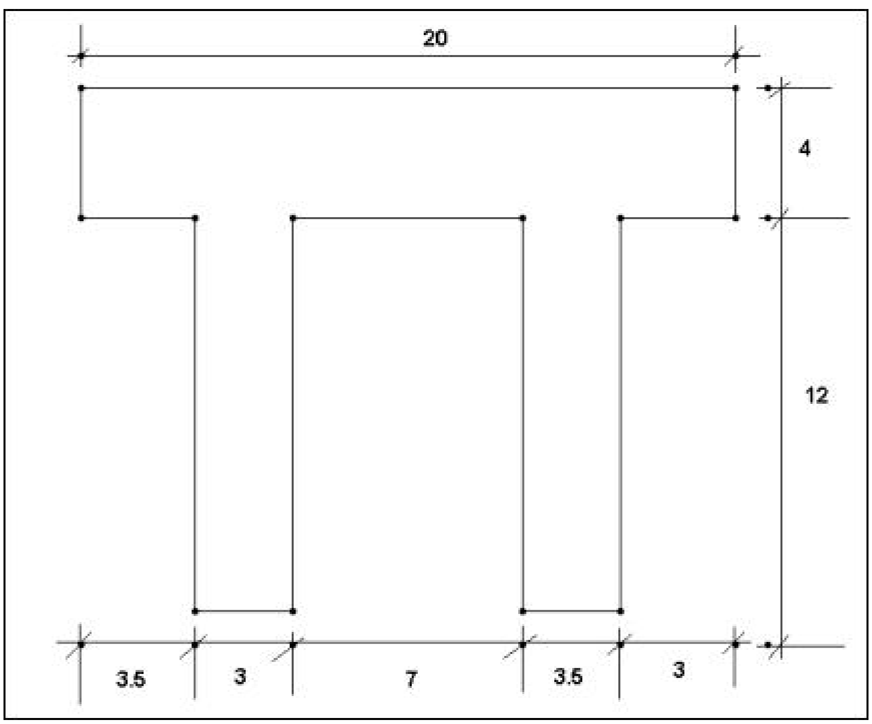
Select **General** for the **Select Section Type.** Click on **OK.**



The table number will appear as 1. Click on **Add New Property.** The following dialog box will appear.



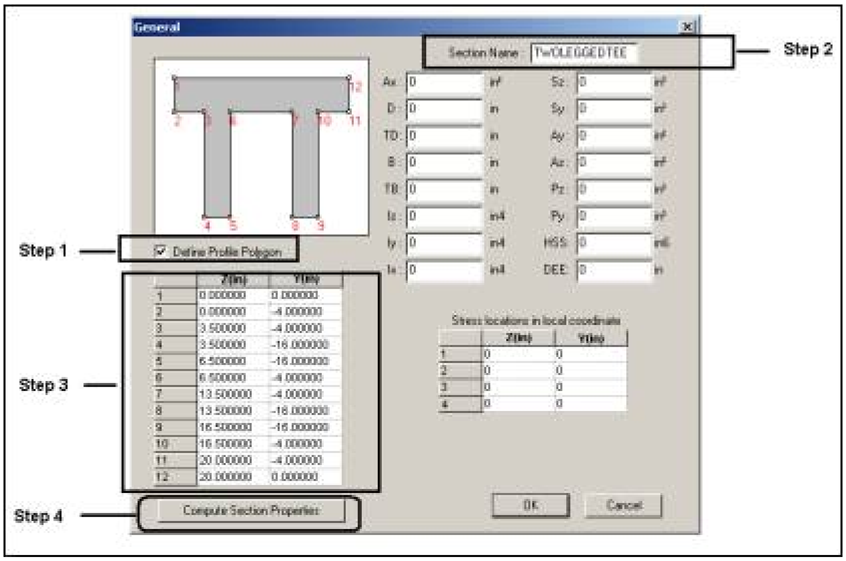
Let us say that we would like to define a cross section as shown below.



Assuming the top left corner of the cross section to be (0,0) for (Y,Z), , Z being along left-right and Y along top-bottom, specify the data as shown in the next figure. The sequence of steps is circled in the next figure. Once the points are specified, click on Compute Section Properties and observe the values being computed and filled in the relevant boxes (step 4 in the next diagram)

Steps

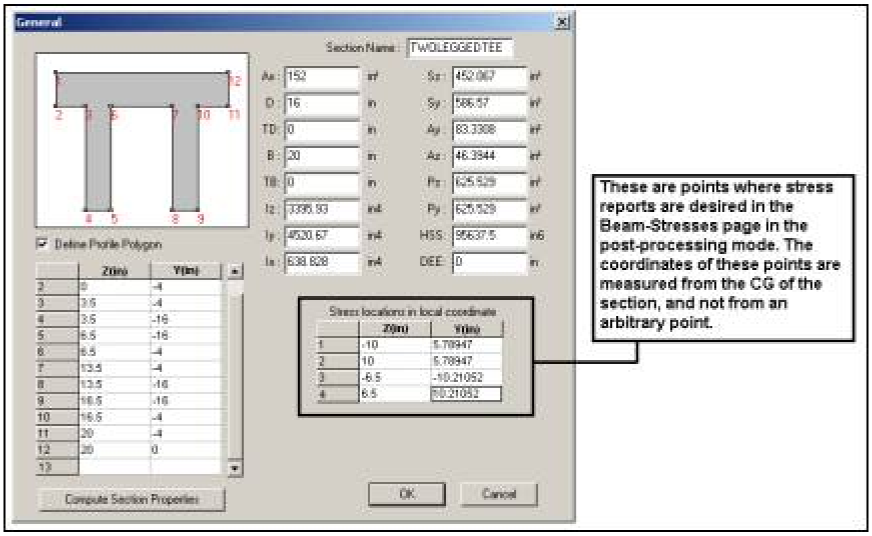
1.	Select **Define Profile Polygon**
2.	Type `TWOLEGGEDTEE` in the **Section Name** field.
3.	Type the vertex coordinates in the table.
4.	Click **Compute Section Properties**.



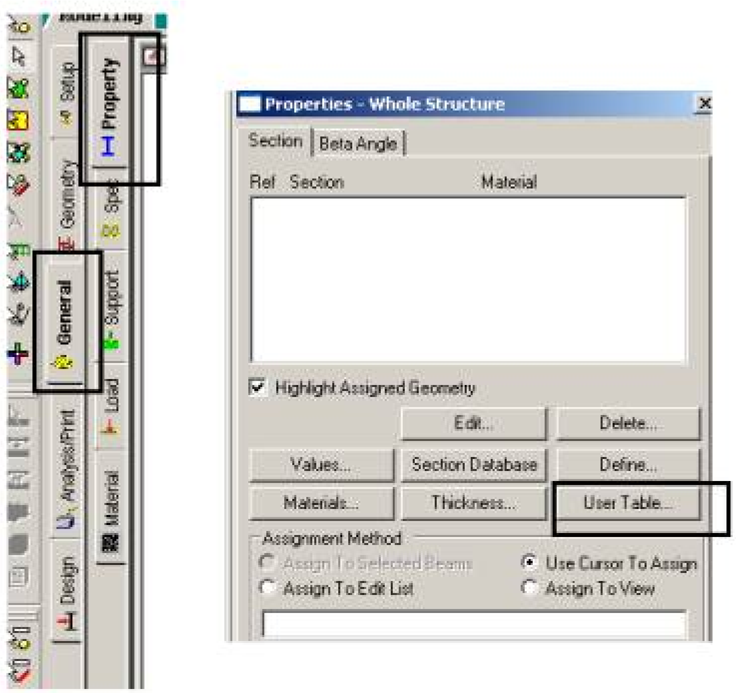
You will observe that when we clicked on Compute Section Properties, the Y and Z coordinates of the corner points that we typed earlier will be replaced by values that are measured from the center of gravity of the section.

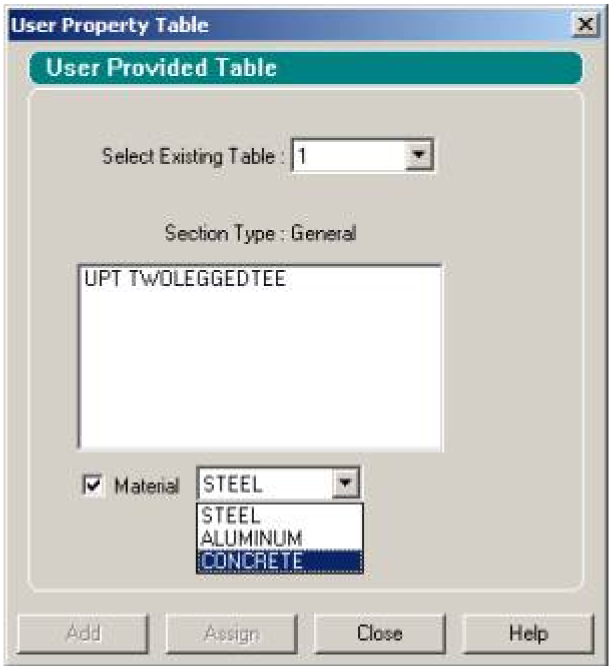
If you wish to specify the locations on the cross section where stresses are desired, they must be provided too. Note that the coordinate locations for that box should be based not on the arbitrary datum point we started out with initially, but on the basis of the center of gravity of the section.

These are points where stress reports are desired in the **Beam | Stresses** page in the post-processing mode. The coordinates of these points are measured from the CG of the section and not from an arbitrary point.



Once the section is defined, it may be assigned from the General-Properties page in the conventional way. Some of those steps are shown in the next 2 figures.





For the case of the example above, the following command syntax will appear in the STAAD input file.

```
START USER TABLE
TABLE 1
UNIT INCHES KIP
GENERAL
TWOLEGGEDTEE
152 16 20 0 3395.93 4520.67 638.828 452.067 586.57 83.3308 -

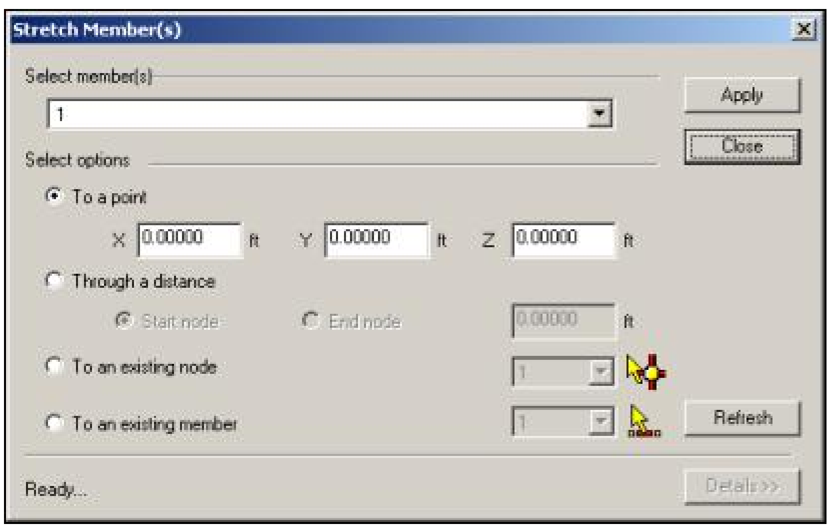
AD.2005.1.6 Stretch Members

This new facility allows one to increase the length of a member in various ways. The benefit it offers is that a member may be extended even if one does not readily know the coordinates of its ends joints in its stretched condition, something a user may appreciate in the case of members whose axis lie at an inclination to the global planes.

Description

Select the member which is to be extended. In the **Geometry** menu at the top of the screen, the option called **Stretch Selected Member(s)** becomes active.

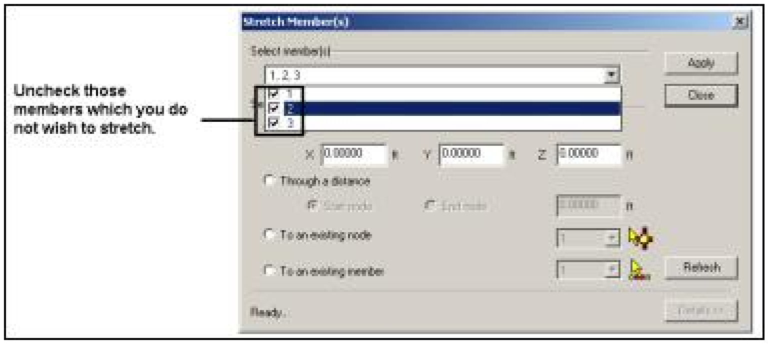
Click on it and the following dialog box will appear.



The various options of the dialog box are explained below.

Select member(s) Multiple members can be selected simultaneously for stretching. However, whether they will get stretched or not depends upon the type of method used in stretching as described later. If you wish to remove one or more members from the list, uncheck the corresponding boxes.

Uncheck those members which you do not wish to stretch.



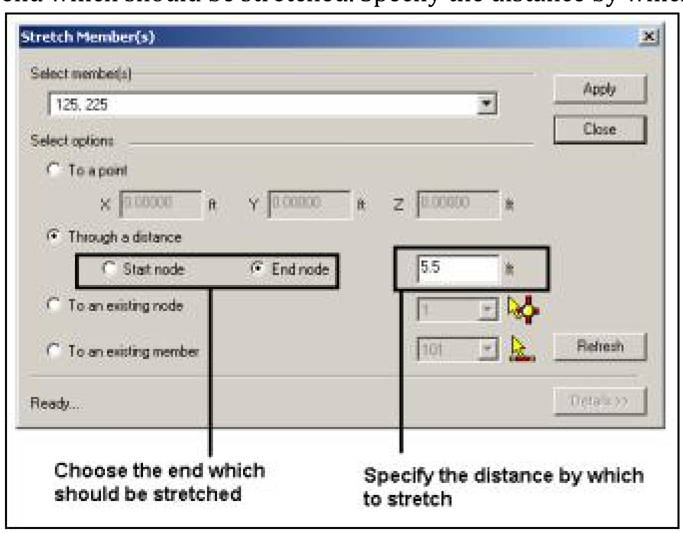
The methods available for stretching are:

To a point Specify the coordinates in current length units of the point to which one of the ends of the member are to be moved. The point must lie on the axis of the member being stretched, or else, the stretching will not be performed. The program automatically determines which of the two ends of the member is to be moved. So, this method involves

- **i.** determining if the point lies on the axis of the member(s) being stretched.
- **ii.** determining which end to move for the member(s) which satisfy criteria (i)
- **iii.** replacing the corresponding nodal coordinates with those of the desired point.

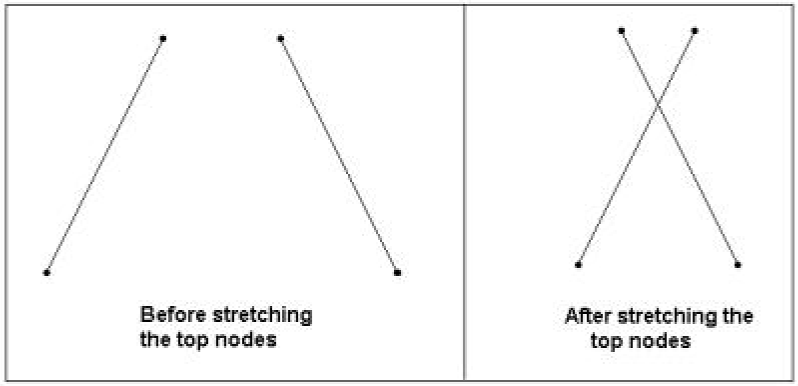
Through a distance In this method, the user has to merely specify the distance by which the start or end node must be stretched.

Choose the end which should be stretched. Specify the distance by which to stretch.



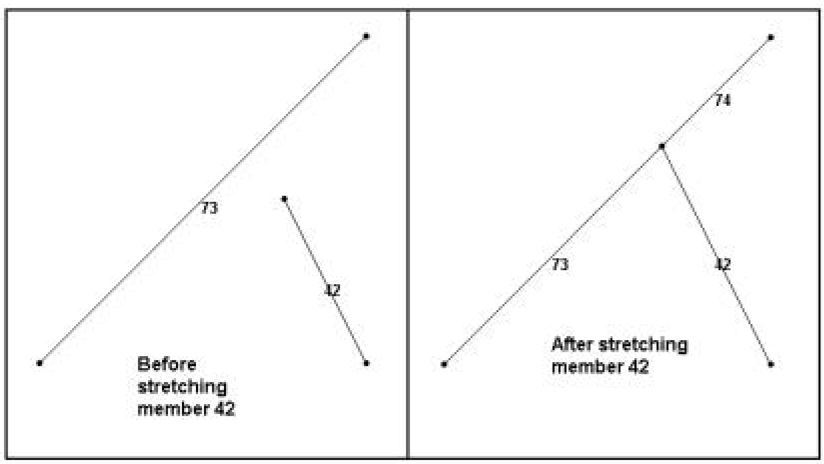
In this method, all members selected for this operation will see the change in length. The next diagram illustrates this. If this causes member to cross each other, the user must create the intersection point using the Geometry – Intersect Selected Members tool as the program does not automatically create it in the Stretch operation.

Before stretching the top node (left). After stretching the top nodes (right).

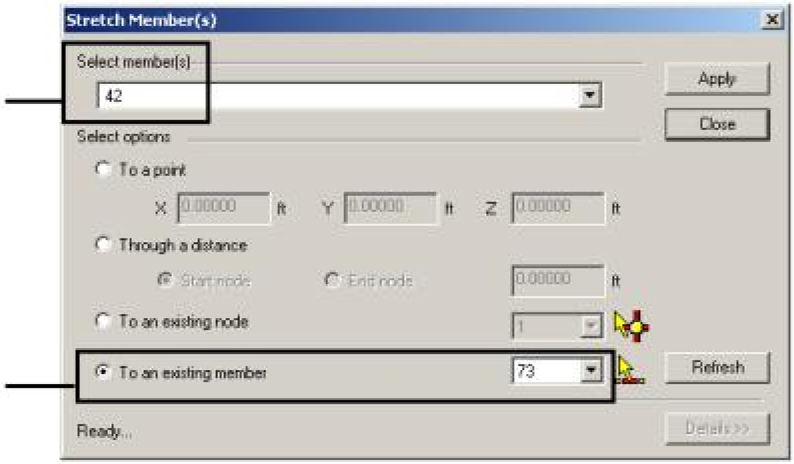


To an existing node This is very similar to the **To a point** method described earlier. The only difference is that instead of explicitly specifying the coordinates of the desired point, that point is already available for identification through its node number.

To an existing member If 2 members are oriented in such a manner that the local X-axis of one of those members can potentially intersect a second member within the span of that member, this method may be used to stretch the first member to meet the second member. In the next figure, member 42 may be stretched so it meets member 73. The second member will be automatically split up at the intersection point into two segments.



The dialog box settings required to achieve this are as follows:



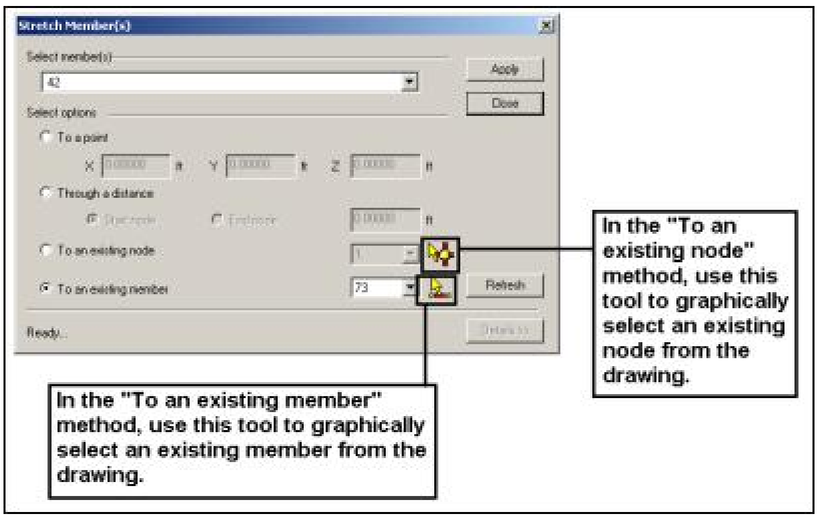
Notes

In the **To an existing node** method, a graphical tool is available for selecting the node from the drawing as shown in the next figure.

In the **To an existing member** method, a graphical tool is available for selecting the member from the drawing as shown in the next figure.

In the **To an existing node** method, use this tool graphically select an existing node from the model.

In the **To an existing member** method, use this tool graphically select an existing node from the model.



The **Details** button may be switched on to view the internal details of the stretch operation.

AD.2005.2 Features Affecting the Post-Processor

The additions and enhancements to the post-processor section of the program are explained in the following pages.

AD.2005.2.1 Floor Vibration Analysis

The adequacy of a floor system from the standpoint of its vibration serviceability due to human activity, specifically walking excitation, can now be assessed using STAAD.Pro. The procedures of Chapters 3 and 4 of the AISC Steel Design Guide Series No. 11 - Floor Vibrations due to Human Activity - have been implemented.

Related Links

- *Floor Vibration Output dialog* (on page 3002)
- *P. To generate a floor vibration report* (on page 1996)

AD.2005.3 Features Affecting Analysis and Design

Some new features have been added and existing features have been modified in the analysis and design part of the program. They are explained in the following pages.

AD.2005.3.1 Designing I-beams w Web Openings per AISC ASD

Design of steel members with web openings per AISC Steel Design Guide 2 - ASD specifications is now available in STAAD. The facility is available for members whose yield strength is 65 ksi or less.

Note: In the current implementation, the web openings are given consideration only during the design phase. The reduction in section properties caused by the presence of the openings is not considered automatically during the analysis phase. Hence, the analysis is performed as if the full section properties are effective for such members.

During the design process, the program first determines the utilization ratio (U.R.) at the location of the opening as though it is an unreinforced opening. If the U.R. is less than 1.0, the member is presumed to have passed the requirements at that location. If the U.R. exceeds 1.0, then it determines the U.R. as though it is a reinforced opening. If it fails this too, the cause of the failure along with the associated numerical values is reported.

3 Tutorials

T.1 – Steel Portal Frame

This chapter provides a step-by-step tutorial for creating a 2D portal frame using STAAD.Pro.

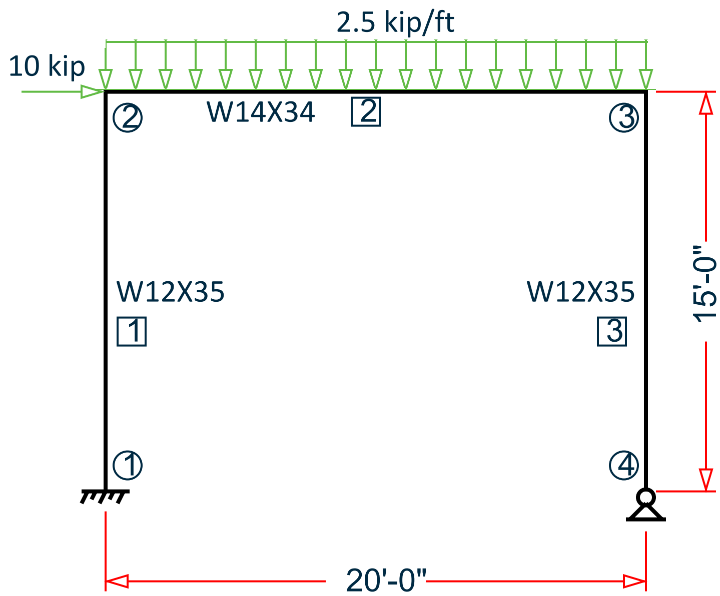

Figure 12: Portal Frame model

A copy of the completed input file is typically installed at `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\Tutorials\Tutorial 1 - Steel Portal Frame.std`.

Related Links

- *EX.Tutorials* (on page 6255)

T.1 Methods of creating the model

There are three methods of creating the structure data:

1. T.1 Creating the Model using the Physical Modeler (on page 391),
2. T.1 Creating the model using the analytical user interface (on page 399),
3. T.1 Creating the model using the command file (on page 442)

The physical model is used to draw structural elements as they are physically constructed. The program will then decompose this into an analytical modeling which is passed to the STAAD.Pro analysis and design engine when you run your model.

The analytical model is a finite element model of the structure which is typically processed directly by the analysis and design engine.

The command input file is a text file which contains the data for your structural model. This file consists of simple English language-like commands. This file is created for you behind the scenes for you when you model your structure using either the physical modeler interface or the analytical model interface.

The physical model will be linked to the command input file so any changes to your physical model *must* be made using the physical modeler interface. This ensures data integrity when the program decomposes the physical model. You can “break” this link to make changes to the underlying analytical model directly, either using the STAAD.Pro analytical modeling interface or using the command input file editor.

You can switch back and forth between the analytical modeling interface and the command input file editor for models created by either of those methods.

All three methods are described in this tutorial, with a detailed focus on the STAAD.Pro Physical Modeler interface.

T.1 Description of the tutorial problem

The structure for this project is a single bay, single story steel portal frame that will be analyzed and designed.

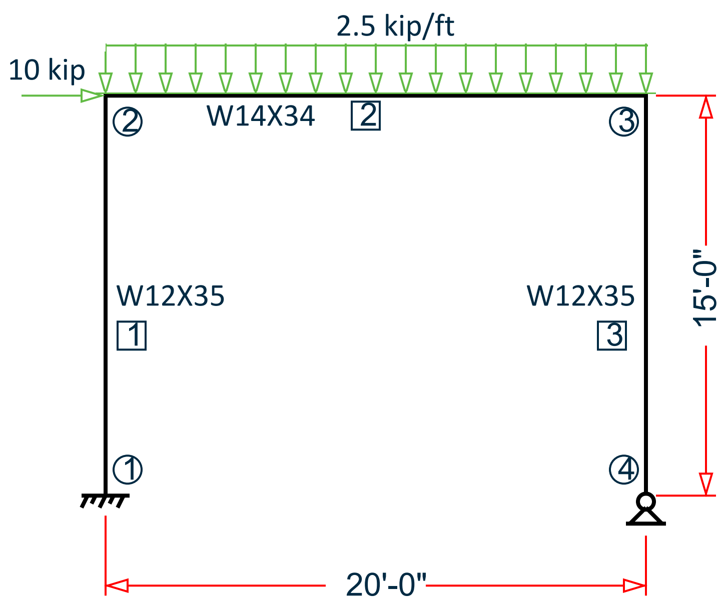

Figure 13: Portal Frame model

Table 22: Basic Data for the Structure

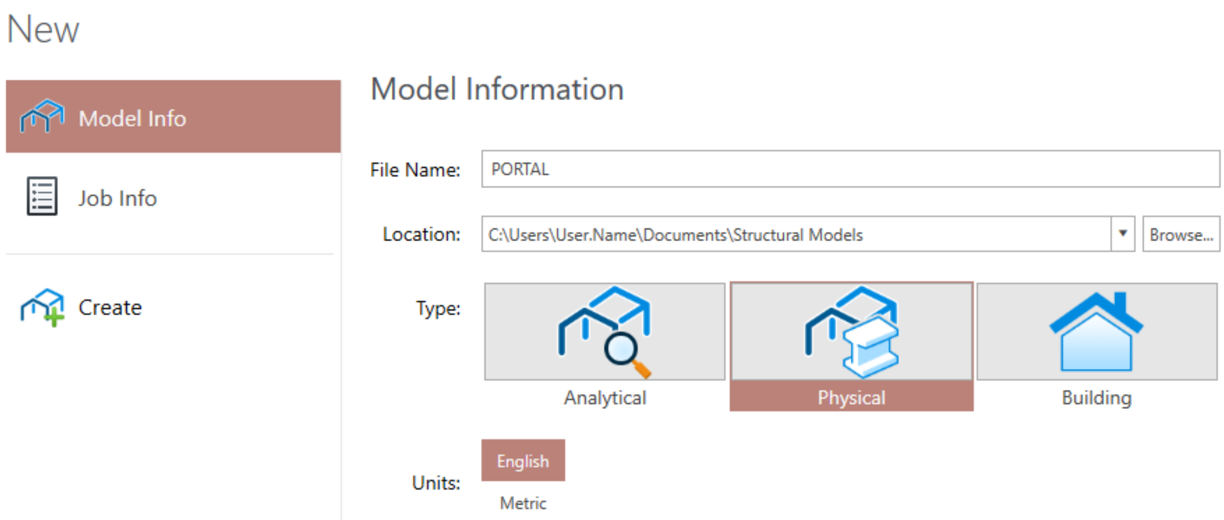
Attribute	Data
Member properties	Members 1 & 3 : W12X35 Member 2 : W14X34
Material Constants	Modulus of Elasticity : 29,000 ksi Poisson's Ratio : 0.30
Member Offsets	6.0 inches along global X for member 2 at both ends
Supports	Node 1 : Fixed Node 4 : Pinned
Loads	Load case 1 : Dead + Live Beam 2 : 2.5 kips/ft downward along global Y Load case 2 : Wind From Left 10 kips point force at Node 2 Load case 3 : 75 Percent of (DL+LL+WL) Load Combination - L1 X 0.75 + L2 X 0.75
Analysis Type	Linear Elastic (PERFORM)
Steel Design	Consider load cases 1 and 3 only. Parameters: Unsupported length of compression flange for bending : 10 ft for members 2 and 3, 15 ft for member 1. Steel Yield Stress : 50 ksi Perform member selection for members 2 and 3

T.1 Creating a new structure

On the Start page **New** tab, you will provide some initial data necessary for building the model.

1. On the Start page, select **New**.

   The **New** page opens to the **Model Info** tab.
2. Type `PORTAL` in the **File Name** field.



3. Specify a **Location** where the STAAD input file will be located on your computer or network.

   You can directly type a file path or click **Browse** to open the **Browse by Folder** dialog, which is used to select a location using a Windows file tree.
4. Select **Physical** for the **Type** of model.

   This option selects the modeling method you want to use:

Analytical	For creating a model using either the STAAD.Pro analytical modeling interface or the command input file editor.
Physical	For creating a model using the STAAD.Pro Physical Modeler interface.
Building	For creating a building model structure using the Building workflow.
5. Select **English** as the system of **Units**.

   Tip: The units can be changed later if necessary, at any stage of the model creation.
6. (Optional) Select the Job Info tab to enter related project details, names and dates for quality analysis, and ProjectWise Project information.
7. Click **Create**.

The STAAD.Pro modeling environment opens and your model file is then opened in the STAAD.Pro Physical Modeler.

Alternatively, if you want to use either the analytical modeling workflow or the command input file editor to create the model, choose **Analytical**, click **Create**, and then proceed to either “ T.1 Creating the model using the analytical user interface (on page 399) ” or “ T.1 Creating the model using the command file (on page 442),” respectively.

T.1 Creating the Model using the Physical Modeler

You are now ready to start building the model geometry. The steps for doing this are described in the following sections.

> **Tip:** Refer to the STAAD.Pro Physical Modeler Application Window Layout for reference on the application window.

T.1 Generating the model geometry

1. On the **Model** ribbon tab, select the **Grid** tool in the **Create** group.

   The **Create Grid** dialog opens.
2. Supply the grid details:
   a. Type `Grid 1` in the **Name** field.
   b. Leave the **Plane** selection as **XY** and the **Creation Method** as **By Spacing**.
   c. Type `20` in the **Number of spaces in X** and `1 ft` in the **Grid spacing X** fields.
   d. Type `15` in the **Number of spaces in Y** and `1 ft` in the **Grid spacing Y** fields.
   e. Click **OK**.
      The grid is created.

   You can control the visibility of individual grids by selecting the **Grids** tool on the **Spreadsheet** ribbon tab, where you can also change the settings for each grid. You can have as many grids as necessary displayed at one time.
3. On the **Model** ribbon tab, select the **Member** tool in the **Create** group.

   The tool is highlighted to show it is active. A yellow circle highlights the grid intersection the cursor "snaps" to when you hover in the view area.
4. Click on the lower, right corner of the grid (i.e., the origin at 0,0,0).
   A dashed line is "rubber banded" from this point to your cursor.
5. Click on the following two points around the edge to draw two members:

   (0,15,0)
   (20,15,0)
6. Double-click on the final point at (20,0,0).

   This instructs the program you are finished drawing connected members.

   > **Tip:** The tool remains active until so you can continue drawing a new set of connected members elsewhere if necessary.
7. Select the **Member** tool again to make it inactive.
8. On the **View** ribbon tab, select the **Grids** tool in the **Reference** group.

The tool is no longer highlighted and all grids are hidden in the display.

9. Switch on the node and beam labels:
   a. On the **View** ribbon tab, select the drop-down list below the **Numbering** tool in the **Model** group.

   b. Select **Node** and **Member** on this list.
      They are both marked with a check.
   c. Select the **Numbering** tool.

You have now created the nodes and members for this model.

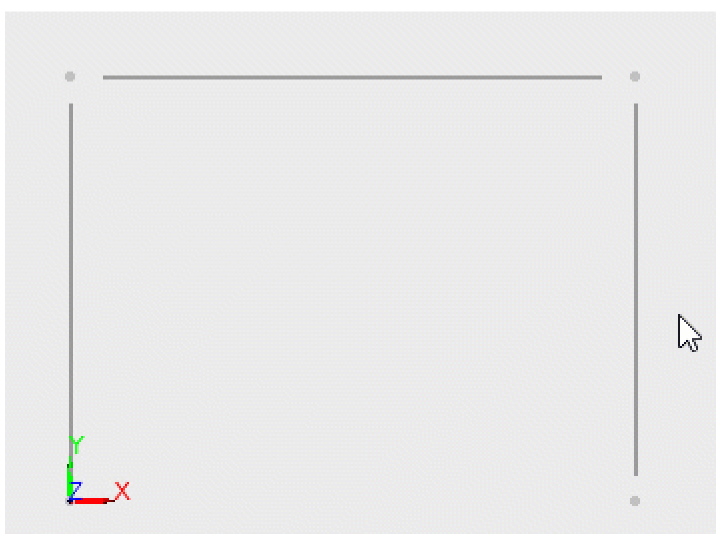
You can review the geometry of each by selecting the **Nodes** tool in the **Nodes** group and **Members** tool in the **Members** group on the **Spreadsheet** ribbon tab, respectively.

T.1 Specifying member properties

Tip: In STAAD.Pro Physical Modeler, you will select a model object and then assign properties, loads, etc. to that object. This fundamental workflow is import to understand as it applies to essentially all actions once you have drawn your model objects.

1. Select the two column members (M1 and M3):
   a. Click anywhere in the empty are in the view window.
      All model objects (members and nodes) are deselected.
   b. Click-and-drag a line horizontally from right to left across the columns to select them.

      This method (i.e., right to left) will select any model object that your drag window crosses.



Note: The **Member** ribbon tab reappears any time you have one or more members in your current selection.

2. On the **Member** ribbon tab, select the **Section** tool in the **Assign properties** group.

   The **Assign Section** dialog opens.
3. Specify the section data for the columns:
   a. Leave all the defaults:

      Type: Standard,
      Country: United States,
      Material: STEEL,
      Category: Hot Rolled,
      Specification: AISC,
      Version: 14 Edition,
      Manufacturer: Generic
   b. Select **W** from the **Table** drop-down list.
      The list of all section names in this table are populated.
   c. Scroll to and select **W12X35** in the list.
   d. Click **OK**.

   The section is assigned to the columns.
4. Click on the beam member.
   It is selected and all other members are deselected.
5. Repeat steps 2 and 3 except to assign a **W14X34** to the beam (M2).
6. Select all three members by either:

   click-and-drag a window around them

   or

   press **<Ctrl+A>**

   or

   on the **Data** ribbon tab, select the **Select all** tool in the **Model** group

Tip: There are numerous ways in which to select all the beams in a model. These are some examples.

7. On the **Member** ribbon tab, select the **Material** tool in the **Assign properties** group.

   The **Assign Material** dialog opens.
8. Specify the material data for the members:

a. Leave the initial defaults:

Source: Catalog
Type: Standard
Country: United States

b. Select **ASTM_STEEL** from the **Specification** drop-down list.
c. Select **A992** from the Name list.
d. Click **OK**.

The material is assigned to the members.

T.1 Specifying member offsets

1. Click the beam member (M2) to select it.
2. On the **Member** ribbon tab, select the **End Offset** tool in the **Edit** group.

   The **Modify Member End Offsets** dialog opens.
3. Specify the start (in this case, left) node offset:
   a. Leave the **Direction** as **Local.**

   > **Tip:** Given the orientation of this beam, the local 1 and global X axis are parallel, but it's best practice to use local coordinates when the offset is taken with respect to the local member's ends.

   b. Type `6 in` in the **x** direction.

   Local axis 1, 2, and 3 correspond to the member's localized X, Y, and Z axis.

   > **Tip:** Notice that even though the default input units are in feet, you are able to type different units and the program converts to the input units for you.
4. Specify the end (in this case, right) node offset:
   a. Leave the **Direction** as **Local.**
   b. Type `-6 in` in the **x** direction.

   > **Note:** The negative sign for the offset value at the end.
5. Click **OK**.
   The end offsets are drawn as red lines from the nodes in their indicated direction.

T.1 Specifying supports

1. Click on the lower-left node (N1) to select it.
   Any other selected items are removed from the current selection set. The node is selected. The node label appears if you have the labeling turned on.
2. On the **Node** ribbon tab, select the **Fixed** tool in the **Supports** group.

   A fixed nodal support type is assigned to this node.
3. Select the lower-right node (N4).
4. On the **Node** ribbon tab, select the **Pinned** tool in the **Supports** group.

A pinned nodal support type is assigned to this node.

Tip: You can use the **Custom** tool in the **Supports** group to generate any restraint or spring nodal boundary condition necessary.

You can review the nodal boundary conditions by selecting either the **Supports** tool or the **Springs** tool in the **Nodes** group on the **Spreadsheet** ribbon tab.

T.1 Viewing the model in 3D

1. Select all model objects by either:

   Right-click in the view area and select **Select All** from the pop-up menu

   or

   Click-and-drag a window area around all model objects

   or

   Press **<Ctrl+A>**
2. On the **View** ribbon tab, select the **3D Rending** tool in the **Model** group.

   The tool is highlighted to indicate it is active. The view displays the rendered model using the member's shapes, materials, and properties such as end offsets.

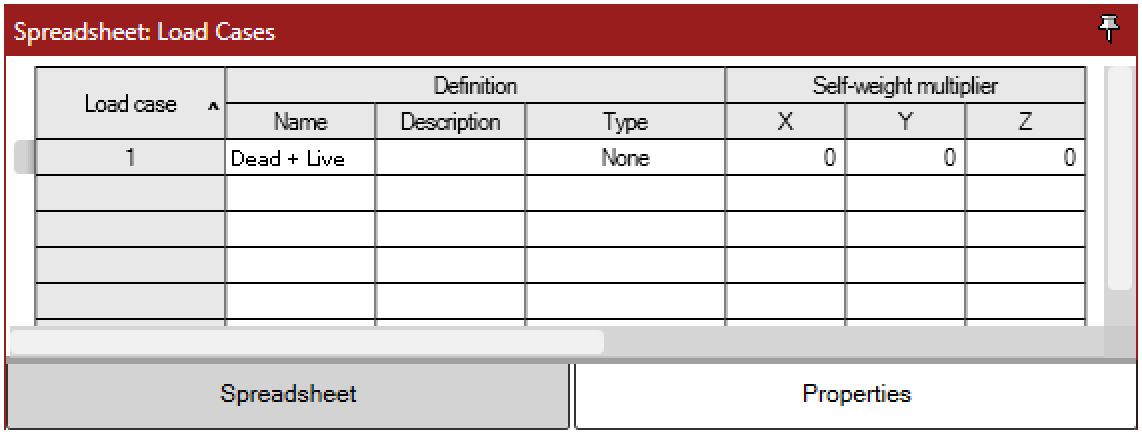
You can continue to model and work with this view option turned on. However, it is typically clearer to work with line drawings. Select the **3D Rendering** tool again to deactivate it.

T.1 Specifying loads

The STAAD.Pro Physical Modeler creates a default Load Group 1 with the no specified load type. You will add the dead and live loads to this load group and then create a new load group for the wind load.

1. On the **Spreadsheet** ribbon tab, select the **Load cases** tool in the **Reference** group.

   
   The Load Cases spreadsheet opens.
2. For Load case 1, type `Dead + Live` in the **Name** cell to rename the load case.



Spreadsheet: Load Cases

Load case	Definition			Self-weight multiplier		
	Name	Description	Type	X	Y	Z
1	Dead + Live		None	0	0	0

Spreadsheet | Properties

3. Click the beam member (M2) to select it.
4. On the **Member** ribbon tab, select the **Distributed** tool in the **Loads** group.

   
   The **Add Member Distributed Load** dialog opens.
5. Specify the load:
   Leave the **Load Group** as **LC: Dead + Live** and the **Load Type** as **Uniform**.
   a. Select **Global Y** as the **Direction**.
   b. Type `-2.5 kip/ft` in the **Magnitude** field.
   c. Click **OK**.

   The load is applied to the beam.
6. On the **Model** ribbon tab, select the **Load Case** tool in the **Loads** group.

   
   The **Add Load Case** dialog opens.
7. Specify the wind load case details:
   a. Type `Wind From Left` in the **Name** field.
   b. Select **Wind** for the **Type**.
   Leave the other items for Self-weight data empty (default).
   c. Click **OK**.

   A new load case is added to the **Load Cases** spreadsheet and the load is automatically selected in the program window status bar as the current load.

   Note: When load items are created they are added to the current load case or load group by default.
8. Select the upper-left node (N2).
9. On the **Node** ribbon tab, select the **Nodal Load** tool in the **Loads** group.

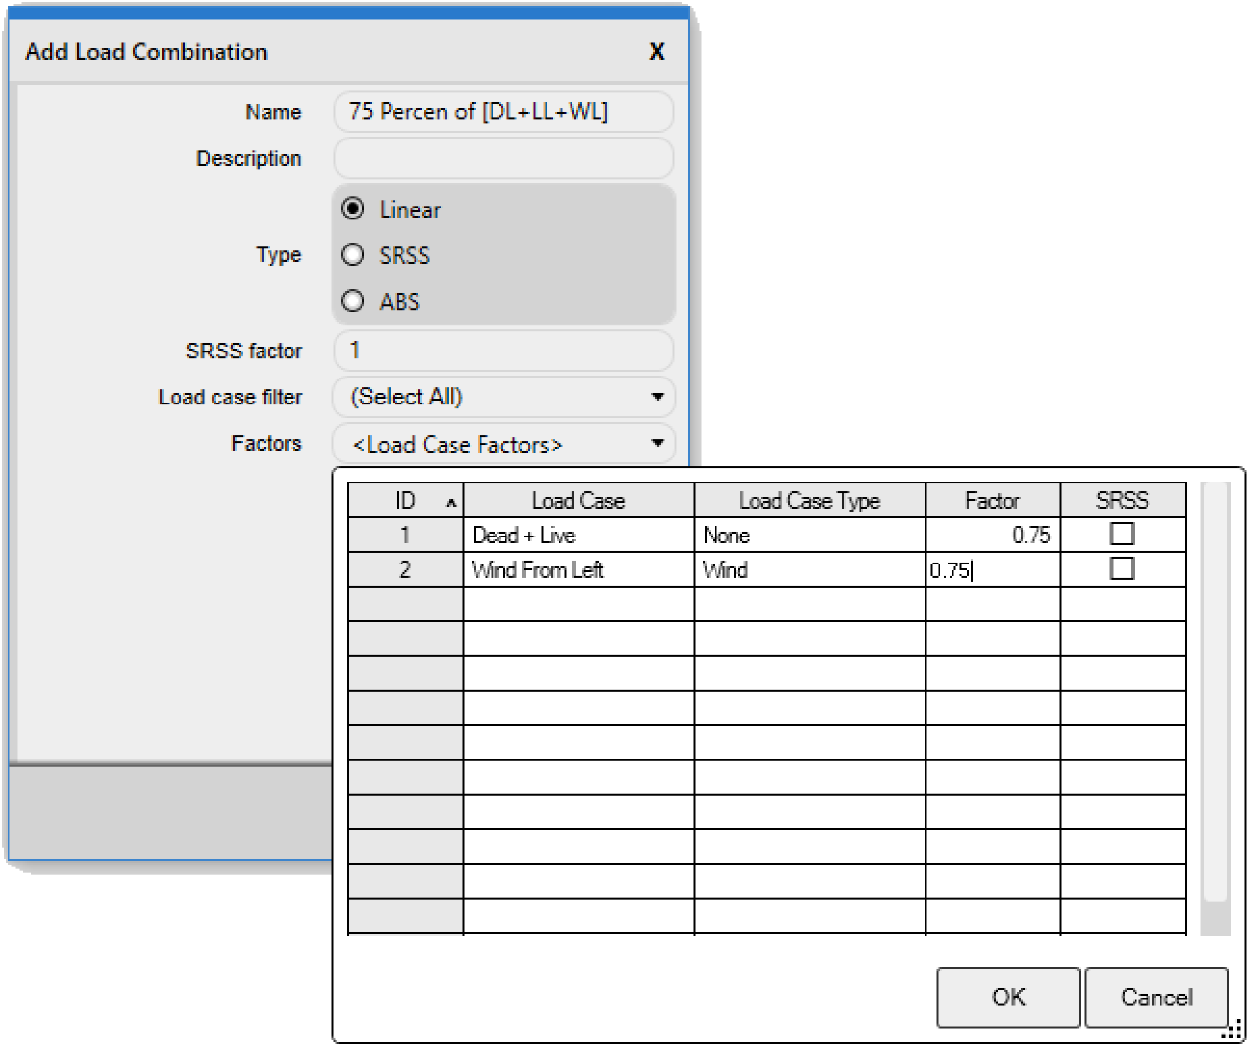
The **Add Nodal Load** dialog opens.

10. Specify the lateral wind load:
    a. Leave the **Load group** selection as **LC:Wind from left**.
    b. Type `10 kip` in the **Fx** field.
    c. Click **OK**.

T.1 Creating a load combination

1. On the **Model** ribbon tab, select the **Load Combination** tool in the **Loads** group.

   
   The **Add Load Combination** dialog opens.
2. Type `75 Percent of [DL+LL+WL]` in the **Name** field.
3. Select **Linear** as the load combination **Type**.
4. Click in the **Load case filter** field and then check the **(Select All)** option.
5. Assign the load case factors:
   a. Click in the **Factors** field.
      The load case factors table opens. All the load cases in the model are included from the previous step.
   b. For load case 1 (the first row in the table), click in the **Factor** cell and type `0.75`.
   c. Repeat step 5a to enter a load case factor of 0.75 for the wind load (load case 2).
   d. Click **OK**.



6. Click **OK**.

T.1 Generate the analysis model

You have now completed the modeling portion of this tutorial. You will now send the model data back to STAAD.Pro where you will create load combinations, add output commands, select analysis criteria, and specify design parameters.

For this tutorial, you will use the default options for analytical model generation. However, for advanced models you can review and change those options in the **Configuration** dialog.

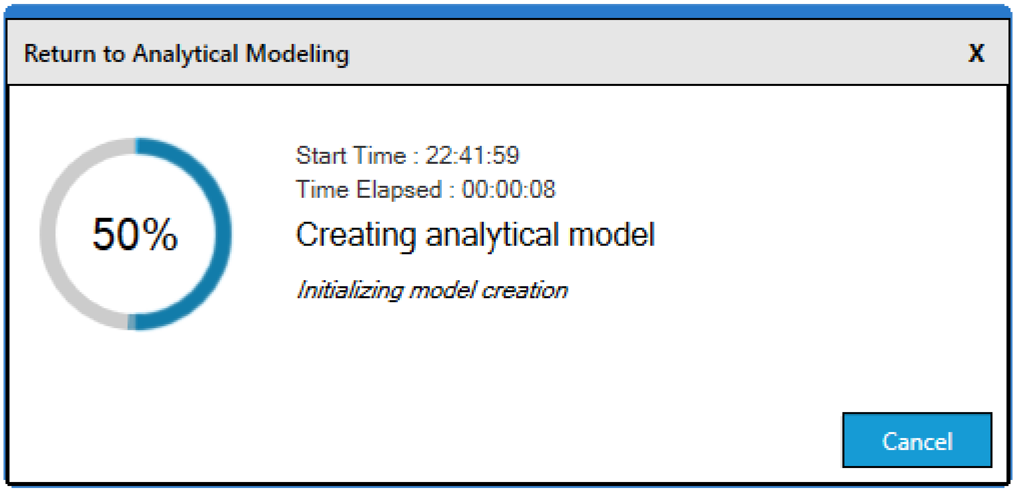
1. Select **Save** to save the physical model.
2. Either:

   On the **Model** ribbon tab, select the **Return to Analytical Modeling** tool in the **STAAD.Pro** group

or

On the **File** ribbon tab, select **Create analysis model** in the backstage tabs

The Return to Analytical Modeling dialog opens and displays the progress of the analytical model being generated.



3. Click **OK**.
   If you have not previously associated this model with a CONNECT Project, you are asked to do so. This is will not be necessary for this tutorial.
4. Click **Cancel** in the **Assign Project** dialog.

The STAAD.Pro Physical Modeler window closes and the model is loaded into the STAAD.Pro analytical modeling interface.

T.1 Creating the model using the analytical user interface

The following procedures describe how to use the traditional STAAD.Pro analytical user interface to build the model. The steps and, wherever possible, the corresponding STAAD.Pro commands (the instructions which get written in the STAAD input file) are described in the following sections.

Tip: Refer to GS. Application Window Layout (on page 54) for reference on the application window.

Note: If you completed the model using the **Physical Modeling** worfkow, then instead proceed to T.1 Analysis and Design (on page 426).

T.1 Generating the model geometry

The structure geometry consists of joint numbers, their coordinates, member numbers, the member connectivity information, plate element numbers, etc.

The STAAD input file commands generated are:

```
JOINT COORDINATES
1 0. 0. ; 2 0. 15. ; 3 20. 15. ; 4 20. 0.
MEMBER INCIDENCE
1 1 2 ; 2 2 3 ; 3 3 4
```

When starting in the Analytical Modeling workflow, a grid is initially displayed in the main view window. This grid is controlled by the **Snap Node/Beam** dialog. The directions of the global axes (X, Y, Z) are represented in the icon in the lower left hand corner of the drawing area.

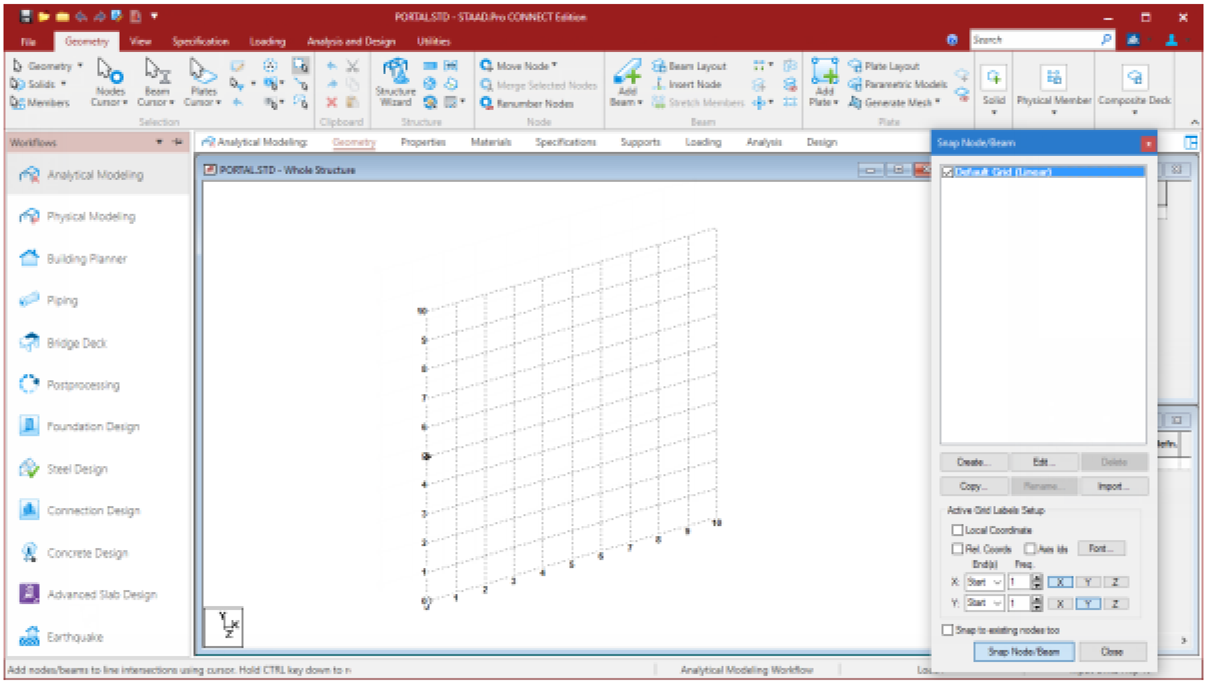


*Figure 14: The STAAD.Pro window with the **Snap Node/Beam** dialog open*

Note: The **Snap Node/Beam** dialog opens on the right side of the screen. You can reopen this dialog by selecting the **Snap Grid Beam** tool  in the **Structure** group on the **Geometry** ribbon tab.

1. On the **Snap Node/Beam** dialog, click **Create**.
   A dialog opens which will enable us to set up a grid.

   Within this dialog, there is a drop-down list from which you can select Linear, Radial, or Irregular form of grid lines.

Linear	used to place the construction lines perpendicular to one another along a "left to right - top to bottom" pattern, as in the lines of a chess board
Radial	used to place construction lines to appear in a spider-web style, which makes it is easy to create circular type models where members are modeled as piece-wise linear straight line segments
Irregular	used to create gridlines with unequal spacing that lie on the global planes or on an inclined plane

2. Select **Linear**, which is the **Default Grid.**

   In this structure, the segment consisting of members 1 to 3, and nodes 1 to 4, happens to lie in the X-Y plane. Leave **X-Y** as the **Plane** of the grid. The size of the model that can be drawn at any time is controlled by the number of **Construction Lines** to the left and right of the origin of axes, and the **Spacing** between adjacent construction lines.
3. Type a **Name** of `Grid 1`.
4. Type `20` as the number of lines to the **Right** of the origin along **X** and `15` above the origin along **Y**

Leave the default spacing of **1** feet between lines along both **X** and **Y**.

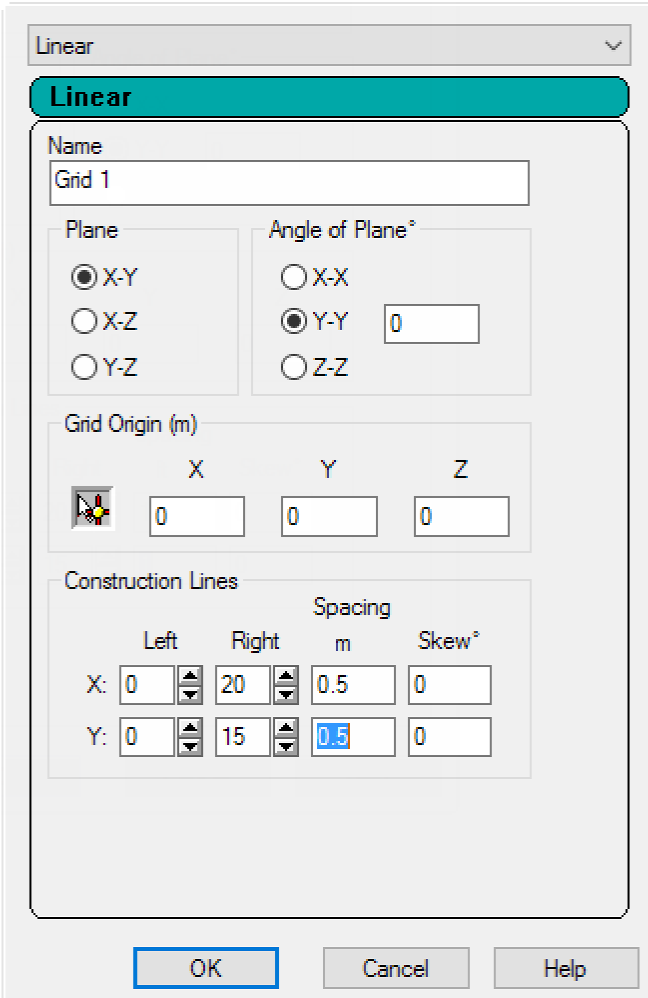

Figure 15:

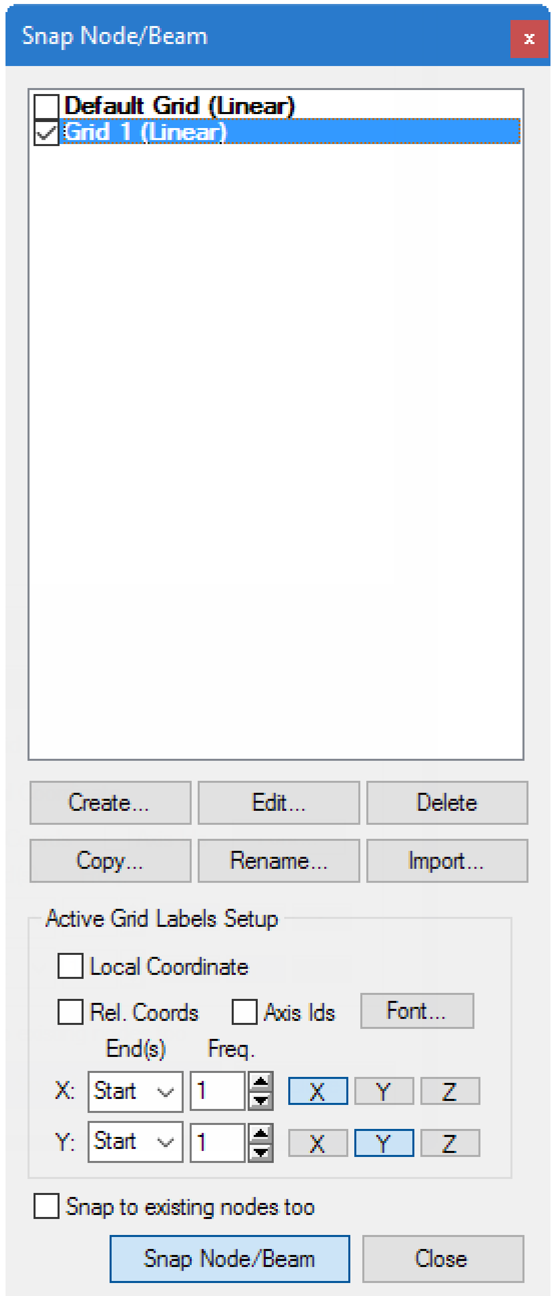
5. Click **OK**.
6. In the **Snap Node/Beam** grids list, check the new **Grid 1** option.

   You can create any number of grids. By providing a name, each new grid can be identified for future reference.

Tip: Please note that these settings are only used to generated construction lines. These construction lines enable you to easily draw the structure but do not restrict our overall model to those limits.

Tip: To change the settings of this grid, select the name in the **Snap Node/Beam** dialog and then click **Edit**.

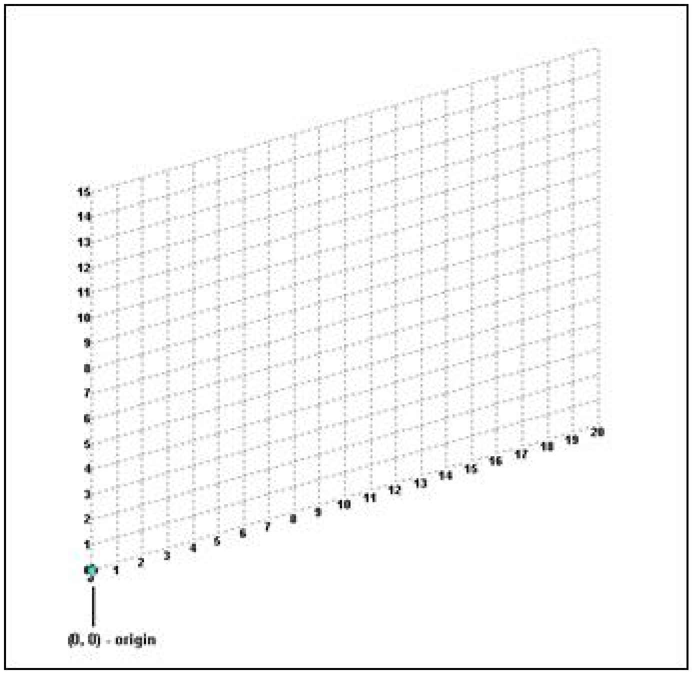
The check by **Default Grid** is automatically cleared. STAAD.Pro will only display a single grid at a time.



7. In the View window, click at the origin (0, 0) to create the first node.

   A line is "rubber-banded" between this node and the mouse pointer, which previews the member to placed with the next mouse click.

   The **Snap Node/Beam** feature is active by default.



8. Click on the following points to create nodes and automatically join successive nodes by beam members.

(0, 15)
(20, 15)
(20, 0)

When steps 1 through 5 are completed, the structure will be displayed in the drawing area as shown below.

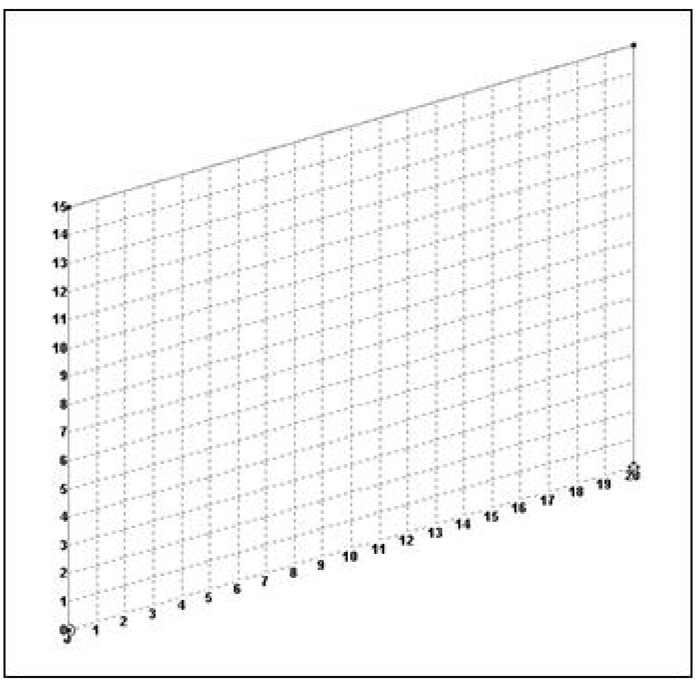


Figure 17:

9. Click **Close** in the **Snap Node/Beam** dialog.
   The grid is hidden.

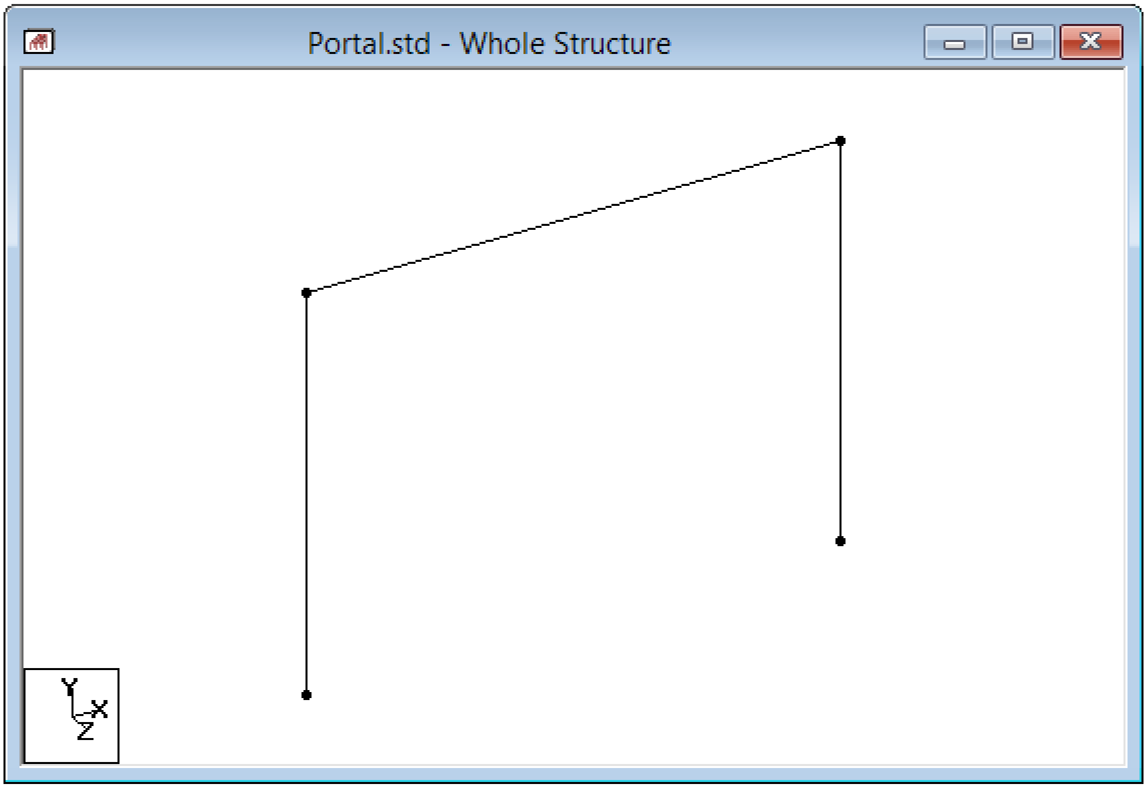

Figure 18: The portal frame members drawn

It is important to save your work often. This helps to avoid loss of data and protect your investment of time and effort against power interruptions, system problems, or other unforeseen events.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.1 Switching on node and beam labels

Node and beam labels are a way of identifying the entities in the View window.

1. Right click anywhere in the view window and select **Labels** from the pop-up menu.

   The **Diagrams** dialog opens to the **Labels** tab.
2. Set the **Node Numbers** and **Beam Numbers** on and then click **OK**.

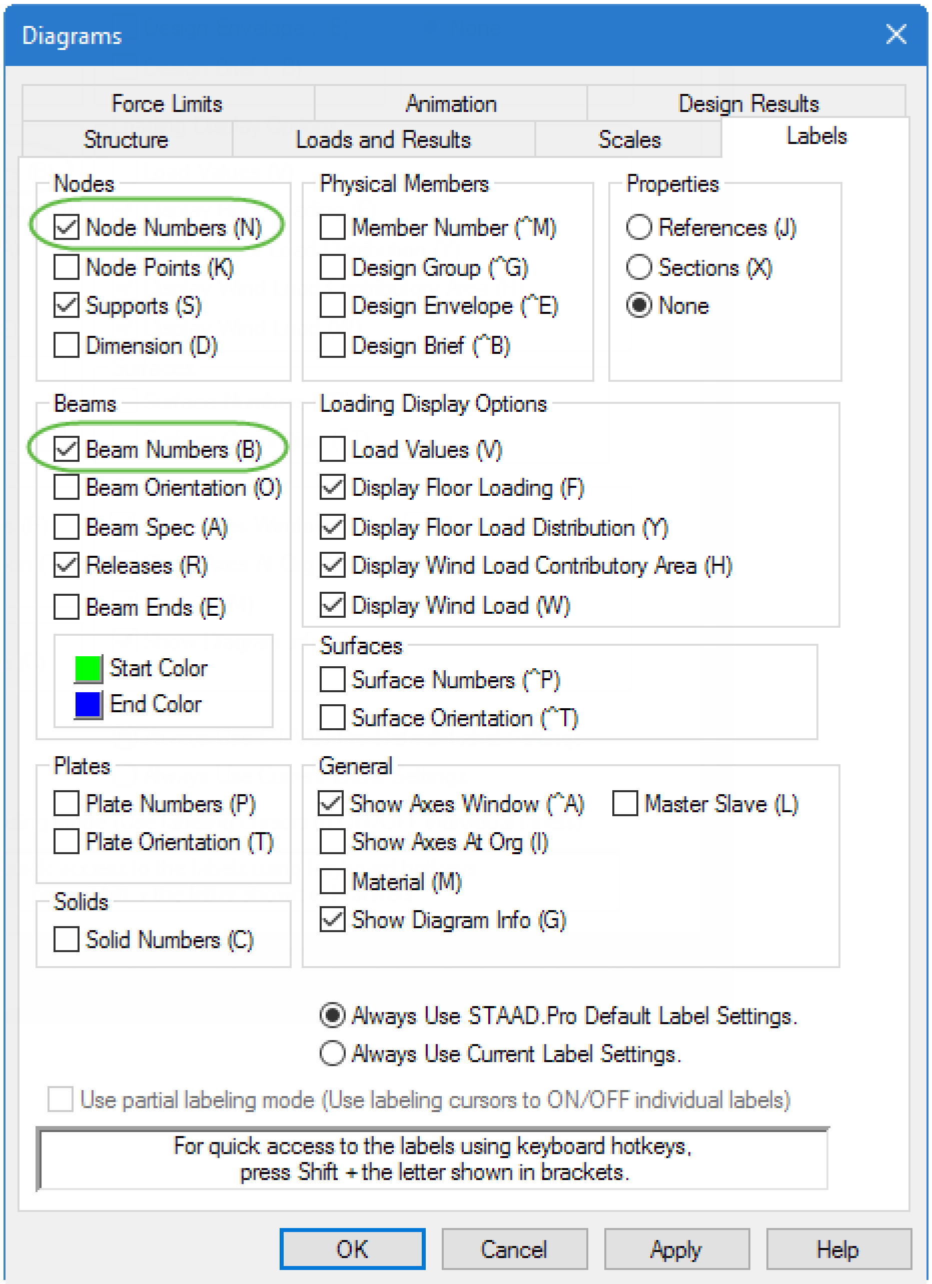

Figure 19: Select the Node and Beam numbers

Tip: Alternatively, you can press **<Shift+N>** and then **<Shift+B>** to quickly toggle the same labels. The letters in parenthesis on the **Labels** tab indicate these **<Shift>** key shortcuts.

Tip: You can change the font of the node/beam labels by selecting the **File** ribbon tab and then selecting **Settings** > **Display Options**. Select the appropriate tab (Node Labels / Beam labels) from the **Options** dialog.

T.1 Specifying member properties

In this procedure, you will assign cross section properties to the beams and columns.

The STAAD input file commands generated are:

```
MEMBER PROPERTY AMERICAN
1 3 TABLE ST W12X35
2 TABLE ST W12X34
```

1. Select the **Properties** page in the Analytical Modeling page control bar.

The **Properties - Whole Structure** dialog opens.

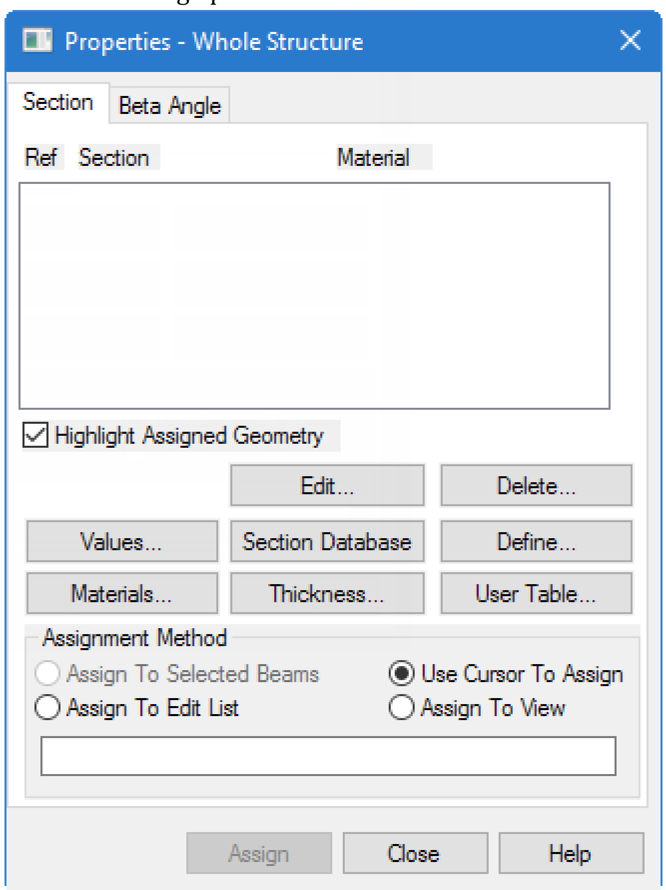

Figure 20:

2. Click **Section Database**.

   The **Section Profile Tables** dialog opens.

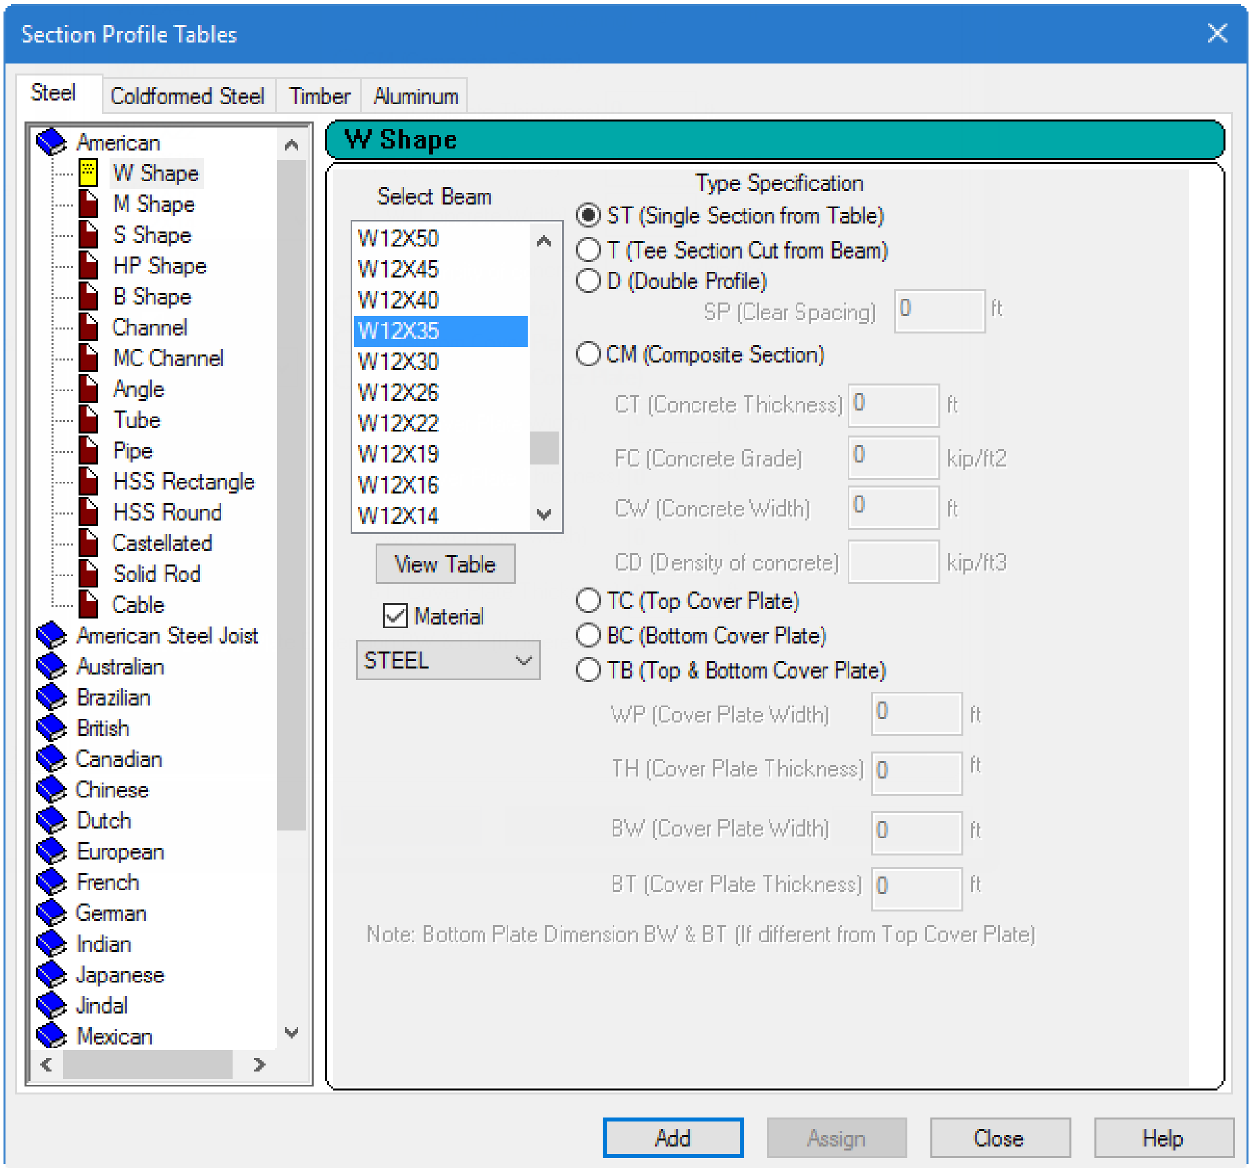

Figure 21:

3. Select the **W Shape** tab under the **American** option.

   The property type we wish to create is the W shape from the AISC table.
4. Choose **W12X35** as the beam size and then select the **ST** option as the section type.

Tip: The **Material** check box is set. Leave this set and the selection set to **Steel** as it will be used to assign the built-in steel material properties when this section is assigned.

5. Click **Add**.

Tip: Detailed explanation of the terms such as ST, T, CM, TC, BC, etc. is available in TR.20.1 Assigning Properties from Steel Tables (on page 2257).

The W12X35 section is added to the Sections list in the **Properties - Whole Structure** dialog.

6. To create the second member property (ST W14X34), select the **W14X34** shape and click **Add**.
7. Click **Close** in the **Section Profile Tables** dialog.
8. Assign these properties with selected members in our model:
   a. Select the first property reference in the **Properties** dialog (W12X35).
   b. Select the **Use Cursor to Assign** option in the Assignment Method group.
   c. Click **Assign**.

      The mouse pointer changes to    d. Click on members 1 and 3.
   e. To stop assigning properties, either:

      click **Assigning**

      or

      press the **<Esc>** key.
9. Repeat step 8 except to assign the second property reference (W14X34) to member 2.

   After the properties are assigned to the respective members, the member labels will indicate the section reference numbers.

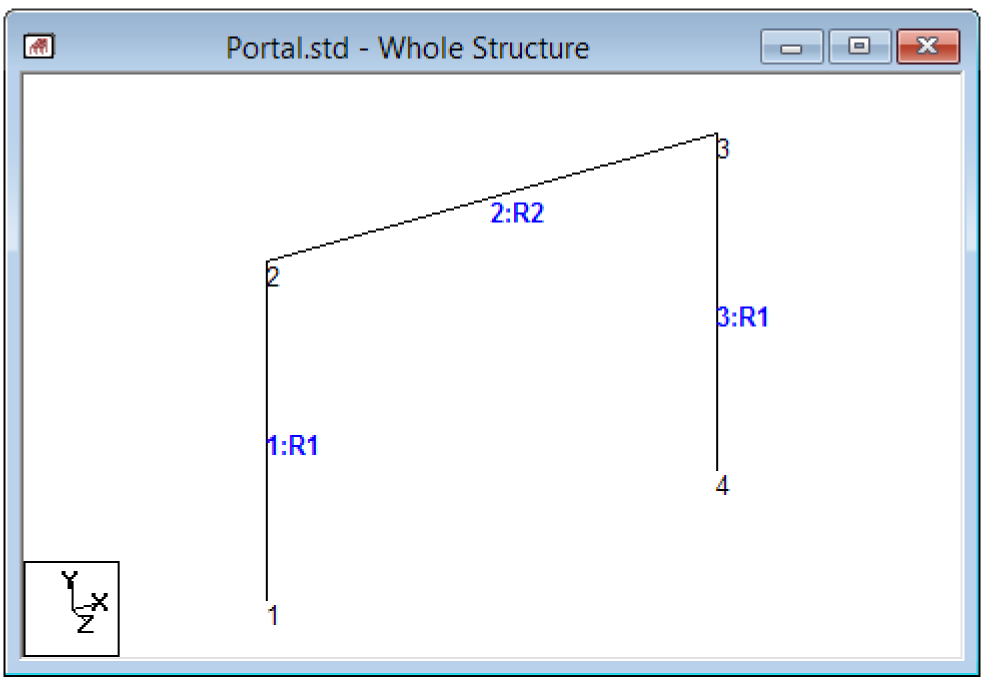

Figure 22:

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.1 Specifying material definition

When T.1 Specifying member properties (on page 406), you kept the **Material** option checked. Consequently, the material definitions were assigned to the members along with the sections.

The STAAD input file commands generated are:

```
DEFINE MATERIAL START
ISOTROPIC STEEL
E 4.176e+006
POISSON 0.3
DENSITY 0.489024
ALPHA 6e-006
DAMP 0.03
TYPE STEEL
STRENGTH FY 5184 FU 8352 RY 1.5 RT 1.2
END DEFINE MATERIAL
...
CONSTANTS
MATERIAL STEEL ALL
```

T.1 Changing the input units of length

For specifying member offset values and for some material definition values, as a matter of convenience, use length units of inches instead of feet.

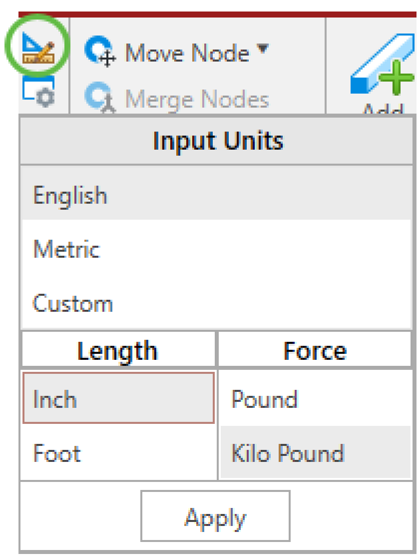
The STAAD input file commands generated are:

```
UNIT INCHES KIP
```

1. On the **Geometry** ribbon tab, select the **Input Units** tool in the **Structure** group.

   The **Set Input Units** pop-up opens.



2. Select **English** as the **Input Units**.
3. Set the **Length** input units to **Inch**.
4. Click **Apply**.

T.1 Specifying member offsets

Member 2 (the beam) actually spans only the clear distance between the column faces rather than the center to center distance. This is modeled by specifying offsets.

Member 2 is offset at the start joint by 6 inches in the global X direction (and 0.0 and 0.0 in Y and Z directions). The same member is offset by negative 6.0 inches at its end joint.

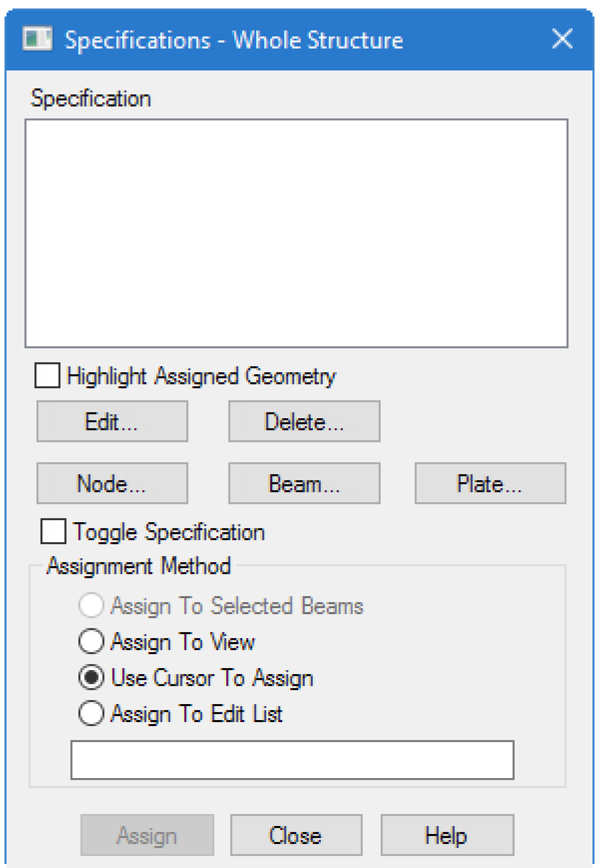
The STAAD input file commands generated are:

```
MEMBER OFFSET
2 START 6.0 0.0 0.0
2 END -6.0 0.0 0.0
```

1. Select member 2 by clicking on it in the view window.

   Note: If the beam cursor isn't currently active, select the **Beam Cursor** tool in the **Selection** group on the **Geometry** ribbon tab. 

   The selected member will be highlighted.
2. Select the **Specifications** page on the Analytical Modeling page bar.
   The **Specifications - Whole Structure** dialog opens. Member releases, offsets, and other beam specifications are defined here.



3. Click **Beam**.

The **Member Specification** dialog opens.

4. Specify the member start offset:
   a. Select the **Offset** tab.

   b. Select **Start** as the **Location**.
   c. Type `6.0`(in.) in the **X** offset field.

      Leave the Direction as Global. It is convenient to define the offset at the start node in the X direction. Since the beam member is aligned with the global X axis, there is no difference between choosing a global or local frame of reference.
   d. Click **Assign**.

   The dialog closes and the offset specification is added to the start of member 2. This is displayed visually on the member as well as listed in the Specification list in the **Specifications - Whole Structure** dialog.
5. On the **Specification** ribbon tab, select the **Beam** > **Offset** tool in the **Specifications** group.

   The **Member Specification** dialog opens to the **Offsets** tab.
6. Specify the member end offset:
   a. Select **End** as the **Location**.
   b. Type `-6.0`(in.) in the **X** offset field.
   c. Click **Assign**.

   The dialog closes and the offset specification is added to the start of member 2.

Tip: Alternatively to steps 5 and 6, you can repeat steps 3 and 4, except for selecting the **End** option and providing a value of `-6.0` for **X**. This procedure is used to demonstrate two methods to complete a similar task.

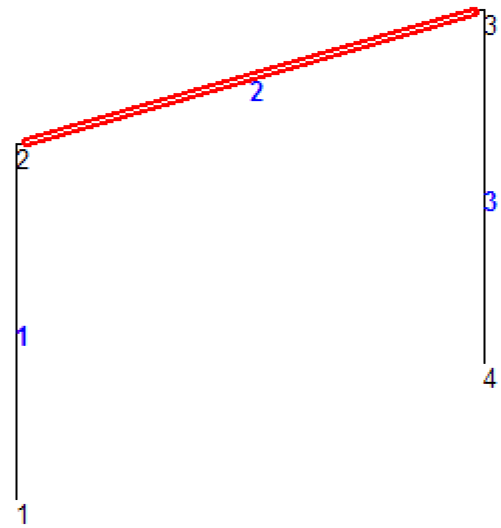


Figure 23: The model after both start and end offsets are assigned

Click anywhere in the drawing area to deselect the member.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.1 Printing member information in the output file

It is useful to view the member information used by the program for analysis. You can add a report in the STAAD output file consisting of information about all the members including start and end joint numbers (incidences), member length, beta angle, and member end releases.

The STAAD input file commands generated are:

```
PRINT MEMBER INFORMATION ALL
```

1. Select all the beam members by one of the following methods:

   on the **Select** ribbon tab, select the **All** tool in the **Beams** group

   or

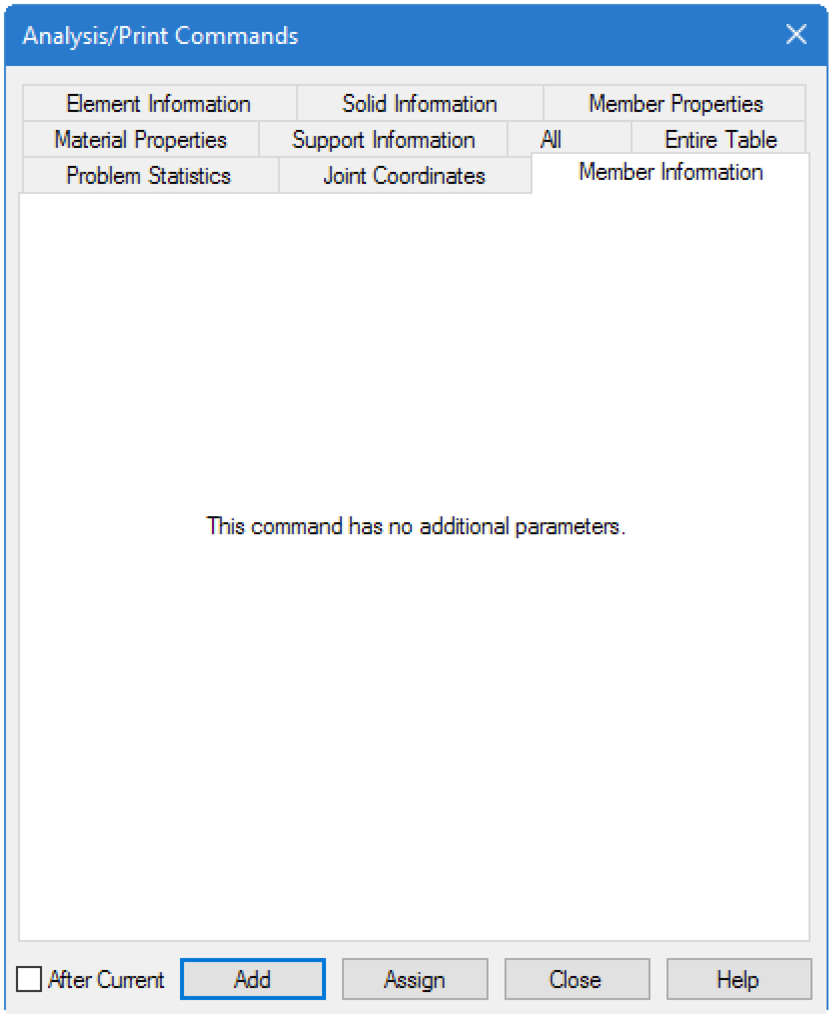
   click-and-drag a window around all members in the View window

   or

   press **<Ctrl+A>**
2. On the **Analysis and Design** ribbon tab, select the **Pre-Analysis Commands** tool in the Analysis Data group.

The **Pre Analysis Print - Whole Structure** dialog opens.

3. In the **Pre Analysis Print - Whole Structure** dialog, click **Define Commands**.
   The **Analysis/Print Commands** dialog opens.
4. Select the **Member Information** tab and then click **Assign**.



5. Click **Close**.

Click anywhere in the drawing area to deselect the member.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.1 Specifying Supports

The boundary conditions of this problem call for restraining all degrees of freedom at node 1 (FIXED support) and a pinned type of restraint at node 4 (restrained against all translations, free for all rotations).

The STAAD input file commands generated are:

```
SUPPORTS
1 FIXED ; 4 PINNED
```

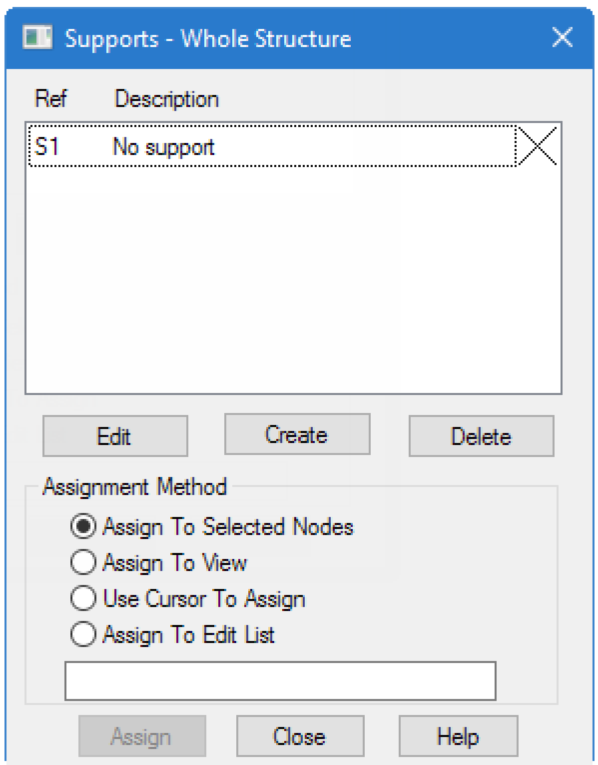
1. On the **Select** ribbon tab, select the **Node Cursor** tool in the **Cursors** group.

2. In the View window, click on nodes 1 to select it.

Note: The **Node Tools** ribbon tab opens when nodes are selected.

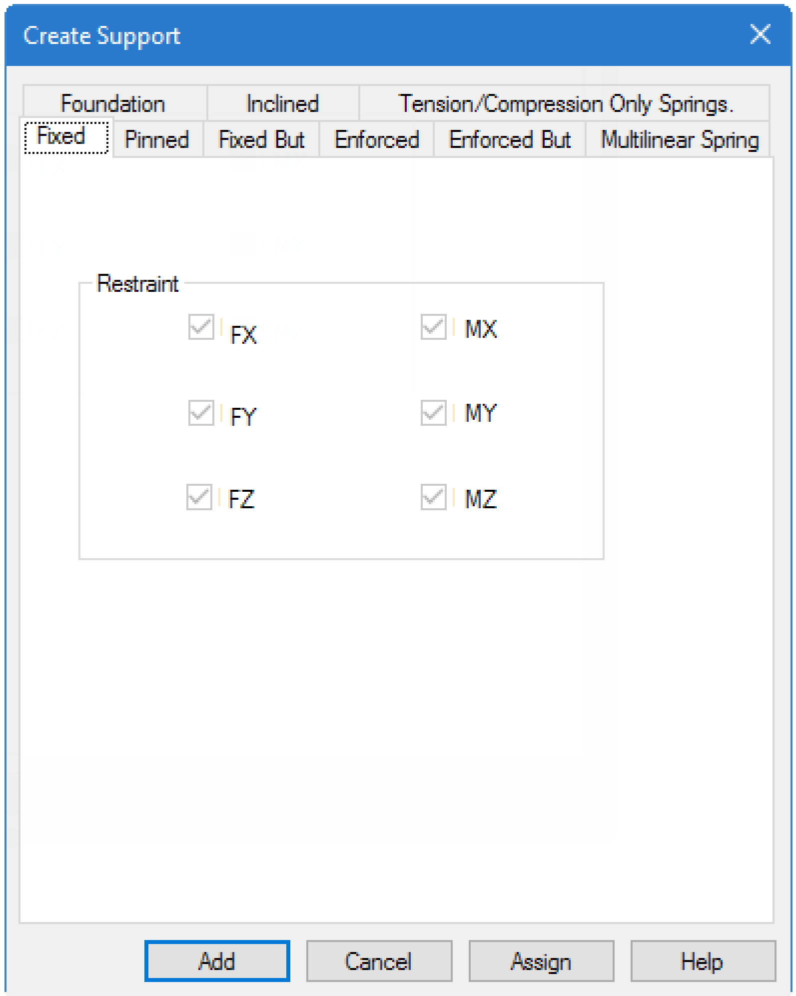
3. On the **Node Tools** ribbon tab, select the **Assign Supports** tool in the **Model** dialog.

The **Supports - Whole Structure** dialog opens.



4. In the **Supports** dialog, click **Create**.

The **Create Support** dialog opens.



5. Select the **Fixed** tab (selected by default) and then click **Assign**.

   This creates a FIXED type of support at node 1 where all 6 degrees of freedom are restrained.
6. To create a PINNED support at node 4, repeat steps 2 through 5, except for selecting node 4 and selecting the **Pinned** tab in the **Create Support** dialog.

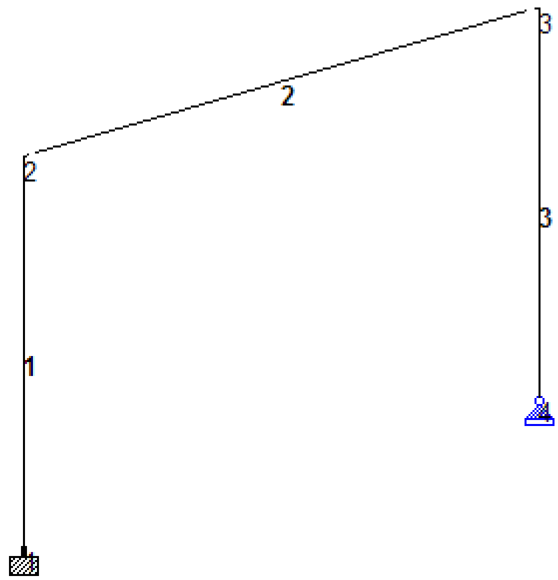


Figure 24: The portal frame with supports assigned

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.1 Viewing the model in 3D

You can review the model in 3D in the STAAD.Pro user interface.

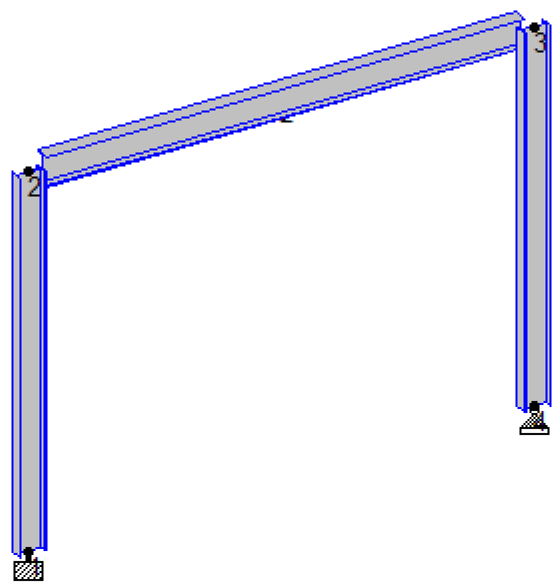

Figure 25: The model rendered in three dimensions

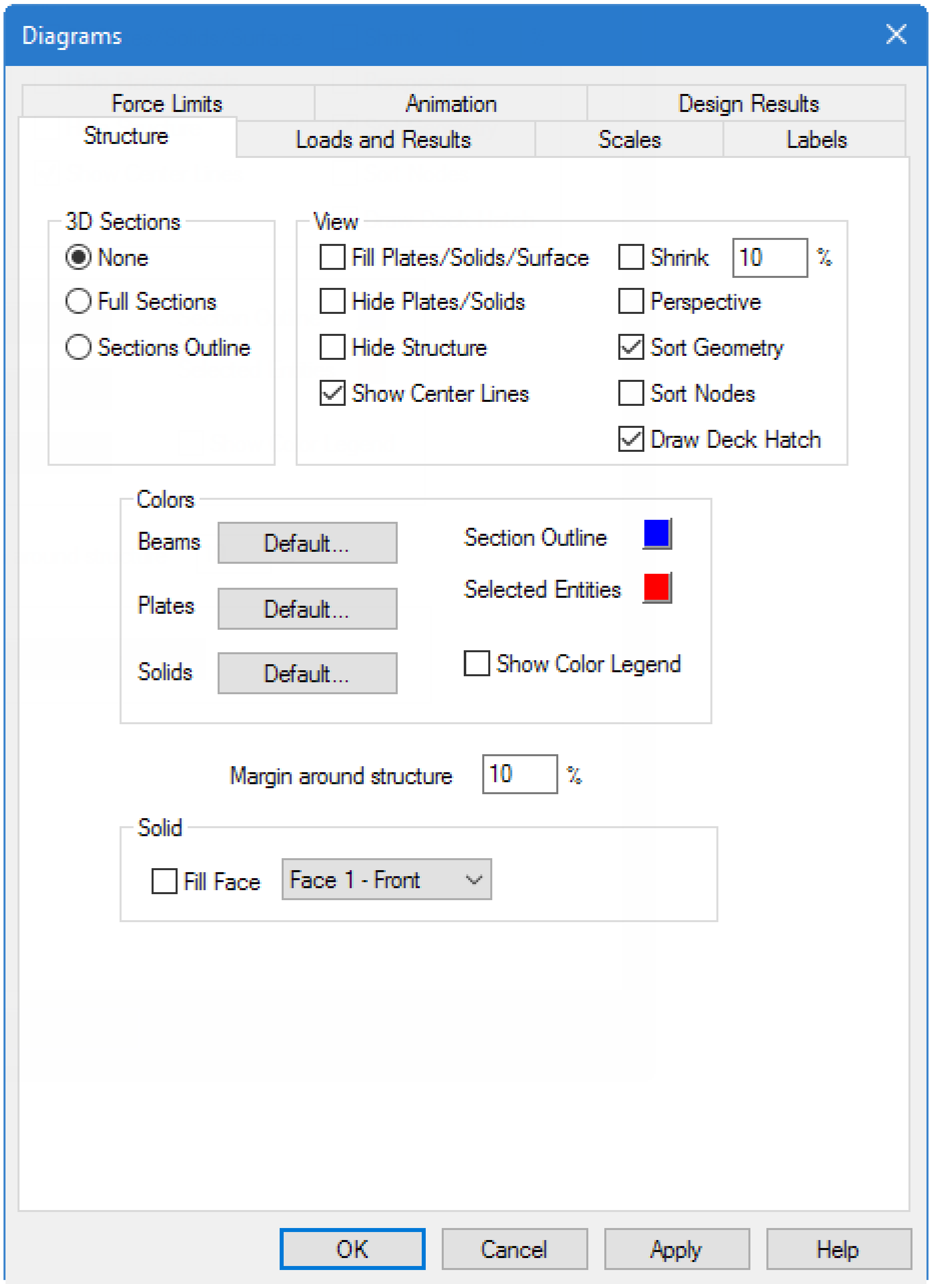
1. Right-click in the view window and select **Structure Diagrams** from the pop-up menu.

The **Diagrams** dialog opens to the **Structure** tab.



The options under **3D Sections** control how the members are displayed.

None	displays the structure without displaying the cross-sectional properties of the members and elements.
Full Sections	displays the 3D cross-sections of members, depending on the member properties.
Sections Outline	displays only the outline of the cross-sections of members.

2. Select **Full Sections** and then click **OK**.

> **Tip:** You can also change the color of the sections by clicking on the **Section Outline** color button in the **Colors** group.

Alternatively, you can quickly render the model in 3D in a new window either by:

selecting the **3D Rendering** tool in the **Windows** group on the **View** ribbon tab  or selecting **View** > **3D Rendering**.

This method has no further settings for colors.

T.1 Specifying Loads

Three load cases are to be created for this structure. Details of the individual cases are explained at the beginning of this tutorial.

The STAAD input file commands generated are:

```
UNIT FEET KIP
LOADING 1 DEAD + LIVE
MEMBER LOAD
2 UNI GY -2.5
LOADING 2 WIND FROM LEFT
JOINT LOAD
2 FX 10.
LOAD COMBINATION 3 75 PERCENT OF (DL+LL+WL)
1 0.75 2 0.75
```

The creation and assignment of load cases involves the following steps:

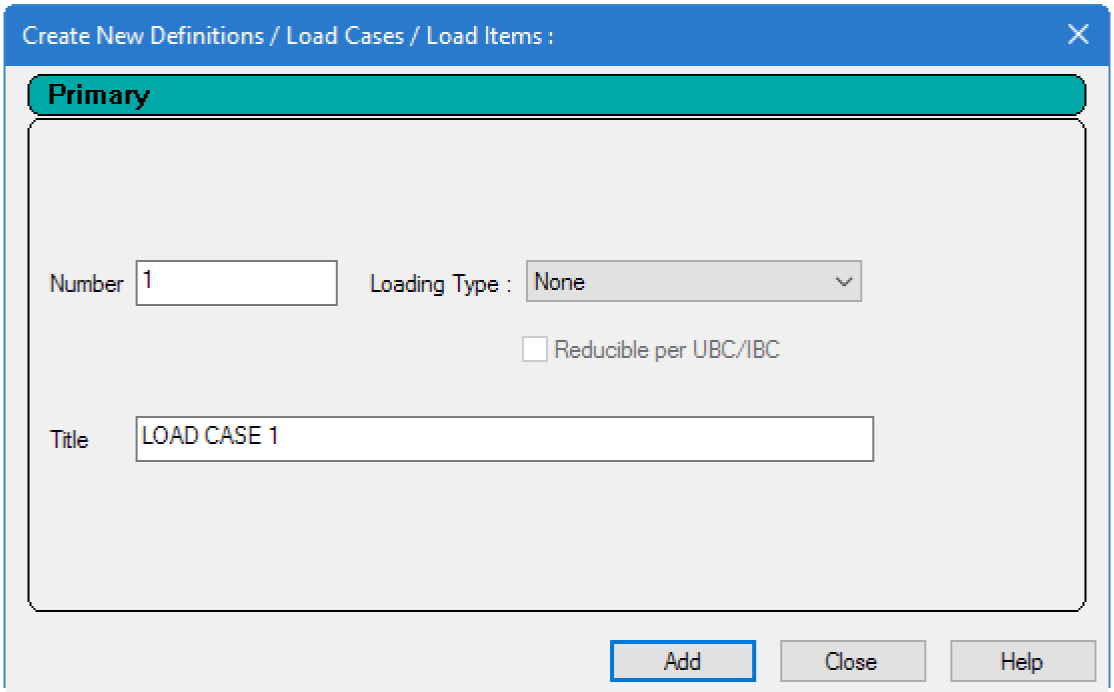
I. Create the two basic load cases
II. Create a load combination as a third load case
III. Assign these loads to the respective members/nodes.

T.1 Creating Load Cases 1 and 2

Load cases 1 and 2 are primary load cases. These load cases are used during analysis of the structure.

1. Change the length units to **Feet** by selecting the length unit in the application window status bar.
   See T.1 Changing the input units of length (on page 409).
2. On the **Loading** ribbon tab, select the **Primary Load Case** in the **Loading Specifications** group.

   
   The **Create New Primary Load Cases** dialog opens.



3. Enter the properties for the first load case:
   a. Type `DEAD + LIVE` in the **Title** field.

      Leave the **Number** as the default value of 1.

      Note: The **Loading Type** list is used to associate the load case we are creating with any of the ACI, AISC, IBC, or other code-prescribed definitions of Dead, Live, Ice, etc. This type of association needs to be done if you intend to use the program's automatically generating load combinations in accordance with those codes. Note that there is a check box labeled **Reducible per UBC/IBC**. This feature is active only when the load case is assigned a Loading Type called **Live** when you create that load case.

      Since this tutorial does not use the automatic load combination generation feature, leave the **Loading Type** as **None**.
   b. Click **Add**.
      The load case appears under the **Load Cases Details** option in the **Load & Definition** dialog.

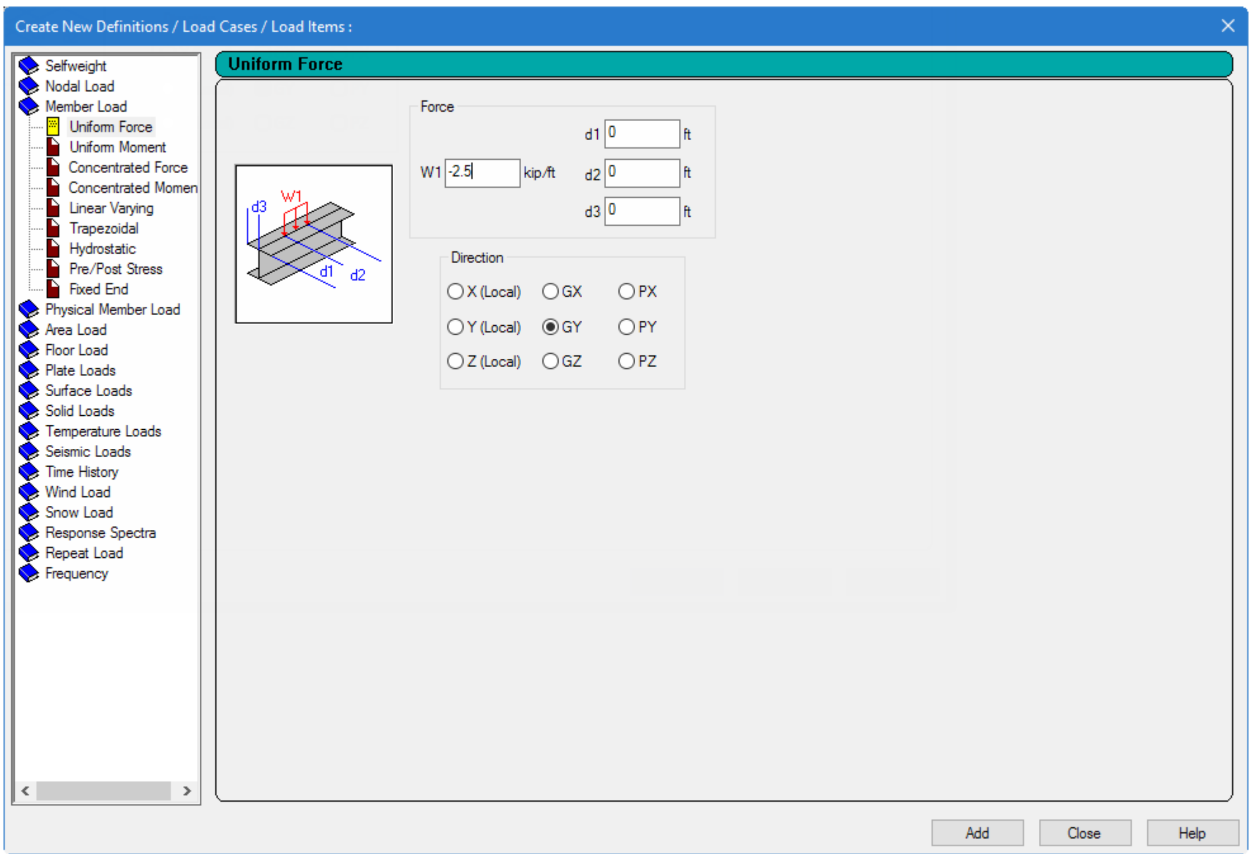
   c. Click **Close**.
4. On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

The **Create New Load Items** dialog opens with entries for adding load items to the current load case.

5. Define the uniform load for this load case:
   a. In the **Create New Load Items** dialog, select the **Uniform Force** tab under the **Member Load** item.
   b. Select **GY** as the **Direction**.
   c. Type `-2.5` in the **W1** field (magnitude of the uniform force).

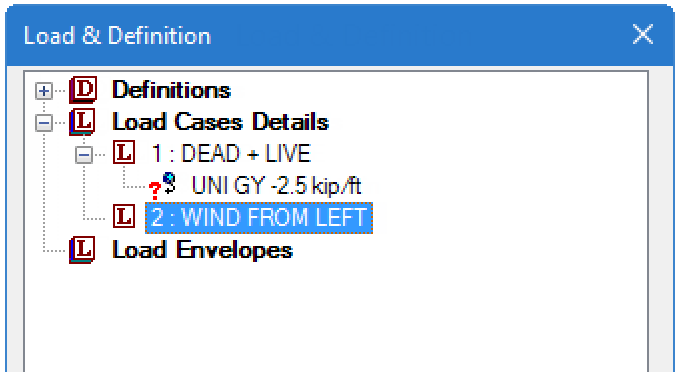
      The negative value indicates the load acts "down".

      Leave the offset fields (d1 through d3) as zero.
   d. Click **Add**.
   e. Click **Close**.



6. Repeat steps 2 and 3 to create the second load case, except title the load case as `WIND FROM LEFT`.

   Again, leave the Loading Type as **None**.

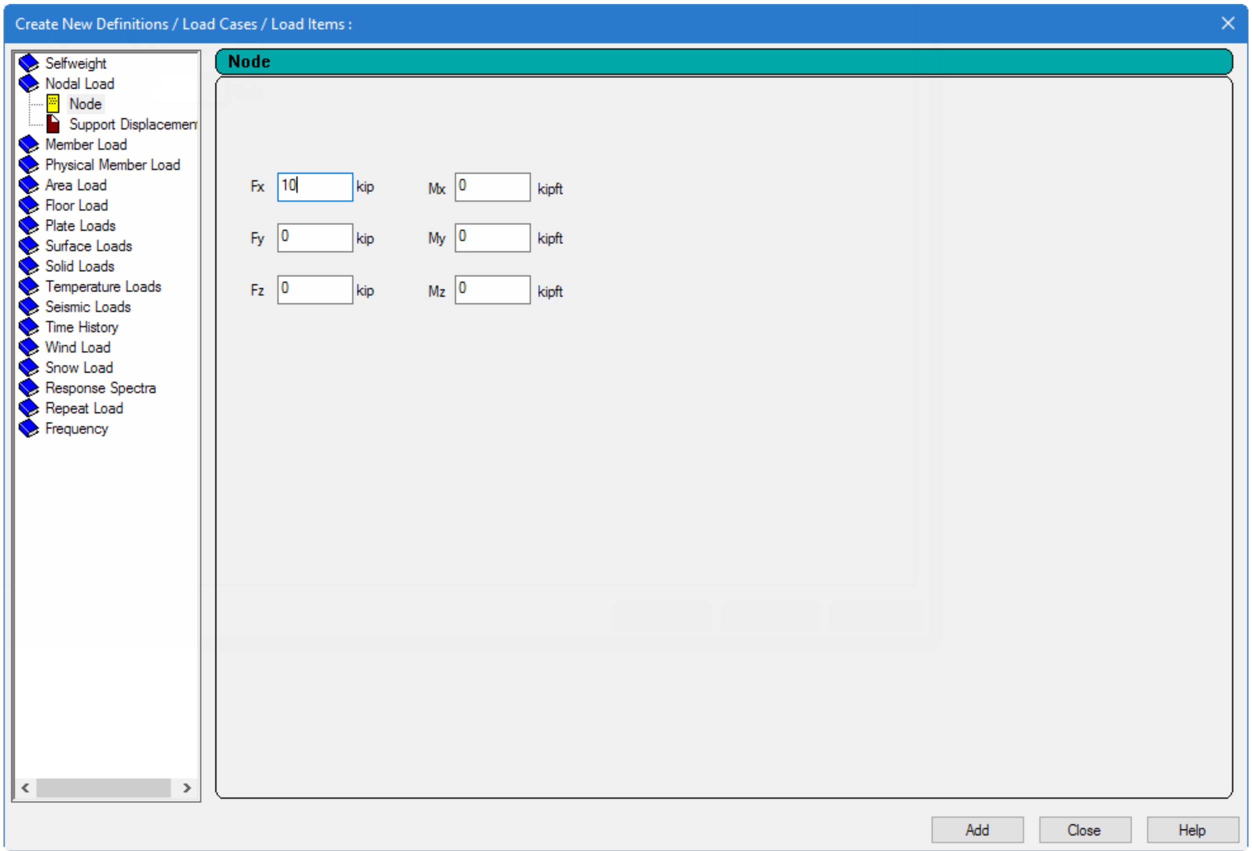


7. Set the wind load case as the current load case:
   a. On the **Loading** ribbon tab, click the down arrow on the **Load** tool in the **Display** group.
   The **Select load** pop-up dialog opens.

   b. Select the **2: Wind From Left** primary load case.

   Load items created using the ribbon tab tools are added to the current load case.
8. On the **Loading** ribbon tab, select the **Load Items** in the **Loading Specifications** group.

   The **Create New Load Items** dialog opens with entries for adding load items to the selected load case.
9. Define the wind load at the joint:
   a. In the **Create New Load Items** dialog, select the **Node** tab under the **Nodal Load** item.
   b. Type `10` in the **Fx** field (magnitude of the force along the global X direction).
   c. Click **Add**.
   d. Click **Close**.

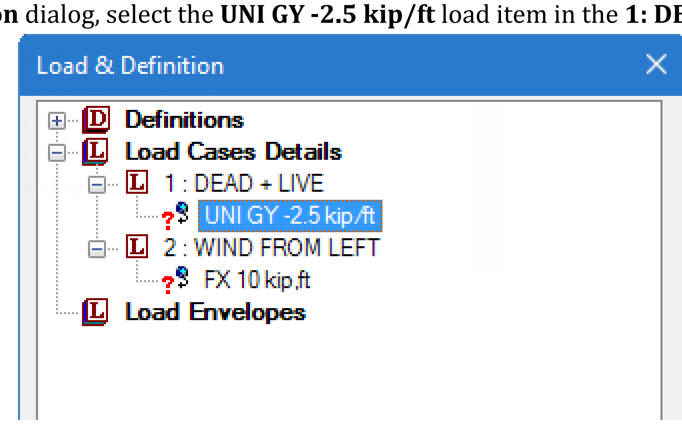


T.1 Assigning load cases to members

Load item assignments are made using the **Load & Definition** dialog, which opens when most of the Loading tools are selected. If this dialog is not currently open, select the Loading page in the Analytical Modeling page control bar to re-open it.

You may notice that the load items in the Load & Definition dialog are listed with an ? icon. This indicates that these load items are not yet assigned to any model objects (i.e., beams or nodes).

1. In the **Load & Definition** dialog, select the **UNI GY -2.5 kip/ft** load item in the **1: DEAD + LIVE** load case .



2. Select the **Use Cursor to Assign** option in the **Assignment Method** group.

3. Click **Assign**.

   The mouse pointer changes to 
4. Click on member 2.

   The uniform load is drawn on member 2 and the load item icon changes to  in the **Load & Definition** dialog.

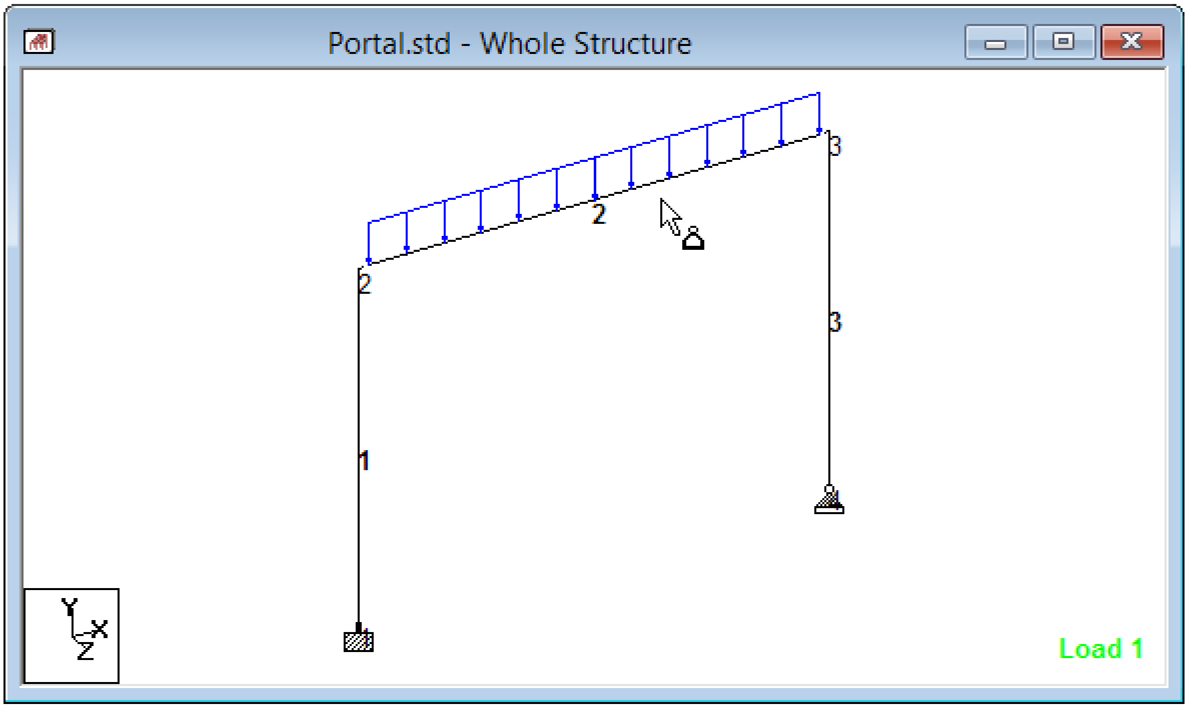


Figure 26: Uniform load item assigned to member 2

5. Repeat steps 1 through 4, except to assign the nodal load item in the second load case (**FX 10 kip, ft**) to Node 2.

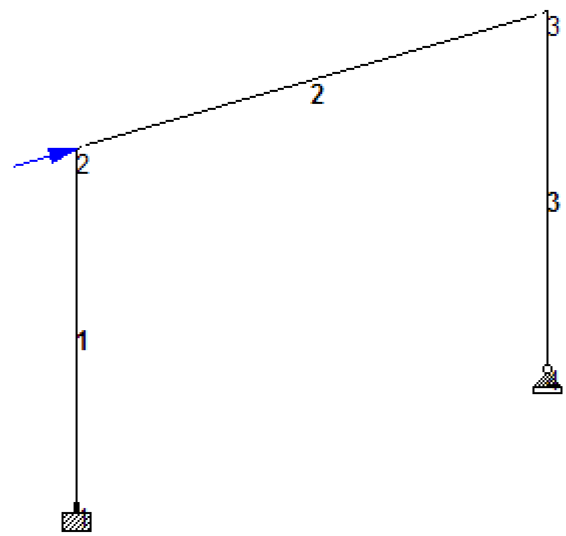

Figure 27: Model with the nodal load item assigned to node 2

6. To stop assignment load items:

   click **Assigning**

   or

   Press the **<Esc>** key.

What about the load combinations? These do not need to be assigned to any model objects. As you may recall, these represent a factored combination of the *results* of the primary load cases and thus are not directly analyzed.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.1 Creating Load Case 3

In this procedure, you will add a load combination of the first two primary load cases.

If you started your model in STAAD.Pro Physical Modeler, first select the **Loading** page in the Analytical Modeling page control bar. The **Load & Definition** dialog opens on the right side of the program window.

Here you will see that the two load groups you created inSTAAD.Pro Physical Modeler have each been added as primary load cases to the analytical model. The loads you added to the physical model are also transferred as load items in the respective load cases.

Load case 3 is a load combination. This means that the results from the primary load cases will be combined as directed by this load case definition.

1. On the **Loading** ribbon tab, select the **Combination Load Case** tool in the **Loading Specifications** group.

   
   The **Create New Load Combinations** dialog opens.

2. Type `75 Percent of [DL+LL+WL]` in the **Name** field.
3. Set the **Type** option to **Normal**.

   This combines the loads algebraically.

   The other combination types available are called SRSS (square root of sum of squares) and ABS (Absolute). The SRSS type offers the flexibility of part SRSS and part Algebraic. That is, some load cases are combined using the square root of sum of squares approach, and the result is combined with other cases algebraically, as in:

   $$A + \sqrt{B^2 + C^2}$$

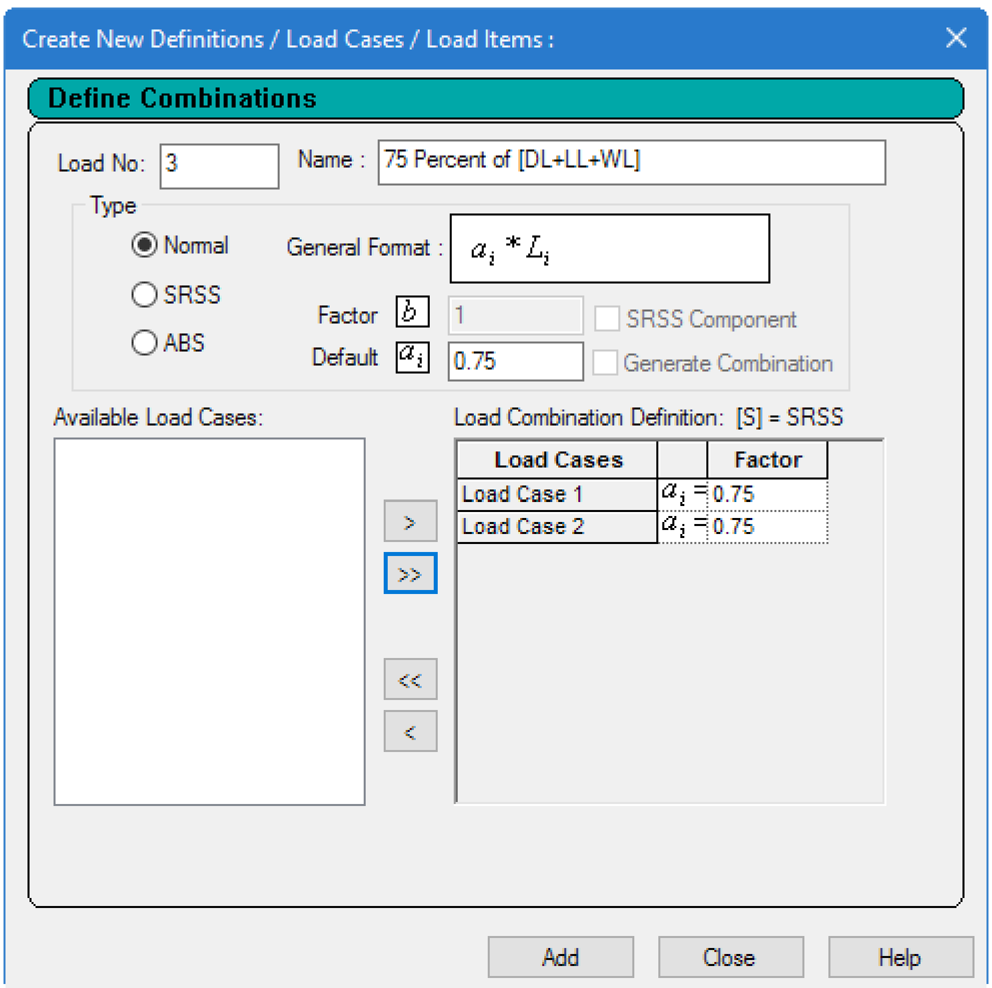
   where

   A, B, and C = the individual primary load cases
4. Type `0.75` in the **Default α1** field.

   This is used as the default factor for normal load combinations.
5. Click **[>>]**.

   Both primary load cases are added to the **Load Case Definition** list using the default factor.

   This indicates that the results of the two load cases will be multiplied by 0.75 and then summed to produce load combination results. Note that such a load combination method should only be used for linear analysis.



6. Click **Add**.
   The load combination is added to the **Load Cases Details** section in the **Load & Definition** dialog as load 3.
7. Click **Close**.

T.1 Analysis and Design

The following procedures describe how to add analysis and design commands to the STAAD input file.

Note: The analysis design commands are added using either the analytical user interface or the STAAD.Pro Editor. The STAAD.Pro Physical Modeler interface is not used to assign analysis and design commands.

T.1 Specifying the analysis type

A linear, static analysis is required for this model. You can also instruct STAAD.Pro to provide a static equilibrium report.

The STAAD input file commands generated are:

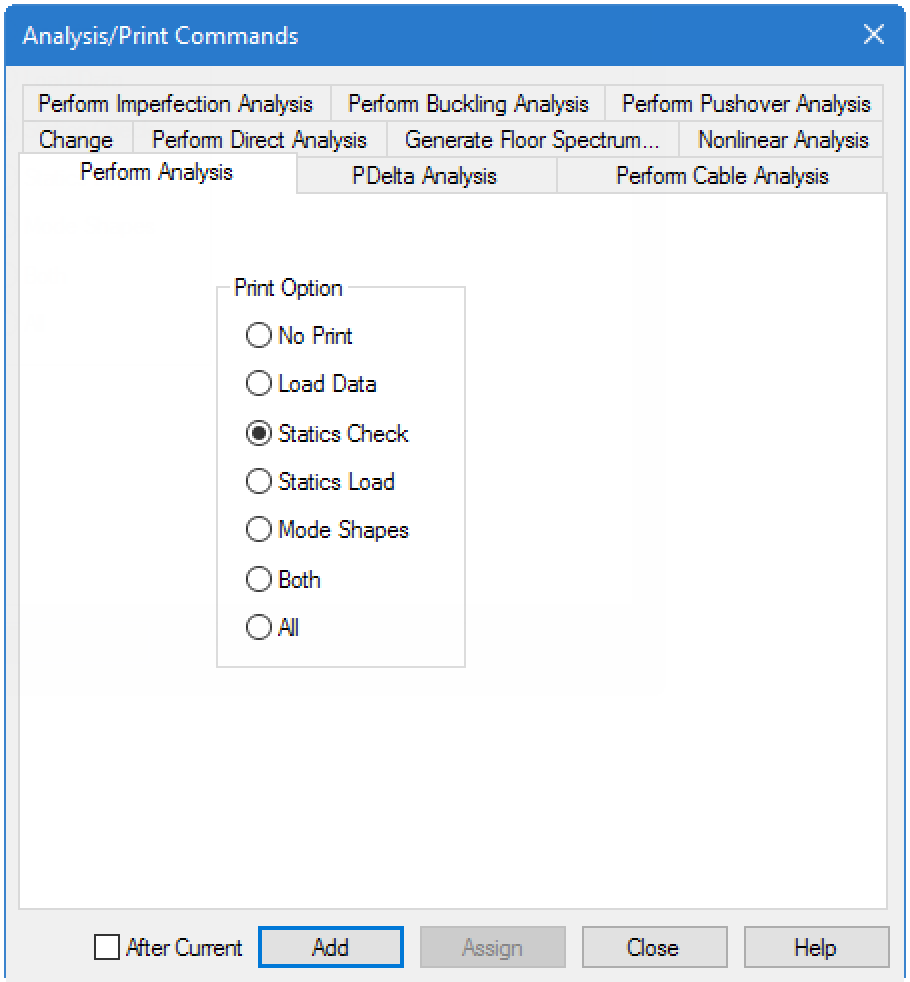
```
PERFORM ANALYSIS PRINT STATICS CHECK
```

1. On the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group.

   The **Analysis/Print Commands** dialog opens.

   Tip: If the **Analysis/Print Commands** dialog does not open automatically, then click **Define Commands** in the **Analysis - Whole Structure** dialog.
2. In the **Analysis/Print Commands** dialog, select the **Perform Analysis** tab.



3. Select the **Statics Check** option.

 Note: In response to this option, a report consisting of the summary of applied loading and summary of support reactions, for each load case, will be produced in the STAAD output file.

4. Click **Add**.

 Tip: The command is added to the list of commands outlined in the **Analysis - Whole Structure** dialog on the right-hand side of the window. The command has a green checkmark to indicate that it is valid. You can review the outline of the command input structure here.

5. Click **Close**.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.1 Specifying post-analysis print commands

Once an analysis has been completed, the program can then provide results of the analysis in the output. In particular, you will request member end forces and support reactions written to the output file.

The STAAD input file commands generated are:

```
PRINT MEMBER FORCES ALL
PRINT SUPPORT REACTION LIST 1 4
```

1. Select all the beam members by one of the following methods:

   on the **Select** ribbon tab, select the **All** tool in the **Beams** group

   or

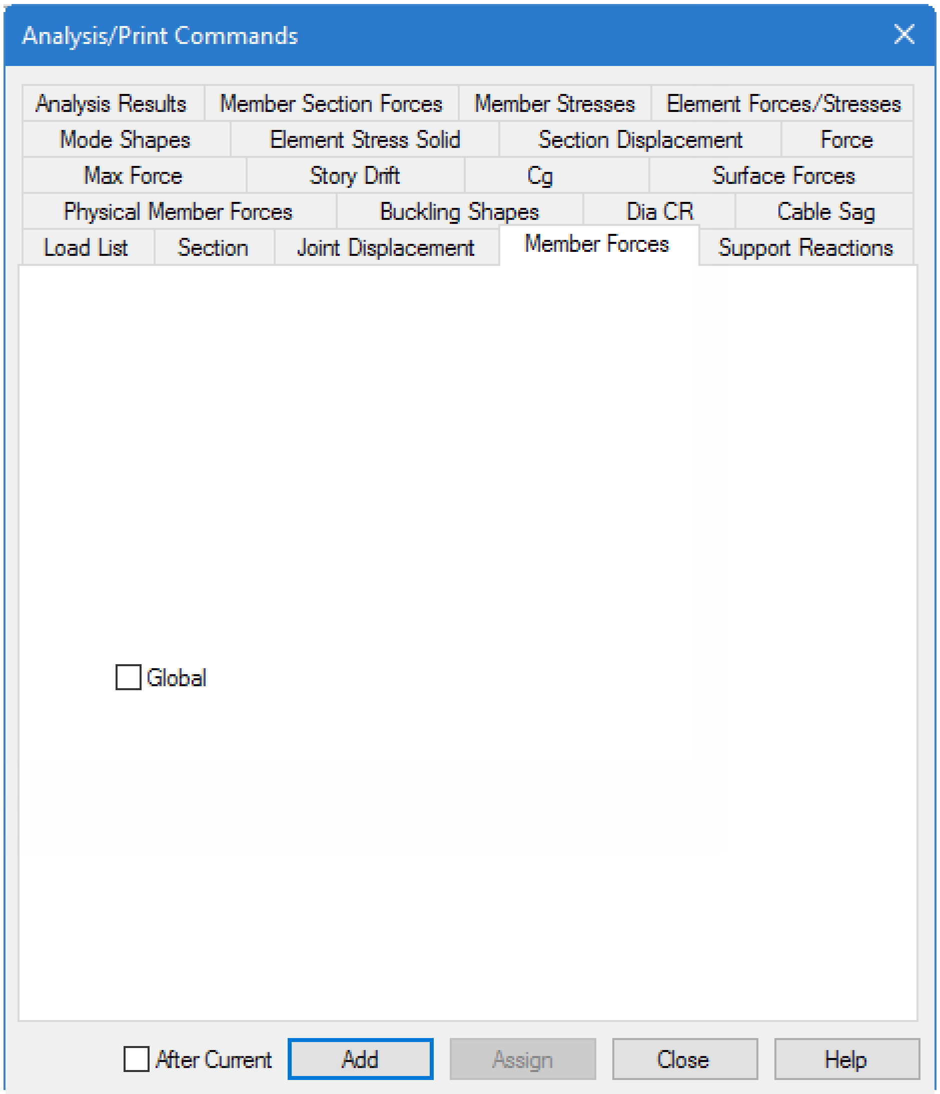
   click-and-drag a window around all members in the View window

   or

   press **<Ctrl+A>**
2. On the **Analysis and Design** ribbon tab, select the **Post-Analysis Commands** tool in the **Analysis Data** group.

3. On the **Post Analysis Print - Whole Structure** dialog, click **Define Commands**.
   The **Analysis/Print Commands** dialog opens.
4. Add the member forces results to the output:
   a. Select the **Member Forces** tab.



b. Click **Assign**.

Tip: Since you first selected the members, you can assign the command to those members directly from this dialog. Otherwise, you would add the command and then assign it —similar to how you assigned load case items— to those members.

c. Click **Close**.

5. On the **Select** ribbon tab, select the **Supports** tool in the **Nodes** group.

The supported nodes (nodes 1 and 4) are both selected.

6. Repeat steps 2 and 3 to open the **Analysis/Print Commands** dialog for the post-print commands.
7. Add the support reactions to the output:

a. Select the **Support Reactions** tab.

b. Click **Assign**.
c. Click **Close**.

The command is added to the list of commands.

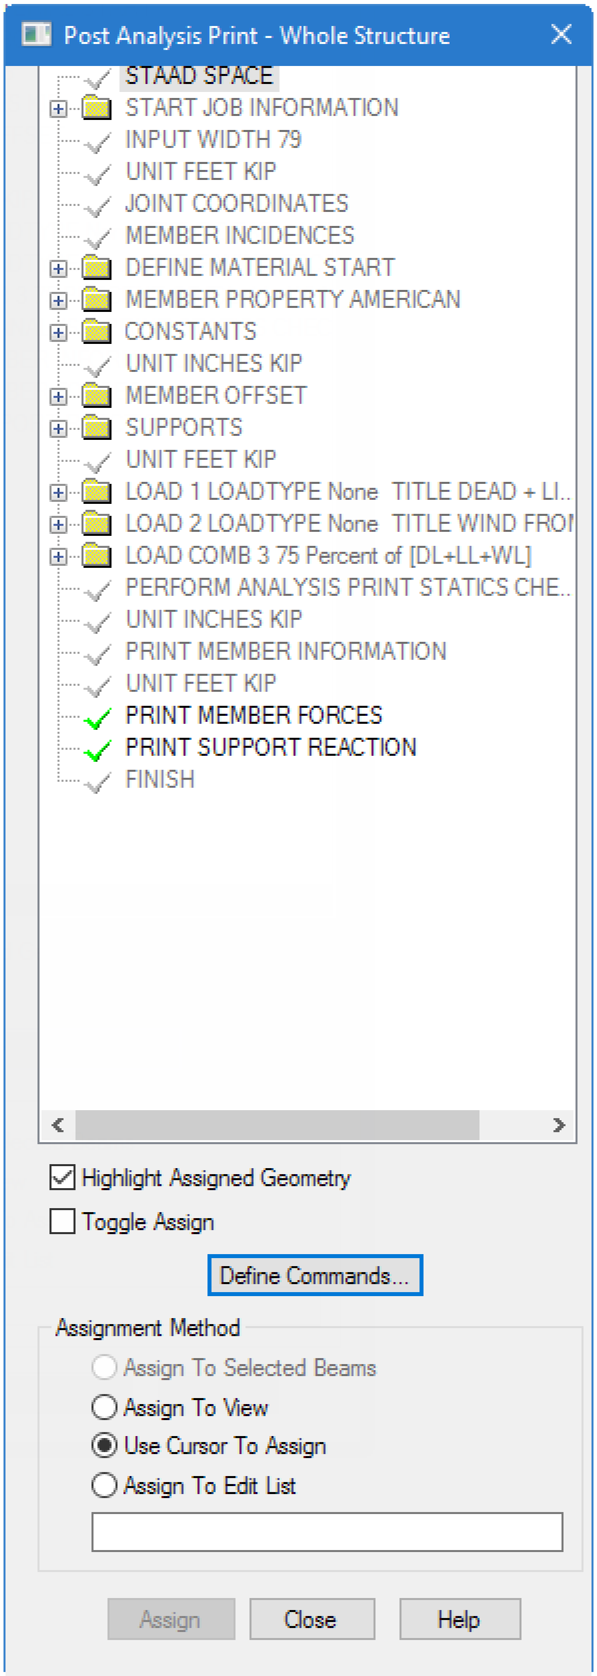


*Figure 28: The **Post Analysis Print** dialog after the post-analysis print commands are added and assigned.*

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.1 Short-listing the load cases to be used in steel design

The steel design has to be performed for load cases 1 and 3 only per the specification at the beginning of this tutorial. To instruct the program to use just these cases, and ignore the remaining, you will use the `LOAD LIST` command.

The STAAD input file commands generated are:

```
LOAD LIST 1 3
```

1. On the **Anlaysis and Design** ribbon tab, select the **Load List** tool in the **Analysis Data** group. 
   The **Load List** dialog opens.

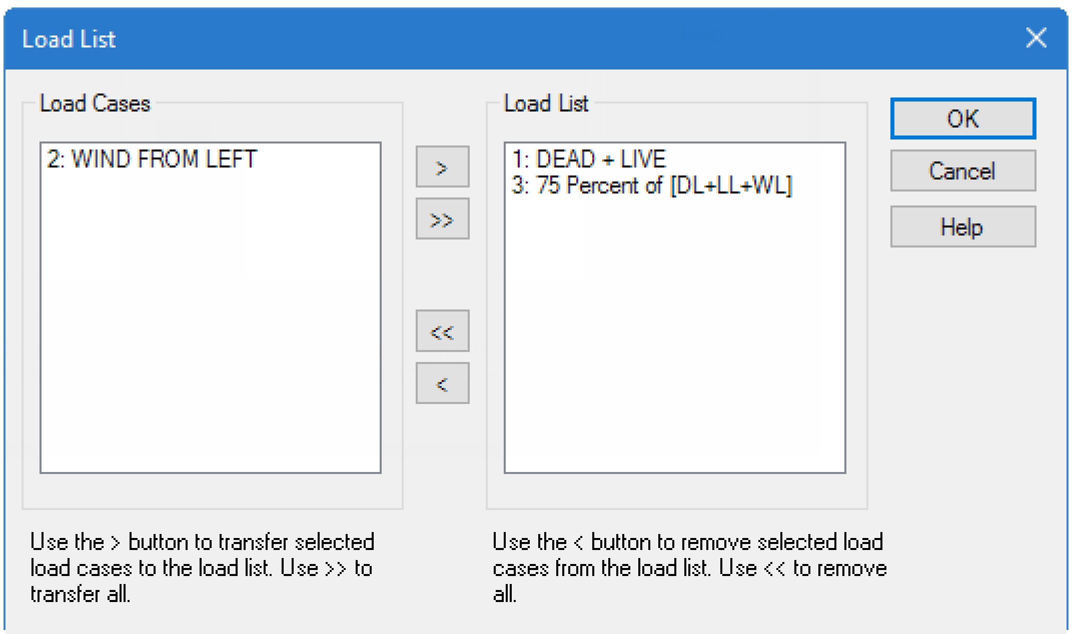

Figure 29:

2. From the **Load Cases** list box on the left, double-click on `1: DEAD + LIVE` and `3: 75 Percent of [DL+LL +WL]` to add these loads to the **Load List** box on the right.
3. Click **OK**.

T.1 Specifying steel design parameters

Designing members per a building code as specified for this tutorial require you to provide values for some of the terms where the default values do not match the problem requirements.

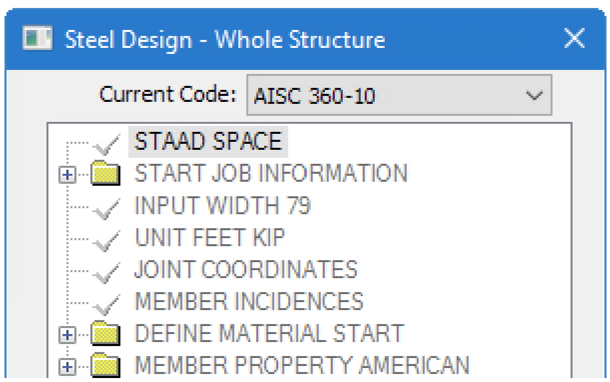
Note: This tutorial uses the 2010 edition of the American Institute of Steel Construction 360 specification for design (AISC 360-10). Details on the code parameters can be found in D1. American Codes (on page 1086) section.

The STAAD input file commands generated are:

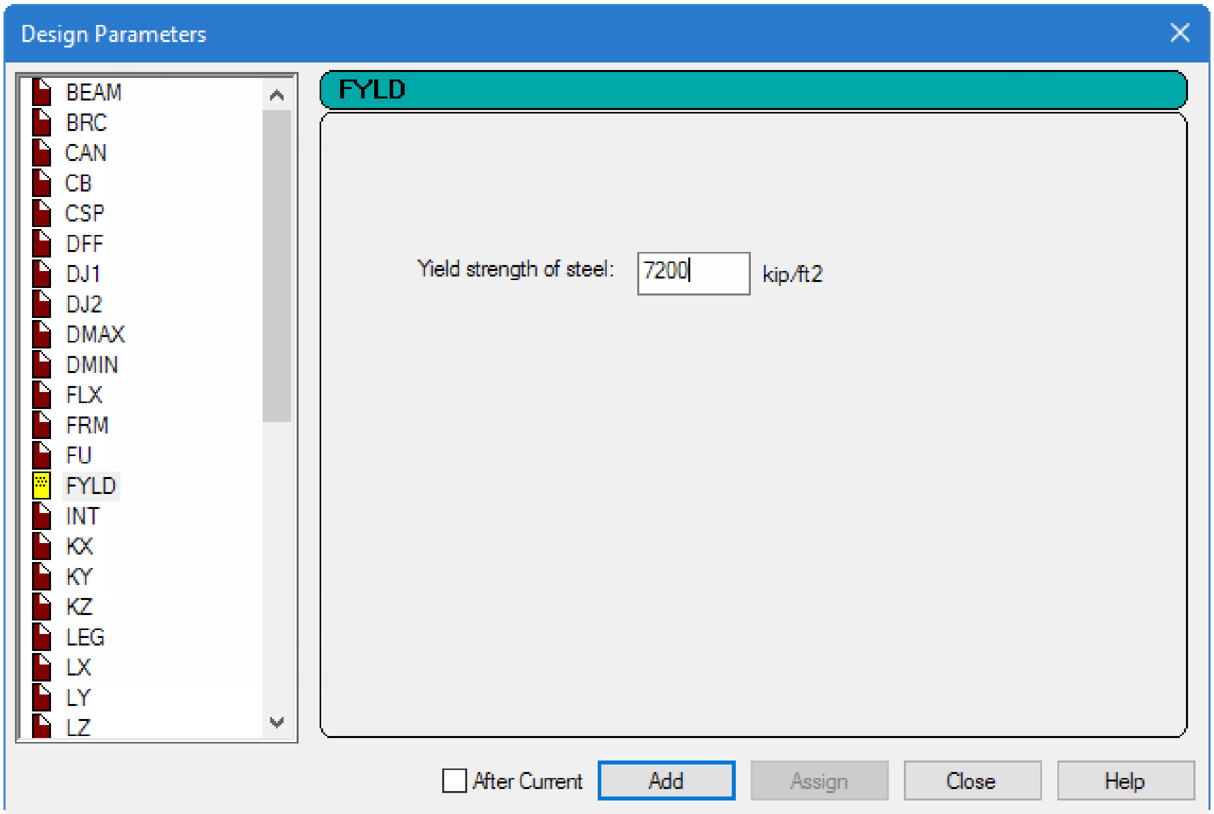
```
PARAMETER
CODE AISC UNIFIED 2010
FYLD 7200 ALL
TRACK 2 MEMB 2 3
UNB 10.0 MEMB 2 3
UNT 10.0 MEMB 2 3
SELECT MEMB 2 3
```

1. On the **Analysis and Design** ribbon tab, select **Steel** in the **Design Commands** gallery.

2. In the **Steel Design - Whole Structure** dialog, select **AISC 360-10** in the **Current Code** list.



3. In the **Steel Design - Whole Structure** dialog, click **Define Parameters**.
   The **Design Parameters** dialog opens.
4. Specify the yield strength parameter:
   a. Select the **FYLD** parameter tab.



b. Type `7200` (kip/ft^2) [50 (kip/in^2)]in the **Yield strength of steel** field.

> **Tip:** This equates to a 50 ksi steel, which is the common strength for American wide flange shapes. You can change the input units before and after this command to use inches for convenience, but this tutorial uses a non-standard unit here for brevity.

c. Click **Add**.
The parameter list is added to the list of commands in the **Steel Design - Whole Structure** dialog, including the selected design code and the yield strength value.

5. To define the remaining parameters, repeat step 4 except for selecting the parameters and providing the values listed below.

Parameter	Value
TRACK	**2** (select the option)
UNB	`10` (ft) [120 (in)]
UNT	`10` (ft) [120 (in)]

6. Click **Close** in the *Design Parameters* dialog.

> **Note:** The steel design parameters are all marked with an icon. This indicates that they need to be assigned to steel members.

7. Assign the yield strength to all members:

a. Select the **FYLD 7200** parameter in the command list.

   b. Select the **Assign to View** option in the Assignment Method group.
   c. Click **Assign**.
   A dialog opens confirming you want to assign to the view (all members currently displayed in the view window).
   d. Click **Yes**.

8. Assign the output detail (TRACK) parameter to members 2 and 3:
   a. Select the **TRACK 2** parameter in the command list.
   b. Select the **Use Cursor to Assign** option in the Assignment Method group.
   c. Click **Assign**.
   The mouse pointer changes to a .
   d. Click on each member in the Frame.
   e. Click on **Assigning** to stop assigning design parameters.

9. Repeat step 8 to assign the other two parameters (UNB and UNT) to members 2 and 3, as well.

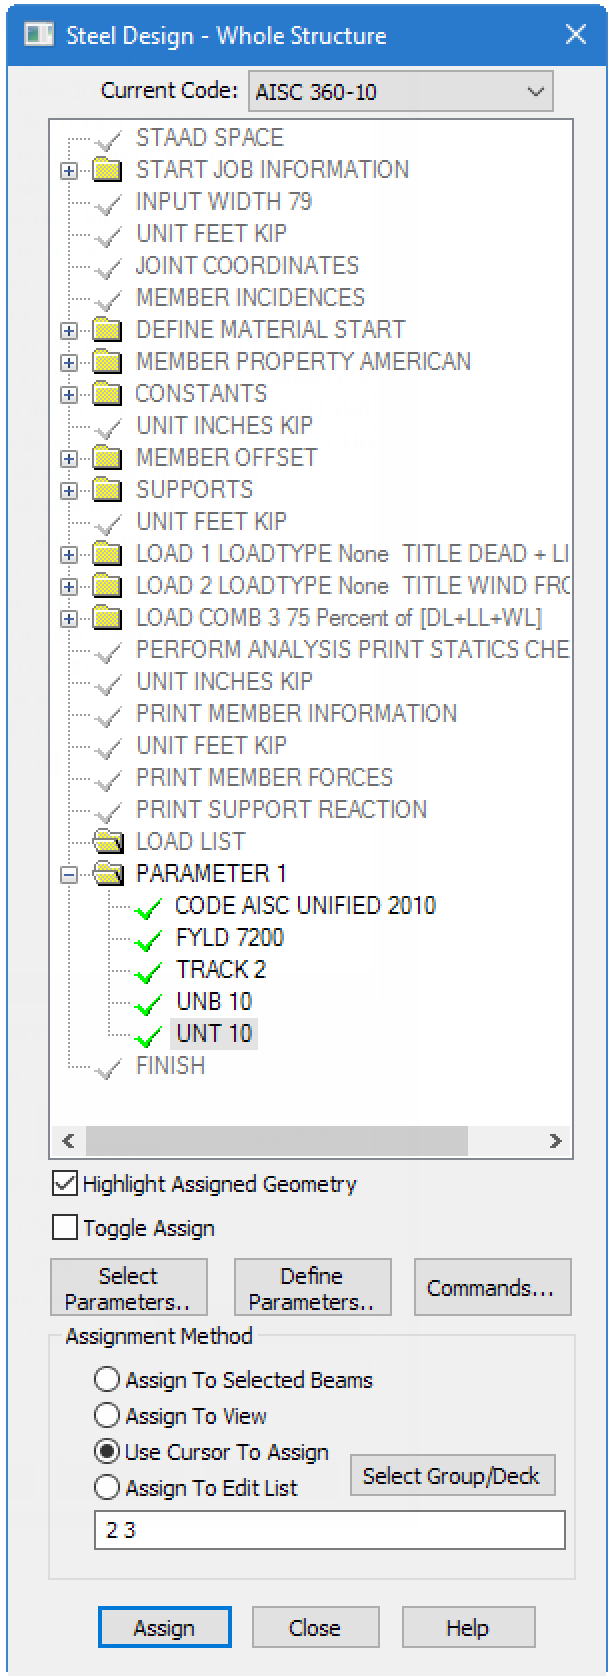


*Figure 30: The **Steel Design - Whole Structure** dialog after the design parameters have been added and*

assigned

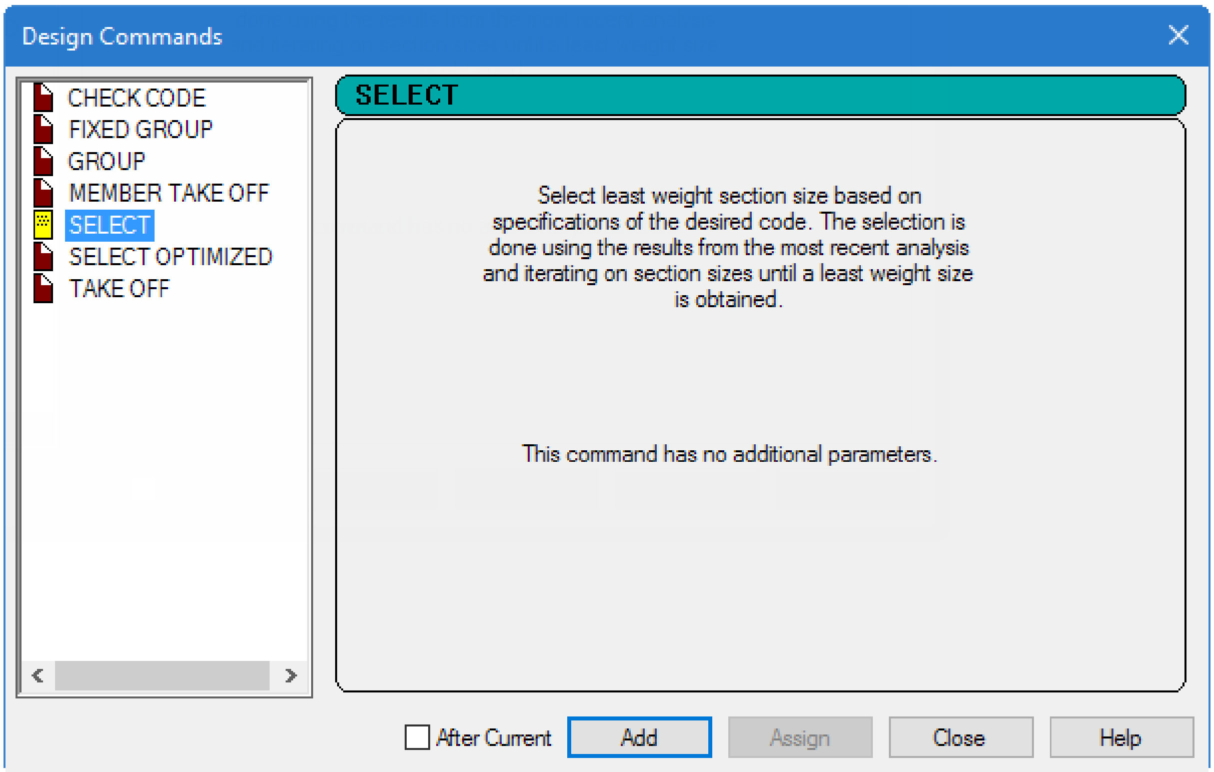
10. Add a command to instruct select sizes for members 2 and 3:

The select command is an instruction to the program to assign the least-weight cross-section which satisfies all the code requirements for the member.

a. In the **Steel Design - Whole Structure** dialog, click **Commands**.

The **Design Commands** dialog opens.

b. Select the **Select** tab.



c. Click **Add**.

d. Click **Close**.

11. Assign the select command to members 2 and 3:

a. Select the **SELECT** parameter in the command list.

b. Select the **Assign to Edit List** option in the Assignment Method group.

c. Type 2 3 in the list.

Notice this is a space-separated list of member numbers.

d. Click **Assign**.

Tip: You may also use either the method of selecting the members first or using the cursor to assign the command to the members.

After the parameters are assigned, click anywhere in the drawing area to deselect the members.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.1 Re-specifying the analysis command

When the analysis and design engine executes the member selection operation you specified in the previous step, a new set of properties will end up being assigned to those members. This changes the stiffness distribution for the entire structure. Since the structure is statically indeterminate, it should be analyzed again to determine the correct the nodal displacements, member forces, etc. to reflect this new stiffness distribution.

The STAAD input file commands generated are:

```
PERFORM ANALYSIS
```

1. Select the **Select** command in the **Analysis - Whole Structure** dialog outline of the model commands.
2. On the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group.

   The **Analysis/Print Commands** dialog opens.

   > **Tip:** If the **Analysis/Print Commands** dialog does not open automatically, then click **Define Commands** in the **Analysis - Whole Structure** dialog.
3. Select the **Perform Analysis** tab.
4. Select the **No Print** option.

   > **Tip:** The statics check report does need to be repeated.
5. Check the **After Current** option.

   This allows you to specify that where the new command is added. This will place the new Perform Analysis *after* the command selected in Step 1, instead of in the first valid point within the model file.
6. Click **Add**.
7. Click **Close**.

> **Tip:** Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.1 Re-specifying the TRACK parameter

The final calculation we need to do is make sure the current set of member properties pass the code requirements based on the up-to-date member forces.

This will require that we do a code checking operation again. To restrict the output produced to a reasonable level, we specify the TRACK parameter again but use a different value.

The STAAD input file commands generated are:

```
PARAMETER
CODE AISC UNIFIED 2010
TRACK 0 ALL
```

1. On the **Analysis and Design** ribbon tab, select **Steel** in the **Design Commands** gallery.

2. In the **Steel Design - Whole Structure** dialog, click **Define Parameters**.
   The **Design Parameters** dialog opens.
3. Specify the track parameter:
   a. Select the **TRACK** parameter tab.
   b. Select option **0**.

   > **Note:** The TRACK 0 command instructs the program to only provide the controlling limit state check for each member assigned to this command.

   c. Click **Add**.
   The parameter list is added to the list of commands in the **Steel Design - Whole Structure** dialog, including the selected track parameter and value.
   d. Click **Close**.
4. Select the **TRACK 0** parameter entry in the list of commands.
5. Select all the beam members by one of the following methods:

   on the **Select** ribbon tab, select the **All** tool in the **Beams** group

   or

   click-and-drag a window around all members in the View window

   or

   press **<Ctrl+A>**
6. In the **Steel Design - Whole Structure** dialog, select the **Assign To Selected Beams** option.
7. Click **Assign**.
   A message dialog prompting you to confirm the assignment.
8. Click **Yes**.

After the parameters are assigned, click anywhere in the drawing area to deselect the members.

> **Tip:** Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.1 Specifying the CHECK CODE command

As part of the iterative process of analysis and design, you must perform a code check on the selected members after they have been analyzed. This ensures that the new set of member forces do not exceed the capacity of the selected members.

A code checking operation which uses the up-to-date cross sections of the members and the latest member forces is used to evaluate that the members have sufficient capacity per the code specifications.

The STAAD input file commands generated are:

```
CHECK CODE ALL
```

1. In the **Steel Design - Whole Structure** dialog, click **Commands.**

   The **Design Commands** dialog opens.
2. Select the **Check Code** tab.

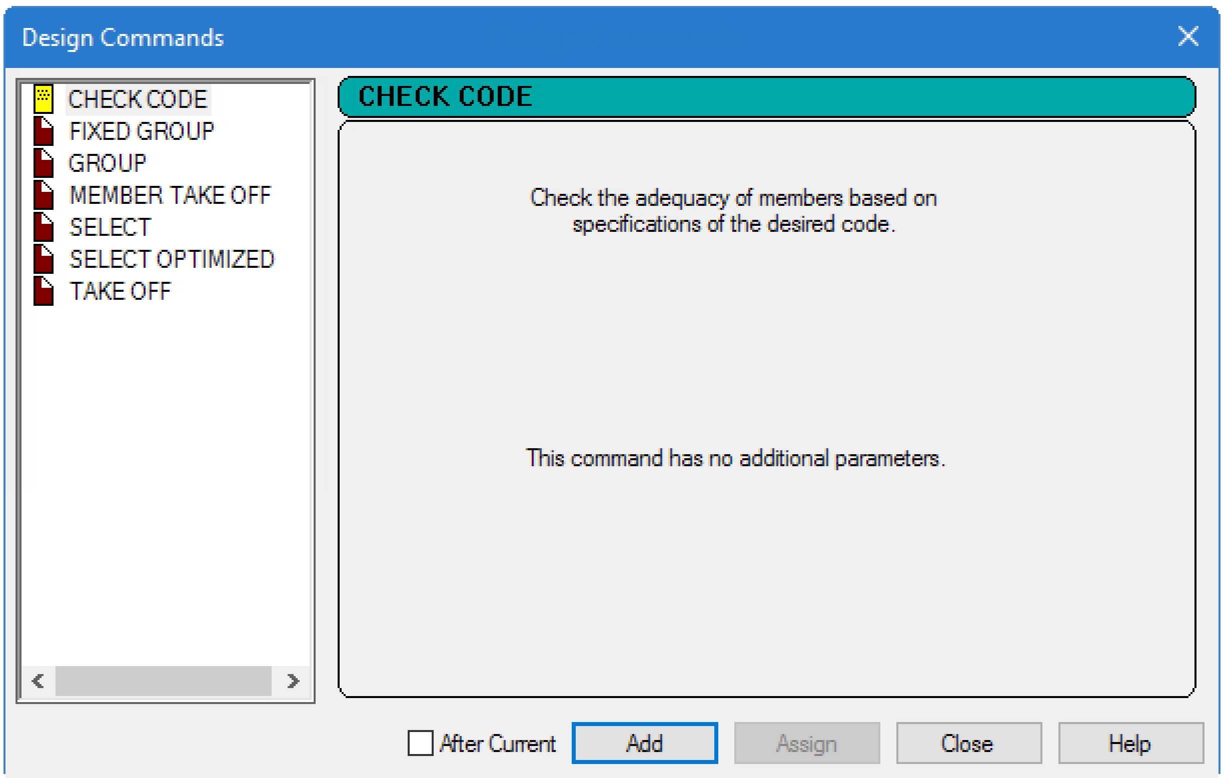


Figure 31:

3. Click **Add**.
4. Click **Close**.
5. Select the unassigned **CHECK CODE** entry in the **Steel Design - Whole Structure** dialog.
6. Select the **Assign to View** option in the **Assignment Method** group.
7. Click **Assign.**
   A message dialog prompting you to confirm the assignment.
8. Click **Yes**.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.1 Viewing the input command file

You can inspect the text data file created during this tutorial.

1. On the **Utilities** ribbon tab, select the **Command File** tool in the **Edit** group.

The STAAD.Pro Editor opens with the contents of the input file.

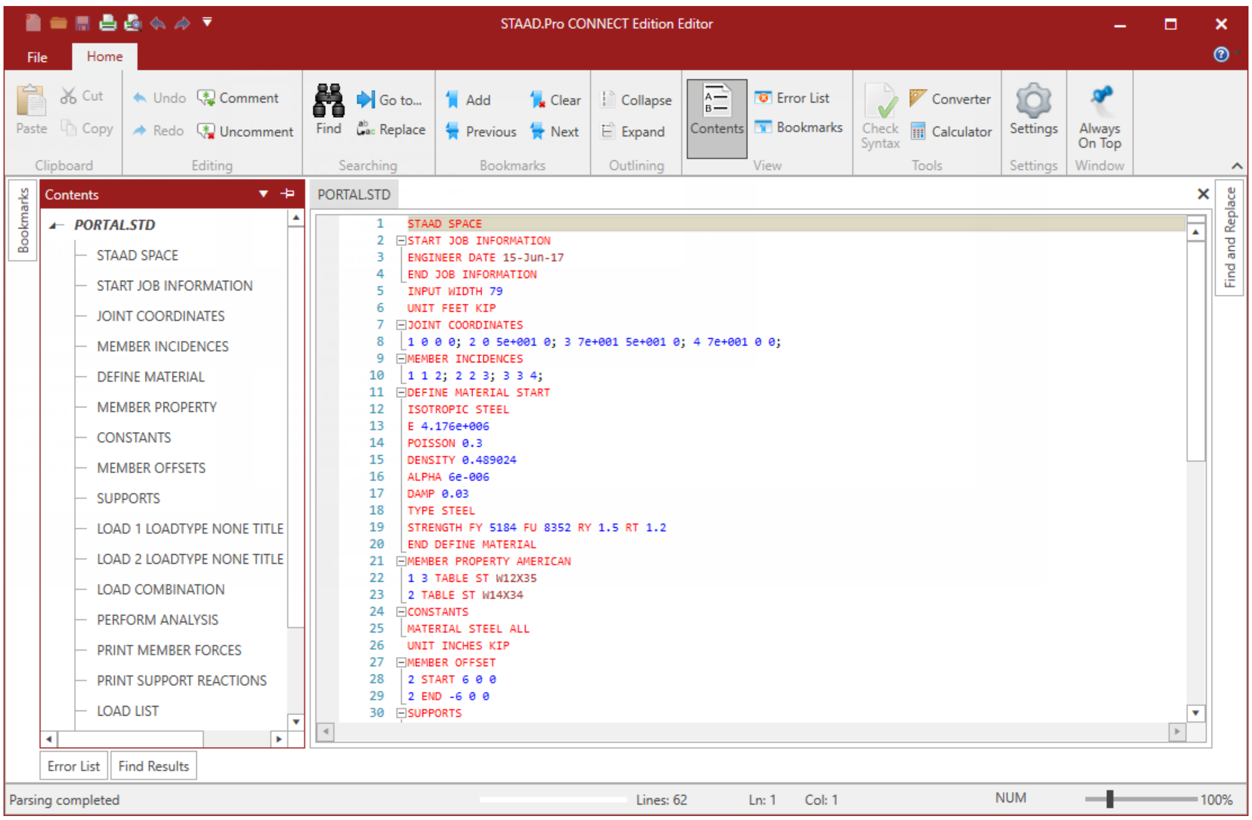

Figure 32: The STAAD.Pro Editor window

2. (Optional) You modify the data of the structure in this editor if necessary.
3. Select **File** > **Exit Editor** in the STAAD.Pro Editor window to close.

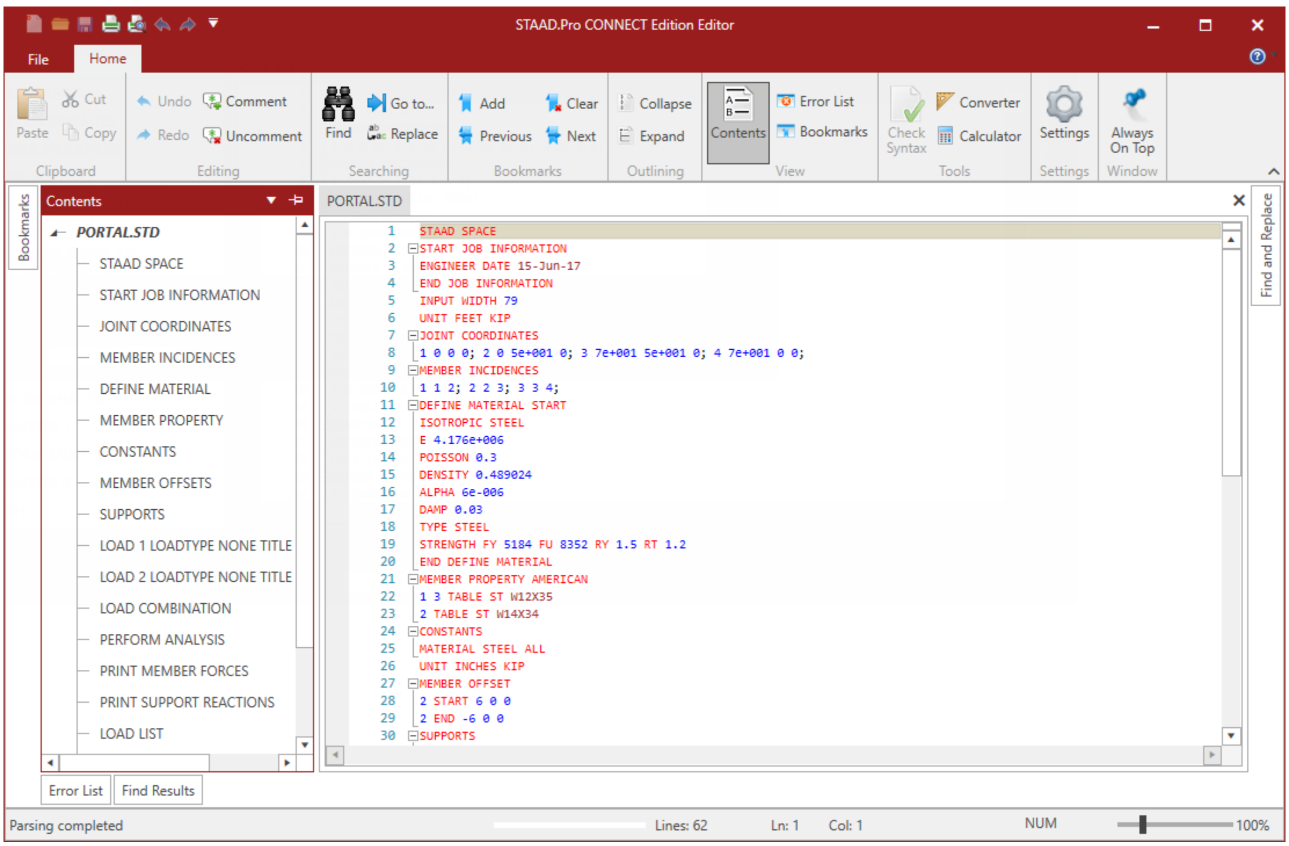
As stated in " T.1 Methods of creating the model (on page 387)," you could also have created the same model by typing the relevant STAAD commands into a text file using the STAAD.Pro Editor. If you would like to understand that method, proceed to the next section.

If you want to skip that part, proceed to " T.1 Performing Analysis/Design (on page 446) " where you will perform the analysis and design on this model.

T.1 Creating the model using the command file

As an alternatively to the procedures described in the proceeding tutorial, you can also create the same STAAD input file using the STAAD.Pro Editor.

Note: A STAAD input file is a plain text file that uses the `.std` file extension. Therefore any standard text editor such as Notepad can also be used to create the command file. However, the STAAD.Pro Editor offers the advantage of syntax checking as you type the commands. The STAAD command syntax are highlighted by command, keyword, value, etc.



To start a new STAAD input file using the STAAD.Pro Editor, follow the procedure described in T.1 Creating a new structure (on page 389). Then select the **Command File** tool in the **Edit** group on the **Utilities** ribbon tab. The STAAD.Pro Editor window opens with the basic commands for your model entered.

For this tutorial, delete all the command lines displayed in the editor window and type the lines shown below. While not necessary, this will allow you to learn more about the required and optional command lines for an input file.

STAAD commands are *not* case sensitive (i.e., they may be typed in upper *or* lower case letters). By convention, this and most input files use all caps, though.

For most all commands and keywords, the first three letters of a keyword are all that are needed. The rest of the letters of the word are not required, but are useful to present a user-friendly command language in mostly plain

English for later reference. By convention, the required letters in a command or keyword are underlined here ("PLANE" = "PLA" = "plane" = "pla").

```
STAAD PLANE PORTAL FRAME
```

Every STAAD input file has to begin with the word STAAD. The word PLANE signifies that the structure is a plane frame (in the XY plane). The remainder of this line is the title of the problem, which is optional.

Note:

If a line is typed with an asterisk in the first column, it signifies that the line is a comment line and should not be executed. For example, one could have put the optional title above on a separate line as follows:

```
* PORTAL FRAME
```

```
UNIT FEET KIP
```

Specify the force and length units for the commands to follow.

```
JOINT COORDINATES
1 0. 0. ; 2 0. 15. ; 3 20. 15. ; 4 20. 0.
```

Joint numbers and their corresponding global X and Y coordinates are provided above. For example, 3 20 15. indicates that node 3 has an X coordinate of 20 ft and a Y coordinate of 15 ft. Note that the reason for not providing the Z coordinate is because the structure is a plane frame. If this were a space frame, the Z coordinate would also be required.

Semicolons (;) are used as line separators. In other words, data which is normally put on multiple lines can be put on one line by separating them with a semicolon.

```
MEMBER INCIDENCE
1 1 2 ; 2 2 3 ; 3 3 4
```

The members are defined by the joints to which they are connected.

```
MEMBER PROPERTY AMERICAN
1 3 TABLE ST W12X35
2 TABLE ST W14X34
```

Members 1 and 3 are assigned a W12X35 section from the built-in AMERICAN steel table. Member 2 has been assigned a W14X34. The word ST stands for standard single section. Refer to subsections 1 through 5 of TR.20 Member Property Specification (on page 2255) for details on the convention for assigning member property names.

```
UNIT INCHES
DEFINE MATERIAL START
ISOTROPIC STEEL
E 29000
POISSON 0.3
DENSITY 283e-006
ALPHA 6e-006
DAMP 0.03
TYPE STEEL
STRENGTH FY 36 FU 58 RY 1.5 RT 1.2
END DEFINE MATERIAL
```

And to use this material definition for all members, add the following:

```
CONSTANTS
MATERIAL STEEL ALL
```

The length unit is changed from FEET to INCHES to use familiar units for most of the material definition. For this example, you use a set of built-in values for steel, so the units are only shown for convenience here. In the user interface, units were not changed until the following commands were generated. See TR.26.1 Define Material (on page 2303) for more information.

```
MEMBER OFFSET
2 START 6.0 0. 0.
2 END -6.0 0. 0.
```

The beam member is physically connected to the 2 columns at the face of the column, and not at the column centerline. This creates a rigid zone, about half the depth of the columns, at the 2 ends of the beam 2. This rigid zone is taken advantage of using member offsets (It is you choice whether or not you wish to use these). So, the above commands define that member 2 is eccentrically connected or OFFSET at its START joint by 6 inches in the global X direction, 0.0 and 0.0 in Y and Z directions. The same member is offset by negative 6.0 inches at its END joint. See TR.25.1 Member Offset Specification (on page 2296) for more information.

```
PRINT MEMBER INFORMATION ALL
```

The information that is printed by this command includes start and end joint numbers (incidence), member length, beta angle and member end releases.

```
SUPPORTS
1 FIXED ; 4 PINNED
```

A fixed support is located at joint 1 and a pinned support (fixed for translations, released for rotations) at joint 4. More information on the support specification is available in TR.27 Support Specifications (on page 2315).

```
UNIT FT
```

The length unit is changed to FEET to facilitate input of loads.

```
LOADING 1 DEAD + LIVE
MEMBER LOAD
2 UNI GY -2.5
```

The above commands identify a loading condition. DEAD + LIVE is an optional title to identify this load case. A Uniformly distributed MEMBER LOAD of 2.5 kips/ft is acting on member 2 in the negative global Y direction. Member Load specification is explained in TR.32 Loading Specifications (on page 2461).

```
LOADING 2 WIND FROM LEFT
JOINT LOAD
2 FX 10.
```

The above commands identify a second load case. This load is a JOINT LOAD. A 10 kip force is acting at joint 2 in the global X direction.

```
LOAD COMBINATION 3 75 PERCENT OF (DL+LL+WL)
1 0.75 2 0.75
```

This command identifies a combination load with an optional title. The second line provides the components of the load combination case - primary load cases and the factors by which they should be individually multiplied.

```
PERFORM ANALYSIS PRINT STATICS CHECK
```

This command instructs the program to proceed with the analysis and produce a report of static equilibrium checks. TR.37 Analysis Specification (on page 2620) offers information on the various analysis options available.

```
PRINT MEMBER FORCES ALL
PRINT SUPPORT REACTION LIST 1 4
```

The above print commands are self-explanatory. The member forces are in the member local axes while support reactions are in the global axes.

```
LOAD LIST 1 3
PARAMETER 1
CODE AISC UNIFIED 2010
FYLD 7200 ALL
TRACK 2.0 MEMB 2 3
UNB 10.0 MEMB 2 3
UNT 10.0 MEMB 2 3
SELECT MEMBER 2 3
```

The above sequence of commands is used to initiate the steel design process. The command PARAMETER is followed by the various steel design parameters. Parameters are specified typically when their values differ from the built-in program defaults. Specifications of the AISC Unified Code LRFD specification are to be followed. A parameter list for the AISC code is available in D1.A.6 Design Parameters (on page 1100). Member numbers 2 and 3 have 10 ft unsupported length for the top and bottom flange (UNT and UNB).

UNT and UNB are used to compute the allowable compressive stress in bending. The yield strength, FYLD, of steel is specified as 7,200 ksf (50 ksi) since it is different from the default value of 36 ksi and it is assigned to ALL members. The TRACK parameter controls the level of description of the output, 2.0 being the most detailed. The LOAD LIST command lists the load cases (1 and 3) to be used in the design. The SELECT MEMBER command asks the program to evaluate the most economical section for members 2 and 3 in the context of the above analysis.

```
PERFORM ANALYSIS
```

When the analysis and design engine executes the member selection operation specified in the member selection , a new set of properties will end up being assigned to those members. This has the effect of changing the stiffness distribution for the entire structure. Since the structure is statically indeterminate, it is best practice to re-analyze it to determine the accurate nodal displacements, member forces, etc. which reflect this new stiffness distribution. The above command instructs the program to do another cycle of analysis.

```
PARAMETER 2
TRACK 0 ALL
```

The TRACK parameter is specified again in a new PARAMETER set. It controls the level of information produced in the steel design output. This time, the value of 0 is used to provide a pass or fail status for each member.

```
CHECK CODE ALL
```

The analysis operation carried out earlier will create a new set of member forces. These forces will very likely be different from those which were used in the member selection operation. Consequently, you should verify that the structure is safely able — from the standpoint of the design code requirements — to carry these new forces. A code checking operation, which uses the up-to-date cross sections of the members, and the latest member forces, will provide a status report on this issue.

```
FINISH
```

A STAAD run is terminated using the FINISH command.

Save the input file and close the editor. The model is opened in the STAAD.Pro interface.

This concludes the session on generating the model as a command file using the built-in editor. If you wish to perform the analysis and design, you may proceed to the T.1 Performing Analysis/Design (on page 446). The post-processing facilities are explained in T.1 Post-Processing (on page 455).

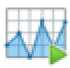
Caution: Remember that without successfully completing the analysis and design, the post-processing facilities will not be accessible.

T.1 Performing Analysis/Design

STAAD.Pro performs Analysis and Design simultaneously.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

1. On the **Analysis and Design** ribbon tab, select the **Run Analysis** tool in the **Analysis** group. .



The **STAAD Analysis and Design** dialog opens and displays messages of the analysis progress.

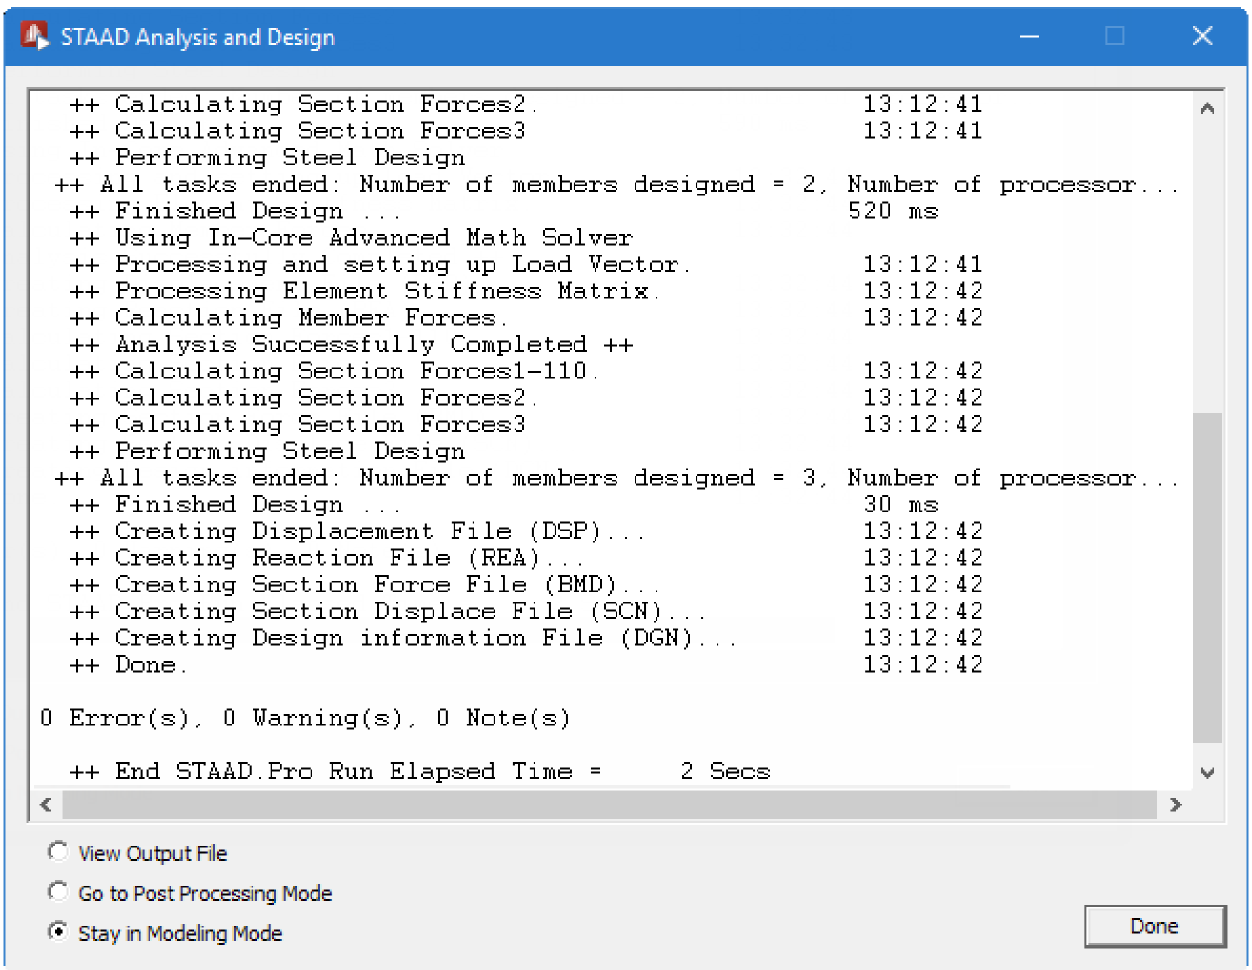


Figure 33:

2. Select the **View Output File** option once the analysis and design are complete.

   The three options are indicative of what will happen after you click **Done.**

View Output File This option opens the output file created by STAAD. The output file contains the numerical results produced in response to the various input commands specified during the model generation process. It also provides you with important messages of any errors were encountered, and if so, whether the analysis and design was successfully completed or not. See T.1 Viewing the output file (on page 447) for details on viewing and understanding the contents of the output file.

Go to Post Processing Mode This option opens the graphical Post-processor mode, which can be used to extensively review and verify the results. This mode allows you to view the results graphically, plot result diagrams, produce reports, etc. See T.1 Post-Processing (on page 455) for details on the Post processing mode.

Stay in Modeling Mode This option closes the dialog and remains in the Model generation mode of the program, where you initiated the analysis. This is useful if you want to make further changes to the input file.

3. Click **Done**.
   The STAAD.Pro Output Viewer window opens.

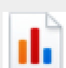
T.1 Viewing the output file

During the analysis process, STAAD.Pro creates an Output file. This file provides important information on whether the analysis was performed properly.

For example, if STAAD.Pro encounters an instability problem during the analysis process, it will be reported in the output file.

Note:

If you did not select to open the output file after running the analysis in the previous procedure, you can open it any time through the user interface. On the **Utilities** ribbon tab, select the **Analysis Output** tool in the **View** group.



Tip: By default, the output file contains a listing of the entire input also. You may choose not to print the echo of the input commands in the Output file. On the **Analysis and Design** ribbon tab, select the **Miscellaneous Commands** > **Set Echo** tool option from the menu bar and the select the **Echo Off** option in the **Set Echo** dialog.

It is *strongly recommended* that you review the entire output file to ensure that the results are reasonable and that there are no error messages or warnings reported, etc. Errors encountered during the analysis & design can disable access to the post-processing mode. The information presented in the output file is a crucial indicator of whether or not the structure satisfies the engineering requirements of safety and serviceability.

T.1 Post-Processing

STAAD.Pro offers extensive result verification and visualization facilities. These facilities are accessed from the **Post Processing** Mode. The **Post Processing** mode is used to verify the analysis and design results and generate reports.

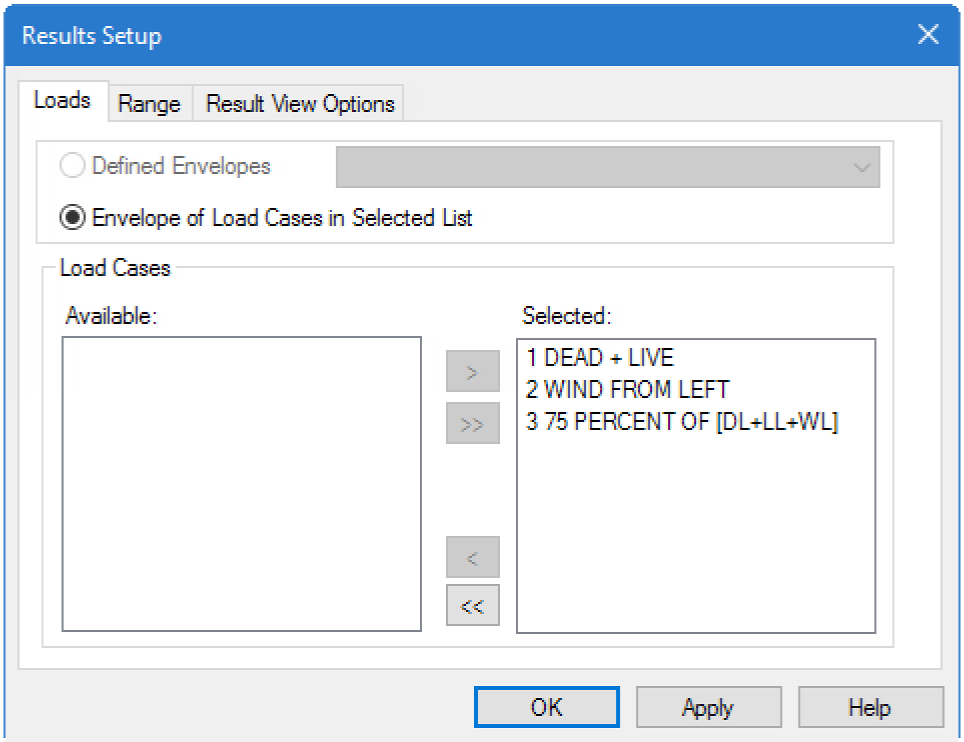
T.1 Opening the postprocessing workflow

You can open the Postprocessing workflow anytime there are current analysis results for your model.

If you selected to open the Postprocessing workflow after T.1 Performing Analysis/Design (on page 446), then you can skip to step 2.

1. On the **Workflows** panel, select **Postprocessing**.

The **Results Setup** dialog opens.



2. (Optional) Select the load cases for which to display the results.

   Tip: All load cases are selected by default.

   For this tutorial, we will use all load cases.
3. Select the **Result View Options** tab and then check the **Enable Automatic Scaling** option.
4. Click **OK**.

Note:

Notice that in the Postprocessing workflow, the **Postprocessing** page control bar is opens above the view window. The ribbon bar updates to include the **Results** ribbon tab.

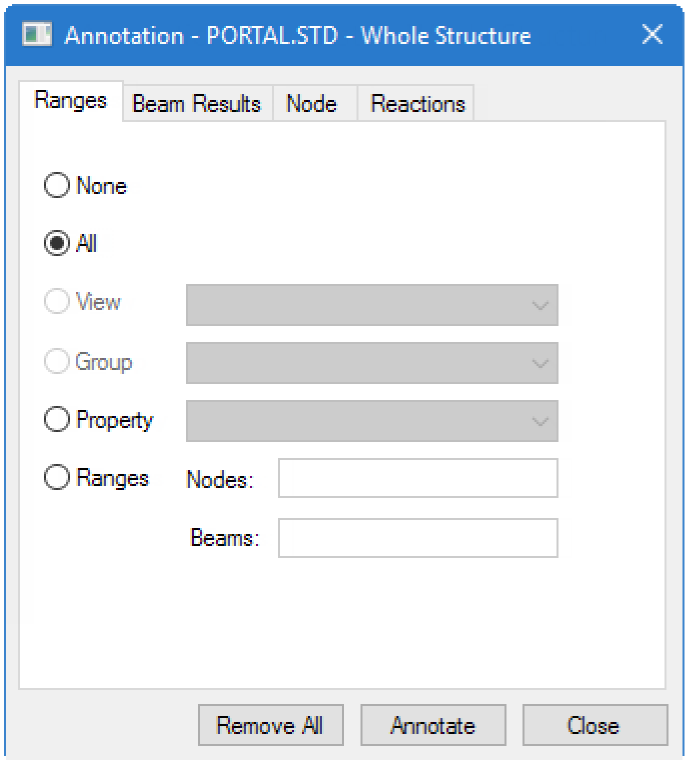
T.1 Annotating the displacements

Annotation is the process of displaying the displacement values on the screen.

1. Select the **Displacements** page in the Postprocessing page control bar.

   The diagram displayed is the node deflection diagram for load case 1 (DEAD + LIVE).
2. On the **Results** ribbon tab, select the **Annotate** tool in the **Configuration** group.

The **Annotation** dialog opens.



3. From the **Ranges** tab, select **All**.

Tip: If you want to annotate deflection for just a few nodes, specify the node numbers in the node list.

4. Select the **Node** tab and then check the **Resultant** option.

   The resultant is the square root of sum of squares of values of X, Y and Z displacements.

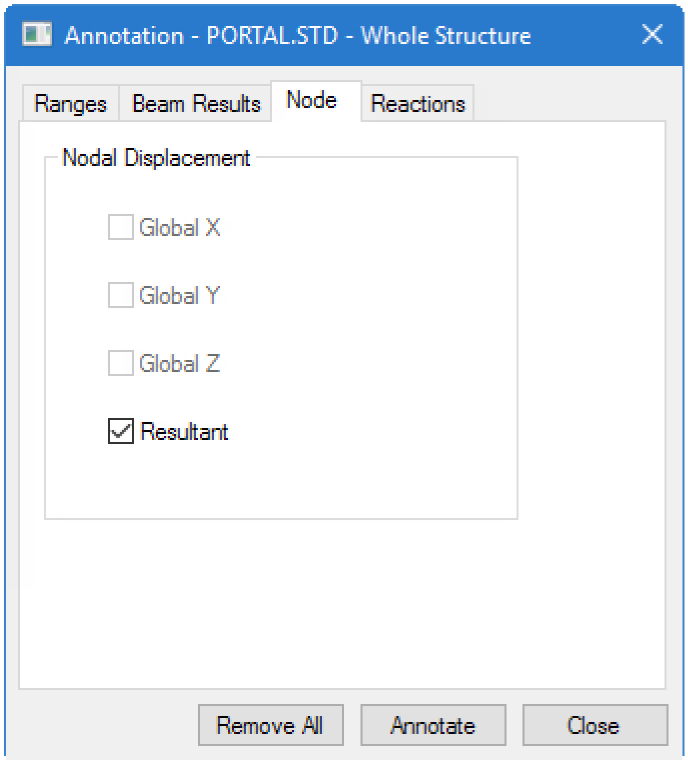


Figure 34:

5. Click the **Annotate**.
   The values appear on the structure.
6. Click **Close**.

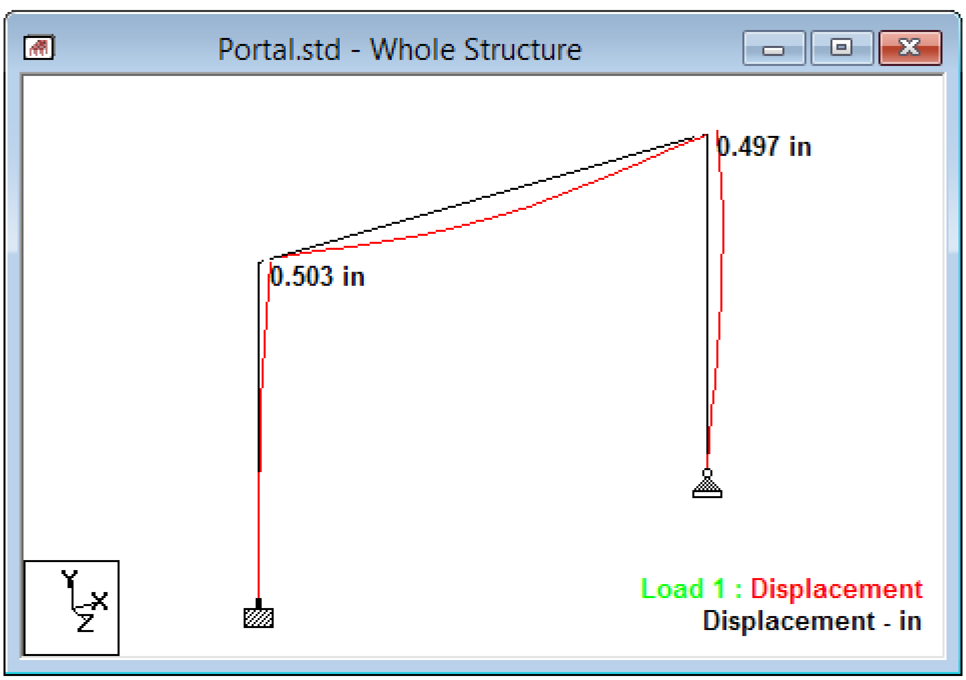

Figure 35: The deflected shape diagram for load case 1

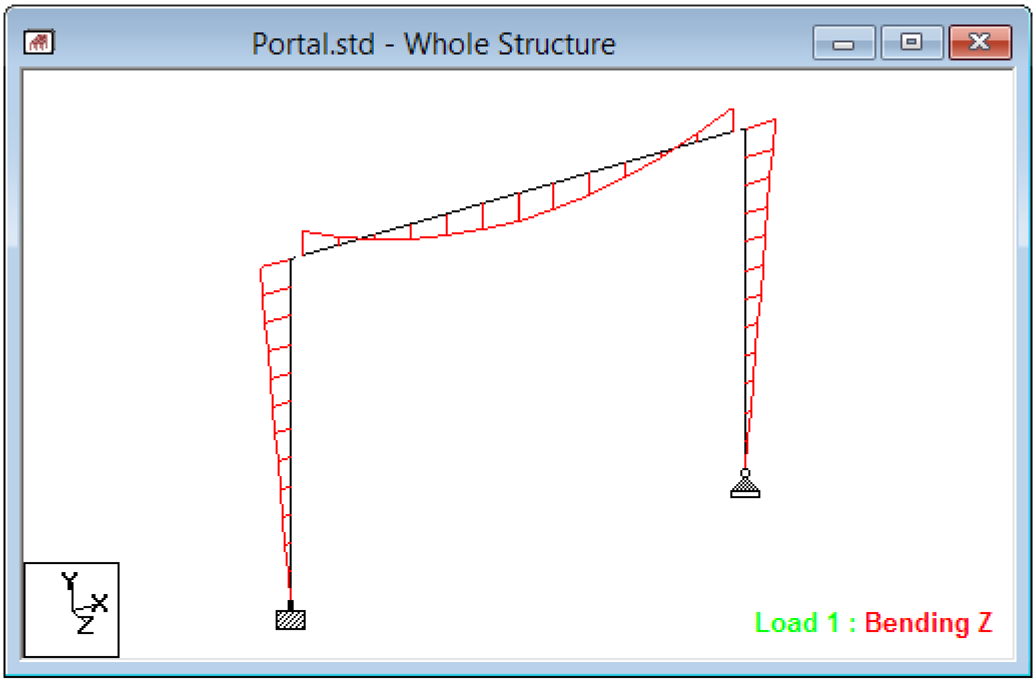
Tip: You can exaggerate the deflected shape by *reducing* the **Deflection** scale in the **Diagrams** dialog **Scales** tab.

T.1 Displaying force and moment diagrams

1. Select the **Beam Results** page in the **Postprocessing** page control bar.

   The bending moment MZ is plotted by default. Note that the **Mz** tool  in the **View Results** group on the **Results** ribbon tab is depressed (active).

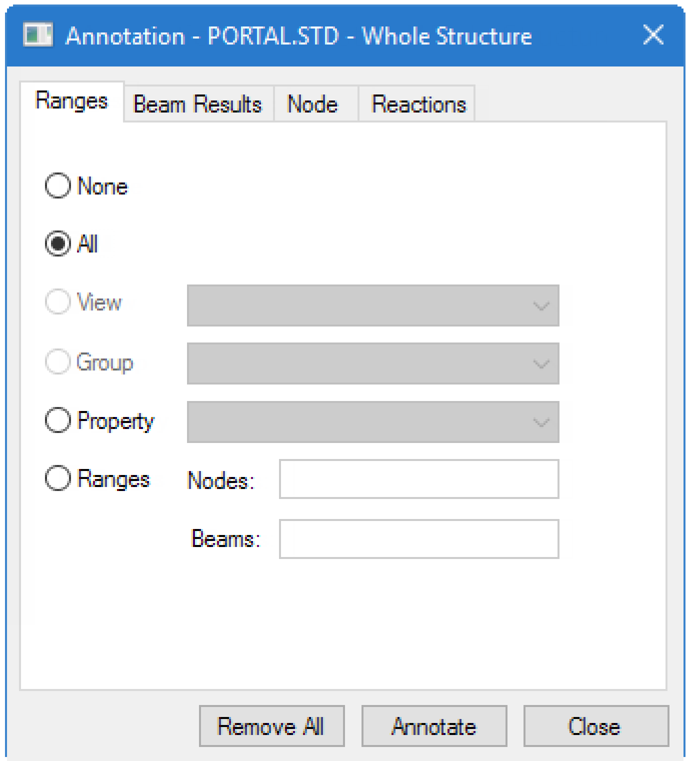
   


2. (Optional) Change the force or moment diagram drawn on the structure in the **Diagrams** dialog:
   a. Right-click in the view window and then select **Structure Diagrams** from the pop-up menu.
   The **Diagrams** dialog opens.
   b. Select the **Loads and Results** tab.
   c. Select a different **Load Case** from the drop-down list.
   d. Select one or more options in the **Beam Forces** group.
   For example, select the Shear yy to display the shear force diagrams in the local y direction on the members.
   e. (Optional) Click on the color block adjacent to any of the force or moment options to change the color for that diagram.
   f. (Optional) The **Beam Forces Diagram** options control how the diagrams are filled.

Tip: Alternatively, you can select which diagrams are displayed and for which load case using the tools and load cases selection in the **View Results** group on the **Result** ribbon tab.

3. On the **Results** ribbon tab, select the **Annotate** tool in the **Configuration** group.

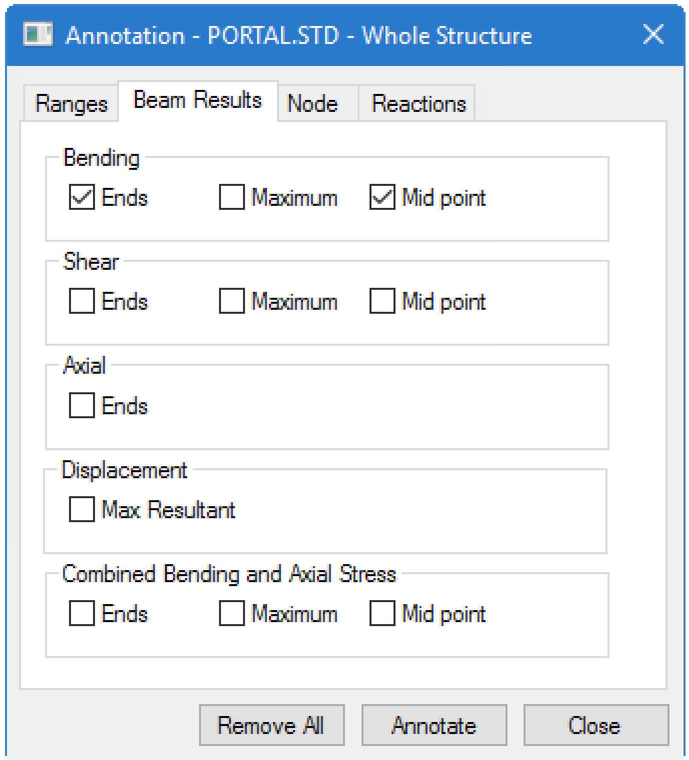
The **Annotation** dialog opens.



4. From the **Ranges** tab, select **All**.

> **Tip:** If you wish to annotate the force/moment for just a few members, specify the beam numbers in the beam list.

5. Select the locations where you want to display results:
   a. Select the **Beam Results** tab
   b. Check the **Ends**and **Mid point** options in the **Bending** group.



6. Click **Annotate**.

   The diagram is updated with annotated values displayed at the selected locations.

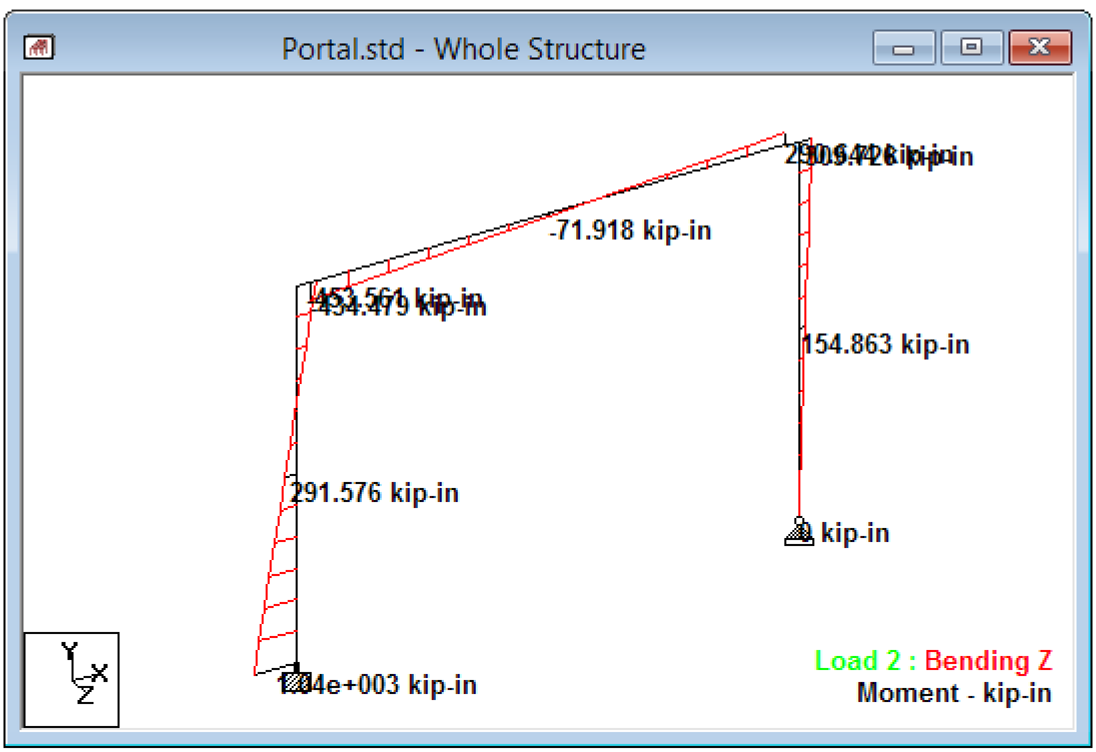


Figure 36: The Mz bending diagram for Load 2 with annotated values

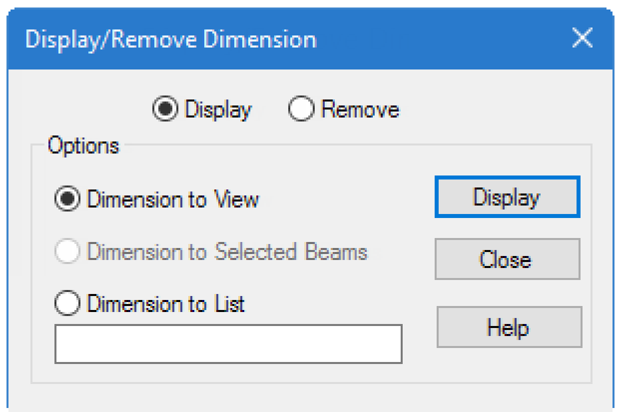
7. Click **Close**.

T.1 Displaying the dimensions of the members

1. On the Utilities ribbon tab, select the **Beam Tools** > **Dimension Beams** tool in the **Geometry Tools** group.

   The **Display/Remove Dimension** dialog opens.

2. Select the **Dimension to View** option.
3. Click **Display**.
4. Click **Close**.
   The dimensions of the members will appear alongside the members.

T.1 Update physical model with design results

If you generated the model geometry using a physical model, then you need to update the physical model with design results.

Since you performed a member selection as part of the member design in the analytical model, the sections need to be updated in the physical model to keep it synchronized. STAAD.Pro Physical Modeler will detect that design results are present and prompt you to do this.

1. Select **Physical Modeling** workflow in the **Workflows** panel.

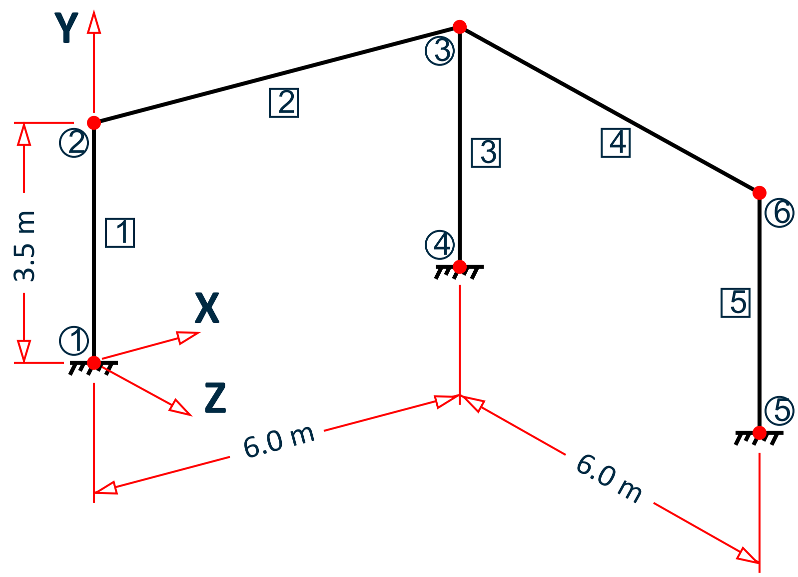
   
   The STAAD.Pro Physical Modeler window opens and the **Member Design Selection** dialog opens.
2. Click the **Profile** selection drop-down.
   The member design results table opens.

> **Note:** Here you can review the different analytical member design results for each physical member. Recall that a physical member may be decomposed into multiple analytical members and each of those may have different design results in STAAD.Pro (unless the `FIXED GROUP` command is used).

3. Click **Accept**.
   The table closes.
4. Click **Commit**.
   The dialog closes and the physical model is updated with the new sections from the STAAD.Pro steel design results.

T.2 - RC Framed Structure

This tutorial provides step-by-step instructions for creating the model of a reinforced concrete framed structure using STAAD.Pro.



A copy of the completed input file is typically installed at `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\Tutorials\Tutorial 2 - RC Frames Structure.std`.

- *EX.Tutorials* (on page 6255)

T.2 Methods of creating the model

As explained in " T.1 Methods of creating the model (on page 387) ", there are three methods of creating the structure data:

1. T.2 Creating the Model using the Physical Modeler (on page 466),
2. T.2 Creating the model using the analytical user interface (on page 472),
3. and T.2 Creating the model using the command file (on page 509).

All three methods are explained in this tutorial.

T.2 Description of the tutorial problem

The structure for this project is a 2 bay, 2 story reinforced concrete frame. The figure below shows the structure. The purpose of this tutorial is to create the model, assign all required input, and perform the analysis and concrete design.

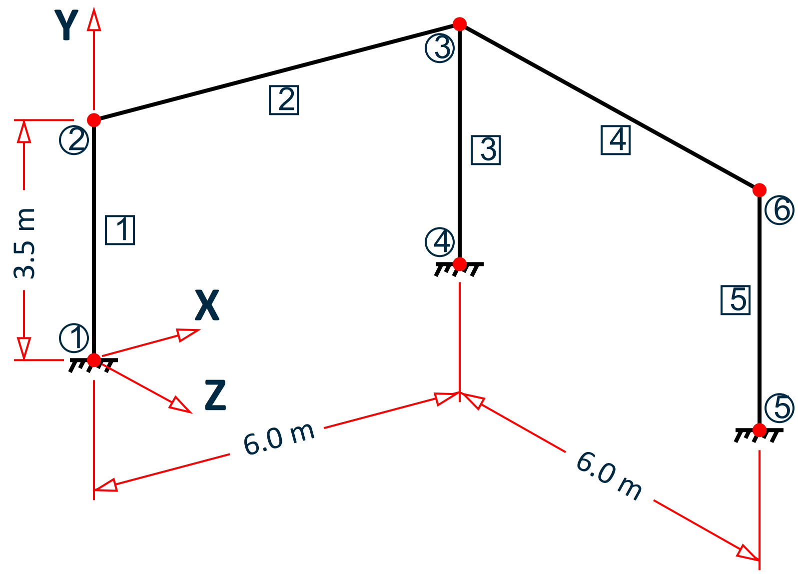

Figure 37:

Basic Data for the Structure

Attribute	**Data**
Member properties	Beams 2 & 5 : Rectangular, 275 mm width × 350 mm depth Columns 1 & 4 : Rectangular, 275 mm width × 300 mm depth Column 3 : Circular, 350 mm diameter
Member Orientation	All members except column 4 : Default Column 4 : Rotated by 90 degrees with respect to default condition
Material Constants	Modulus of Elasticity : 22 kN/mm^2 Density : 17 kn/m^3 (lightweight concrete) Poisson's Ratio : 0.17
Supports	Base of all columns : Fixed

Attribute	Data
Loads	Load case 1 : Dead Load Selfweight of the structure. Beams 2 & 5 : 400 kg/m in global Y downward Load case 2 : Live Load Beams 2 & 5 : 600 kg/m in global Y downward Load case 3 : Wind Load Beam 1 : 300 kg/m along positive global X Beam 4 : 500 kg/m along positive global X Load Case 4 : DEAD + LIVE L1 X 1.2 + L2 X 1.5 (Use REPEAT LOAD, not Load Combination) Load Case 5 : DEAD + WIND L1 X 1.1 + L2 X 1.3 (Use REPEAT LOAD, not Load Combination)
Analysis Type	PDELTA
Concrete Design	Consider load cases 4 and 5 only. Parameters: Ultimate Strength of Steel: 415 N/mm^2 Concrete Strength: 25 N/mm^2 Clear cover for top: 25 mm Clear cover for bottom: 30 mm Clear cover for side: 25 mm Design beams 2 and 5 Design columns 1, 3 and 4

T.2 Creating a new structure

On the Start page **New** tab, you will provide some initial data necessary for building the model.

1. On the Start page, select **New**.

   The **New** page opens to the **Model Info** tab.
2. Type as `RCFrame` in the **File Name** field.
3. Specify a **Location** where the STAAD input file will be located on your computer or network.

   You can directly type a file path or click **Browse** to open the **Browse by Folder** dialog, which is used to select a location using a Windows file tree.

4. Select **Physical** for the **Type** of model.
   This option selects the modeling method you want to use:

Analytical	For creating a model using either the STAAD.Pro analytical modeling interface or the command input file editor.
Physical	For creating a model using the STAAD.Pro Physical Modeler interface.
Building	For creating a building model structure using the Building workflow.

5. Select **Metric** as the system of **Units**.

   Tip: The units can be changed later if necessary, at any stage of the model creation.

6. (Optional) Select the Job Info tab to enter related project details, names and dates for quality analysis, and ProjectWise Project information.
7. Click **Create**.

The STAAD.Pro modeling environment opens and your model file is then opened in the STAAD.Pro Physical Modeler.

Alternatively, if you want to use either the analytical modeling workflow or the command input file editor to create the model, choose **Analytical**, click **Create**, and then proceed to either “ T.1 Creating the model using the analytical user interface (on page 399) ” or “ T.2 Creating the model using the command file (on page 509),” respectively.

T.2 Creating the Model using the Physical Modeler

You are now ready to start building the model geometry. The steps for doing this are described in the following sections.

Tip: Refer to the STAAD.Pro Physical Modeler Application Window Layout for reference on the application window.

T.2 Generate the model geometry

1. On the **Model** ribbon tab, select the **Grid** tool in the **Create** group.

   The **Create Grid** dialog opens.
2. Supply the grid details:
   a. Type `Grid 1` in the **Name** field.
   b. Leave the **Plane** selection as **XY** and the **Creation Method** as **By Spacing**.
   c. Type `6` in the **Number of spaces in X** and `1 m` in the **Grid spacing X** fields.
   d. Type `7` in the **Number of spaces in Y** and `0.5 m` in the **Grid spacing Y** fields.

e. Click **OK**.
The grid is created.

3. Use the **Member** tool to create the first portal frame:

a. On the **Model** ribbon tab, select the **Member** tool in the **Create** group.

b. Click on the following points on Grid 1, in sequence.

Double-click the final point to stop creating connected members.

(0,0,0)
(0,3.5,0)
(6,3.5,0)
(6,0,0)

c. Select the **Member** tool again to deactivate the tool.

Note: Refer to T.1 Generating the model geometry (on page 391) in Tutorial 1 for detailed steps on how to draw a portal frame.

4. On the **View** ribbon tab, select the **Grids** tool in the **Reference** group.

The tool is no longer highlighted and all grids are hidden in the display.

5. Switch on the node and beam labels:

a. On the **View** ribbon tab, select the drop-down list below the **Numbering** tool in the **Model** group.

b. Select **Node** and **Member** on this list.
They are both marked with a check.

c. Select the **Numbering** tool.

6. On the **Model** ribbon tab, select the **Circular Copy** tool in the **Edit** group.

The **Copy Model Circular** dialog opens.

7. Specify the circular copy details:

a. Leave the **Method** selection as **Global**.
b. Select **Y** as the **Axis of rotation**.
c. Type `6 m` in the Pivot point **X** field.
d. Type `90 deg` in the **Arc angle** field.
e. Type `1` in the **Copies** field.
f. Click **OK**.

The dialog closes and the selection elements of the portal frame are copied at 90° from the right end.

8. In the lower, right corner of the view window, click the **Switch to isometric view** tool to display the frame in an isometric view.

T.2 Assign user-defined concrete material

If you don't still have all the members selected, press **<Ctrl+A>**.

1. On the **Member Tools** ribbon tab, select the **Material** tool in the **Assign properties** group.

   The **Assign material** dialog opens.
2. Select the concrete specification:
   a. Select **Custom** from the **Type** drop-down list.

      Leave the **Source** as **Catalog** and the **Country** as **United States**.
   b. Select **CONCRETE_ACI318** from the **Material type** drop-down list.
3. Define the custom lightweight concrete material:
   a. Type `0.17` in the **Mu** field (Poisson's ratio).
   b. Type `0.1E-6` in the **Alpha** field (coefficient of thermal expansion).
   c. Type `0.05` in the **CDAMP** field (composite damping ratio)
   d. Type `25 N/mm2` in the **Fck** field (concrete ultimate strength).

      Tip: You can type any appropriate unit in any unit system into the field and it will automatically be converted to the current default units.
   e. Type `19080 N/m3` in the **Gamma** field (material density).
   f. Type `CONCRETE-LTW` in the **Name** field.
   g. Click **OK**.

   The **CONCRETE-LTW** material is assigned to all the members. This material is also added to the model catalog for later use if necessary.

On the **Model** ribbon tab, select the **Catalog** tool in the **Catalog** group.  The model catalog window opens.

Select the **Material** tool so it is highlighted in the display control toolbar found in the lower-left corner. The **CONCRETE-LTW** material is shown as a tile in the Materials section. Select this tile to review the material values. You can use this interface to make changes to the custom materials and sections in your model.

Once you are done reviewing, click the back arrow in the top-left corner of the window.

T.2 Assign the member properties

1. While holding **<Ctrl>**, click on both the end columns (M1 and M4).
2. On the **Member** ribbon tab, select the **Section** tool in the **Assign properties** group.

The **Assign Section** dialog opens.

3. Define the rectangular column section:

   Leave the Source selection as Catalog.

   a. Select **Prismatic** in the **Type** drop-down list.

      Leave the **Source** selection as **Catalog**.

   b. Select **Solid Rectangle** in the **Shape** drop-down list.
   c. Select **RECT** in the **Template** drop-down list.
   d. Type `300 mm` in the **YD** field and `275 mm` in the **ZD** field.
   e. Type `RECT-COL` in the **Name** field.
   f. Click **OK**.
4. Repeat steps 1-3 except to define a 350mm (depth, YD) by 275 mm (width, ZD) rectangular prismatic section named `RECT-BEAM` to the beam members (M2 and M5).
5. Repeat steps 1-3 again except to define a 350mm diameter (YD) solid circular prismatic section named `CIRC-COL` to the middle column (M3).
6. Rotate the right column by 90 deg (Beta angle):

   a. Select the right column (M4).
   b. On the **Member Tools** ribbon tab, select the **Rotate** tool in the **Edit** group and then select **Rotate 90°** from the list.

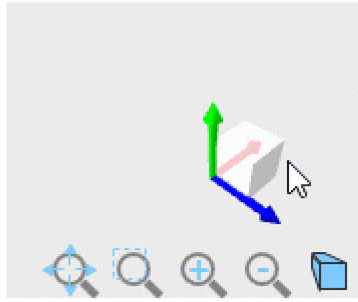
      The column is rotated about its local 1 axis by 90°.
   c. On the **View** ribbon tab, select the **Local Axes** tool in the **Model** group.

      
      You can confirm that the local z axis of M4 is now rotate 90° away from the global Z axis.

T.2 Assign supports

1. Orient the view to front view:

   a. (Optional) If the rotation controls are hidden, click the rotation widget in the lower-right corner of the view window.
   b. Select the **Switch to front** view tool.
   c. (Optional) Click the rotation widget again to hide the controls.



Tip: Alternatively, you can press and hold the right mouse button and drag the mouse pointer to quickly rotate the view so it is easy to select the column bases.

2. Click and drag a box from the right side of the to the left to enclose the column base nodes (N1, N4, and N5).
3. On the **Node** ribbon tab, select the **Fixed** tool in the **Supports** group.

   A fixed support is assigned to the selected nodes.

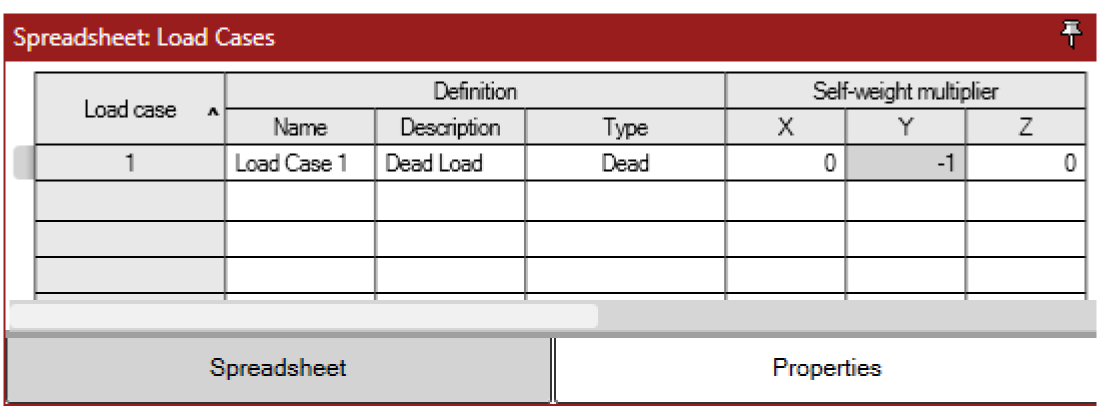
T.2 Assign loads to load cases

1. On the **Spreadsheet** ribbon tab, select the **Load Cases** tool in the **References** group.

   
   The Load Cases spreadsheet opens.
2. For Load 1:
   a. Type `Dead Load` in the description field of Load case 1.
   b. Select **Dead** as the **Type**.
   c. Type `-1` in the **Self-weight multiplier** in field **Y**.

   Note: This value is negative.

   d. Press **<Enter>**.



Spreadsheet: Load Cases

Load case	Definition			Self-weight multiplier		
	Name	Description	Type	X	Y	Z
1	Load Case 1	Dead Load	Dead	0	-1	0

3. Select the beam members (M2 and M5).
4. Add the uniform distributed dead load:
   a. On the **Member** ribbon tab, select the **Distributed** tool in the **Loads** group.

   
   The **Add Member Distributed Load** dialog opens. The Load group is already selected to use Load case 1.
   b. Select the **Load type** as **Uniform**.
   c. Select **Global Y** as the **Direction**.
   d. Type `-400 kg/m` in the **Magnitude** field.

   > **Note:** This value is negative and uses different units than the default, so be sure to type out the units as indicated above. It will be automatically converted into the default units of kN/m.

   e. Click **OK**.
5. Create the live load group:
   a. On the **Model** ribbon tab, select the **Load Case** tool in the **Load** group.

   
   The **Add Load Case** dialog opens.
   b. Type `Live Load` in the **Description** field.
   Leave the Name as Load Case 2.
   c. Select **Live** as the **Type**.
   Leave the self weight modifiers all as zero.
   d. Click **OK**.

   The live load case is added and selected as the active load case as indicated in the application status bar.
6. Repeat steps 3 and 4 except to add a uniform distributed load of `-600 kg/m` (in the **Global Y** direction) to the beam members (M2 and M5).
7. Repeat steps 5 and 6 except to add a Load case 3 with a description of `Wind Load` and type of **Wind**.
   This load group will have the following to load items:
   - a uniform force of `300 kg/m` in the Global X direction and is applied to the left column (M1).
   - a uniform force of `500 kg/m` in the Global X direction and is applied to the right column (M4).

> **Note:** As this model uses a second-order, P-Delta analysis, load combinations are *not* recommended. Instead, repeat loads will be used to combine the load cases so that the combinations are processed by the analysis engine directly. These Repeat loads will be added in the Analytical Modeling workflow.
>
> Refer to TR.37.2 P-Delta Analysis Options (on page 2621) for further details on load types appropriate for P-Delta analysis.

T.2 Generate the Analysis Model

You have now completed the modeling portion of this tutorial. You will now send the model data back to STAAD.Pro where you will create load combinations, add output commands, select analysis criteria, and specify design parameters.

For this tutorial, you will use the default options for analytical model generation. However, for advanced models you can review and change those options in the **Configuration** dialog.

1. Select **Save** to save the physical model.
2. Either:

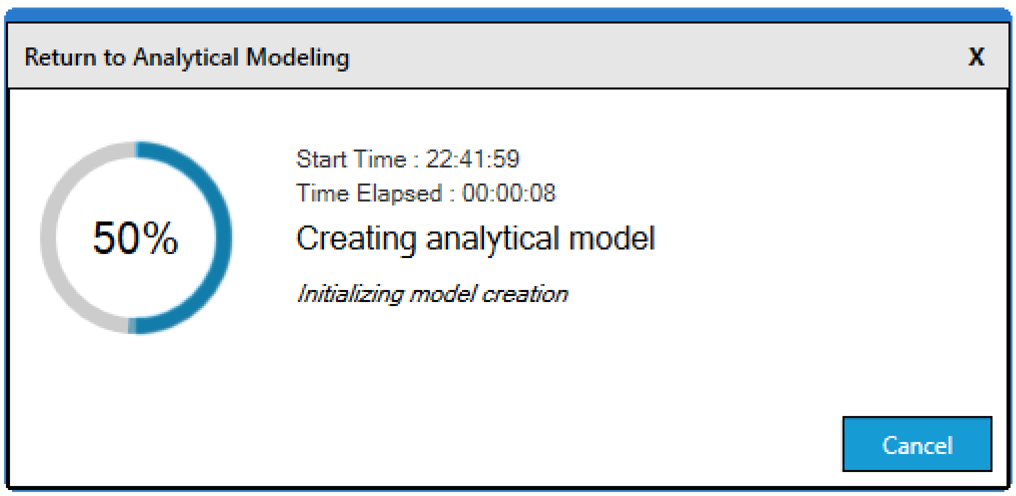
   On the **Model** ribbon tab, select the **Return to Analytical Modeling** tool in the **STAAD.Pro** group

   or

   On the **File** ribbon tab, select **Create analysis model** in the backstage tabs

   The Return to Analytical Modeling dialog opens and displays the progress of the analytical model being generated.

3. Click **OK**.
   If you have not previously associated this model with a CONNECT Project, you are asked to do so. This is will not be necessary for this tutorial.
4. Click **Cancel** in the **Assign Project** dialog.

The STAAD.Pro Physical Modeler window closes and the model is loaded into the STAAD.Pro analytical modeling interface.

T.2 Creating the model using the analytical user interface

The following procedures describe how to use the traditional STAAD.Pro analytical user interface to build the model. The steps and, wherever possible, the corresponding STAAD.Pro commands (the instructions which get written in the STAAD input file) are described in the following sections.

Tip: Refer to GS. Application Window Layout (on page 54) for reference on the application window.

T.2 Generating the model geometry

The structure geometry consists of joint numbers, their coordinates, member numbers, the member connectivity information, plate element numbers, etc.

The STAAD input file commands generated are:

```
JOINT COORDINATES
1 0.0 0.0 0.0 ; 2 0.0 3.5 0.0
3 6.0 3.5 0.0 ; 4 6.0 0.0 0.0
5 6.0 0.0 6.0 ; 6 6.0 3.5 6.0
MEMBER INCIDENCE
1 1 2 ; 2 2 3 ; 3 3 4 ; 4 5 6 ; 5 3 6
```

When starting in the Analytical Modeling workflow, a grid is initially displayed in the main view window. This grid is controlled by the **Snap Node/Beam** dialog. The directions of the global axes (X, Y, Z) are represented in the icon in the lower left hand corner of the drawing area.

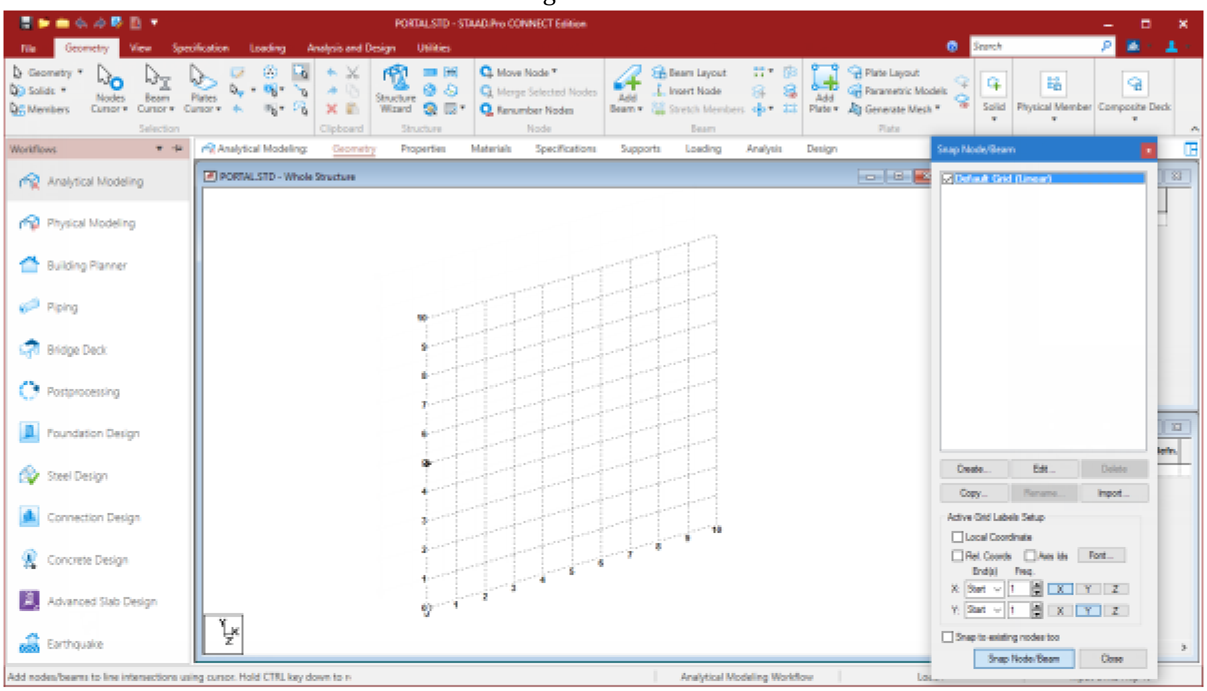


*Figure 38: The STAAD.Pro window with the **Snap Node/Beam** dialog open*

Note: The **Snap Node/Beam** dialog opens on the right side of the screen. You can reopen this dialog by selecting the **Snap Grid Beam** tool  in the **Structure** group on the **Geometry** ribbon tab.

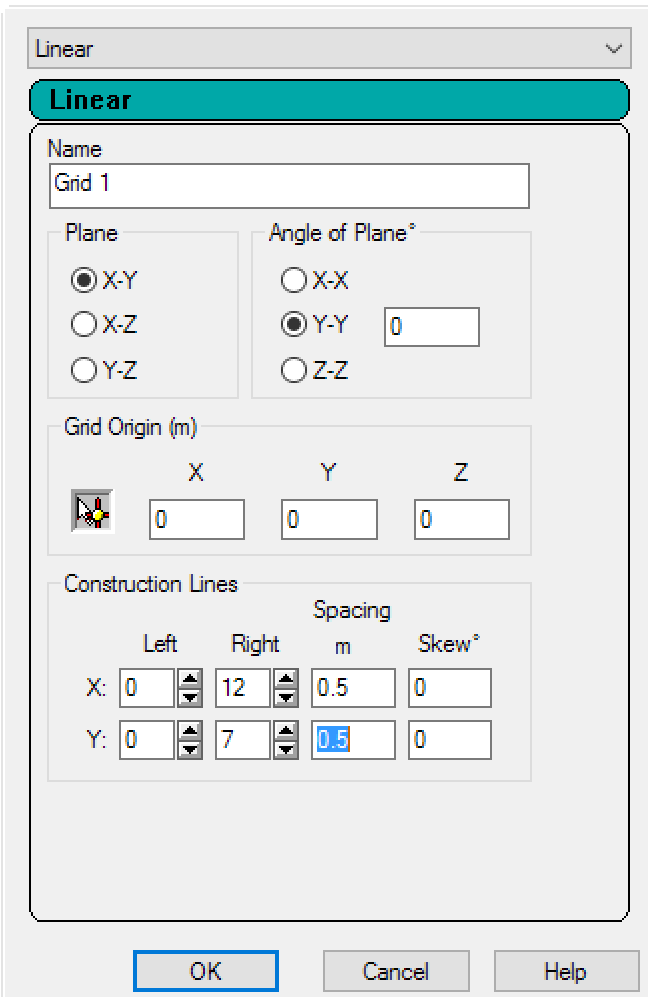
1. On the **Snap Node/Beam** dialog, click **Create**.
   A dialog opens which will enable us to set up a grid.

   Within this dialog, there is a drop-down list from which you can select Linear, Radial, or Irregular form of grid lines.

Linear	used to place the construction lines perpendicular to one another along a "left to right - top to bottom" pattern, as in the lines of a chess board
Radial	used to place construction lines to appear in a spider-web style, which makes it is easy to create circular type models where members are modeled as piece-wise linear straight line segments
Irregular	used to create gridlines with unequal spacing that lie on the global planes or on an inclined plane

2. Select **Linear**,which is the Default Grid.

   In this structure, the portion consisting of members 1 to 3, and nodes 1 to 4, happens to lie in the X-Y plane. Leave **X-Y** as the **Plane** of the grid. The size of the model that can be drawn at any time is controlled by the number of **Construction Lines** to the left and right of the origin of axes, and the **Spacing** between adjacent construction lines.
3. Type a **Name** of `Grid 1`.
4. Type `12` as the number of lines to the **Right** of the origin along **X** and `7` above the origin along **Y**.
5. Type a **Spacing** of `0.5` m between lines along both **X**and**Y** (see figure below) we can draw a frame 6m X 3.5m, adequate for our segment.



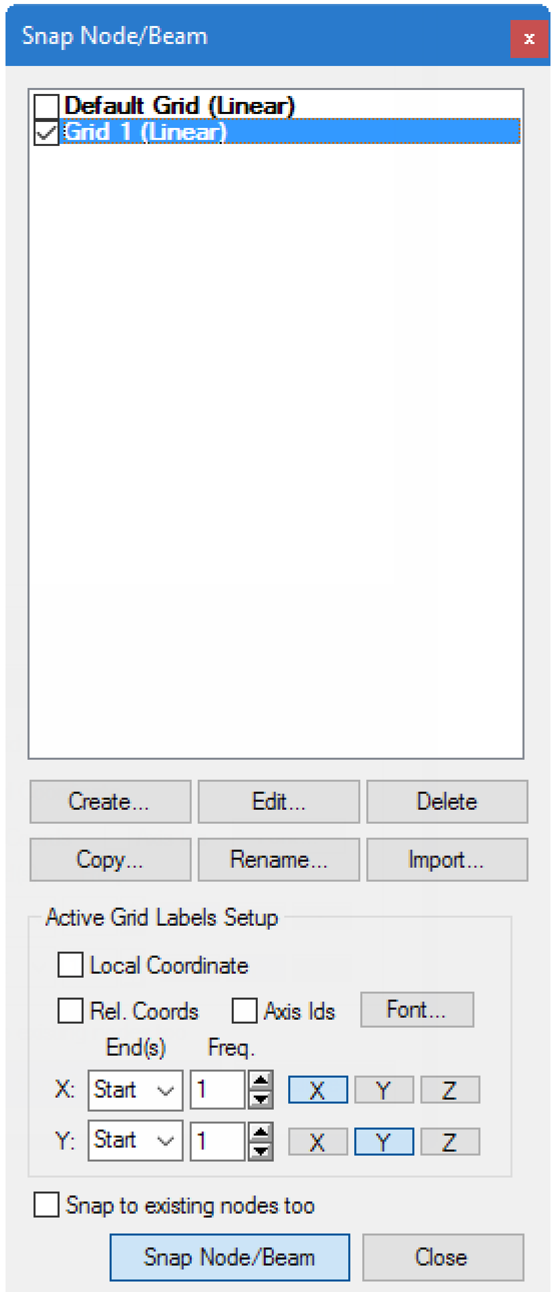
6. Click **OK**.
7. In the **Snap Node/Beam** grids list, check the new **Grid 1** option.

You can create any number of grids. By providing a name, each new grid can be identified for future reference.

Tip: Please note that these settings are only used to generated construction lines. These construction lines enable you to easily draw the structure but do not restrict our overall model to those limits.

Tip: To change the settings of this grid, select the name in the **Snap Node/Beam** dialog and then click **Edit**.

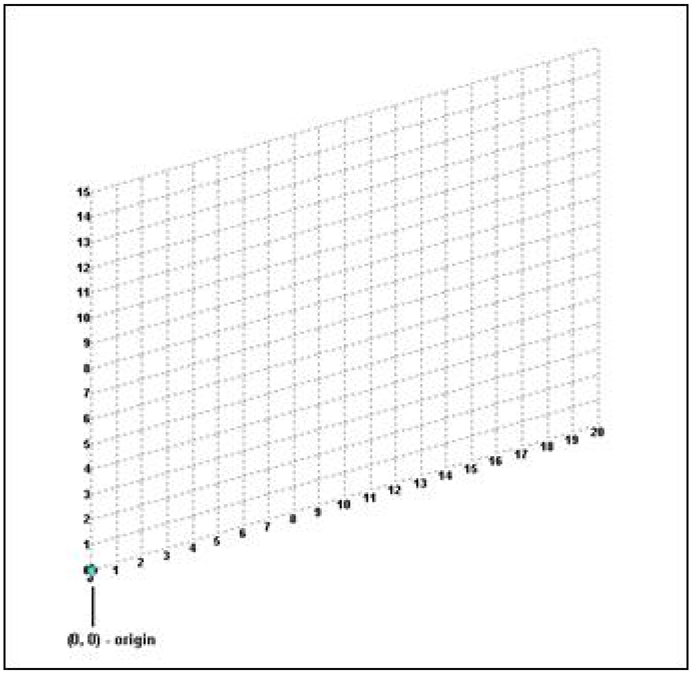
The check by **Default Grid** is automatically cleared. STAAD.Pro will only display a single grid at a time.



8. In the View window, click at the origin (0, 0) to create the first node.

A line is "rubber-banded" between this node and the mouse pointer, which previews the member to placed with the next mouse click.

The **Snap Node/Beam** feature is active by default.



9. Click on the following points to create nodes and automatically join successive nodes by beam members.

   (0, 3.5)
   (6, 3.5)
   (6, 0)

10. Click **Close** in the **Snap Node/Beam** dialog.
    The grid is hidden.

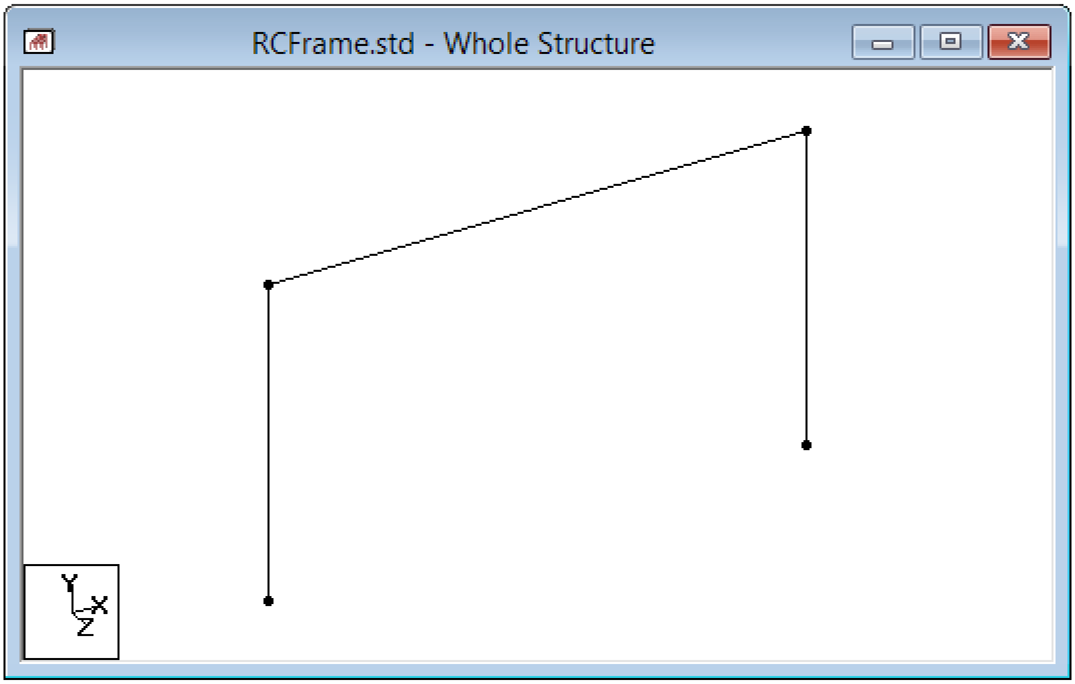


Figure 40: The first part of the frame drawn

It is very important that we save our work often, to avoid loss of data and protect our investment of time and effort against power interruptions, system problems, or other unforeseen events.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.2 Copying Model Objects by Circular Repeat

By examining the structure diagram for this tutorial exercise, you may have observed that members 4 and 5 can be easily generated if we could first create a copy of members 1 and 2 and then rotate those copied units about a vertical line passing through the point (6, 0, 0, that is, node 4) by 90 degrees. Fortunately, such a facility does exist which can be executed in a single step. It is called **Circular Repeat** and is available under the **Geometry** menu.

1. Right click anywhere in the view window and select **Labels** from the pop-up menu.

   The **Diagrams** dialog opens to the **Labels** tab.
2. Set the **Node Numbers** and **Beam Numbers** on and then click **OK.**

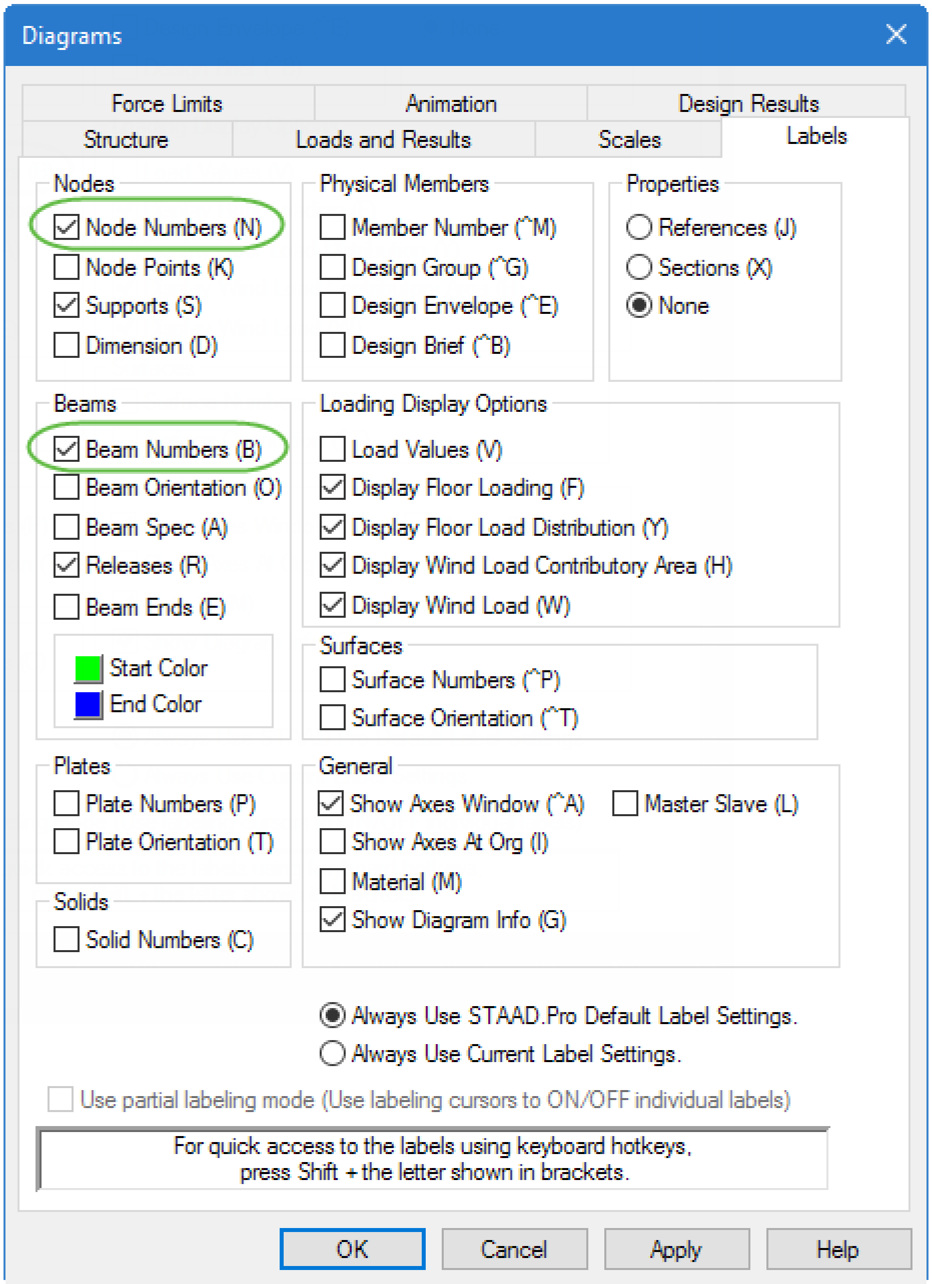

Figure 41: Select the Node and Beam numbers

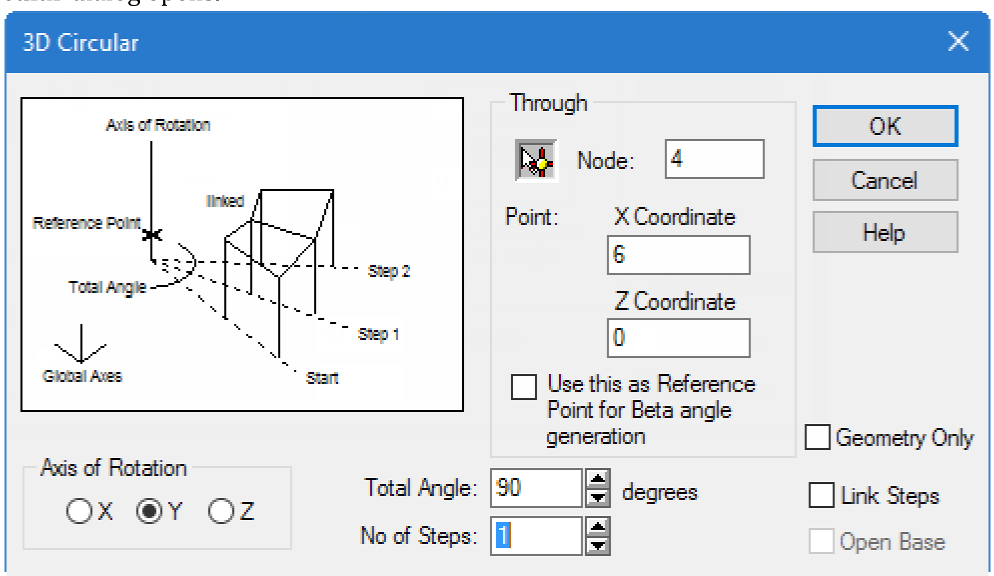
Tip: Alternatively, you can press **<Shift+N>** and then **<Shift+B>** to quickly toggle the same labels. The letters in parenthesis on the **Labels** tab indicate these **<Shift>** key shortcuts.

3. (Optional) You can change the font of the labels by selecting **File** > **Settings** > **Display Options** and then changing the corresponding label Font size in the **Options** dialog.
4. Select the first column and beam for copying:
   a. On the **Select** ribbon tab, select the **Beam Cursor** tool in the **Cursors** group.

b. Holding the **<Ctrl>** key, click on members 1 and 2.

5. On the **Geometry** ribbon tab, select the **Circular Repeat** tool in the **Structure** group.

The **3D Circular** dialog opens.



6. Specify the circular repeat details:
   a. Select **Y** as the **Axis of Rotation**.
   b. Type 4 in the **Node** field.

   This is the node number through which the rotation axis will pass.

   Tip: You can click the Node Selection tool here and then click on the node you want the rotation axis to pass through in the View window.

   c. Type `6` in the point **X Coordinate** field and type `0` in the point **Z Coordinate** field.
   d. Type `90` in the **Total Angle** field.
   e. Set the **No of Steps** value to `1`.
   f. Clear the **Link Steps**, **Geometry Only**, and **Use this as the Reference Point for the Beta angle generation** options.
   g. Click **OK**.
7. Click anywhere away from the members in the View window to deselect the members.

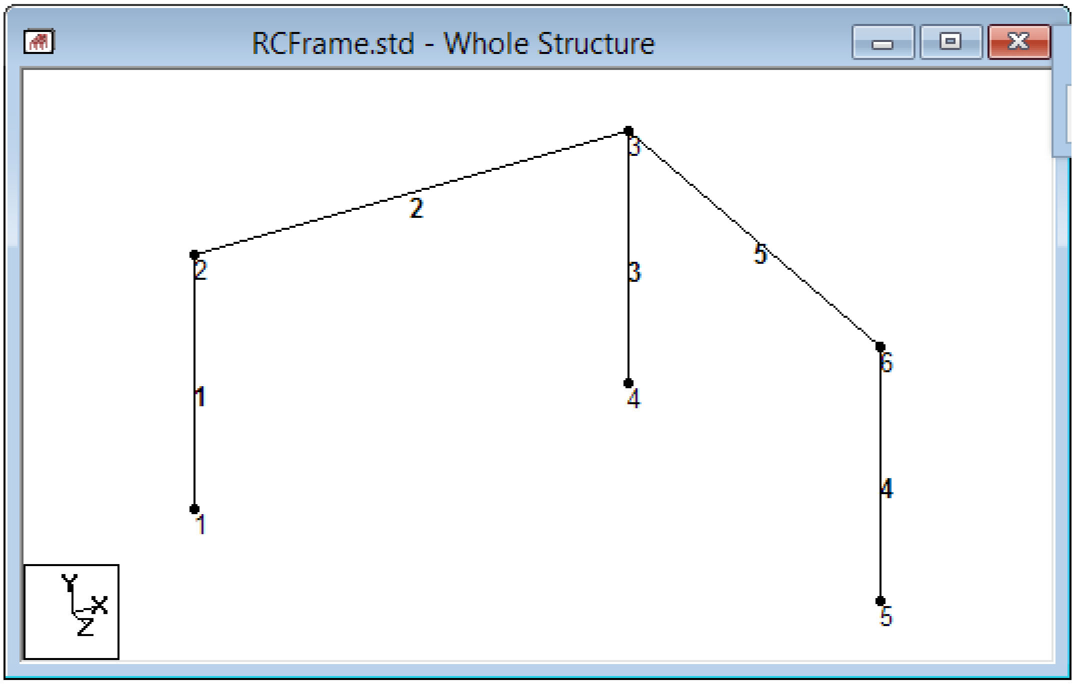


Figure 42: The frame members drawn

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.2 Changing the input units of length

For specifying member properties for the structure, it is more convenient to use length units are millimeter instead of meter. This requires changing the current length units of input.

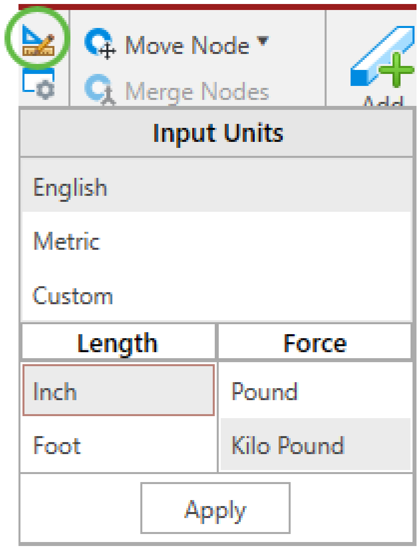
The STAAD input file commands generated are:

```
UNIT MMS KN
```

1. On the **Geometry** ribbon tab, select the **Input Units** tool in the **Structure** group.

   The **Set Input Units** pop-up opens.



2. Select **Metric** as the **Input Units**.
3. Set the **Length Units** to **Milimeter**.

   Leave the **Force Units** set to **KiloNewton**.
4. Click **Apply**.

T.2 User-defined concrete material

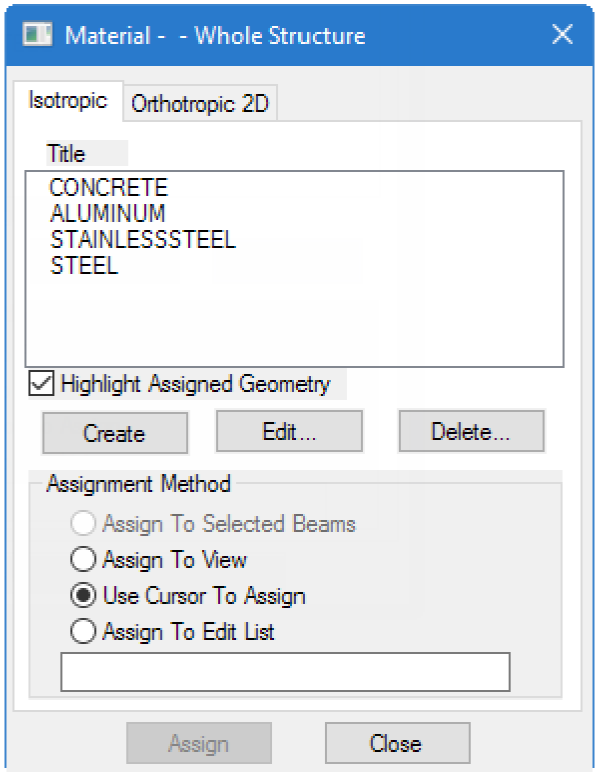
The STAAD input file commands generated are:

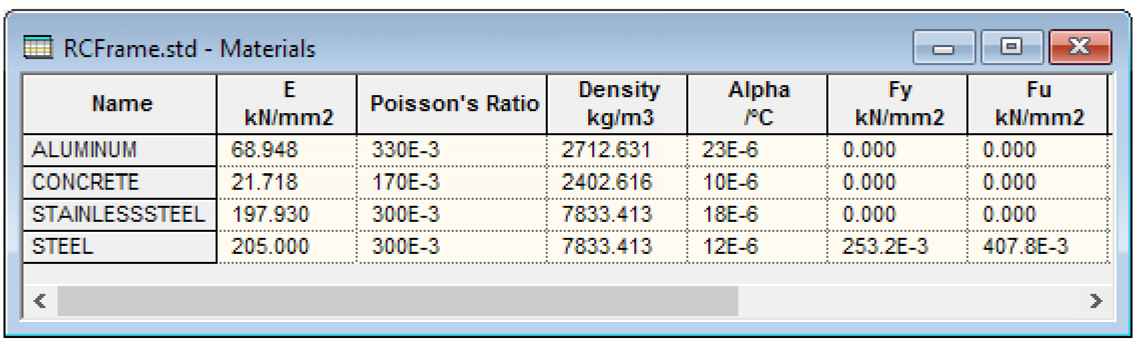
```
DEFINE MATERIAL START
ISOTROPIC CONCRETE-LTW
E 22
POISSON 0.17
DENSITY 1.9e-008
TYPE CONCRETE
STRENGTH RY 1 RT 1 FCU 0.025
END DEFINE MATERIAL
```

You will create a material definition for a lightweight concrete to use for all members.

1. Select the **Materials** page in the **Analytical Modeling** page control bar.

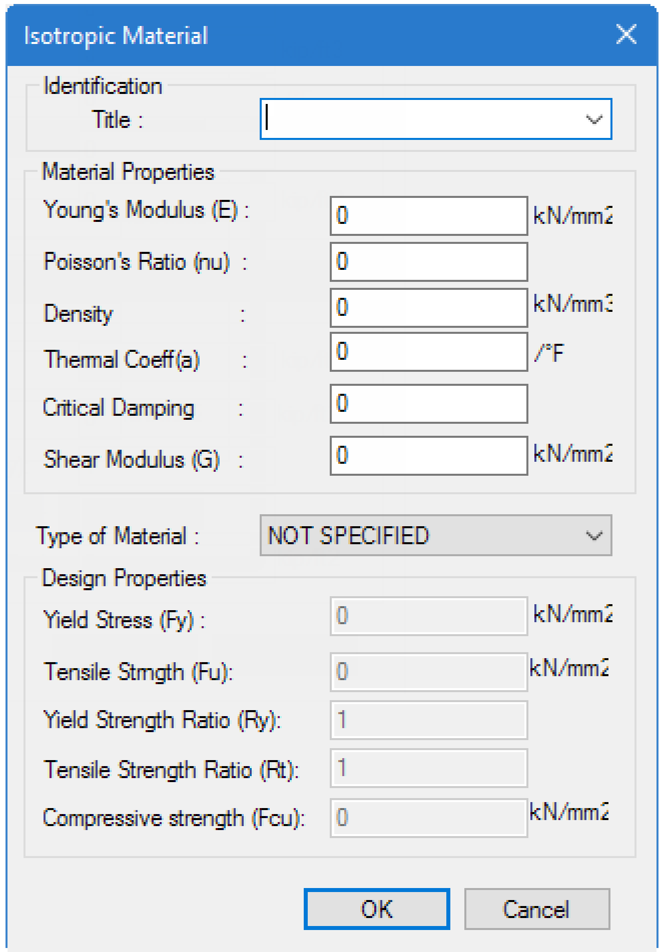
   The **Material - Whole Structure** dialog and the **Materials** table open.





2. In the **Material - Whole Structure** dialog **Isotropic** tab, click **Create**.

   The **Isotropic Material** dialog opens.



3. Input the required, user-defined material values for a lightweight concrete:
   a. Type `CONCRETE-LTW` in the **Title** field.
   b. Type 22 in the **Young's Modulus (E)** field.
   c. Type `0.17` in the **Poisson's Ratio (nu)** field.
   d. Type `1.9e-008` in the **Density** field.
   e. Select **CONCRETE** from **Type of Material** drop-down list.
   f. Type **0.025** in the **Compressive strength (Fcu)** field.

   Leave the remaining property fields as zero for this tutorial exercise. The shear modulus is calculated based on E and Poisson's ratio and the thermal coefficient and critical damping default to zero. Refer to the TR.26.1 Define Material (on page 2303) for details.

   Tip: The material definition can be edited later by selecting the material in the isotropic materials list and clicking Edit.

   The new material is added to the **Material** table and the list of isotropic materials.

T.2 Specifying member properties

Next you will assign cross section properties for the beams and columns.

The STAAD input file commands generated are:

```
MEMB PROP
1 4 PRIS YD 300 ZD 275
2 5 PRIS YD 350 ZD 275
3 PRIS YD 350
...
MATERIAL CONCRETE-LTW ALL
```

1. Select the **Properties** page in the Analytical Modeling page control bar.

The **Properties - Whole Structure** dialog opens.

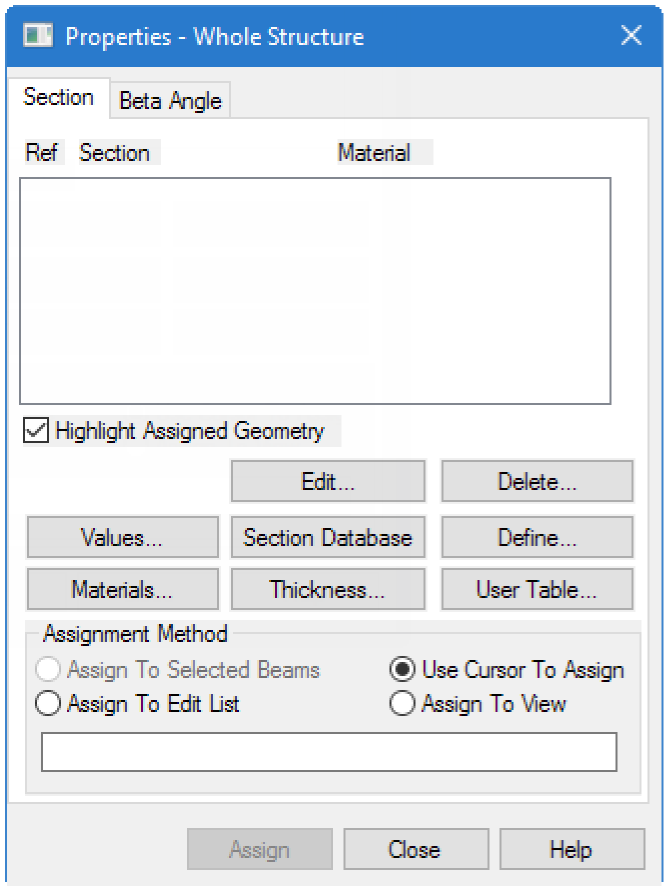


Figure 43:

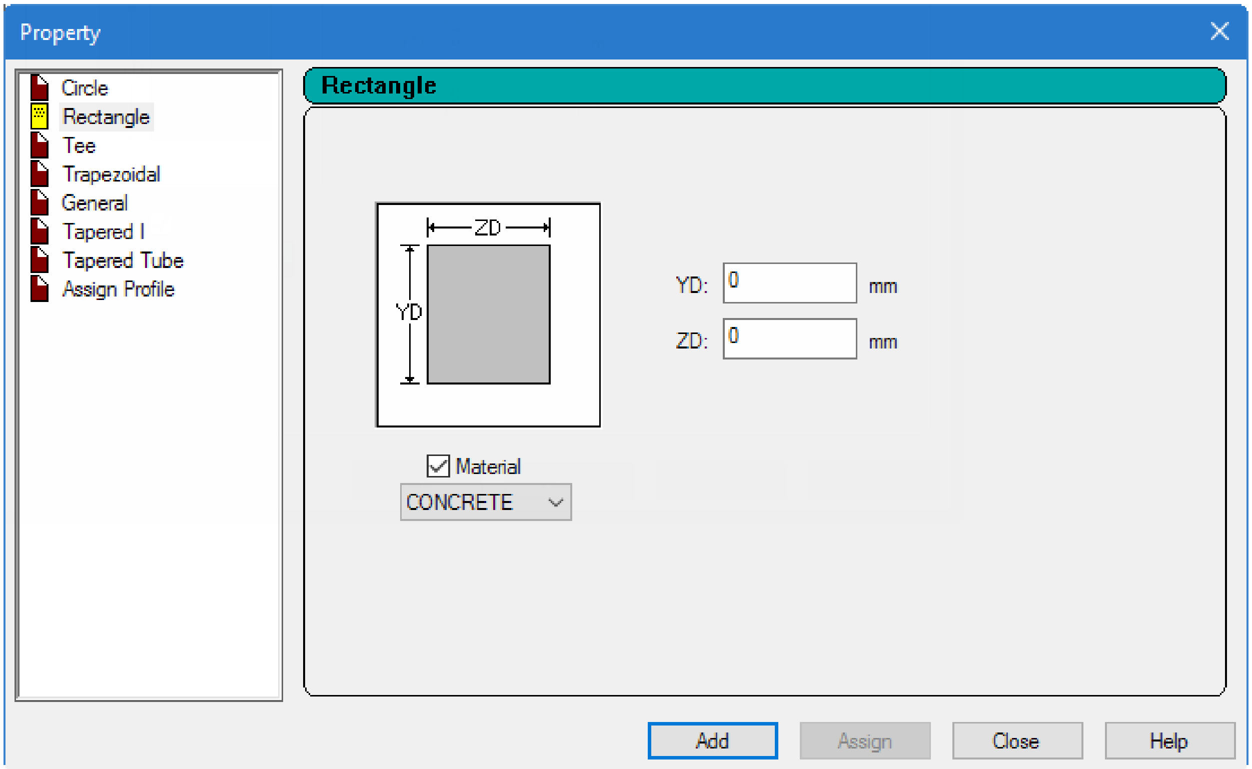
2. Either:

on the **Specifications** ribbon tab, click the **Prismatic** tool in the **Beam Profiles** group

or

click **Define**

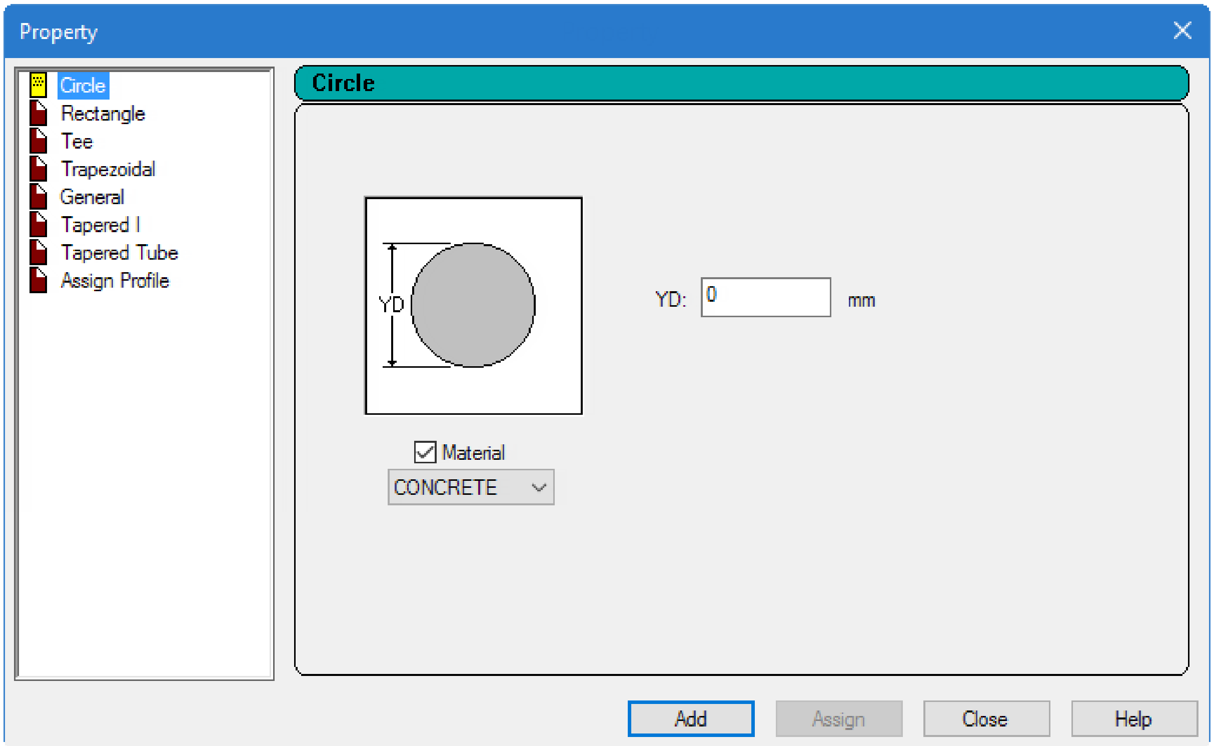
The **Property** dialog opens.



3. Define a 30 cm x 27.5 cm rectangular, concrete beam:
   a. Select the **Rectangle** tab.
   b. Check the **Material** option and select **CONCRETE-LTW** from the list.

   Note: This will automatically assign the user-defined material created in a previous procedure to the sections.

   c. Type `300` (mm) in the **YD** field.
   d. Type `275` (mm) in the **ZD** field.
   e. Click **Add**.
4. Repeat step 3 to define the beam member property, this time with a depth (**YD**) of `350` and a width (**ZD**) of `275`.
5. Define a 35 cm round, concrete column:
   a. Select the **Circle** tab.



b. Check the **Material** option and select **CONCRETE-LTW** from the list.
c. Specify the diameter (**YD**) as `350 mm`.
d. Click **Add**.

6. Click **Close**.
7. Assign the 30 cm x 27.5 cm shape to members 1 and 4 (end columns):

a. Select **Rect 0.30x0.28** in the list of sections.
b. Select the **Use Cursor to Assign** option in the Assignment Method group.
c. Click **Assign**.

The mouse pointer changes to 
d. In the view window, click on members 1 and 4.
e. To stop assigning members, either:

click **Assigning**

or

press the **<Esc>** key.

8. Repeat step 7 to assign the 0.35cm x 27.5 cm rectangular shape to members 2 and 5 (beams).
9. Repeat step 7 to assign the 0.35cm circular shape to members 3 (center column).

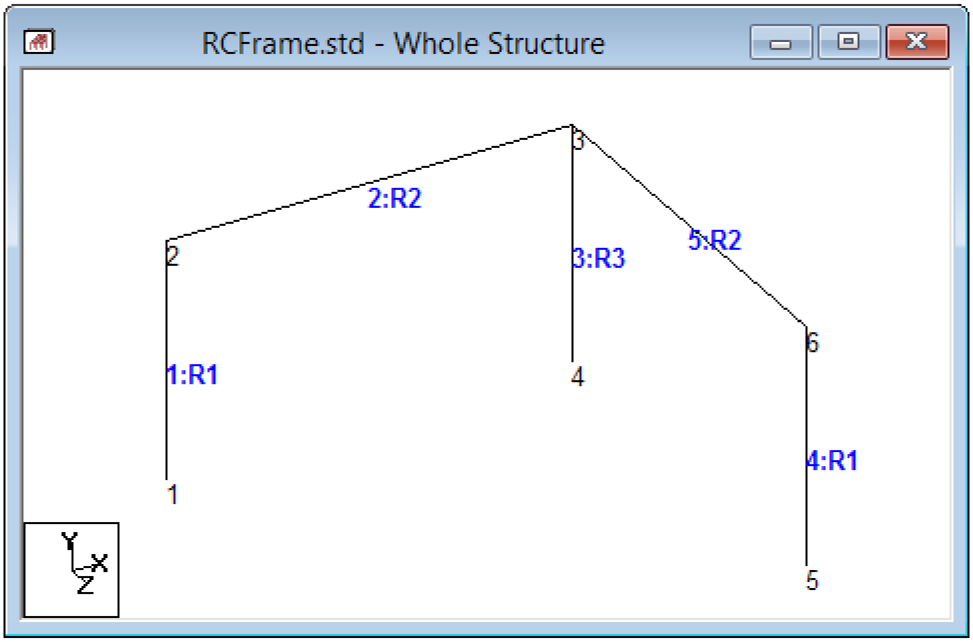


Figure 44: The frame with sections assigned

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.2 Specifying geometric constants

You need to orient member 4 so that its longer edges (sides parallel to local Y axis) are parallel to the global Z axis. This requires applying a beta angle of 90 degrees.

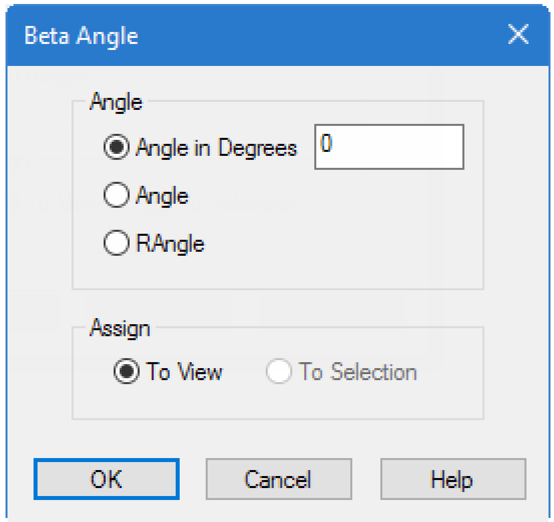
In the absence of any explicit instructions, STAAD.Pro will orient the beams and columns of the structure in a predefined way. Orientation refers to the directions along which the width and depth of the cross section are aligned with respect to the global axis system. The rules which dictate this default orientation are explained in General Engineering Theory (on page 2085).

The STAAD input file commands generated are:

```
BETA 90 MEMB 4
```

1. Select the **Properties** page in the **Analytical Modeling** page control bar.
   The **Properties** dialog opens.
2. On the **Properties** dialog, select the **Beta Angle** tab.
3. Click **Create Beta Angle**.

   The **Beta Angle** dialog opens.



4. Type `90` in the **Angle in Degrees** field.
5. Click **OK**.
   The property **Beta 90** is added to the beta angles list.
6. Select the property **Beta 90**.
7. Assign the beta angle to member 4:
   a. Select the **Use Cursor to Assign** option in the Assignment Method group.
   b. Click **Assign**.

      The mouse pointer changes to    c. In the view window, click on member 4.
   d. To stop assigning members, either:

      click **Assigning**

      or

      press the **<Esc>** key.
8. To view the orientation of the member local axes:

   right-click in the view window and select **Labels** from the pop-up menu, check the option for **Beam Orientation**, and click **Apply**.

   or

   press **<Shift+O>**.

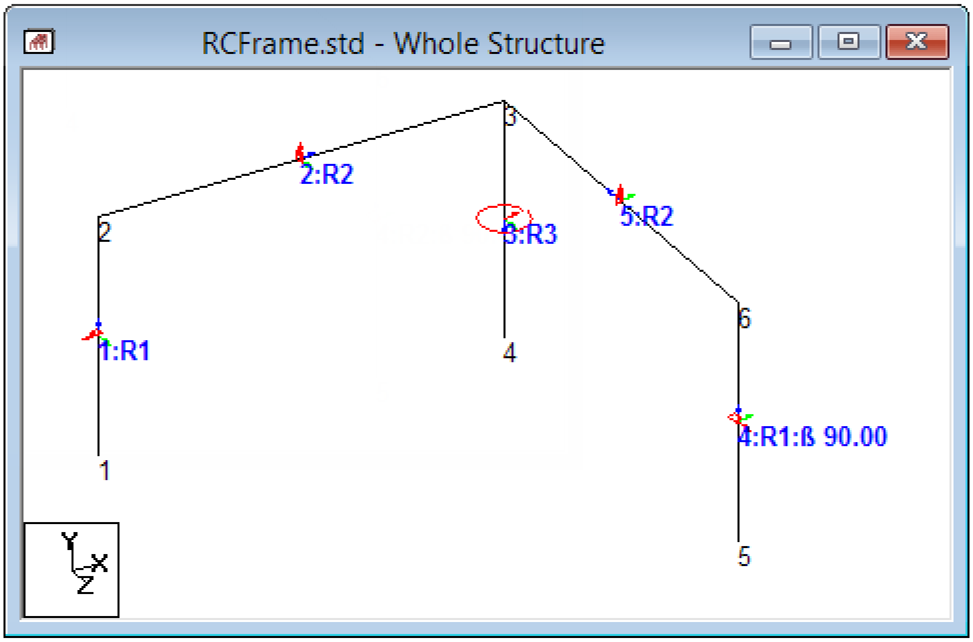

Figure 45: The Beta Angle applied to Member 4

Alternatively, you can assign a beta angle to a selected member set. On the **Specification** ribbon tab, select the **Beam** > **Beta Angle** tool in the **Specifications** group. Type the beta **Angle in Degrees** to use. Make sure that the **To Selection** option is selected and then click **OK**.

T.2 Specifying Supports

The base nodes of all the columns are restrained against translation and rotation about all the 3 global axes (i.e., fixed supports at those nodes).

The STAAD input file commands generated are:

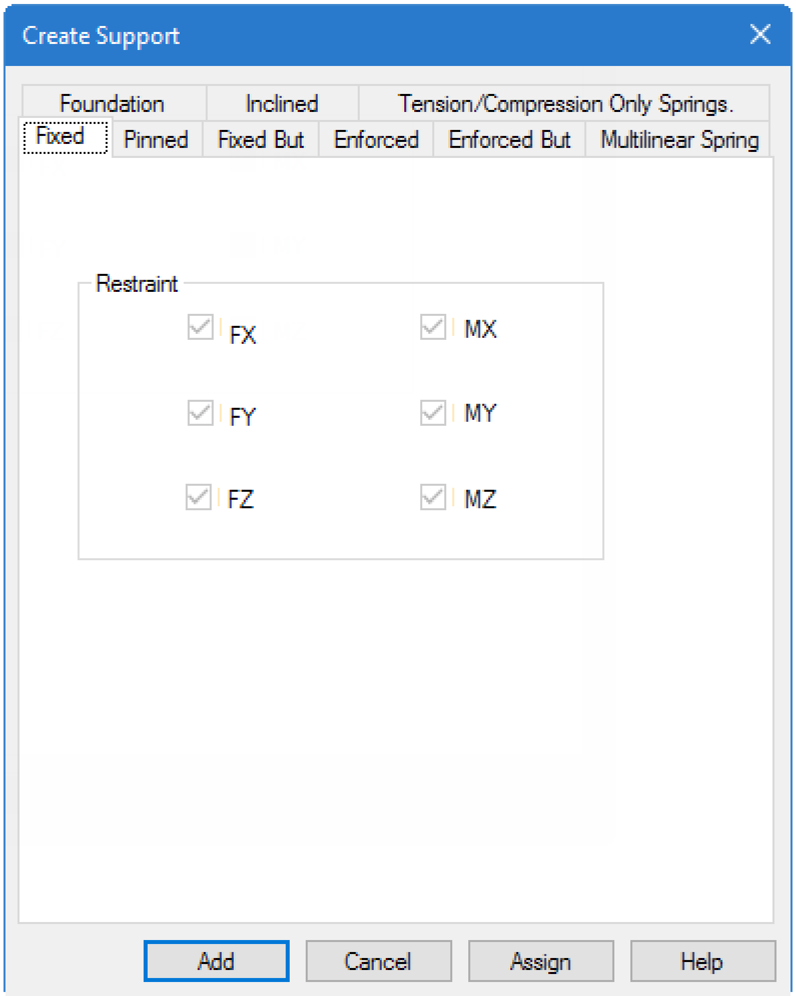
```
SUPPORTS
1 4 5 FIXED
```

1. On the **Select** ribbon tab, select the **Node Cursor** tool in the **Cursors** group.

2. In the View window, hold **<Ctrl>** and click on nodes 1, 4, and 5 to select them.
3. In the **Supports** dialog, click **Create**.

   The **Create Support** dialog opens.



4. Select the **Fixed** tab (selected by default) and then click **Assign**.

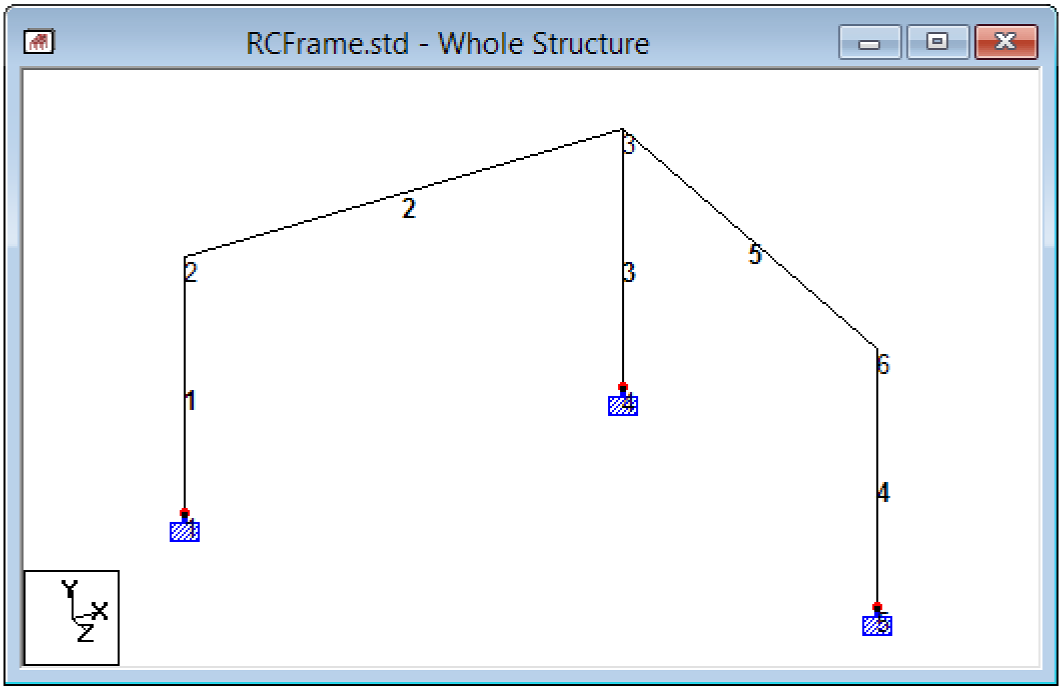


Figure 46: The structure with the supports assigned

5. Click any open space in the View window to deselect all selected nodes.

   This prevents accidental assignment of unwanted data to those nodes.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.2 Specifying Loads

Five load cases are to be created for this structure. Details of the individual cases are explained at the beginning of this tutorial.

The STAAD input file commands generated are:

```
UNIT METER KG
LOAD 1 DEAD LOAD
SELFWEIGHT Y -1
MEMBER LOAD
2 5 UNI GY -400
LOAD 2 LIVE LOAD
MEMBER LOAD
2 5 UNI GY -600
LOAD 3 WIND LOAD
MEMBER LOAD
1 UNI GX 300
4 UNI GX 500
LOAD 4 DEAD + LIVE
REPEAT LOAD
1 1.2 2 1.5
LOAD 5 DEAD + WIND
```

```
REPEAT LOAD
1 1.1 3 1.3
```

T.2 Creating Load Cases 1, 2, and 3

The load values are listed in the beginning of this tutorial in **kg** and **meter** units. Rather than convert those values to the current input units, we will conform to those units.

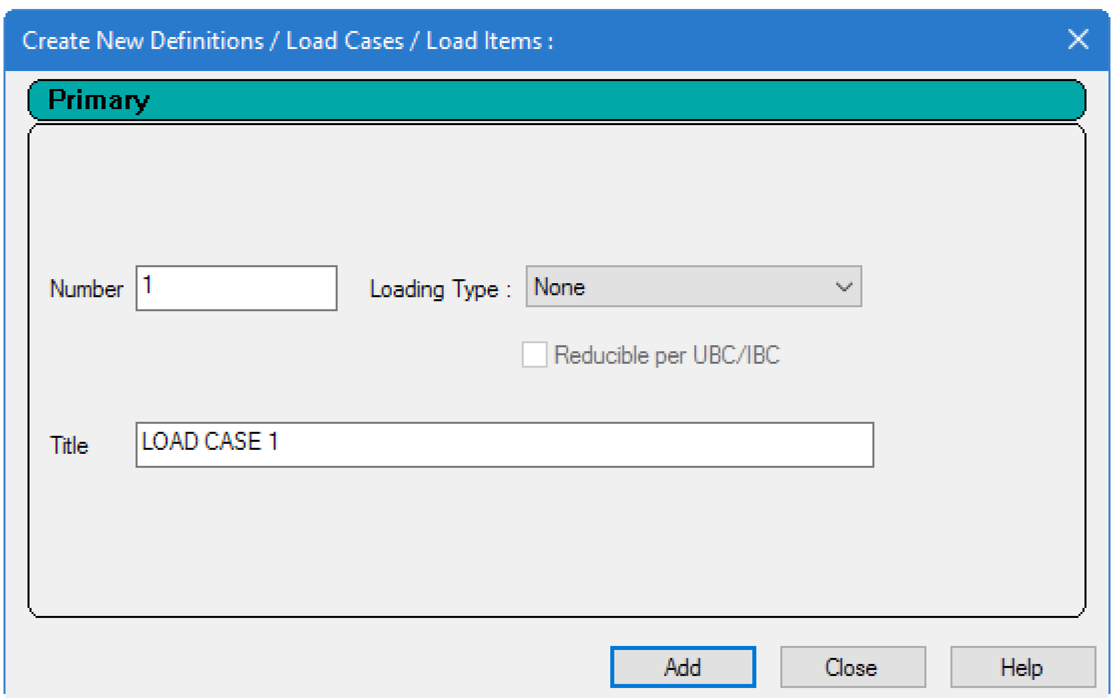
STAAD.Pro does not allow to change the units while editing load cases. An error message is displayed if this is attempted.

Create the primary load cases for this model.

1. Change the force unit to **Kilogram** and the length unit to **Meter**.

   Refer to T.2 Changing the input units of length (on page 480) for details.
2. On the **Loading** ribbon tab, select the **Primary Load Case** in the **Loading Specifications** group.

   
   The **Create New Primary Load Cases** dialog opens.

3. Enter the properties for the first load case:
   a. Type `DEAD LOAD` in the **Title** field.

      Leave the **Number** as the default value of 1.

> **Note:** The **Loading Type** list is used to associate the load case we are creating with any of the ACI, AISC, IBC, or other code-prescribed definitions of Dead, Live, Ice, etc. This type of association needs to be done if you intend to use the program's automatically generating load combinations in accordance with those

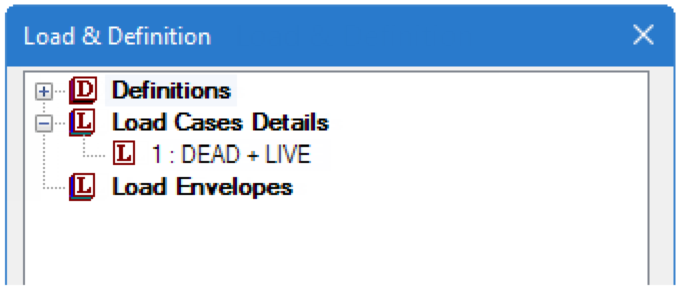
codes. Note that there is a check box labeled **Reducible per UBC/IBC**. This feature is active only when the load case is assigned a Loading Type called **Live** when you create that load case.

Since this tutorial does not use the automatic load combination generation feature, leave the **Loading Type** as **None**.

b. Click **Add**.

c. Click **Close**.

The load case appears under the **Load Cases Details** option in the **Load & Definition** dialog.



4. To create the selfweight dead load, either:

on the **Loading** ribbon tab, select the Load Items tool

a. Select the **1: DEAD LOAD** entry.

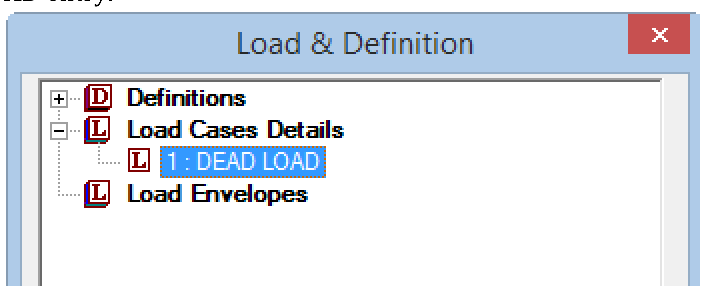


Figure 47:

b. Click **Add**.

The **Add New Load Items** dialog opens with entries for adding load items to the selected load case.

5. Define the selfweight load:

a. In the **Add New Load Items** dialog, select the **Selfweight Load** option under the **Selfweight** item.

b. Select **Y** as the **Direction**.

c. Type `-1.0` in the **Factor** field (multiplier for the calculated selfweight of members).

d. Click **Add**.

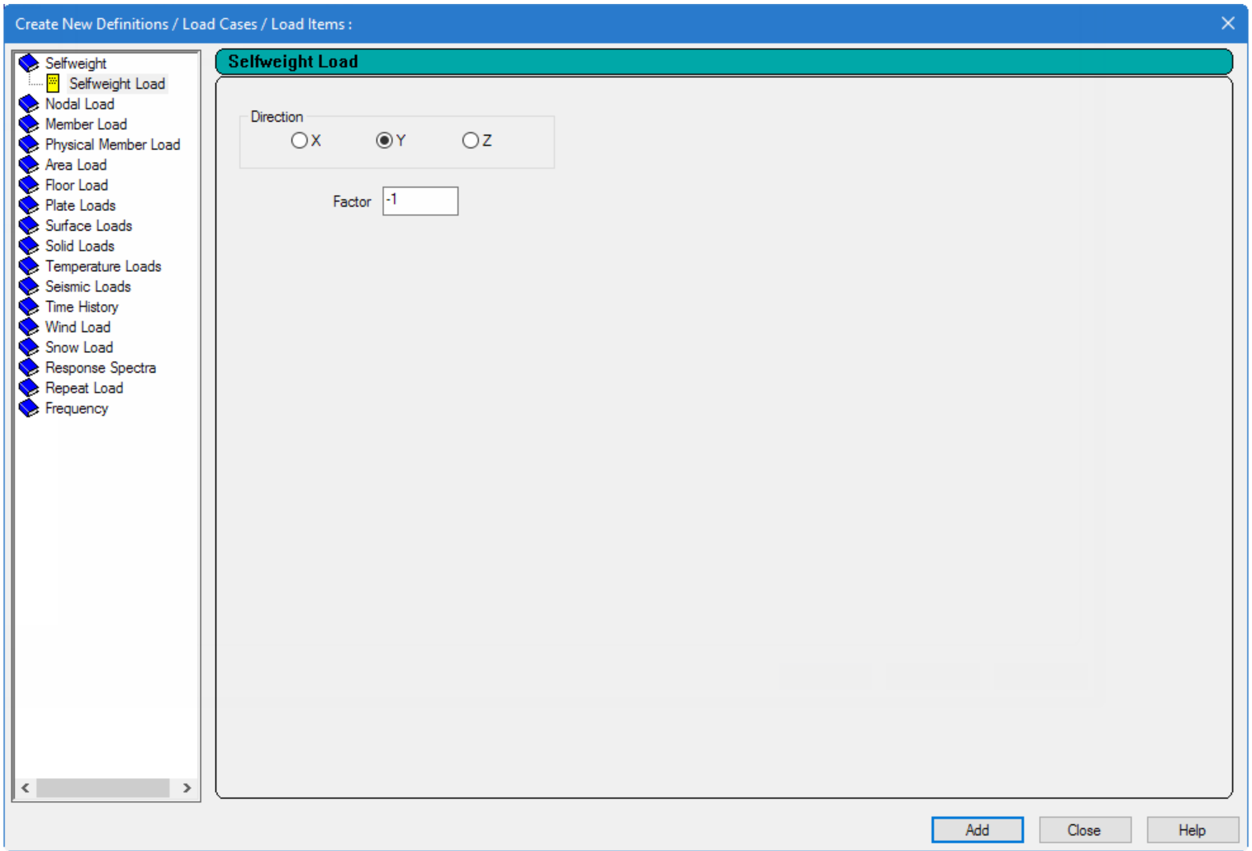

Figure 48:

6. With the **Add New Load Items** dialog still open, add the member loads to be applied to the beams:
   a. In the **Add New Load Items** dialog, select the **Uniform Force** tab under the **Member Load** item.
   b. Select **GY** as the **Direction**.

   Tip: For these members, since the local Y axis coincides with the global Y axis, selecting Y (local member Y) and GY (global Y direction) have the same effect. Press **<Shift+O>** to view the member orientation.

   c. Type `-400` (kg/m) in the **W1** field (magnitude of the uniform force).

      The negative value indicates the load acts "down".

      Leave the offset fields (d1 through d3) as zero.
   d. Click **Add**.
   e. Click **Close**.

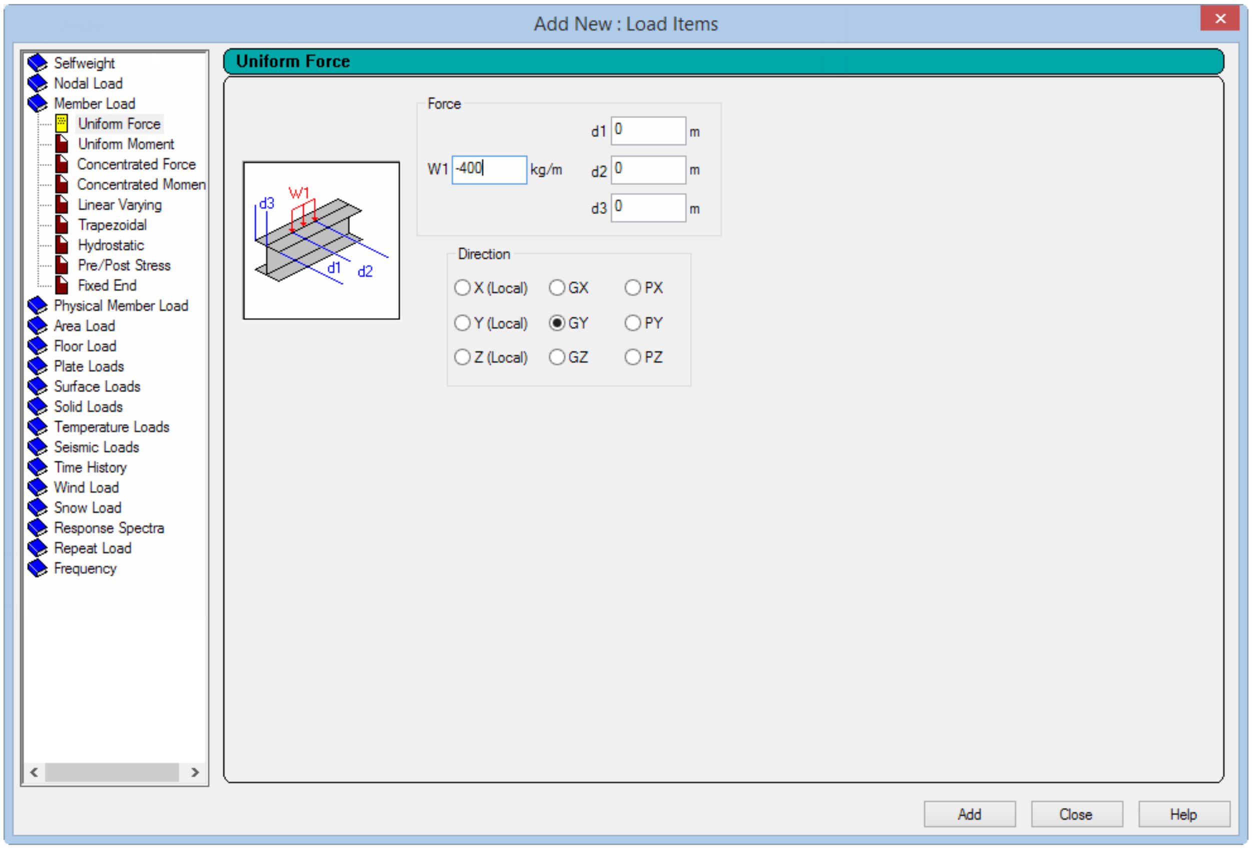

Figure 49:

7. Assign the selfweight load to all members:
   a. Select the **SELFWEIGHT Y -1** entry in the **Load & Definitions** dialog.

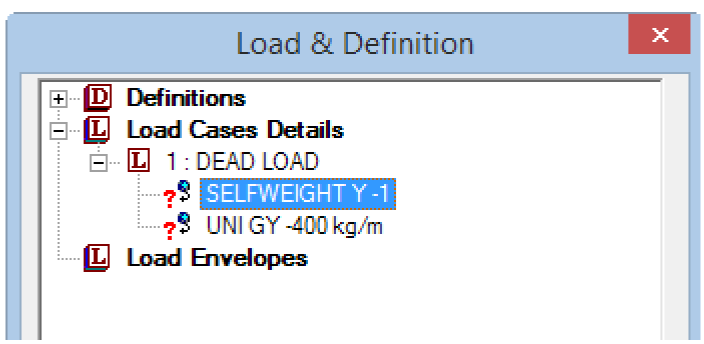

Figure 50:

   b. Select the **Assign to View** option.
   c. Click **Assign**.

      A message box opens to opens prompting you to confirm you want to make this assignment.
   d. Click **Yes**.
   e. Click anywhere in the View window away from the members to deselect all members.
8. Assign the member load to members 2 and 5:
   a. Select the **UNI GY -400 kg/m** entry in the **Load & Definitions** dialog.

b. Press and hold **<Ctrl>** and then select members 2 and 5 in the View window.

The **Beams Cursor** tool  is automatically selected when the **Load & Definition** dialog is opened.

c. Select the **Assign to Selected Beams** option.

d. Click **Assign**.

A message box opens to opens prompting you to confirm you want to make this assignment.

e. Click **Yes**.

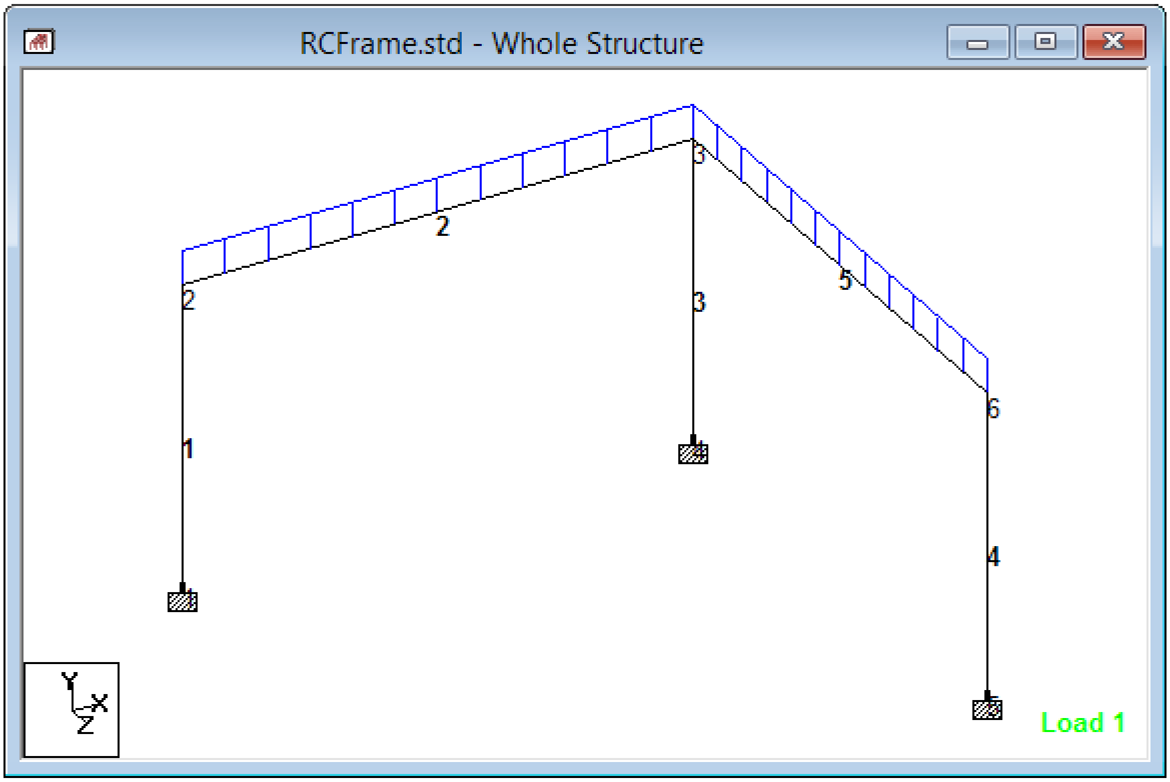

Figure 51: Structure after uniform force is assigned to beams

Tip: Use a scale of 6 kN/m per m for distributed forces if the loads are not visible or are too large for the View window when viewing the entire structure.

9. Repeat steps 3, 4, 6, and 8 to create a new load case titled `Live Load` which contains a uniform force of `-600` kg/m in the global Y direction and is applied to members 2 and 5.

Note: Be sure to select the **Live Load** on the **Loading** ribbon tab **Display** group to add load items to this load case.

10. Repeat steps 3 through 4 and then 6 through 8 to create a new load case titled `Wind Load` which contains the following two load items:

Note: Be sure to select the **Wind Load** on the **Loading** ribbon tab **Display** group to add load items to this load case.

a uniform force of `+300` kg/m in the **GX** (global X) direction and is applied to member 1
a uniform force of `+500` kg/m in the **GX** (global X) direction and is applied to member 4

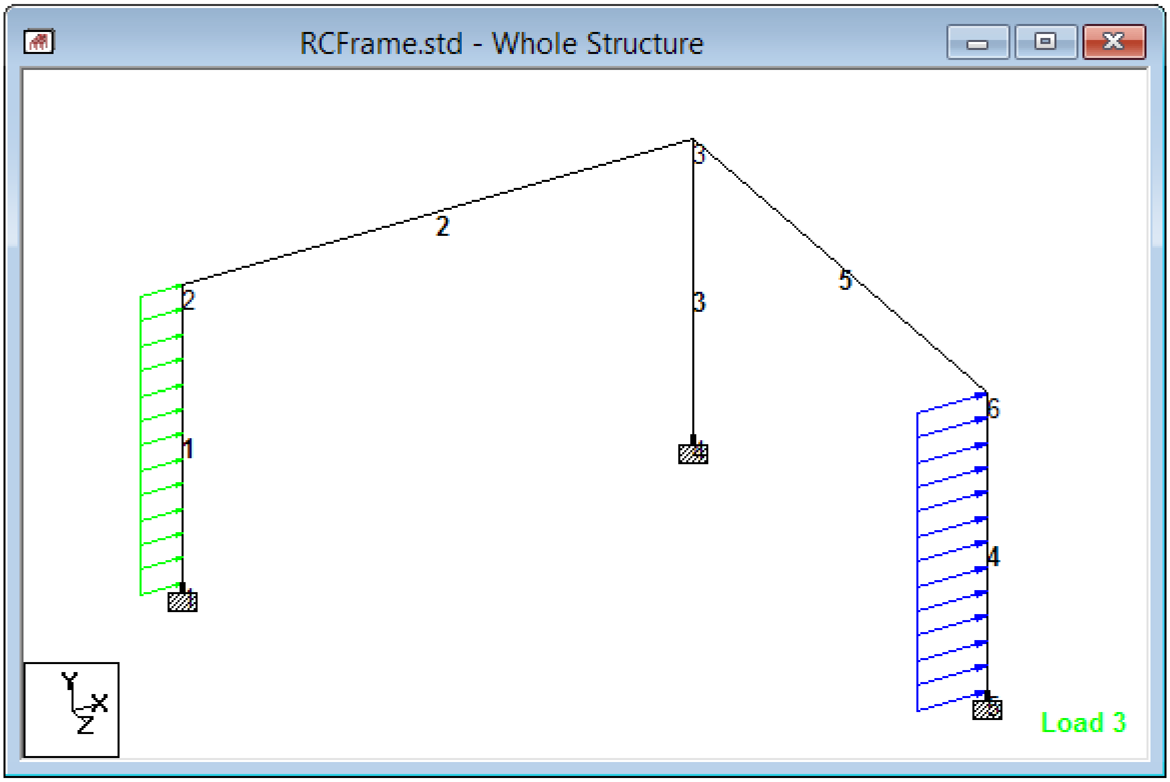

Figure 52: Structure after the wind load items are assigned

T.2 Analysis and Design

The following procedures describe how to add analysis and design commands to the STAAD input file.

Note: The analysis design commands are added using either the analytical user interface or the STAAD.Pro Editor. The STAAD.Pro Physical Modeler interface is not used to assign analysis and design commands.

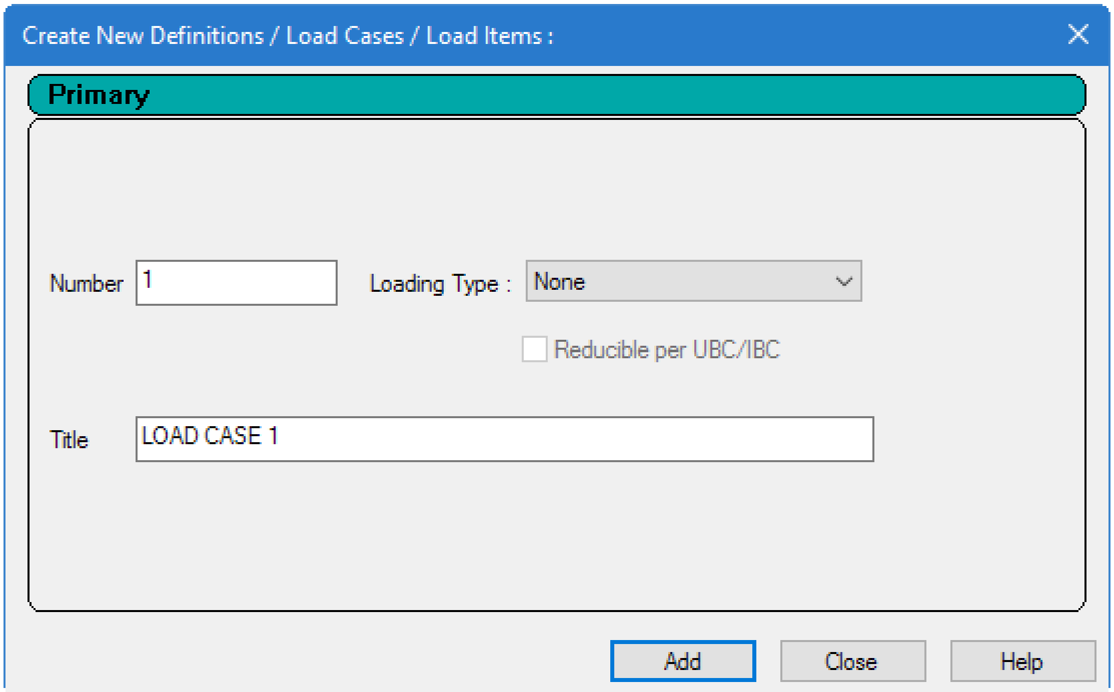
T.2 Creating Load Cases 4 and 5

Use repeat load cases for the load combinations used in a nonlinear analysis.

Load cases 4 and 5 are to be generated using a combination load type called `REPEAT LOAD` (as opposed to a standard load combination). The instructions at the beginning of this tutorial specify using a PDelta analysis. A PDelta analysis is a non-linear type of analysis. In STAAD, to accurately account for the PDelta effects arising from the simultaneous action of previously defined horizontal and vertical loads, those previous cases must be included as components of the combination case using the `REPEAT LOAD` type.

1. On the **Loading** ribbon tab, select the **Primary Load Case** in the **Loading Specifications** group.

   
   The **Create New Primary Load Cases** dialog opens.



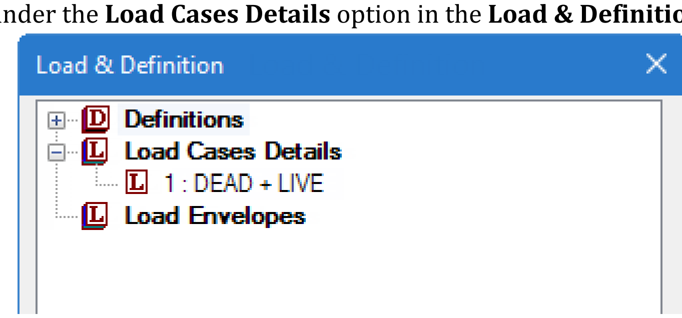
2. Enter the properties for the load case:
   a. Type `DEAD + LIVE` in the **Title** field.

   Leave the **Number** as the default value of 4.

   > **Note:** The **Loading Type** list is used to associate the load case we are creating with any of the ACI, AISC, IBC, or other code-prescribed definitions of Dead, Live, Ice, etc. This type of association needs to be done if you intend to use the program's automatically generating load combinations in accordance with those codes. Note that there is a check box labeled **Reducible per UBC/IBC**. This feature is active only when the load case is assigned a Loading Type called **Live** when you create that load case.

   b. Click **Add**.

   The load case appears under the **Load Cases Details** option in the **Load & Definition** dialog.



3. To create the dead + live repeat load case:
   a. Select the **4: DEAD + LIVE** entry.

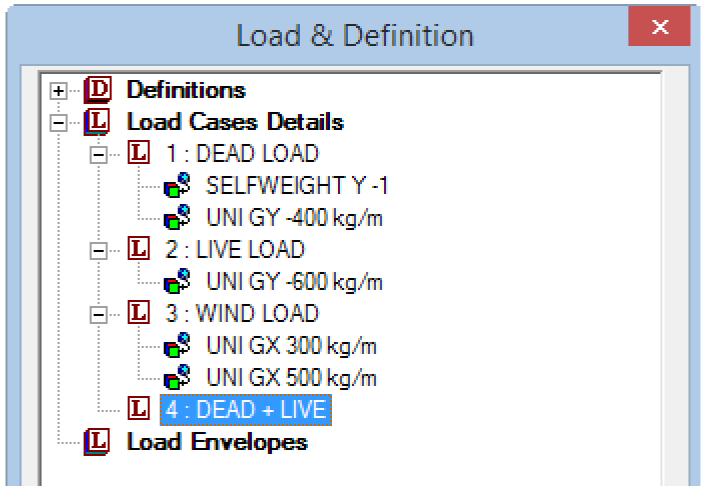


Figure 53:

b. Click **Add**.

The **Add New Load Items** dialog opens with entries for adding load items to the selected load case.

4. Define the repeat load:

a. In the **Add New Load Items** dialog, select the **Repeat Load** option under the **Repeat Load** item.

b. Select **1: DEAD LOAD** as the **Available Load Cases** list and then click **[>]**.
This load is added as Load Case 1 in the **Repeat Load Definition** list.

c. Type `1.2` in the **Factor** field for **Load Case 1** in the **Repeat Load Definition** list.

This indicates that the load data values from load case 1 are multiplied by a factor of 1.2, and the resulting values are utilized in load case 4.

d. Select **2: LIVE LOAD** as the **Available Load Cases** list and then click **[>]**.
This load is added as Load Case 2 in the **Repeat Load Definition** list.

e. Type `1.5` in the **Factor** field for **Load Case 1** in the **Repeat Load Definition** list.

f. Click **Add**.

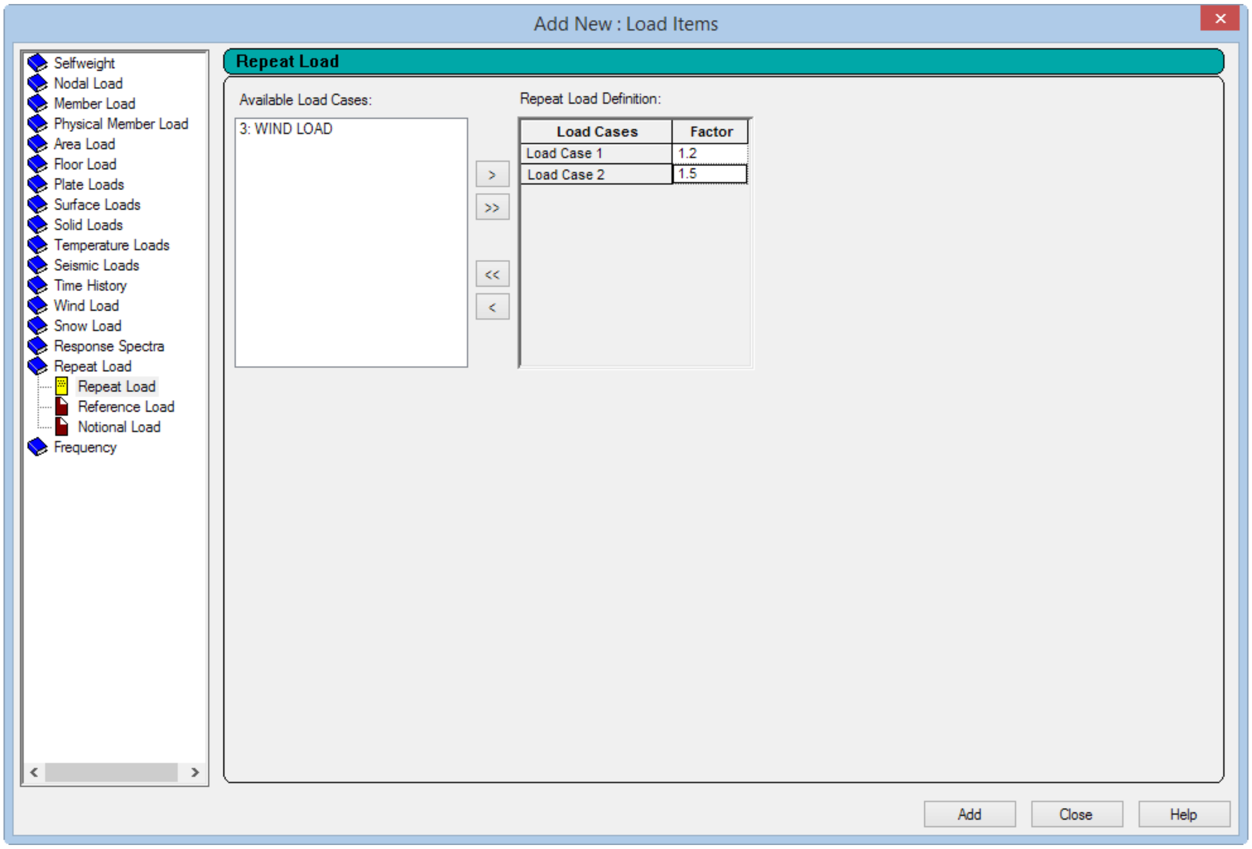

Figure 54:

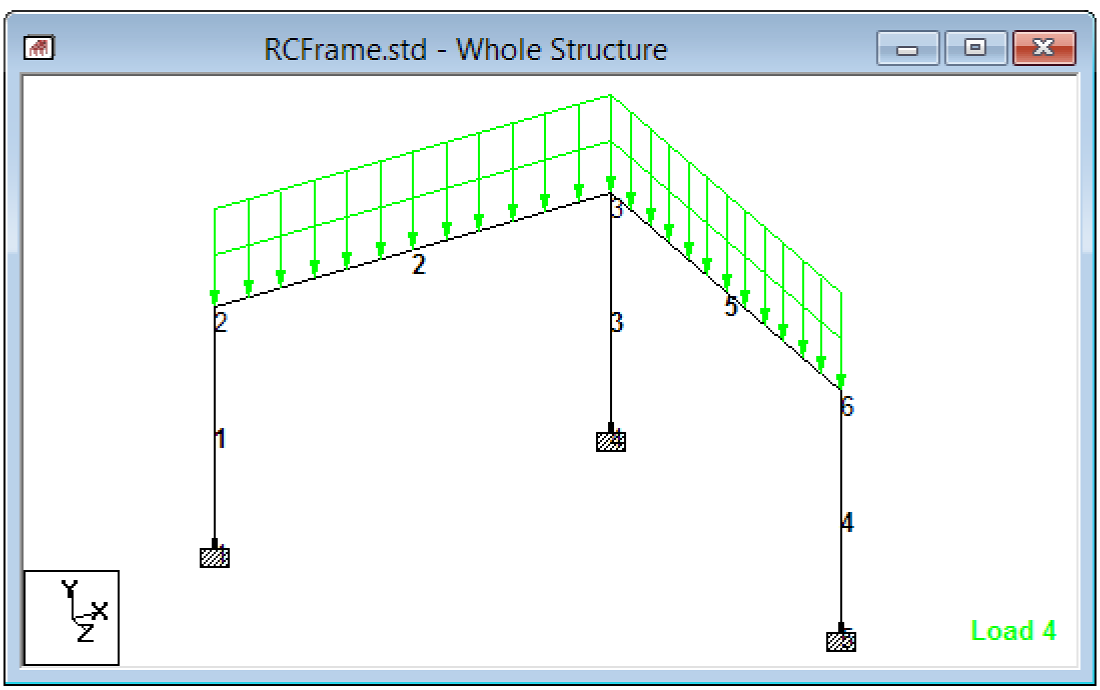

Figure 55: Structure with repeat load case selected

5. Click **Close**.
6. Repeat steps 3 and 5 to create another repeat load case for load case 5, except:

    title load case 5 **Dead + Wind**
    add the Dead Load case with a factor of 1.1
    add the Wind Load case with a factor of 1.3

Note: No member assignment is not necessary for repeat load cases. The members assigned to which the primary load cases are assigned are used for the repetition of the load.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.2 Specifying the analysis type

The analysis type for this structure is called P-Delta.

Since this problem involves concrete beam and column design per the ACI code, second-order analysis is required and has to be done on factored loads acting simultaneously. The factored loads have been created earlier as cases 4 and 5. Now is the time to specify the analysis type.

The STAAD input file commands generated are:

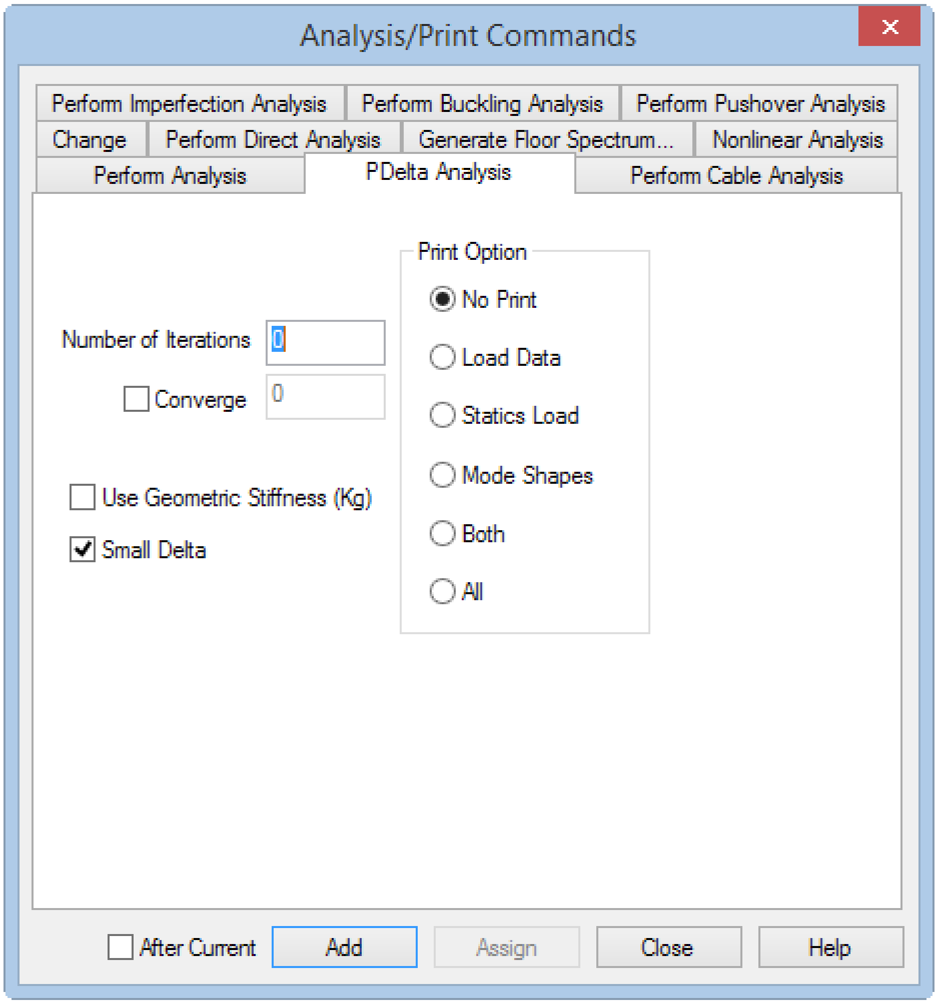
```
PDELTA ANALYSIS SMALLDELTA
```

1. On the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group.

    The **Analysis/Print Commands** dialog opens.

    Tip: If the **Analysis/Print Commands** dialog does not open automatically, then click **Define Commands** in the **Analysis - Whole Structure** dialog.
2. Select the **PDelta Analysis** tab.



Note: Leave the parameters on this page as their default values and options.

3. Click **Add**.
4. Click **Close**.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.2 Short-listing the load cases to be used in concrete design

The concrete design should only be performed for load cases 4 and 5 since those are the factored cases. Use the load list to instruct the program to use just these cases.

The STAAD input file commands generated are:

```
LOAD LIST 4 5
```

1. On the **Anlaysis and Design** ribbon tab, select the **Load List** tool in the **Analysis Data** group. 

   The **Load List** dialog opens.

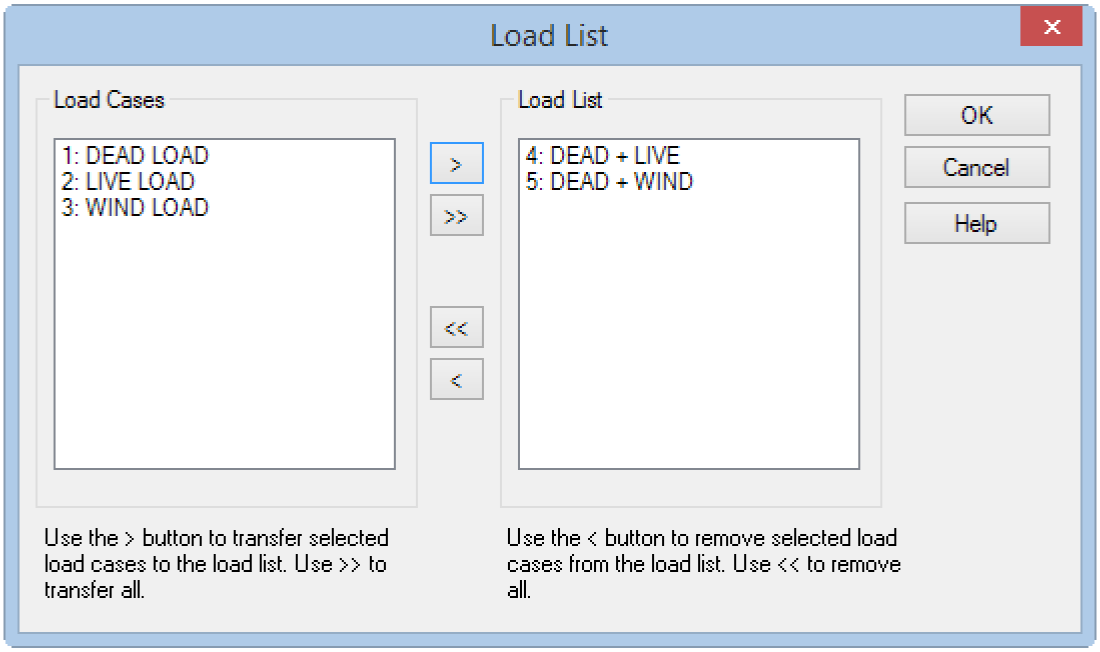


Figure 56:

2. Press and hold the **<Ctrl>** key and then select load cases **4: DEAD + LIVE** and **5: DEAD + WIND**.
3. Click **[>]**.
   Load cases 4 and 5 will be selected and placed in the **Load List** selection box.
4. Click **OK**.

T.2 Specifying concrete design parameters

Concrete design parameters allow you to directly specify some of the terms used in the equations for concrete member design.

For example, the grade of concrete or the maximum size of reinforcing bar you want to use.

Note: This tutorial uses the 2011 edition of the American Concrete Institute 318 specification for design (ACI 318-11). Details on the code parameters can be found in D1.F.3 Design Parameters (on page 1201).

The STAAD input file commands generated are:

```
UNIT MMS NEWTON
CODE ACI
CLB 30 ALL
CLS 25 ALL
CLT 25 ALL
FC 25 ALL
FYMAIN 415 ALL
TRACK 1 ALL
```

1. Set the force units as **Newton** and the length units as **Millimeter**.

   Refer to T.2 Changing the input units of length (on page 480) for details.
2. On the **Analysis and Design** ribbon tab, select **Concrete** in the **Design Commands** gallery.

The **Concrete Design - Whole Structure** dialog opens.

3. On the **Concrete Design - Whole Structure** dialog, select **ACI 318 2011** from the **Current Code** drop-down list.
4. Click **Define Parameters** in the **Concrete Design** dialog.

   The **Design Parameters** dialog opens.

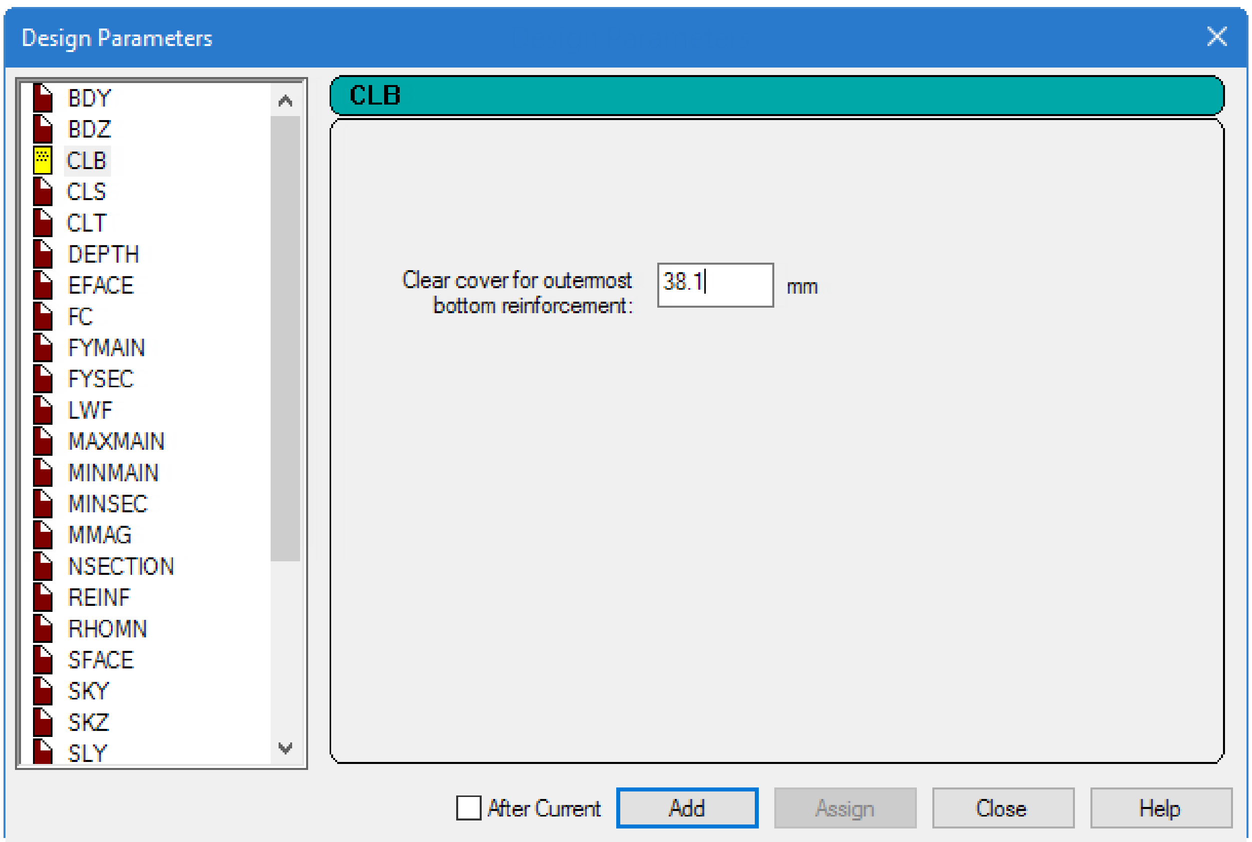

Figure 57:

5. Specify the clear cover on bottom:
   a. Select the **CLB** parameter tab.
   b. Type as `30` (mm) in the parameter value field.
   c. Click **Add**.
6. Repeat step 5 to define the remaining parameters:

Parameter	Value
CLS	25
CLT	25
FC	25
FYMAIN	415
TRACK	1 (select option from list)

7. Click **Close**.

   The **Concrete Design** dialog displays the parameters in the concrete design command.

Figure 58:

8. Assign these parameters to all the members in the model:
   - **a.** Select the first unassigned parameter in the **Concrete Design | Whole Structure** dialog.
   - **b.** Select the **Assign to View** option.
   - **c.** Click **Assign**.

     A message dialog opens confirming you want to make this assignment.
   - **d.** Click **Yes**.
   - **e.** Repeat steps 8a though 8d for each unassigned parameter to assign them to all members.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.2 Specifying design commands

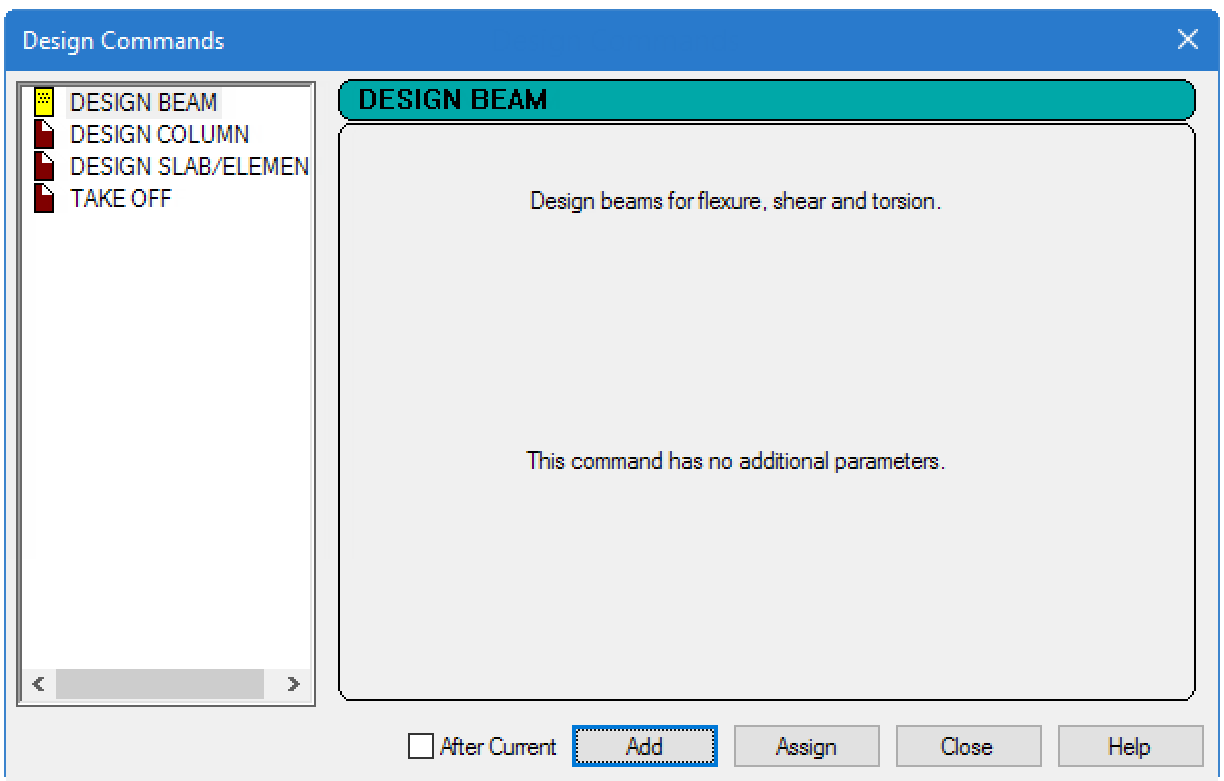
Design commands are the actual instructions for the design of beams and columns.

The STAAD input file commands generated are:

```
DESIGN BEAM 2 5
DESIGN COLUMN 1 3 4
```

1. On the **Concrete Design - Whole Structure** dialog, click **Commands**.

   The **Design Commands** dialog opens.



2. Select the **Design Beam** tab and then click **Add**.
3. Select the **Design Column** option and then click **Add**.
4. Click **Close**.

5. Assign the Design Beam command to the beams:
   a. Press and hold the **<Ctrl>** key and click members 2 and 5

   > **Tip:** The **Beams Cursor** tool  is selected when the **Concrete Design - Whole Model** dialog opens.

   b. Select the **Assign to Selected Beams** option.
   c. Click **Assign**.

      A message box opens to opens prompting you to confirm you want to make this assignment.
   d. Click **Yes**.
6. Repeat steps 5 to assign the **Design Column** command to members 1, 3, and 4.

> **Tip:** Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

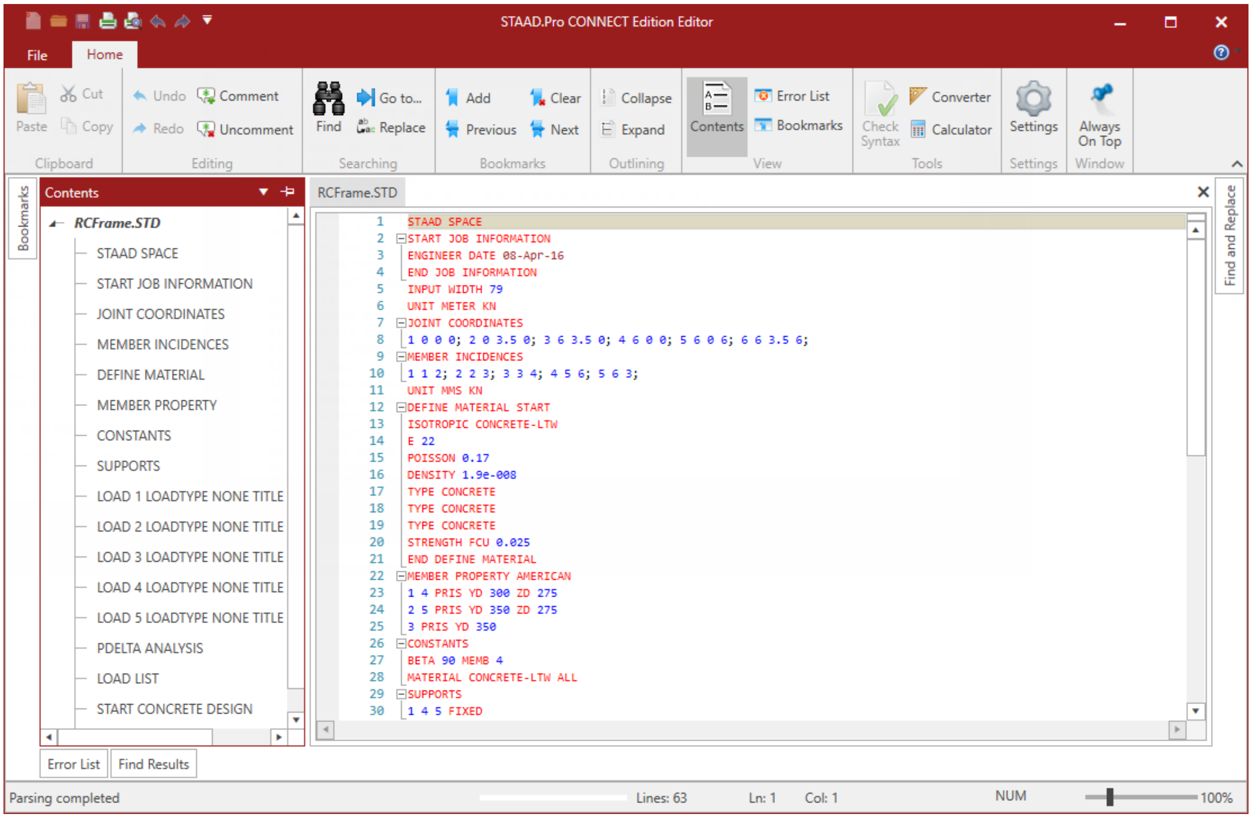
T.2 Viewing the input command file

You can inspect the text data file created during this tutorial.

1. On the **Utilities** ribbon tab, select the **Command File** tool in the **Edit** group.

   The **STAAD Editor** window opens.



2. (Optional) You modify the data of the structure in this editor if necessary.
3. Select **File** > **Exit Editor** in the STAAD.Pro Editor window to close.

As stated in " T.2 Methods of creating the model (on page 463) ", you could also have created the same model by typing the relevant STAAD commands into a text file using the STAAD.Pro Editor. If you would like to understand that method, proceed to the next section. If you want to skip that part, proceed to " T.2 Performing the analysis and design (on page 513) " where you will perform the analysis and design on this model.

T.2 Creating the model using the command file

As an alternatively to the procedures described in the proceeding tutorial, you can also create the same STAAD input file using the STAAD.Pro Editor.

Note: A STAAD input file is a plain text file that uses the `.std` file extension. Therefore any standard text editor such as Notepad can also be used to create the command file. However, the STAAD.Pro Editor offers the advantage of syntax checking as you type the commands. The STAAD command syntax are highlighted by command, keyword, value, etc.

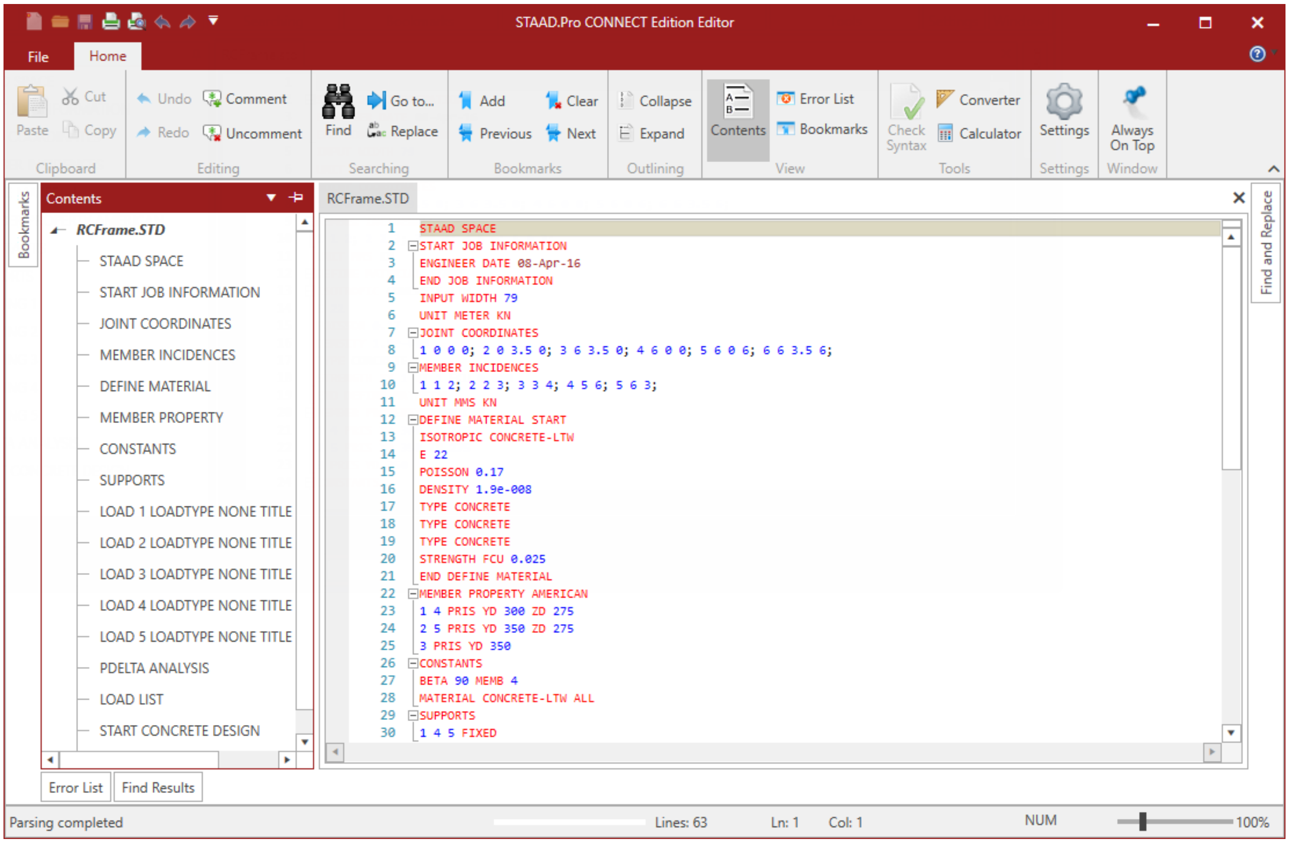


Figure 59:

To start a new STAAD input file using the STAAD.Pro Editor, follow the procedure described in T.2 Creating a new structure (on page 465). Then select the **Command File** tool in the **Edit** group on the **Utilities** ribbon tab. The STAAD.Pro Editor window opens with the basic commands for your model entered.

For this tutorial, delete all the command lines displayed in the editor window and type the lines shown below. While not necessary, this will allow you to learn more about the required and optional command lines for an input file.

STAAD commands are *not* case sensitive (i.e., they may be typed in upper *or* lower case letters). By convention, this and most input files use all caps, though.

For most all commands and keywords, the first three letters of a keyword are all that are needed. The rest of the letters of the word are not required, but are useful to present a user-friendly command language in mostly plain English for later reference. By convention, the required letters in a command or keyword are underlined here (“`PLANE`” = “`PLA`” = “`plane`” = “`pla`”).

```
STAAD SPACE RC FRAMED STRUCTURE
```

Every input has to start with the word STAAD. The word SPACE signifies that the structure is a space frame structure (3-D) and the geometry is defined through X, Y and Z coordinates.

```
UNIT METER KN
```

Specifies the unit to be used.

```
JOINT COORDINATES
1 0 0 0 ; 2 0 3.5 0 ; 3 6 3.5 0
4 6 0 0 ; 5 6 0 6 ; 6 6 3.5 6
```

Joint number followed by X, Y and Z coordinates are provided above. Semicolon signs (;) are used as line separators. That enables you to provide multiple sets of data on one line.

```
MEMBER INCIDENCES
1 1 2 ; 2 2 3 ; 3 3 4
4 5 6 ; 5 6 3
```

Defines the members by the joints they are connected to.

```
UNIT MMS
KN
MEMBER PROPERTY AMERICAN
1 4 PRIS YD 300 ZD 275
2 5 PRIS YD 350 ZD 275
3 PRIS YD 350
```

Member properties have been defined above using the PRISMATIC attribute for which YD (depth) and ZD (width) values are provided in MM unit. When YD and ZD are provided together, STAAD considers the section to be rectangular. When YD alone is specified, the section is considered to be circular. Details are available in Technical Reference of STAAD Commands (on page 2196).

```
CONSTANTS
E 22 MEMB 1 TO 5
```

Material constant E (modulus of elasticity) is specified as 22KN/sq.mm following the command CONSTANTS.

```
UNIT METER KN
CONSTANTS
DENSITY 25.0 ALL
POISSON 0.17 ALL
```

Length unit is changed from MMS to METER to facilitate the input of Density. Next, the Poisson's Ratio is specified.

```
BETA 90 MEMB 4
```

In the absence of any explicit instructions, STAAD will orient the beams and columns of the structure in a pre-defined way (see General Engineering Theory (on page 2085) for details.) In order to orient member 4 so that its longer edges (sides parallel to local Y axis) are parallel to the global Z axis, you must apply a beta angle of 90 degrees.

```
SUPPORT
1 4 5 FIXED
```

Joints 1, 4 and 5 are defined as fixed supported.

```
UNIT METER KG
LOAD 1 DEAD LOAD
```

Force units are changed from KN to KG to facilitate the input of loads. Load case 1 is initiated along with an accompanying title.

```
SELFWEIGHT Y -1
```

One of the components of load case 1 is the selfweight of the structure acting in the global Y direction with a factor of -1.0. Since global Y is vertically upward, the factor of -1.0 indicates that this load will act downwards.

```
MEMBER LOAD
2 5 UNI
GY -400
```

Load 1 contains member loads also. GY indicates that the load is in the global Y direction. The word UNI stands for uniformly distributed load. Loads are applied on members 2 and 5.

```
LOAD 2 LIVE LOAD
```

Load case 2 is initiated along with an accompanying title.

```
MEMBER LOAD
2 5 UNI
GY -600
```

Load 2 also contains member loads. GY indicates that the load is in the global Y direction. The word UNI stands for uniformly distributed load. Loads are applied on members 2 and 5.

```
LOAD 3 WIND LOAD
```

Load case 3 is initiated along with an accompanying title.

```
MEMBER LOAD
1 UNI
GX 300
4 UNI
GX 500
```

Load 3 also contains member loads. GX indicates that the load is in the global X direction. The word UNI stands for uniformly distributed load. Loads are applied on members 1 and 4.

```
LOAD 4  DEAD + LIVE
```

Load case 4 is initiated along with an accompanying title.

```
REPEAT LOAD
1 1.2 2 1.5
```

Load case 4 illustrates the technique employed to instruct STAAD to create a load case which consists of data to be assembled from other load cases specified earlier. This repeat load case instructs the program to analyze the structure for loads from cases 1 and 2 acting simultaneously. The load data values from load case 1 are multiplied by a factor of 1.2, and the resulting values are utilized in load case 4. Similarly, the load data values from load case 2 are multiplied by a factor of 1.5, and the resulting values too are utilized in load case 4.

```
LOAD 5 DEAD + WIND
```

Load case 5 is initiated along with an accompanying title.

```
REPEAT LOAD
1 1.1 3 1.3
```

This repeat load case instructs the program to analyze the structure for loads from cases 1 and 3 acting simultaneously.

```
PDELTA ANALYSIS
```

The PDELTA ANALYSIS command is an instruction to the program to execute a second-order analysis and account for P-delta effects.

```
LOAD LIST 4 5
```

The above LOAD LIST command is a means of stating that all further calculations should be based on the results of load cases 4 and 5 only. The intent here is to restrict concrete design calculations to that for load cases 4 and 5 only.

```
START CONCRETE DESIGN
CODE ACI
UNIT MMS
NEWTON
CLT 25 ALL
CLB 30 ALL
CLS 25 ALL
FC 25 ALL
FYMAIN 415 ALL
TRACK 1 ALL
```

The first line is the command that initiates the concrete design operation. The values for the concrete design parameters are defined in the above commands. Design is performed per the ACI Code. The length units are changed from METER to MMS to facilitate the input of the design parameters. Similarly, force units are changed from KG to NEWTON. The TRACK value dictates the extent of design related information which should be produced by the program in the output. The parameters specified include CLT (Clear cover for top surface), CLB (Clear cover for bottom surface), CLS (Clear cover for sides), FC(Strength of concrete), and FYMAIN (Ultimate strength of steel). These parameters are described in D1.F.3 Design Parameters (on page 1201).

```
DESIGN BEAM 2 5
DESIGN COLUMN 1 3 4
```

The above commands instruct the program to design beams 2 and 5 for flexure, shear and torsion, and to design columns 1, 3 and 4 for axial load and biaxial bending.

```
END CONCRETE DESIGN
```

This command terminates the concrete design operation.

```
FINISH
```

This command terminates the STAAD run.

Save the input file and close the editor. The model is opened in the STAAD.Pro interface.

T.2 Performing the analysis and design

STAAD.Pro performs Analysis and Design simultaneously.

1. On the **Analysis and Design** ribbon tab, select the **Run Analysis** tool in the **Analysis** group. .

   

   As the analysis progresses, several messages appear on the screen as shown in the figure below.

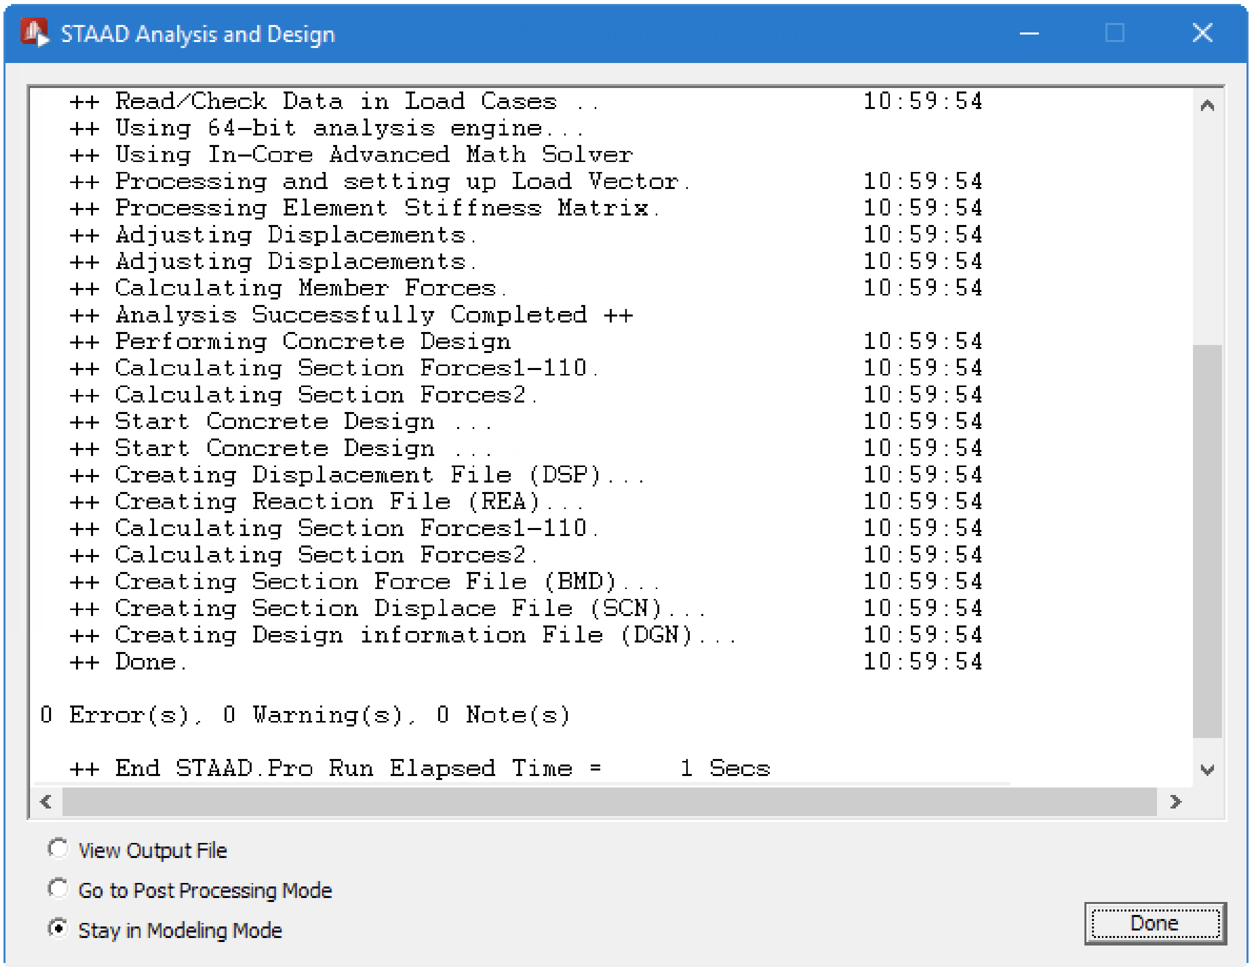

Figure 60:

2. Select the **View Output File** option once the analysis and design are complete.

   The three options are indicative of what will happen after you click **Done**.

View Output File	This option opens the output file created by STAAD. The output file contains the numerical results produced in response to the various input commands specified during the model generation process. It also provides you with important messages of any errors were encountered, and if so, whether the analysis and design was successfully completed or not. See T.1 Viewing the output file (on page 447) for details on viewing and understanding the contents of the output file.
Go to Post Processing Mode	This option opens the graphical Post-processor mode, which can be used to extensively review and verify the results. This mode allows you to view the results graphically, plot result diagrams, produce reports, etc. See T.1 Post-Processing (on page 455) for details on the Post processing mode.
Stay in Modeling Mode	This option closes the dialog and remains in the Model generation mode of the program, where you initiated the analysis. This is useful if you want to make further changes to the input file.

3. Click **Done**.
   The STAAD.Pro Output Viewer window opens.

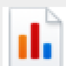
T.2 Viewing the output file

During the analysis process, STAAD.Pro creates an Output file. This file provides important information on whether the analysis was performed properly.

For example, if STAAD.Pro encounters an instability problem during the analysis process, it will be reported in the output file.

Note:

If you did not select to open the output file after running the analysis in the previous procedure, you can open it any time through the user interface. On the **Utilities** ribbon tab, select the **Analysis Output** tool in the **View** group.



Tip: By default, the output file contains a listing of the entire input also. You may choose not to print the echo of the input commands in the Output file. On the **Analysis and Design** ribbon tab, select the **Miscellaneous Commands** > **Set Echo** tool option from the menu bar and the select the **Echo Off** option in the **Set Echo** dialog.

It is *strongly recommended* that you review the entire output file to ensure that the results are reasonable and that there are no error messages or warnings reported, etc. Errors encountered during the analysis & design can disable access to the post-processing mode. The information presented in the output file is a crucial indicator of whether or not the structure satisfies the engineering requirements of safety and serviceability.

T.2 Post-Processing

STAAD.Pro offers extensive result verification and visualization facilities. These facilities are accessed from the **Post Processing** Mode. The **Post Processing** mode is used to verify the analysis and design results and generate reports.

T.2 Opening the postprocessing workflow

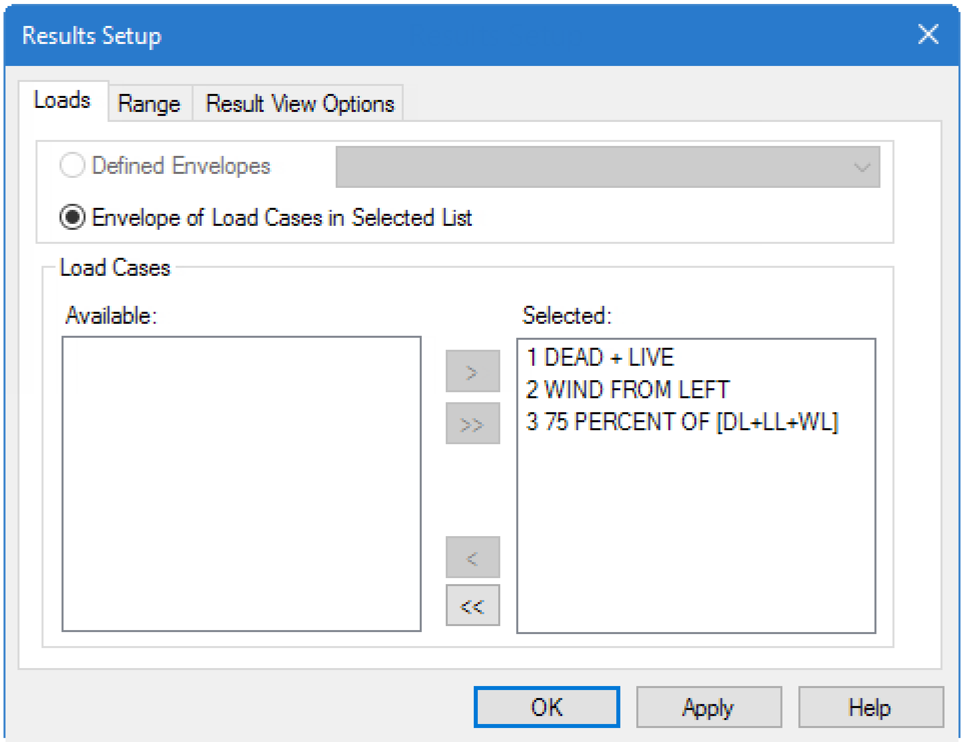
You can open the Postprocessing workflow anytime there are current analysis results for your model.

If you selected to open the postprocessing mode after T.2 Performing the analysis and design (on page 513), then you can skip to step 2.

1. On the **Workflows** panel, select **Postprocessing**.

   The **Results Setup** dialog opens.



2. (Optional) Select the load cases for which to display the results.

   Tip: All load cases are selected by default.

   For this tutorial, we will use all load cases.

T.2 Viewing the deflection diagram

1. Select the **Displacement** page in **Postprocessing** page control bar.

   Tip: This page is the default page when you open the Postprocessing workflow.

   Note: You can display the Deflection diagram on most results pages by selecting the **Deflection** tool . The tool remains depressed when the displacement is displayed.

   The displacement diagram is drawn on the structure. The **Node Displacements table** and **Beam Relative Displacement Detail** table open. See T.2 The Node Displacements Table (on page 526) for details on these tables.
2. (Optional) If the deflection is not exaggerated enough to clearly identify, you can change the scale:
   a. On the Results ribbon tab, select the **Scale** tool in the **Configuration** group.

   
   The **Diagrams** dialog opens displaying the **Scales** tab.

> **Tip:** You can also open the **Diagrams** dialog by selecting the **Structure** tool or by right-clicking in the View area and then selecting **Structure Diagrams** from the pop-up menu.

b. Change the **Displacement** value.

> **Tip:** Smaller numbers exaggerate the deflected shape.

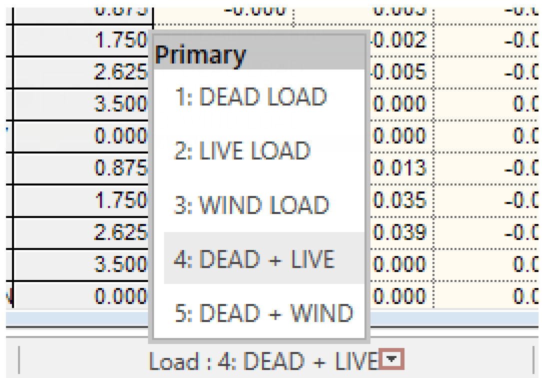
Type a value of 5 (mm per m) to clearly see the deflection due to load case 5.

c. Click **Apply**.

> **Tip:** You can set the **Apply Immediately** option on this tab to view the scale change as you use the up/ down arrows in the Displacement field.

d. Click **OK**.

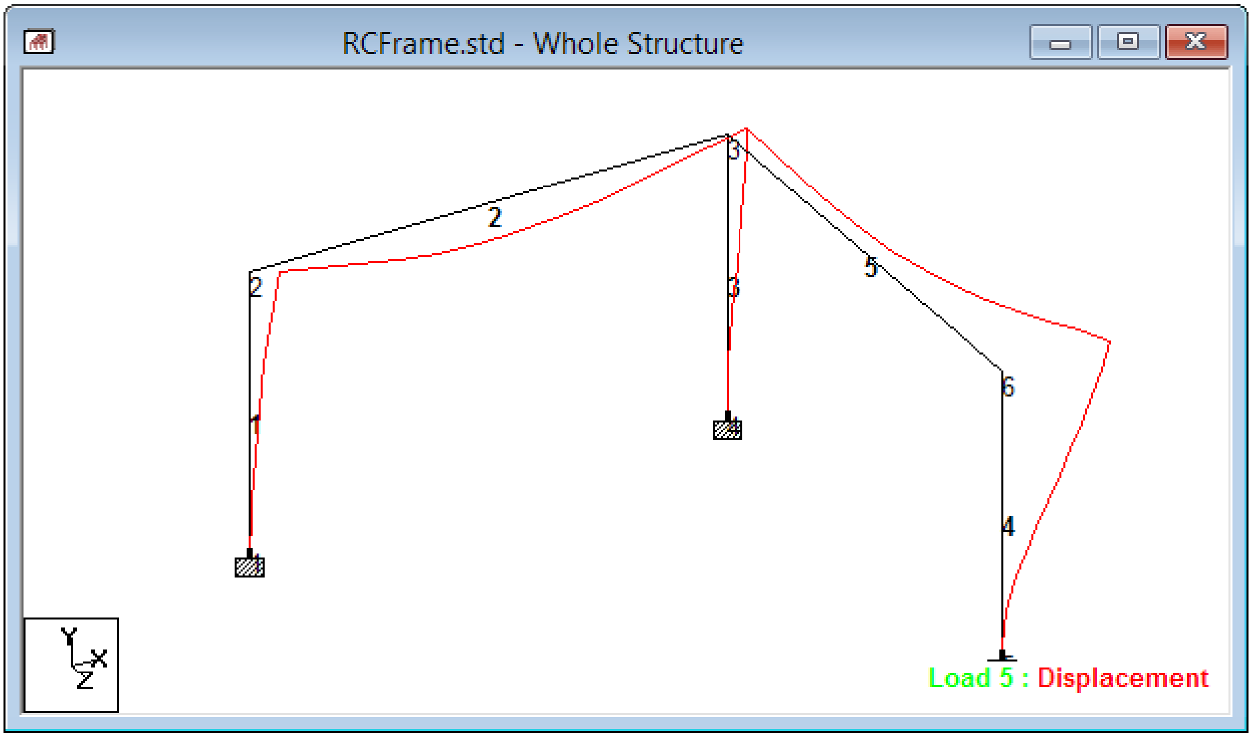
3. To change the load case being displayed, select from the current **Load** list in the window status bar.



> **Tip:** Alternatively, select the **Structure** tool  in the **Configuration** group on the **Results** toolbar. The active load case can be selected on the **Load and Results** tab in the **Diagrams** dialog.

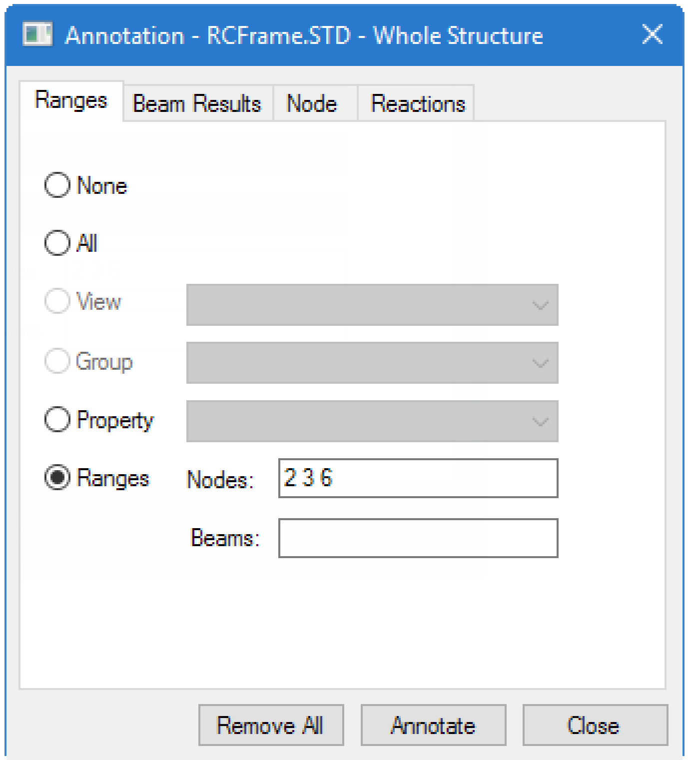
The results displayed are for the selected load case only.

Select **5: DEAD + WIND** for this tutorial.



4. Annotate the deflection at specific nodes:
   a. On the Results ribbon tab, select the **Annotate** tool in the **Configuration** group.

   The **Annotation** dialog opens.
   b. On the **Ranges** tab, select the **Ranges** option and then type 2 3 6 (spaced node number list) in the **Nodes** field.



c. Select the **Node** tab and then check the **Resultant** option.

Resultant stands for the square root of sum of squares of values of X, Y and Z displacements.

d. Click **Annotate** and then click **Close**.

The structure deflection diagram is annotated for load case 5, as in the following figure.

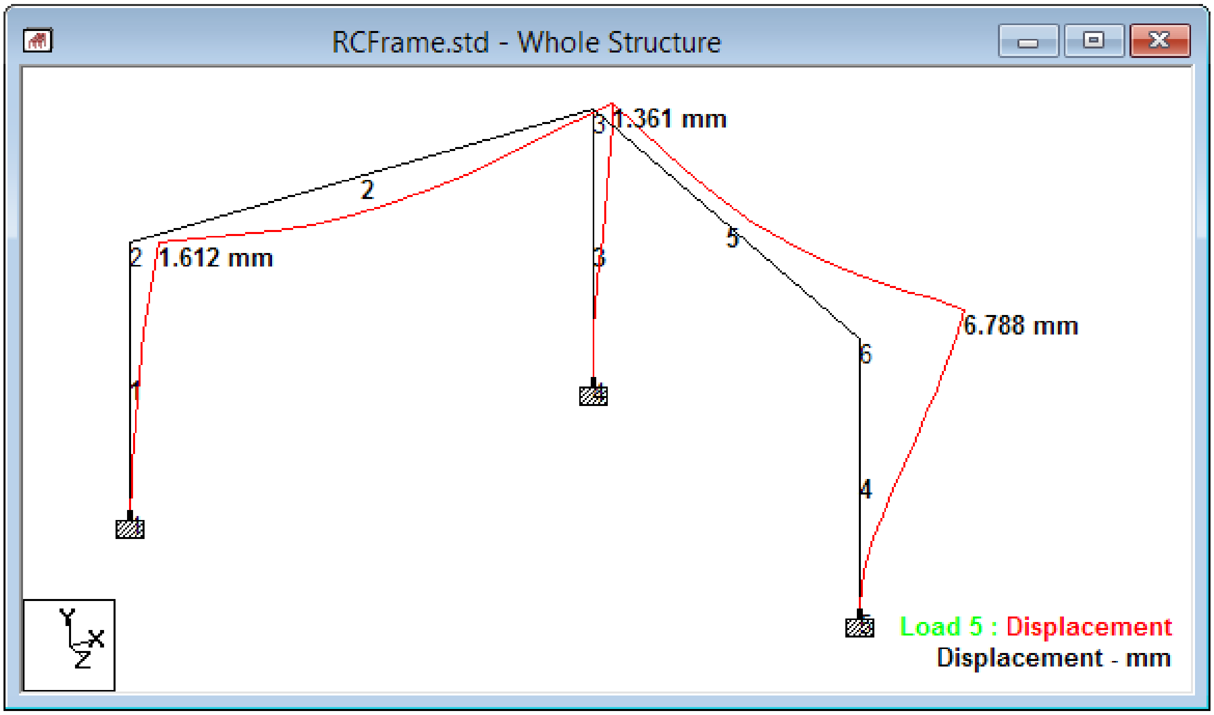


Figure 61:

5. Change the display units for displacement:

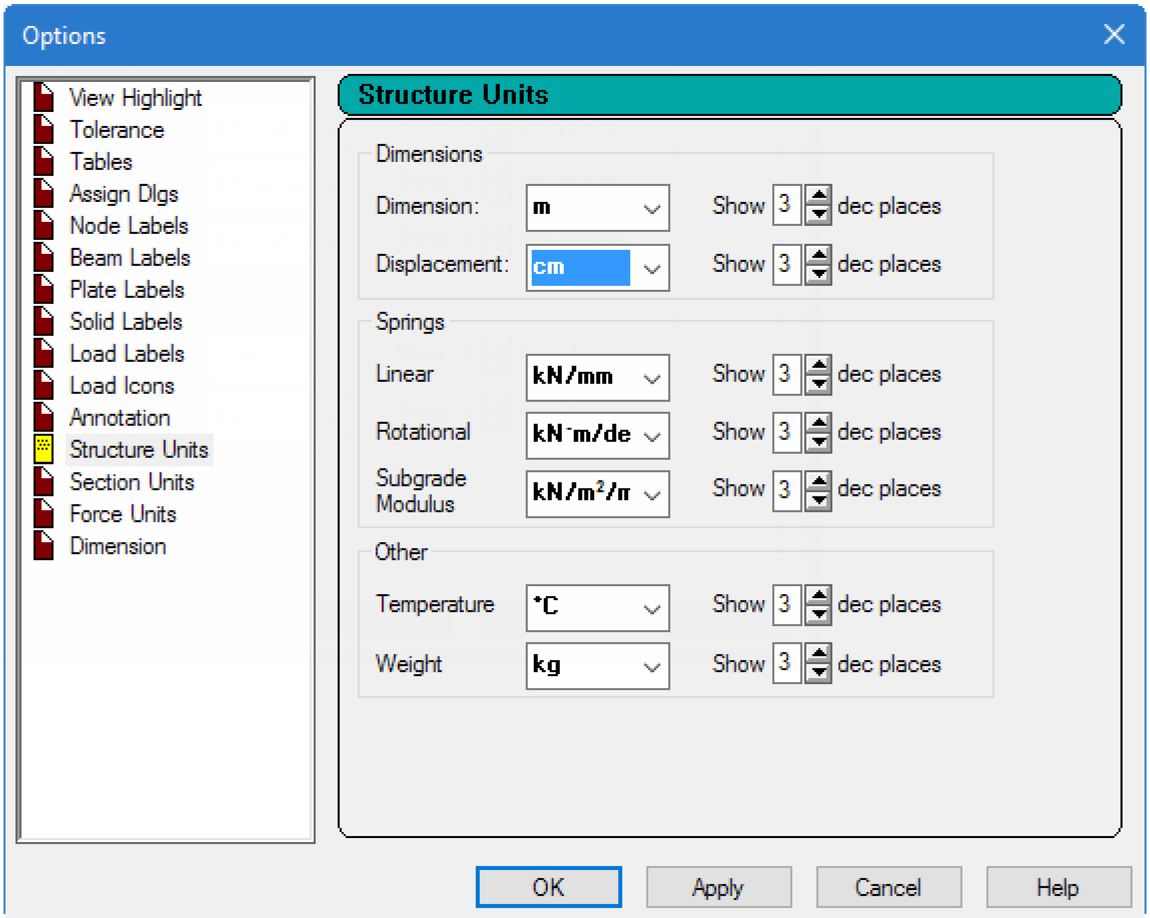
   The units in which displacement values are displayed in the post-processing mode are referred to as the display units.

   a. On the **File** ribbon tab, select **Display Options** on the **Settings** tab.

      The **Options** dialog opens.

   b. Select the **Structure Units** tab.

   c. Change **Displacement** selection from **mm** (millimeter) to **cm** (centimeter).



d. Click **OK**.

The diagram will be updated to reflect the new units.

T.2 The Node Displacements Table

When the **Displacements** page is selected, two tables open on the right side of the program window.

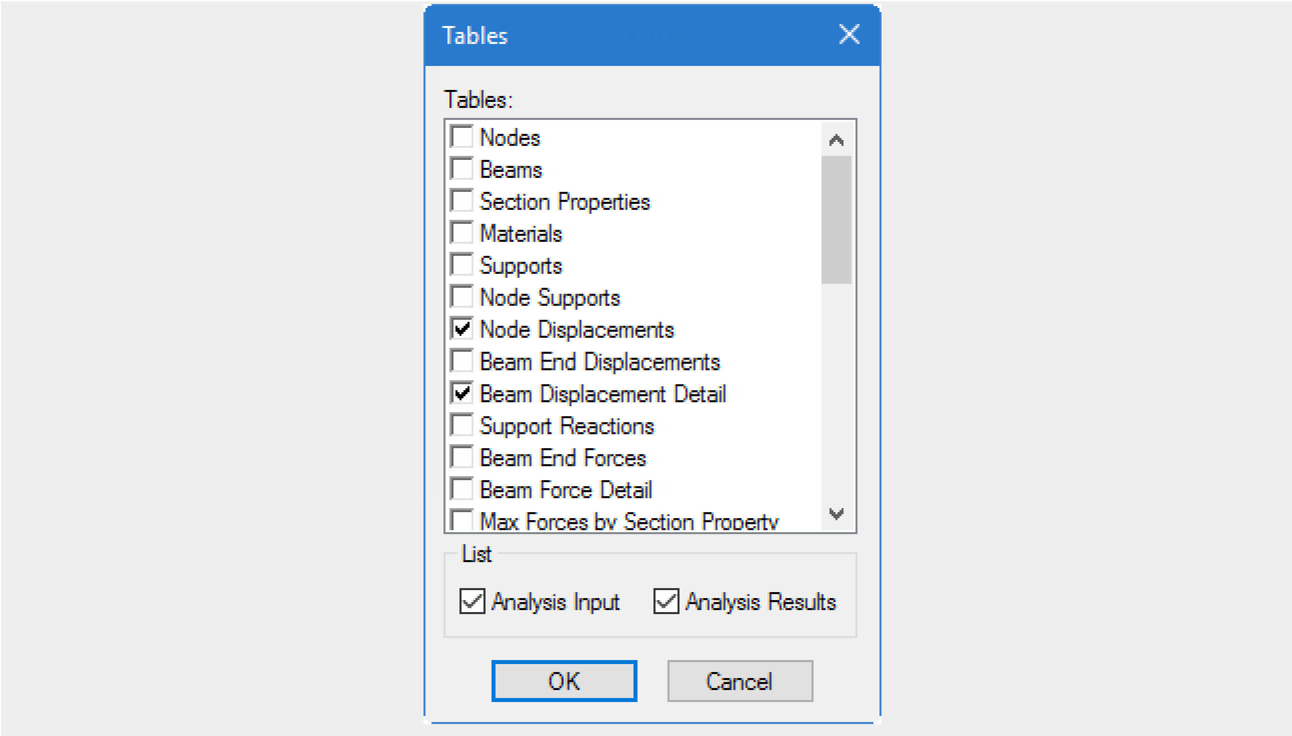
The **Node Displacements** table lists the displacement values for every node for every selected load case.

The **Beam Relative Displacement Detail** table displays the displacements along beams at intermediate points.

Note: The load cases included in results tables can be restricted using the **Results Setup** dialog. Refer to T.2 Restricting the load cases for results (on page 536) for details.

Tip:

You can reopen any closed tables from the **Tables** dialog, which is opened by selecting the **Tables** tool in the **Windows** group on the **View** ribbon tab.



The **Node Displacements** table

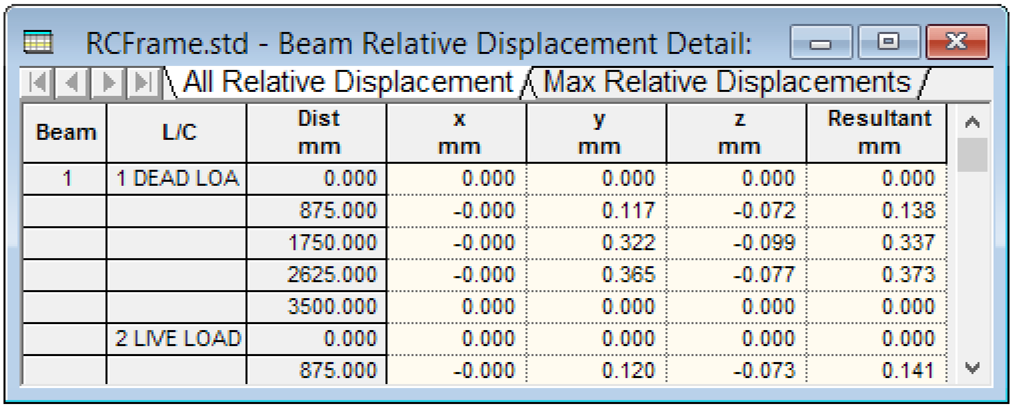
		Horizontal	Vertical	Horizontal	Resultant	Rotational		
Node	L/C	X mm	Y mm	Z mm	mm	rX rad	rY rad	rZ rad
1	1 DEAD LOA	0.000	0.000	0.000	0.000	0.000	0.000	0.000
	2 LIVE LOAD	0.000	0.000	0.000	0.000	0.000	0.000	0.000
	3 WIND LOA	0.000	0.000	0.000	0.000	0.000	0.000	0.000
	4 DEAD + LIV	0.000	0.000	0.000	0.000	0.000	0.000	0.000
	5 DEAD + WI	0.000	0.000	0.000	0.000	0.000	0.000	0.000
2	1 DEAD LOA	-0.062	-0.038	0.369	0.376	0.000	0.000	-0.001

Figure 62:

All This tab presents all nodal displacements in tabular form for all load cases and all degrees of freedom.

Summary This tab, shown in the figure below, presents the maximum and minimum nodal displacements (translational and rotational) for each degree of freedom. All nodes and all Load Cases specified during the Results Setup are considered. Maximum values for all degrees of freedom are presented with the corresponding Node of occurrence and Load Case number (L/C).

The Beam Relative Displacement Detail table



Beam	L/C	Dist mm	x mm	y mm	z mm	Resultant mm
1	1 DEAD LOA	0.000	0.000	0.000	0.000	0.000
		875.000	-0.000	0.117	-0.072	0.138
		1750.000	-0.000	0.322	-0.099	0.337
		2625.000	-0.000	0.365	-0.077	0.373
		3500.000	0.000	0.000	0.000	0.000
	2 LIVE LOAD	0.000	0.000	0.000	0.000	0.000
		875.000	-0.000	0.120	-0.073	0.141

Figure 63:

All	The **All** tab presents the displacements of members at intermediate section points. All specified members and all specified load cases are included. The table shows displacements along the local axes of the members, as well as their resultants.
Max Displacements	The **Max Displacements** tab presents the summary of maximum sectional displacements (see figure below). This table includes the maximum displacement values and location of its occurrence along the member, for all specified members and all specified load cases. The table also provides the ratio of the span length of the member to the resultant maximum section displacement of the member.

T.2 Viewing the force and moment diagrams

Tip: You can display force or moment diagrams on most any page in the Post-Processing, but is recommended to use the Beam | Forces page to do so.

1. Select the **Beam Results** page on the **Postprocessing** page control bar.

   Note: You can display force and moment diagrams on most results pages by selecting corresponding tool from the **View Result** group on the **Results** ribbon tab. The corresponding tool remains depressed when the diagram is displayed.

   The bending moment MZ is drawn on the structure by default. The **Beam End Forces** table and **Beam Force Detail** table open. T.2 The Beam Forces Table (on page 533) for details on these tables.
2. To change the force or moment (i.e., degree of freedom) diagram displayed, either:

   select the corresponding diagram tool from the **View Result** group on the **Results** ribbon tab

   or

   select **Structure** tool in the **Configuration** group on the **Results** ribbon tab and then select the degrees of freedom to display from the **Beam Forces** group on the **Loads and Results** tab.

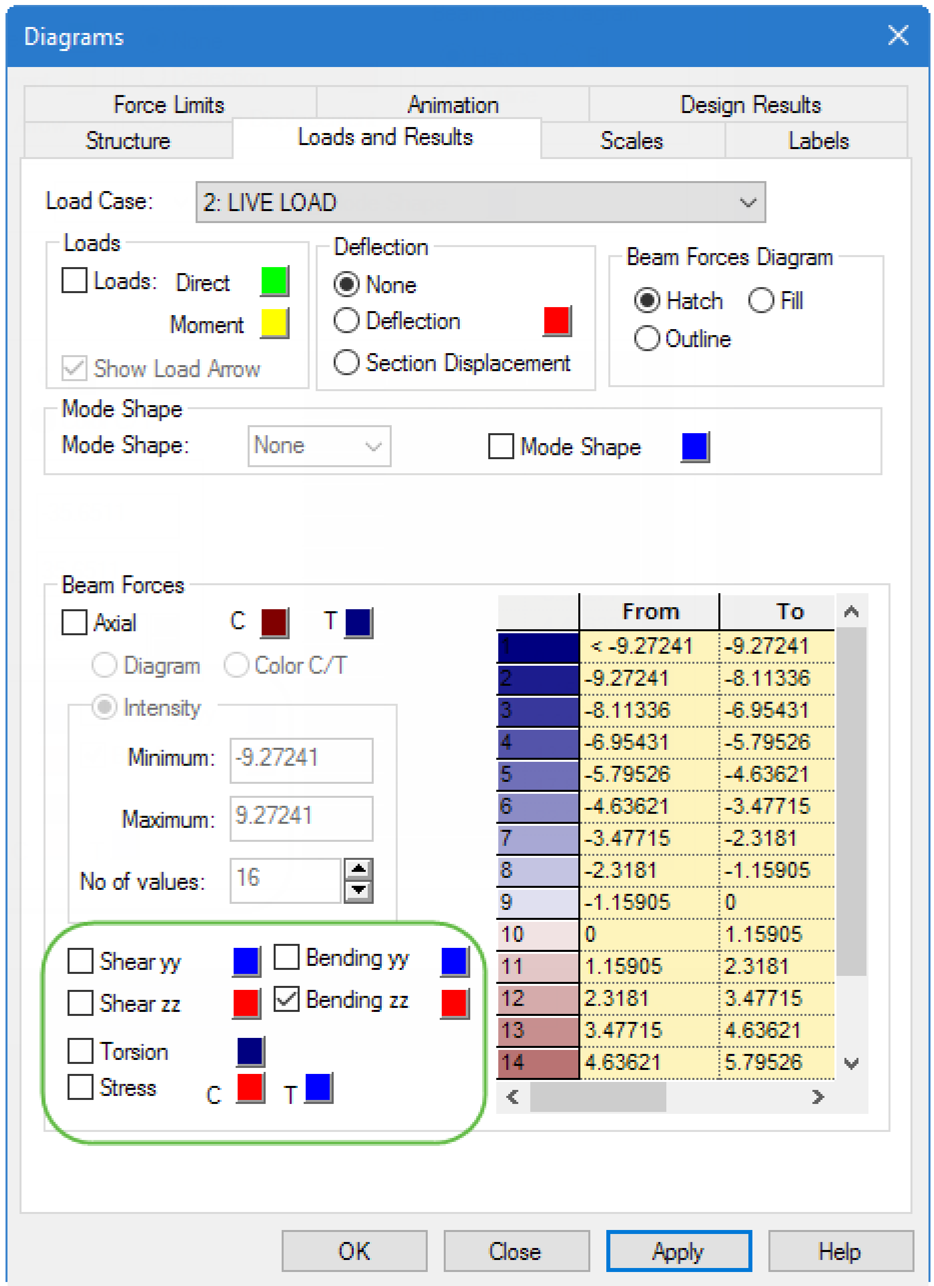


Table 23: Results diagram tools

Tool	What it does
	Displays the axial force diagram
	Displays the shear Y diagram

Tool	What it does
	Displays the shear Z diagram
	Displays the torsion diagram
	Displays the bending Y diagram
	Displays the bending Z diagram
	Displays the beam stress (tension and compression) diagrams.

Note: The **Load and Results** tab on the **Diagrams** dialog can also be used to select the color for each diagram as well as the display method (i.e., hatched, filled, or outline).

Tip: You can display multiple diagrams simultaneously.

3. (Optional) If the force or moment diagram is not exaggerated enough to clearly identify, you can change the scale:
   a. On the Results ribbon tab, select the **Scale** tool in the **Configuration** group.

      
      The **Diagrams** dialog opens displaying the **Scales** tab.

      Tip: You can also open the **Diagrams** dialog by selecting the **Structure** tool or by right-clicking in the View area and then selecting **Structure Diagrams** from the pop-up menu.

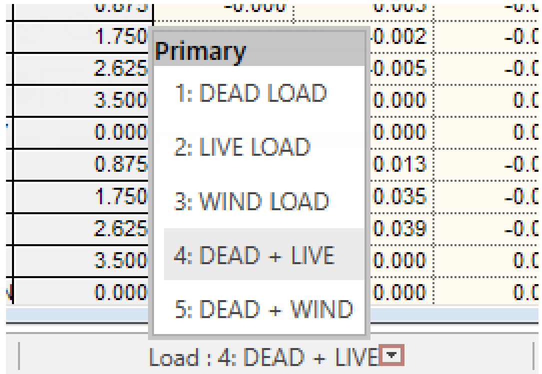
   b. Change the value in the corresponding **Results Scales** group to the diagram currently displayed.

      Tip: Smaller numbers exaggerate the diagram.

      Type a value of `50` (kN/m per m) to clearly see the **Bending Z** due to load case 5.
   c. Click **Apply**.

      Tip: You can set the **Apply Immediately** option on this tab to view the scale change as you use the up/down arrows in any of the **Result Scales** fields.

   d. Click **OK**.
4. To change the load case being displayed, select from the current **Load** list in the window status bar.



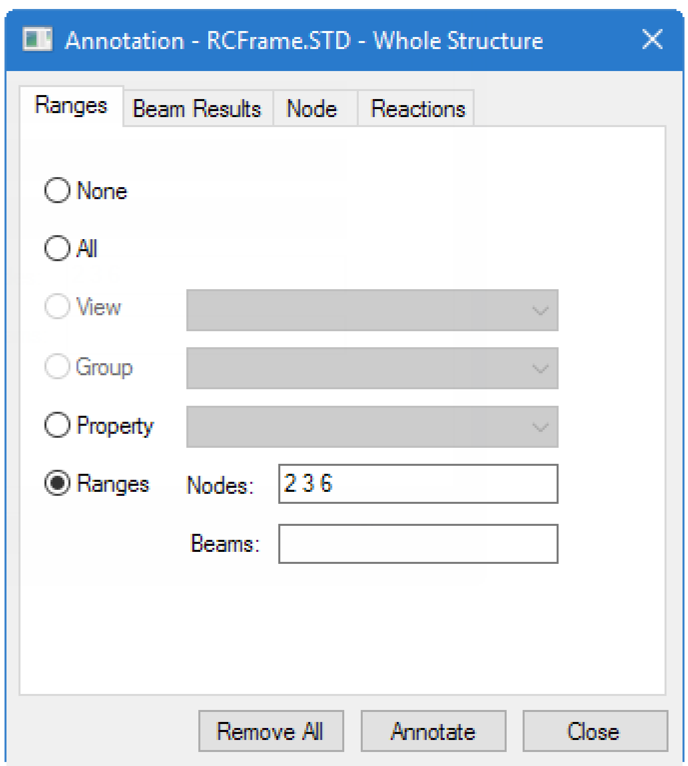
Tip: Alternatively, select the **Structure** tool in the **Configuration** group on the **Results** toolbar. The active load case can be selected on the **Load and Results** tab in the **Diagrams** dialog.

The results displayed are for the selected load case only.

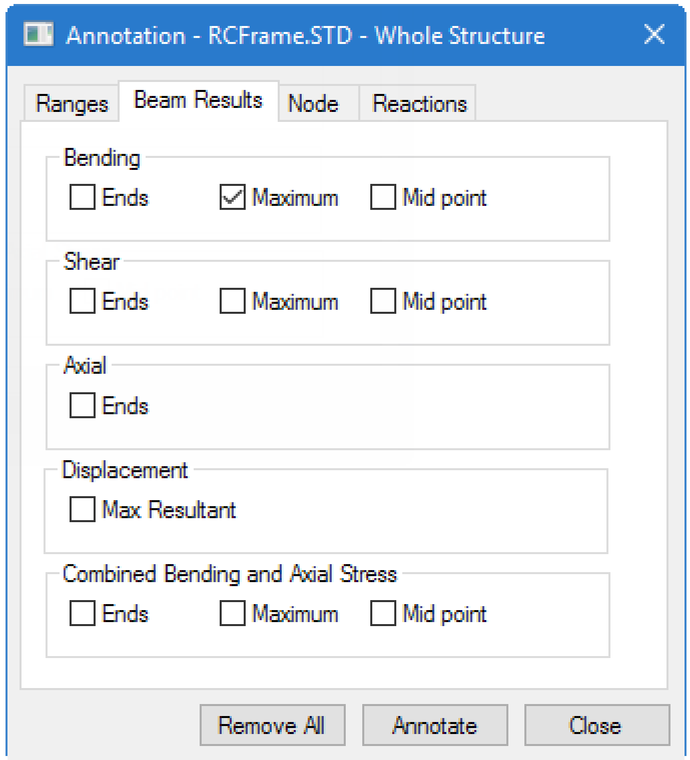
5. Annotate the bending Z moment diagram to display the maximum moment in the beams for load case 5:

a. Select **Results** > **View Value**.
The **Annotation** dialog opens.

b. On the **Ranges** tab, select the **Ranges** option and then type 2 5 (spaced node number list) in the **Beams** field.



c. Select the **Beam Results** tab and then check the **Maximum** option in the **Bending** group.



d. Click **Annotate** and then click **Close**.

The bending Z moment diagram is annotated for load case 5, as in the following figure.

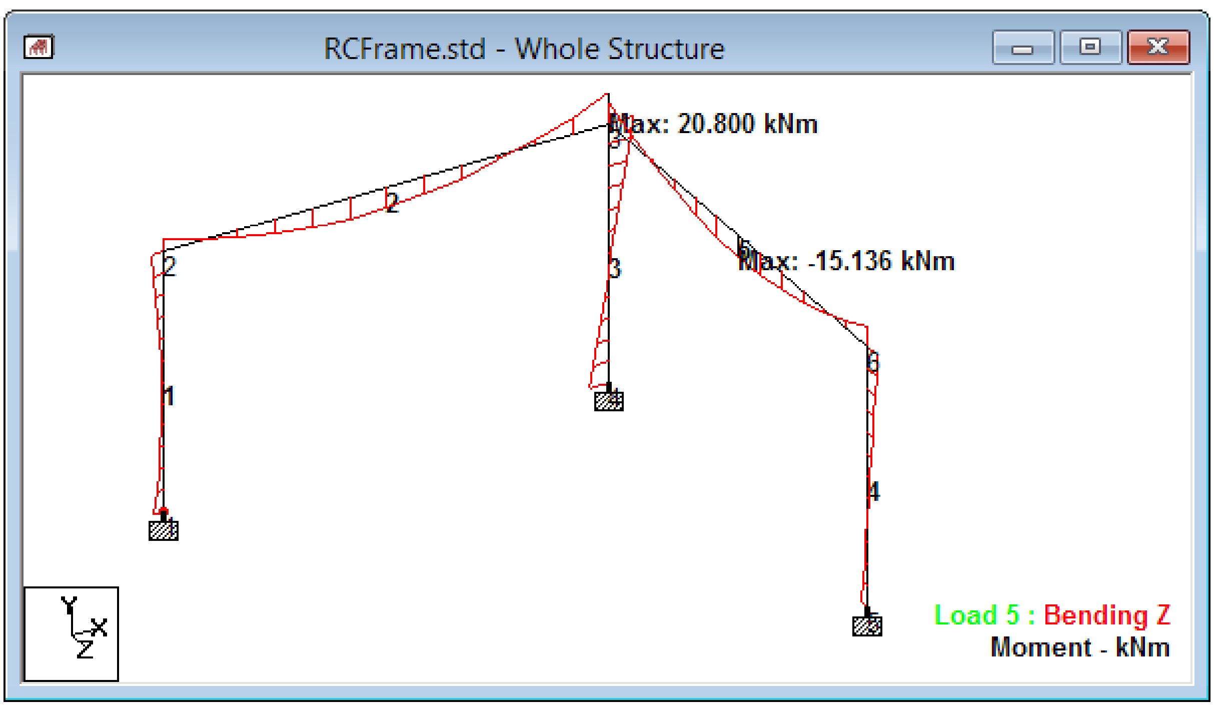


Figure 64:

6. Change the display units for bending moments:

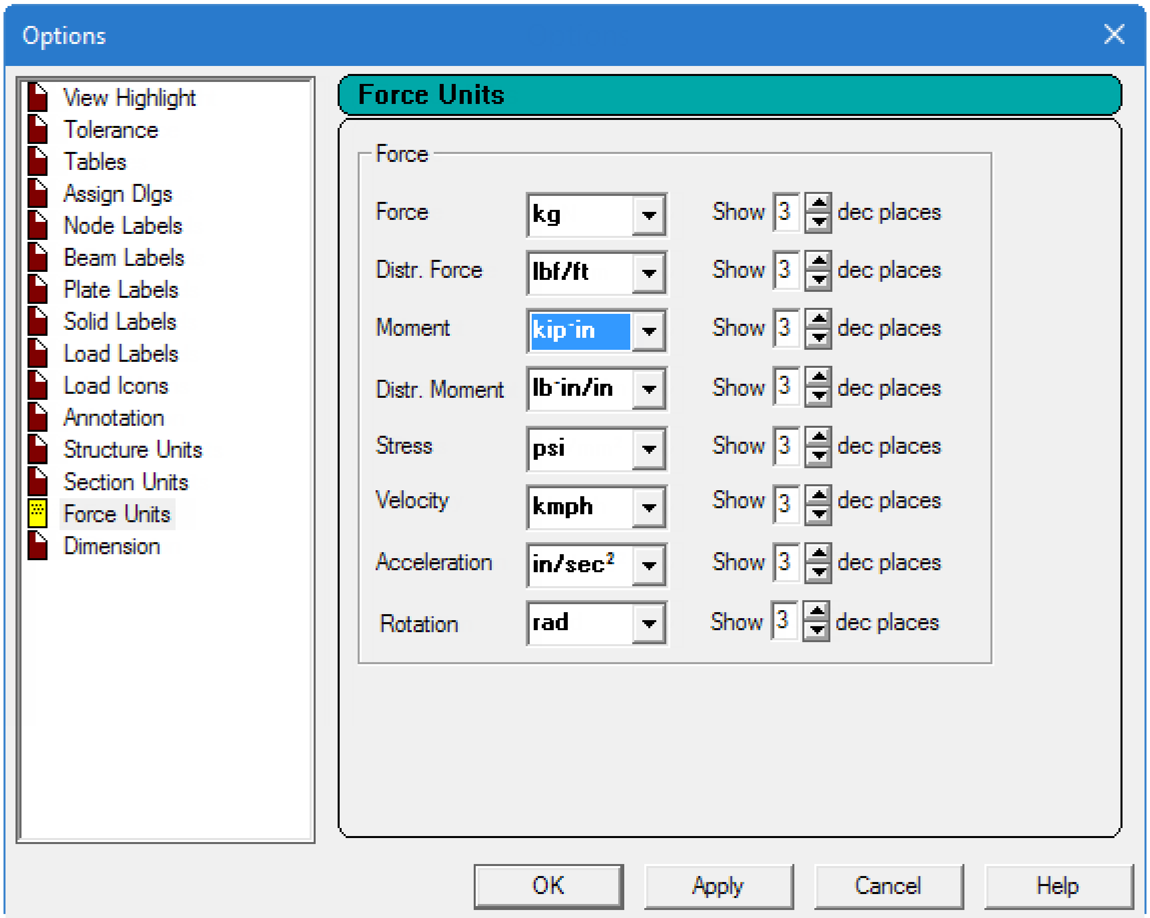
The units in which results values are displayed in the post-processing mode are referred to as the display units.

a. On the **File** ribbon tab, select **Display Options** on the **Settings** tab.

The **Options** dialog opens.

b. Select the **Force Units** tab.

c. Change **Moment** selection from **kNm** (kilonewton meters) to **kip-ft** (kilopound feet).



d. Click **OK**.

The diagram updates to reflect the new units.

T.2 The Beam Forces Table

When the **Beam Results** page is selected in the **Postprocessing** workflow, two tables open on the right side of the program window.

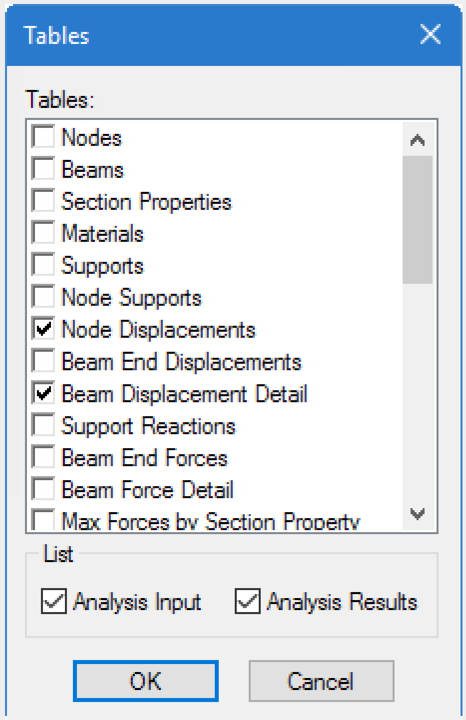
The **Beam End Forces** table lists the axial forces and shear forces, bending and torsional moments in all selected beams for all selected load cases are displayed in a tabular form along the right half of the screen.

The **Beam Force Detail** table lists force and moment values for every node for every selected load case.

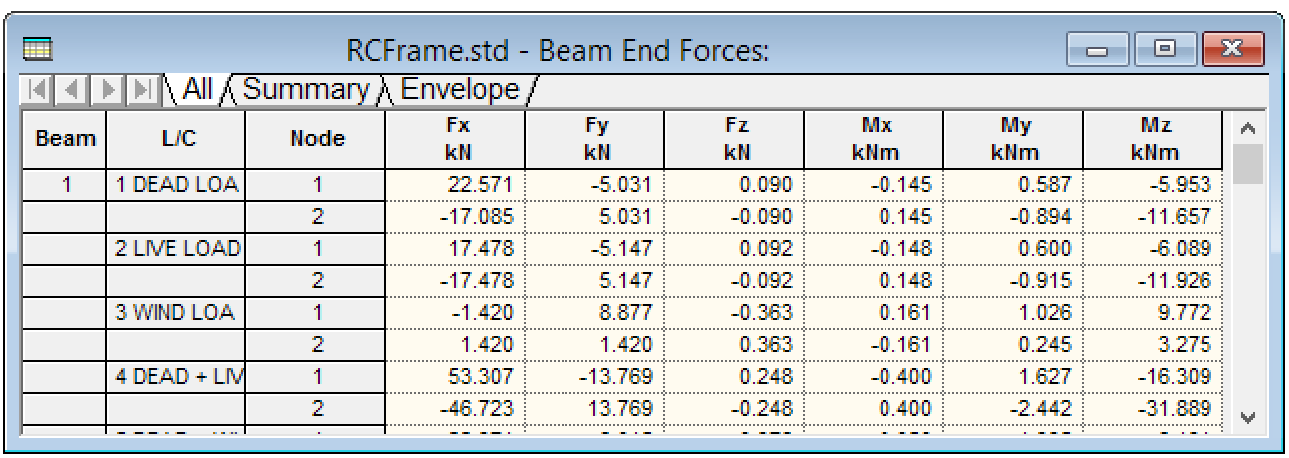
Note: The load cases included in results tables can be restricted using the **Results Setup** dialog. Refer to T.2 Restricting the load cases for results (on page 536) for details.

Tip:

You can reopen any closed tables from the **Tables** dialog, which is opened by selecting the **Tables** tool in the **Windows** group on the **View** ribbon tab.



The **Beam End Forces** table



RCFrame.std - Beam End Forces:

All | Summary | Envelope

Beam	L/C	Node	Fx kN	Fy kN	Fz kN	Mx kNm	My kNm	Mz kNm
1	1 DEAD LOA	1	22.571	-5.031	0.090	-0.145	0.587	-5.953
		2	-17.085	5.031	-0.090	0.145	-0.894	-11.657
	2 LIVE LOAD	1	17.478	-5.147	0.092	-0.148	0.600	-6.089
		2	-17.478	5.147	-0.092	0.148	-0.915	-11.926
	3 WIND LOA	1	-1.420	8.877	-0.363	0.161	1.026	9.772
		2	1.420	1.420	0.363	-0.161	0.245	3.275
	4 DEAD + LIV	1	53.307	-13.769	0.248	-0.400	1.627	-16.309
		2	-46.723	13.769	-0.248	0.400	-2.442	-31.889

Figure 65:

All This tab presents all forces and moments corresponding to all 6 degrees of freedom at the start and end of each selected member for all selected load cases.

Summary This tab, shown in the next figure, presents the maximum and minimum values (forces and moments) for each degree of freedom. All beams and all Load Cases specified during the Results

Setup are considered. Maximum values for all degrees of freedom are presented with the corresponding Node of occurrence and Load Case number (L/C).

Envelope This tab shows a table consisting of the maximum and minimum for each degree of freedom for each member, and the load case responsible for each of those values.

T.2 Viewing the force and moment graphs

The **Graphs** results in the Postprocessing workflow are used to view moment and force graphs such as Axial, Bending zz, Shear yy and Combined Stresses for individual members.

1. Display the beam results graphs:
   a. On the **Results** ribbon tab, select the **Tables** tool in the **View Results** group.
   b. In the **Beam Results** group, select **Graphs**.

   The View window shows the loading on the structure. On the right side of the screen, the force/moment diagrams appear.
2. Select a member in the View window.

   The graphs are plotted for that member in the data area.

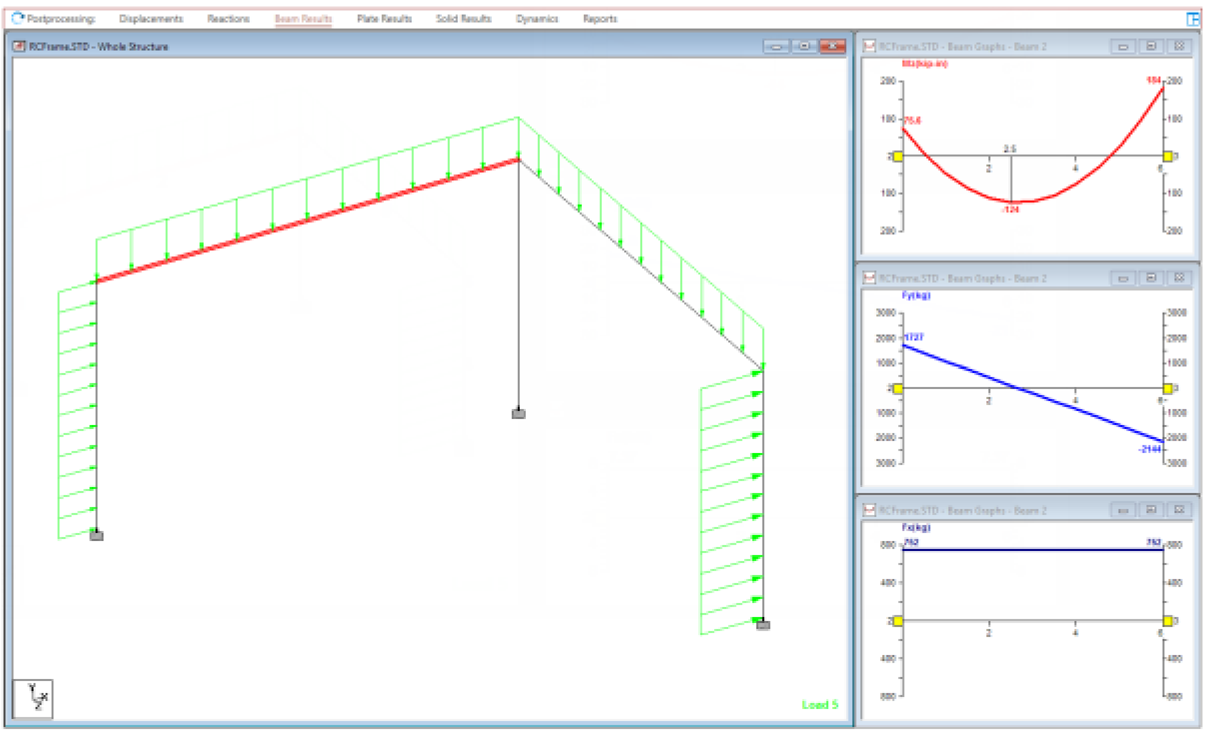


Figure 66: Bending, shear, and axial graphs for Beam 2 under load case 5: DEAD + WIND.

3. To change the diagrams displayed for the current beam and load case selection:
   a. Right-click on any graph window and select **Diagrams** from the pop-up menu.
      The **Diagram** dialog opens.
   b. Set the check box for the degrees of freedom you wish to view in the diagram.

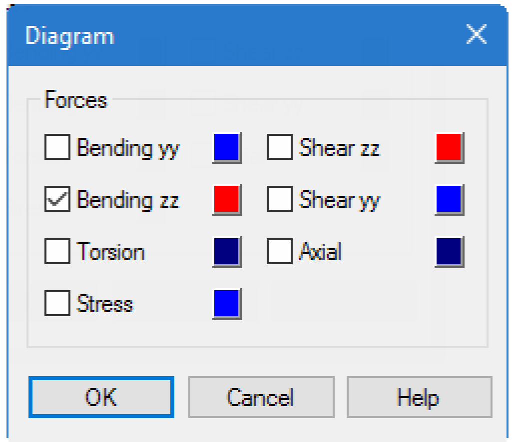

Figure 67:

c. Click **OK** .
The selected degree of freedom is plotted in that window.

T.2 Restricting the load cases for results

To restrict the load cases for which results are viewed, use the following procedure.

1. On the **Results** ribbon tab, select the **Select Load Case** tool in the **Configuration** group.

   The **Results Setup** dialog opens.
2. Click **[<<]**.

   All load cases are moved from the Selected list to the Available list.

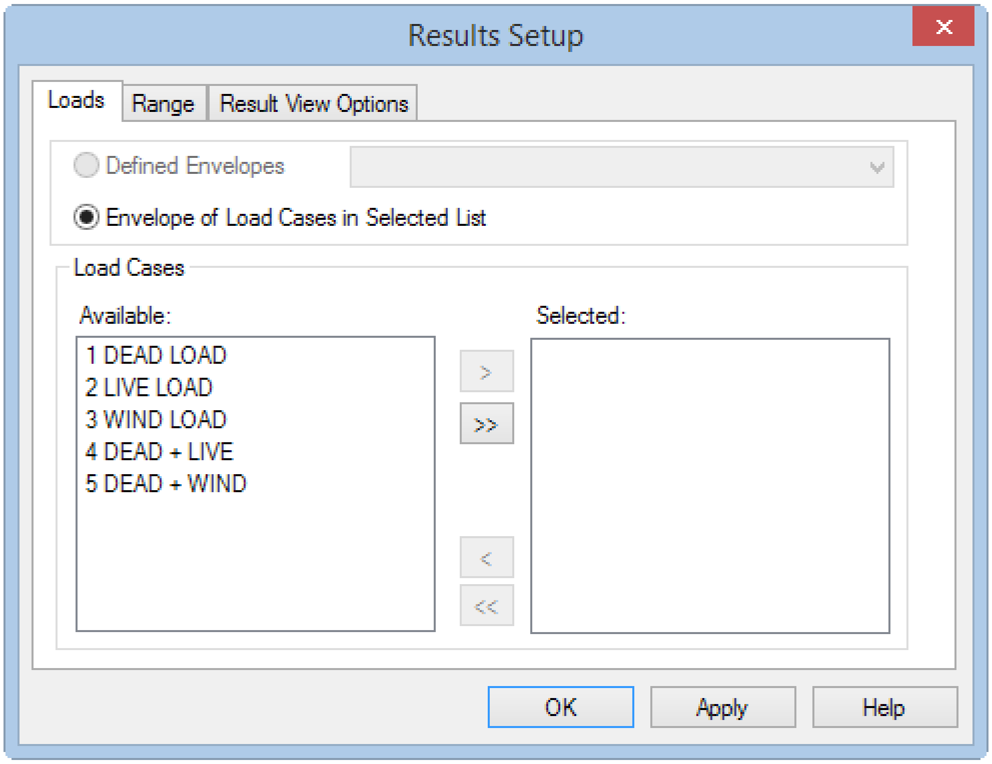

Figure 68:

3. Select two load cases to use for viewing results:
   - **a.** Press and hold the **<Ctrl>** key and then select load cases **1 DEAD LOAD** and **3 WIND LOAD**.
   - **b.** Click **[>]**.
   - **c.** Click **OK**.

T.2 Using Member Query

Member query is a facility where several results for specific members can be viewed at the same time from a single dialog. It is also a place from where many of the member attributes such as the property definition, specifications (releases, truss, cable, etc.) and beta angle can be changed for input purposes.

Note: The **Beam Cursor** tool  is active when the **Beam Results** page is selected.

1. Double-click a member in the View window.

   Tip: Alternately, if you have selected a member you can then select **Tools** > **Query** > **Member**.

   For this example, double-click on member 4.

   The **Beam** dialog opens.

   In the Modeling mode, you can actively edit members using this dialog. In the Post-Processing mode, the member data is presented for review only.

Note: The tabs in the member query dialog reflect the properties of the member along with any analysis and design results available. Changing the model will void any results and thus remove these tabs until another analysis is performed.

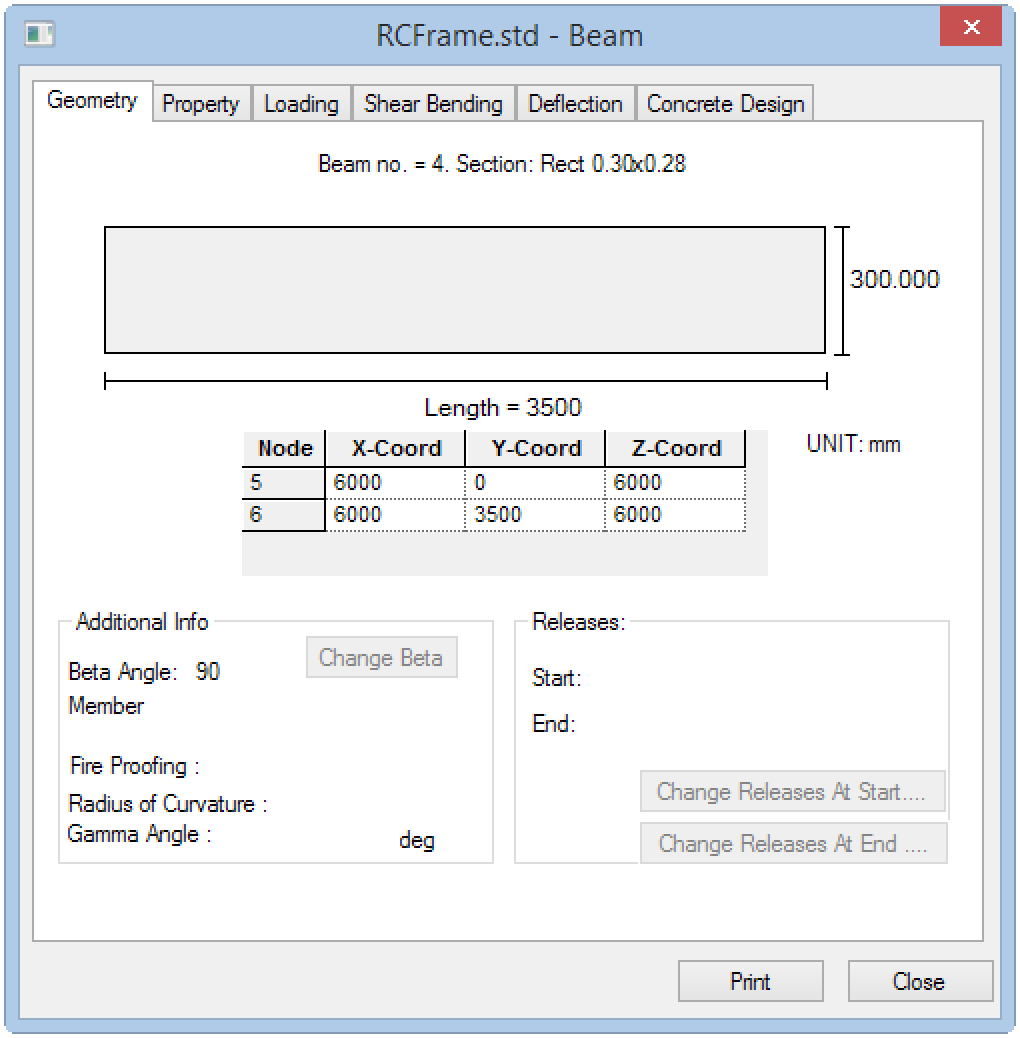

Figure 69:

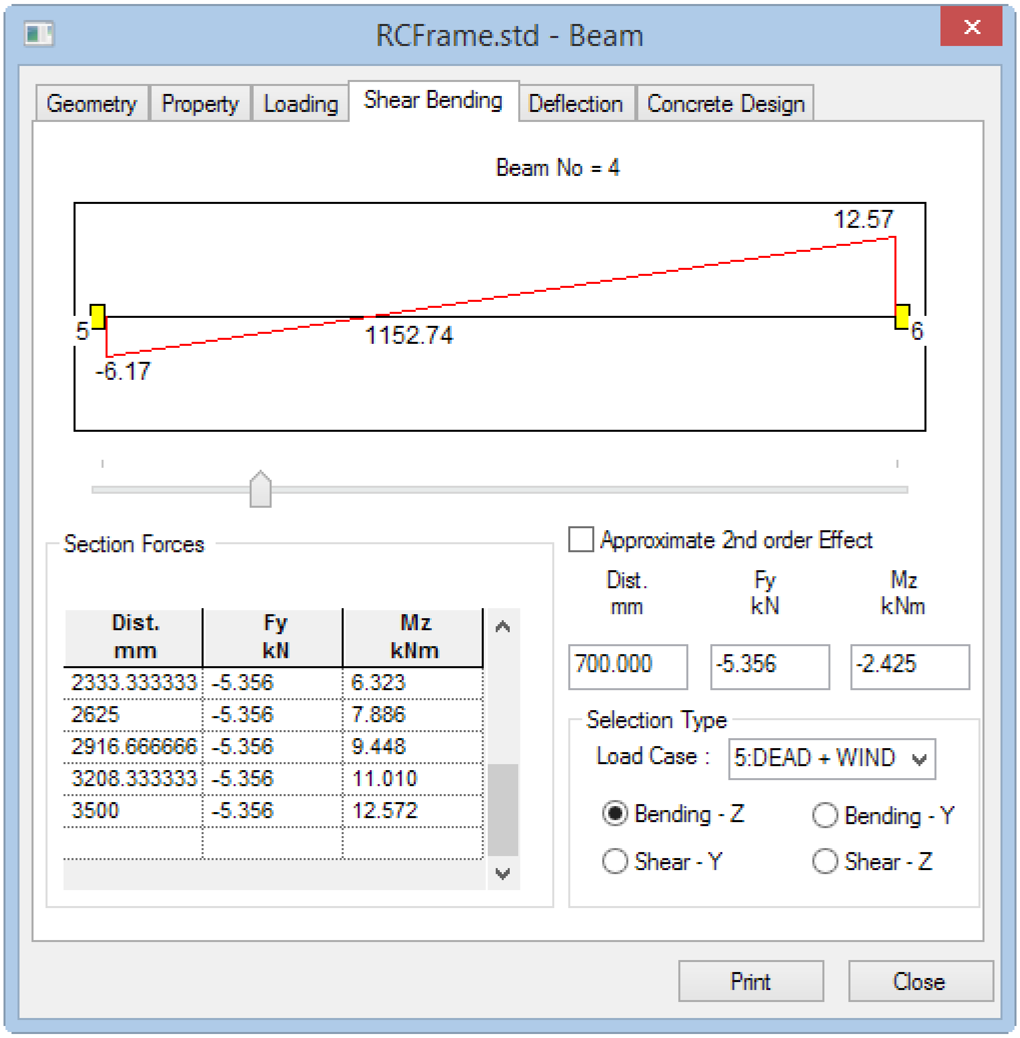
2. Select the **Shear Bending** tab.

   Here you can review shear and bending diagrams for the member for a selected load case. A table presents the shear and bending a specific locations along the member length. The slider control can be used to review the values at distance.



3. Select the **Deflection** tab.

Here, a similar diagram of the member deflection is shown for the selected load case. A table displays the deflection values at specific points along the member length.

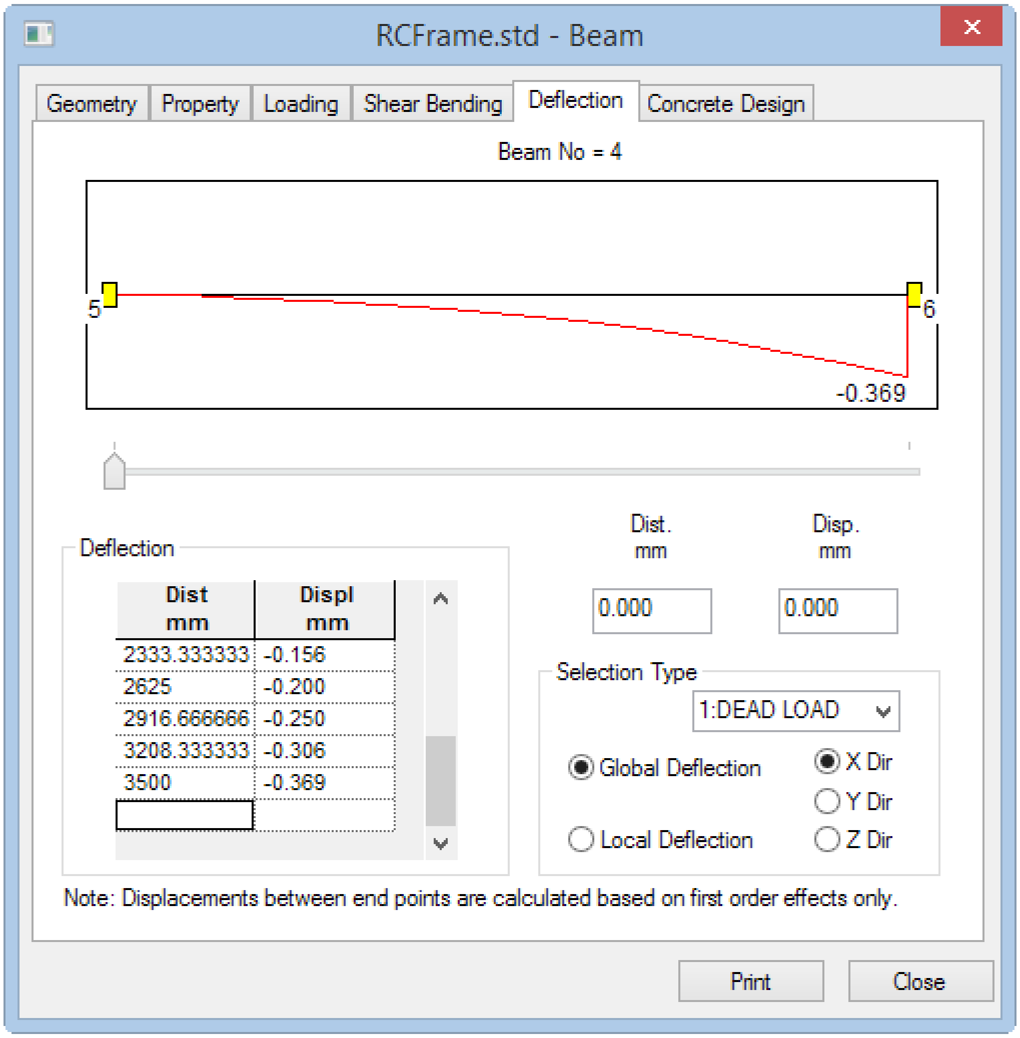


Figure 70:

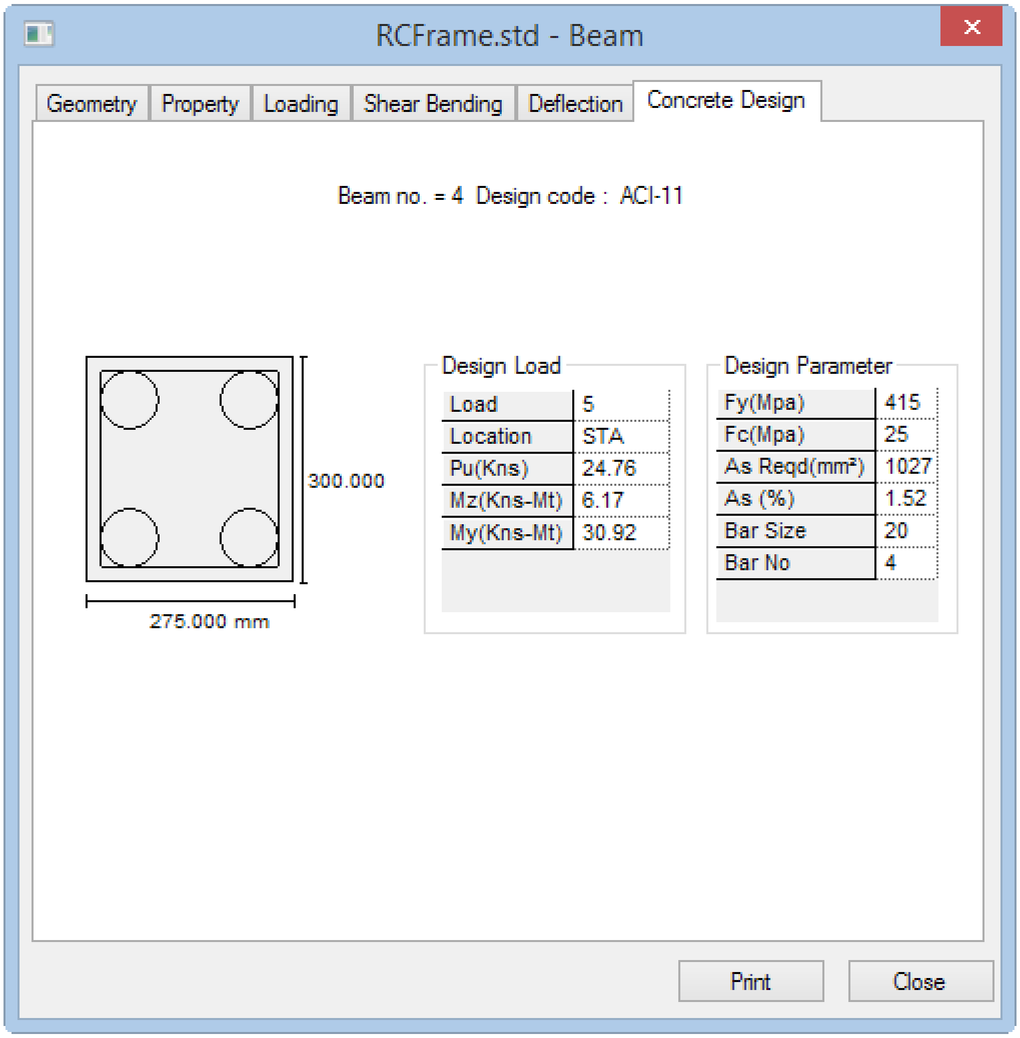
4. Select the **Concrete Design** tab.

Note: This tab is only available for concrete members which have been designed using the concrete design command and after a successful analysis has been performed.



5. (Optional) Click **Print**

   The query results for the current dialog tab are printed using the report output settings. Refer to T.2 Creating Customized Reports (on page 544) for details on the report settings.
6. Click **Close**.

To review the member query results of another beam, the **Beam** dialog must be closed. Repeat this procedure for another member to query it.

T.2 Producing an on-screen report

Occasionally, we will come across a need to obtain results conforming to certain restrictions, such as, say, the resultant node displacements for a few selected nodes, for a few selected load cases, sorted in the order from low to high, with the values reported in a tabular form. The facility which enables us to obtain such customized on-screen results is the Report menu on top of the screen.

Here, you will create a report that includes a table with the member major axis moment (MZ) values sorted in the order High to Low, for members 1 and 4 for all the load cases.

Note: The **Beam Cursor** tool  is active when the **Beam Results** page is selected.

1. Press and hold **<Ctrl>** and click both members 1 and 4 in the View window to select them.
2. On the **Results** ribbon tab, select the **Reports** > **Beam End Forces** tool in the **Reports** group.

   The **Beam End Force** dialog opens.

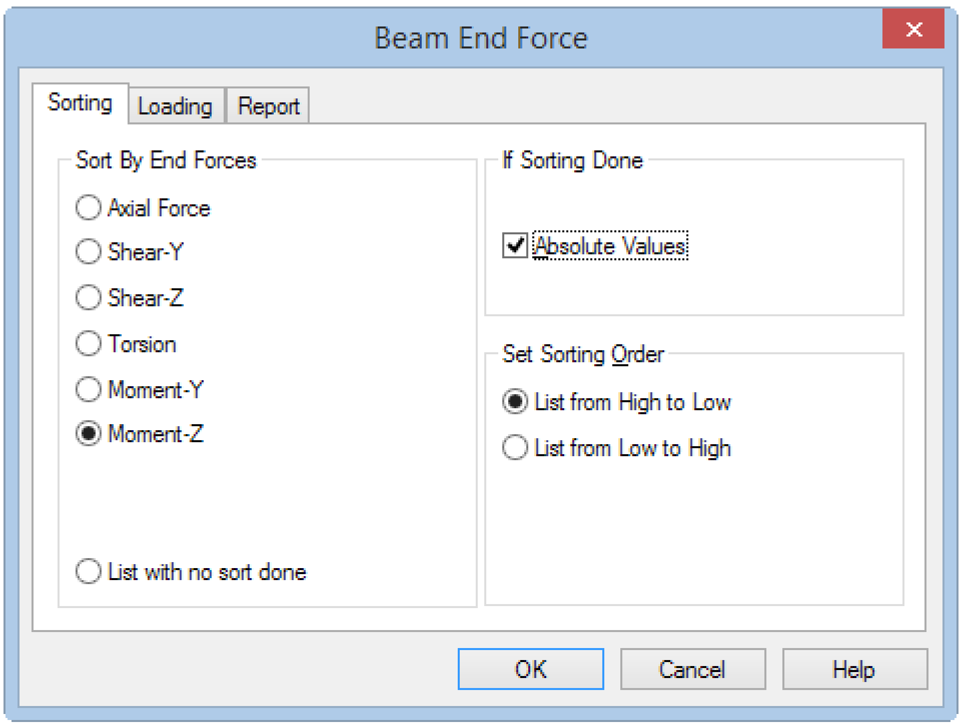


Figure 71:

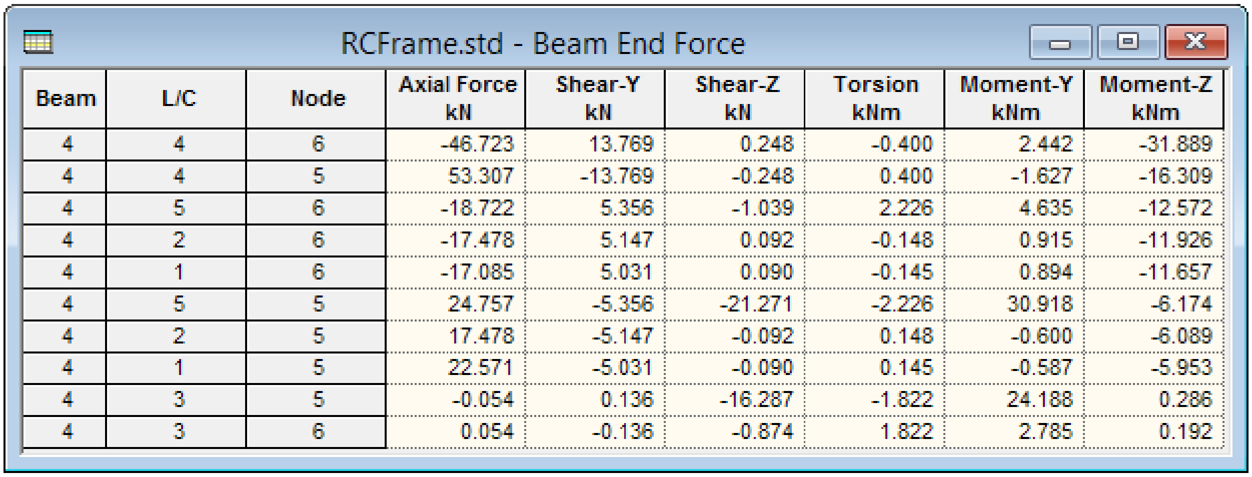
3. Specify the report contents:
   a. Select the **Sorting** tab.
   b. Select the **Moment-Z** option in the **Sort By End Force** group.
   c. Select **List from High to Low** option in the **Set Sorting Order** group.
   d. Check the **Absolute Values** option in the **If Sorting done** group.
4. Select the **Loading** tab and ensure all the five load cases are added to the **Selected** list.
5. (Optional) You can save this report for future use,
   a. Select the **Report** tab
   b. Type a **Title** for the report.
   c. Set the **Save Report** check box.
6. Click **OK**.

   The member end forces sorted table opens with the MZ values sorted from High to Low based on Absolute numbers.



RCFrame.std - Beam End Force

Beam	L/C	Node	Axial Force kN	Shear-Y kN	Shear-Z kN	Torsion kNm	Moment-Y kNm	Moment-Z kNm
4	4	6	-46.723	13.769	0.248	-0.400	2.442	-31.889
4	4	5	53.307	-13.769	-0.248	0.400	-1.627	-16.309
4	5	6	-18.722	5.356	-1.039	2.226	4.635	-12.572
4	2	6	-17.478	5.147	0.092	-0.148	0.915	-11.926
4	1	6	-17.085	5.031	0.090	-0.145	0.894	-11.657
4	5	5	24.757	-5.356	-21.271	-2.226	30.918	-6.174
4	2	5	17.478	-5.147	-0.092	0.148	-0.600	-6.089
4	1	5	22.571	-5.031	-0.090	0.145	-0.587	-5.953
4	3	5	-0.054	0.136	-16.287	-1.822	24.188	0.286
4	3	6	0.054	-0.136	-0.874	1.822	2.785	0.192

Figure 72:

7. (Optional) To print this table, right-click anywhere within the table and select **Print**

T.2 Taking Pictures

To take a screen capture of the View window contents for use generating external reports, use the following procedure.

1. On the **Utilities** ribbon tab, select the **Take Picture** tool in the **Utilities** group.

   The **Picture #** dialog opens.

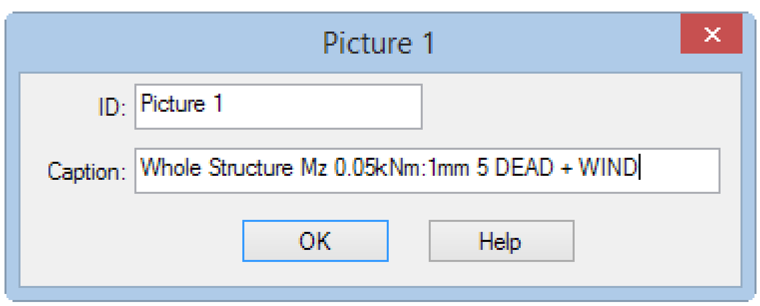


Figure 73: The Picture # dialog with the ID and Capture automatically generated

2. (Optional) Type a Picture **ID**

   The ID is incremented automatically.

3. (Optional) Type a **Caption**

> **Note:** For most View window contents, the caption will be automatically completed with a description of the contents.

4. Click **OK**.
   This picture is saved for use in reports.

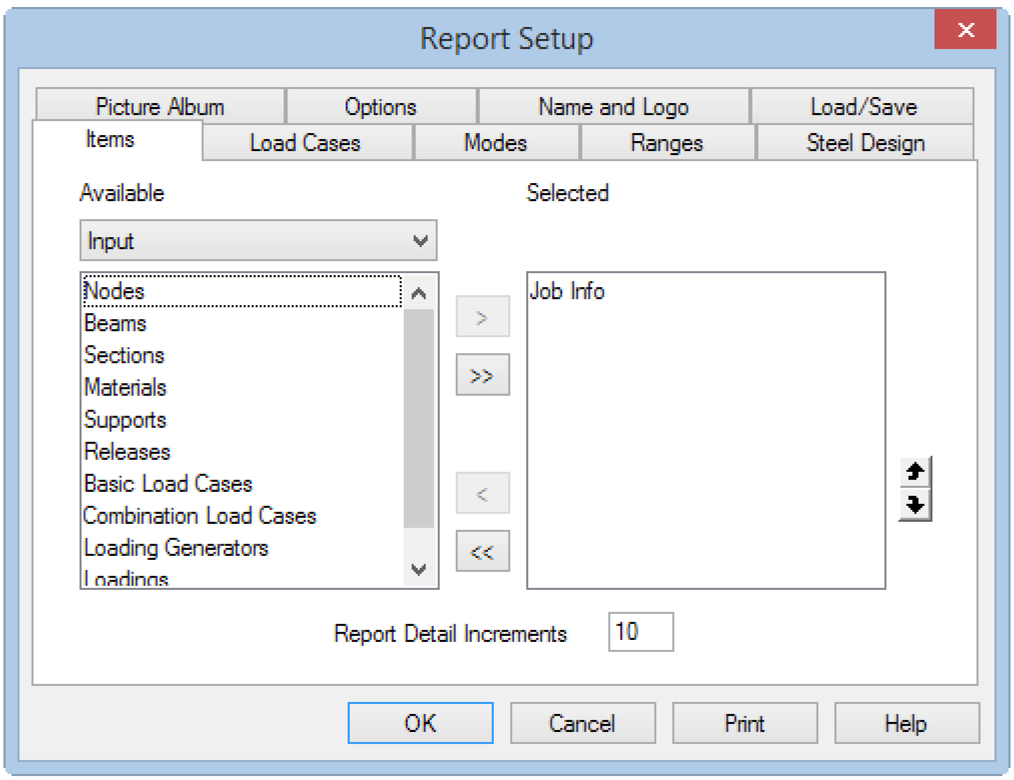
T.2 Creating Customized Reports

STAAD.Pro offers extensive report generation facilities.

Items which can be incorporated into such reports include input information, numerical results, steel design results, etc. You can choose from among a select set of load cases, mode shapes, structural elements, etc. You can also include any picture of the screen taken using the **Take Picture** tool. Other customizable parameters include the font size, title block, headers, footers, etc.

1. Open the Report Setup:
   - **a.** Select the **File** ribbon tab.
     The Backstage view opens.
   - **b.** Select the **Report** tab and then **Setup**.

   The **Report Setup** dialog opens.



Note: The Available items list is filtered by the drop-down selection list above it. This allows you to sort your reports.

2. Add model Output to the report:

   Tip: Job Information from the Input is selected by default.

   - **a.** Select **Output** from the drop-down list.
     The Available list displays output items.
   - **b.** Double-click **Node Displacement Summary** in the Available list.
     This item is added to the Selected list.

   c. Double-click **Beam Max Moments** in the Available list.
      This item is added to the Selected list.
   d. Select **Pictures** from the drop-down list.
      The Available list displays the picture captured earlier in the tutorial.
   e. Double-click **Picture 1**.
      This item is added to the Selected list.

   Leave the **Report Detail Increments** at 10. This is the number of segments into which a member is divided for sectional reports (i.e., displacements, forces, etc.).

3. Select the load cases to include in the report as well as how to order the results:
   a. Select the **Load Cases** tab.
   b. If all the load cases are not already included in the output, click **[>>]**.
   c. Select the **by Load Case** option for the **Grouping for Load Tables**.
   d. Select the **by Node/Beam** option for **Grouping for Result Tables**.

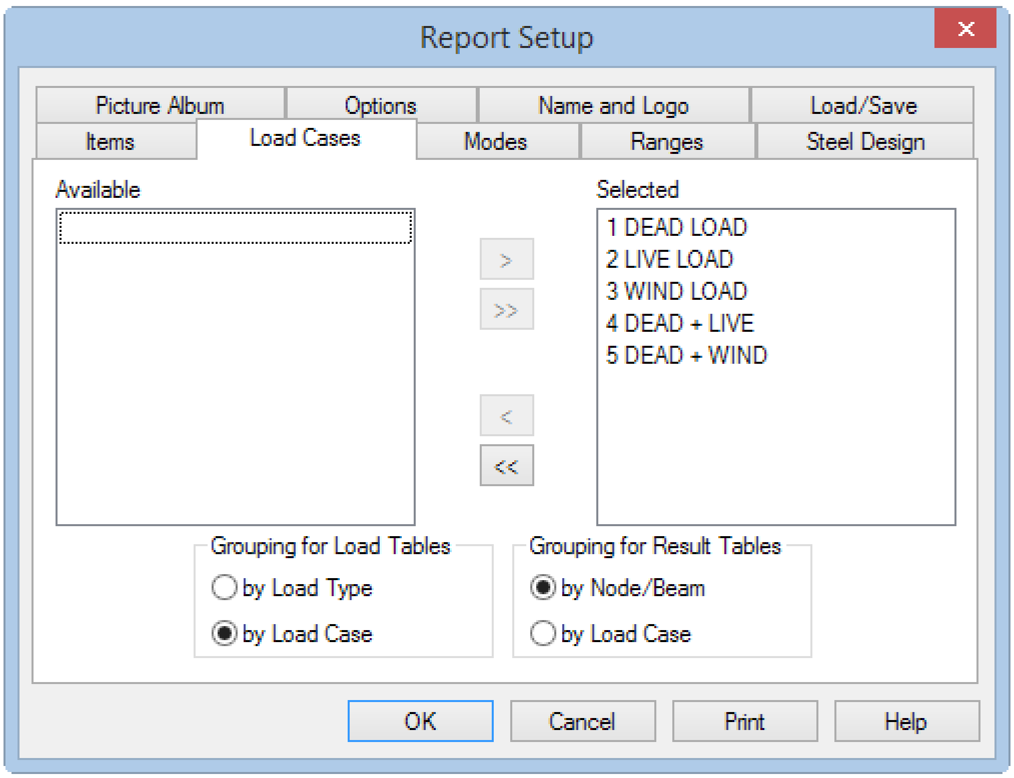


Figure 74:

4. (Optional) Select the **Picture Album**

Tip: You can manage pictures taken using the **Take Picture** tool here.

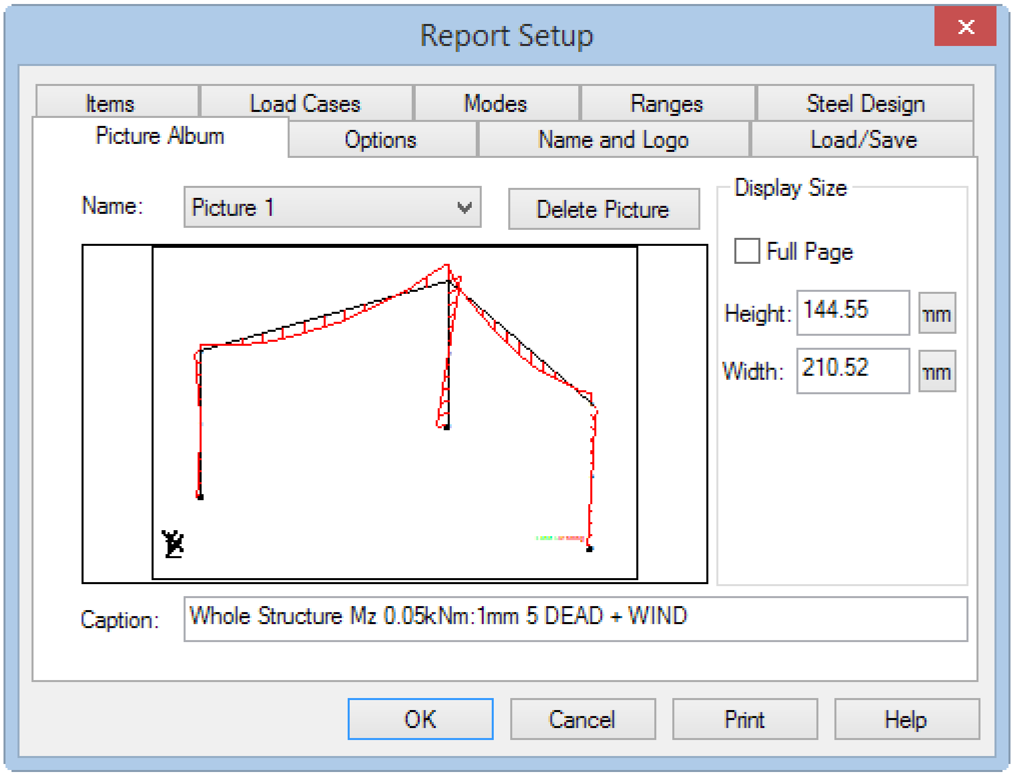

Figure 75:

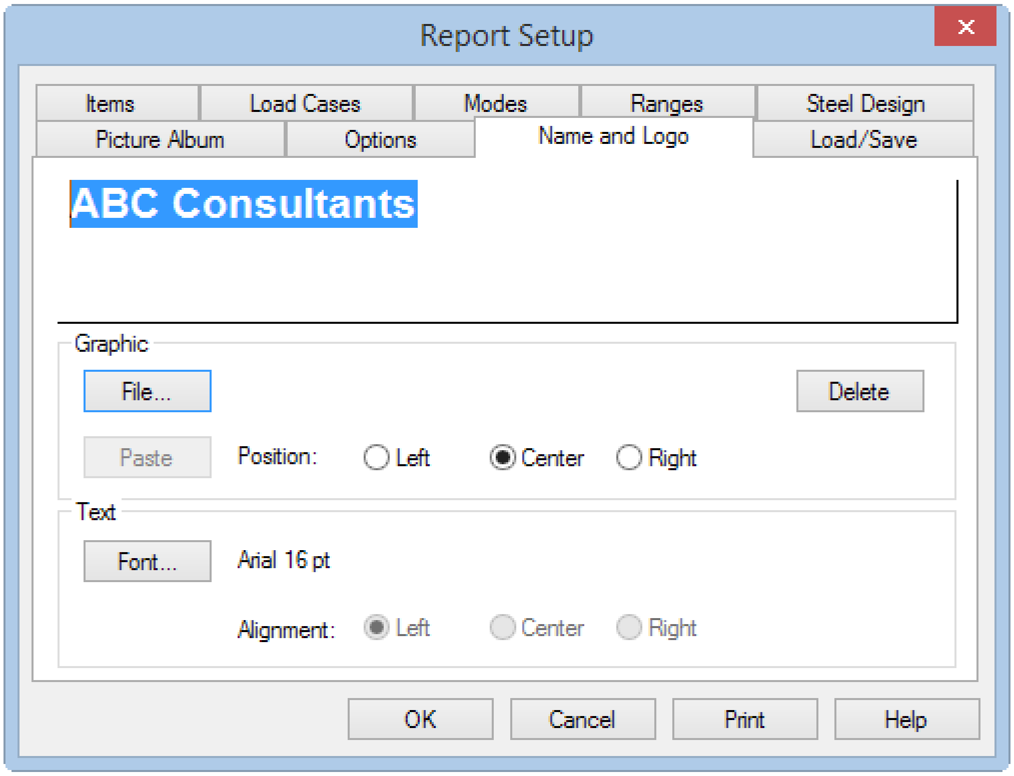
5. Customize the title block of your report with your organization's information:
   a. Select the **Name and Logo** tab.
   b. Click in the empty text field and type the name and address of your organization.
   c. (Optional) Click **File Graphic**

      By default, the Bentley Systems, Inc. logo is used for STAAD.Pro reports.

      Logo files must be in Bitmap (file extension `.bmp`) format.
   d. Click **Font** in the **Text** group.
      The Font dialog opens. You can select any Windows font, style, and size. Click OK when done.



6. Click **OK**.

Tip: You can click Print to print the report directly from this dialog, but it is recommended to preview the report prior to printing.

7. Select the **File** ribbon tab and then select **Report** > **Print Preview**.

   The Print Preview window opens with the report contents. Here you can review and print the report.

   The first and the last pages of the report are shown in the next two figures.

8. Click **Close**.

This brings us to the end of this tutorial.

T.3 - Analysis of a slab

This tutorial provides step-by-step instructions for modeling and analysis of a slab supported along two edges.

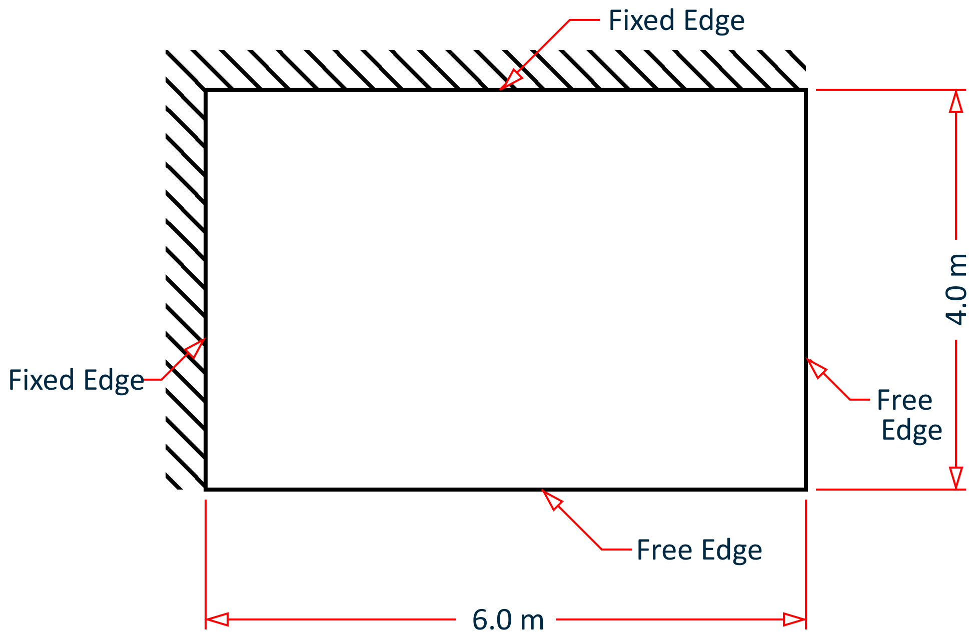

Figure 76: A slab with two supported edges

A copy of the completed input file is typically installed at
`C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models \Tutorials\Tutorial 3 - Analysis of a Slab.std`.

Related Links

- *EX.Tutorials* (on page 6255)

T.3 Methods of creating the model

As explained in T.1 Methods of creating the model (on page 387) in Tutorial 1, there are three methods of creating the structure data:

1. T.3 Creating the Model using the Physical Modeler (on page 553),
2. T.3 Creating the model using the analytical user interface (on page 561),
3. and T.3 Creating the model using the command file (on page 601).

All three methods of creating the model are explained in this tutorial. The physical modeling method is explained first, beginning with " T.3 Creating the Model using the Physical Modeler (on page 553)," then the analytical model method is explained beginning with " T.3 Description of the tutorial problem (on page 550)." The command file method is explained in " T.3 Creating the model using the command file (on page 601)."

T.3 Description of the tutorial problem

The structure for this project is a slab fixed along two edges. You will model it using 6 quadrilateral (i.e., 4-noded) plate elements. The structure and the mathematical model are shown in the figures below. It is subjected to selfweight, pressure loads and temperature loads. The purpose of this tutorial to create the model, assign all required input, perform the analysis, and review the results.

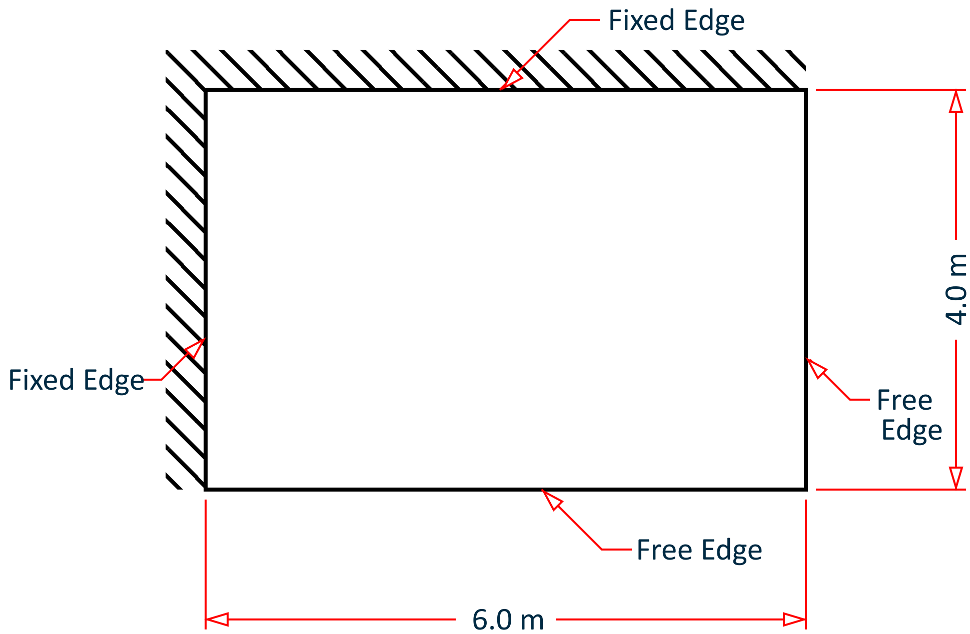

Figure 77: Theoretical model

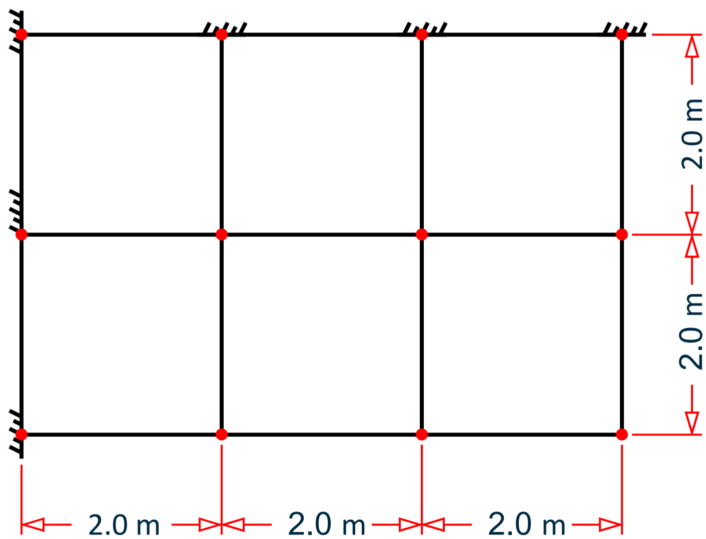

Figure 78: Analytical model

Basic Data for the Structure

Attribute	**Data**
Element properties	Slab is 300 mm thick

Attribute	Data
Material Constants	E, Density, Poisson, Alpha — Default values for concrete
Supports	Nodes along 2 adjacent edges; fixed against rotation and translation
Primary Loads	Load 1: Selfweight Load 2: Pressure Load of 300 kg/m^2 acting vertically downwards Load 3: 75 degree F uniform expansion, plus top surface is 60 degrees hotter than the bottom
Combination Loads	Case 101: Case 1 + Case 2 Case 102: Case 1 + Case 3
Analysis Type	Linear Elastic

T.3 Creating a new structure

On the Start page **New** tab, you will provide some initial data necessary for building the model.

1. On the Start page, select **New**.

   The **New** page opens to the **Model Info** tab.
2. Type as `Plates Tutorial` in the **File Name** field.
3. Specify a **Location** where the STAAD input file will be located on your computer or network.

   You can directly type a file path or click **Browse** to open the **Browse by Folder** dialog, which is used to select a location using a Windows file tree.
4. Select **Physical** for the **Type** of model.

   This option selects the modeling method you want to use:

Analytical	For creating a model using either the STAAD.Pro analytical modeling interface or the command input file editor.
Physical	For creating a model using the STAAD.Pro Physical Modeler interface.
Building	For creating a building model structure using the Building workflow.
5. Select **Metric** as the system of **Units.**

   Tip: The units can be changed later if necessary, at any stage of the model creation.
6. (Optional) Select the Job Info tab to enter related project details, names and dates for quality analysis, and ProjectWise Project information.
7. Click **Create**.

The STAAD.Pro modeling environment opens and your model file is then opened in the STAAD.Pro Physical Modeler.

Alternatively, if you want to use either the analytical modeling workflow or the command input file editor to create the model, choose **Analytical**, click **Create**, and then proceed to either " T.3 Creating the model using the analytical user interface (on page 561) " or " T.3 Creating the model using the analytical user interface (on page 561)," respectively.

T.3 Creating the Model using the Physical Modeler

You are now ready to start building the model geometry. The steps for doing this are described in the following sections.

Tip: Refer to the STAAD.Pro Physical Modeler Application Window Layout for reference on the application window.

T.3 Generate the model geometry

1. On the **Model** ribbon tab, select the **Grid** tool in the **Create** group.

   The **Create Grid** dialog opens.
2. Supply the grid details:
   a. Type `Grid 1` in the **Name** field.
   b. Select **XZ** as the **Plane**.
   c. Leave the **Creation Method** as **By Spacing**.
   d. Type `3` in the **Number of Spaces in X** and `2 m` in the **Grid spacing X** field.
   e. Type `2` in the **Number of Spaces in Z** and `2 m` in the **Grid spacing Z** field.
   f. Click **OK**.
   The grid is created.
3. Orient the view from the top:
   a. (Optional) If the rotation controls are hidden, click the rotation widget in the lower-right corner of the view window.
   b. Select the **Switch to top view** tool.
   c. (Optional) Click the rotation widget again to hide the controls.

   Tip: Alternatively, you can press and hold the right mouse button and drag the mouse pointer to quickly rotate the view so it is easy to select the column bases.
4. On the **Model** ribbon tab, select the **Surface** tool in the **Create** group.

5. Draw the surface:
   a. Click on the grid point at (0,0,0) (i.e,. top-left corner).
   b. Click on the grid corners in a counterclockwise order. Double-click on the last point to stop drawing surface vertices.

      (6,0,0)
      (6,0,4)
      (0,0,4)

   c. Select the **Surface** tool again to deactivate the tool.
6. On the **View** ribbon tab, select the **Local Axis** tool in the **Model** group.

   
   The local axes are displayed on the center of the surface. Note that local axis x is aligned with the edge defined by the first two nodes.

T.3 Specifying element and material properties

1. Select the surface element.
2. On the **Surface Tools** ribbon tab, select the **Material** tool in the **Assign Properties** group.

   The **Assign material** dialog opens.
3. Assign a catalog concrete material:
   a. Select the **Source** as **Catalog**.
   b. Select the **Type** as **Standard**.
   c. Select the **Country** as **United States**.
   d. Select the **Material type** as **CONCRETE_ACI318**.
   e. Select **4000 psi** from the **Material name** list.
   f. Click **OK**.

   The dialog closes and the material name is displayed on the surface.
4. On the **Surface Tools** ribbon tab, select the **Thickness** tool in the **Assign Properties** group.

   The **Assign Surface Thickness** dialog opens.
5. Type `300 mm` in the **Thickness** field and then click **OK**.
   The dialog closes and the thickness is displayed on the surface.

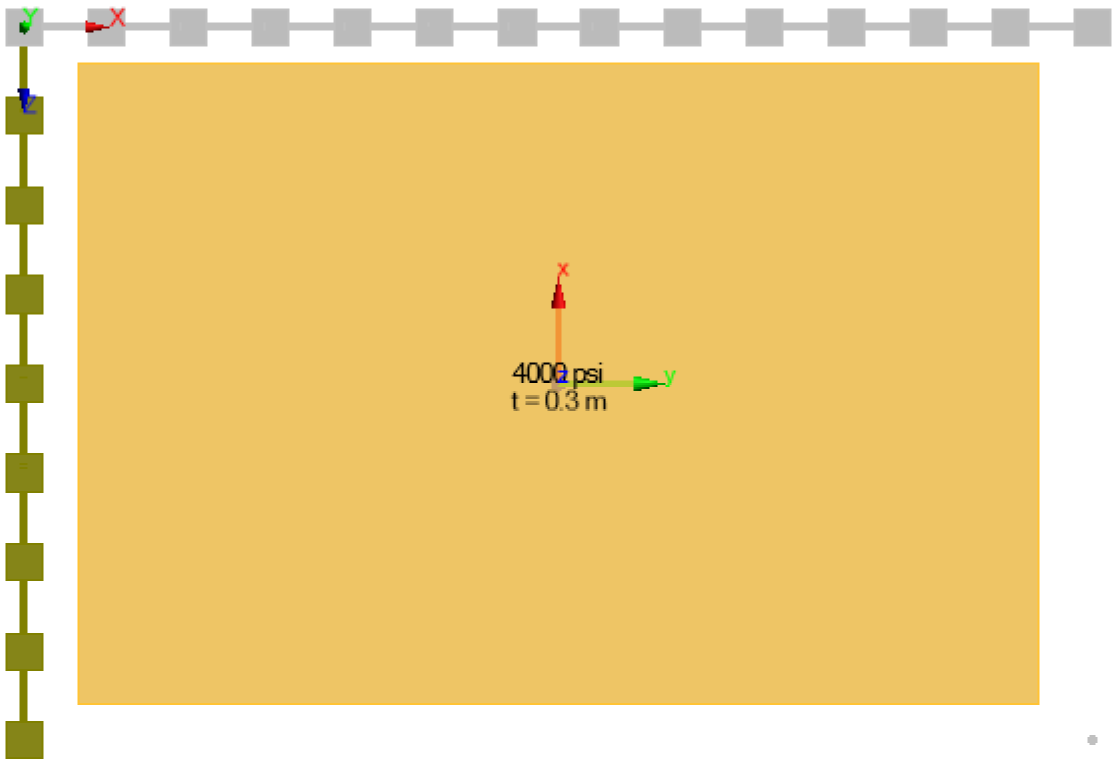
T.3 Specifying supports

Tip: You may want to turn off the display of Loads to make selecting the surface easier. To do so, select the **Loads** tool in the **Toggle Attributes** group on the **View** ribbon tab.

1. Select the surface and the nodes along the “top” edge:
   a. Click in an empty area of the view window to deselect all objects.
   b. Click on the surface to select it.
   c. While holding **<Ctrl>**, drag a rectangular area surrounding nodes N2 and N3.
2. On the **Surface Tools** ribbon tab, select the **Linear** tool in the **Mat and Edge Supports** group.

   
   The **Assign Custom Linear Support** dialog opens.
3. Specify the support parameters:
   Leave the **Support type** selection as **Restraints.**
   a. Type 3 in the **Segments** field.
   b. Check all the restrained options for **X**, **Y**, and **Z** in both the **Translation** and **Rotation** groups.
   c. Click **OK**.

   A series of blocks are drawn along the edge to indicate the support condition.
4. Repeat steps 1 through 3 but select the “left” edge nodes (N1 and N2) and use 2 segments.



T.3 Specifying load groups 1 and 2

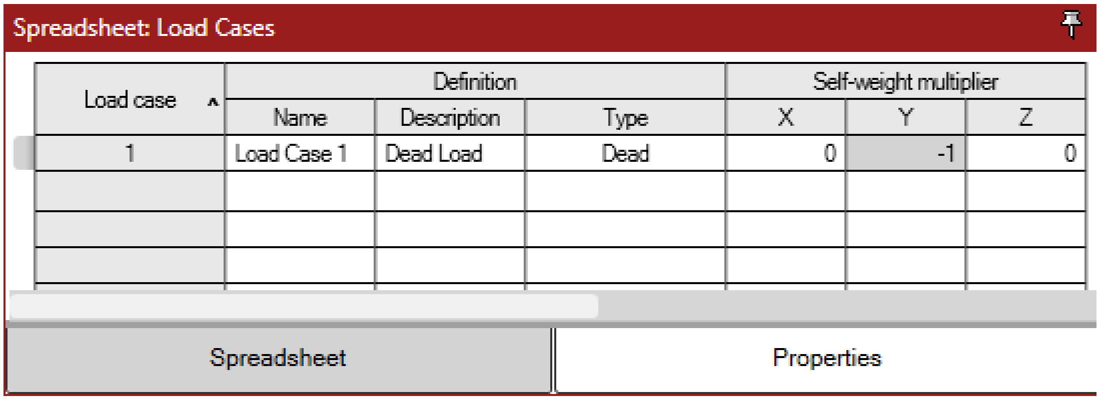
1. On the **Spreadsheet** ribbon tab, select the **Load Cases** tool in the **References** group.

The Load Cases spreadsheet opens.

2. For Load 1:
   a. Type `Dead Load` in the description field of Load case 1.
   b. Select **Dead** as the **Type**.
   c. Type `-1` in the **Self-weight multiplier** in field **Y**.

   Note: This value is negative.

   d. Press **<Enter>**.



3. Create a load group for the external pressure load:
   a. On the **Model** ribbon tab, select the **Load Case** tool in the **Load** group.

   
   The **Add Load Case** dialog opens.
   b. Type `External Pressure Load` in the **Name** field.
   c. Select **Floor Unspecified** as the **Type**.
   d. Click **OK**.

   The new load group is created and selected as the active load group.
4. On the **Surface Tools** ribbon tab, select the **Pressure** tool in the **Loads** group.

   The **Add Surface Uniform Pressure** dialog opens.
5. Specify the pressure load:
   a. Type `-300 kg/m2` in the **Pressure** field.
   b. Select **Global Y** as the **Direction**.

   > **Tip:** Since the surface is parallel to the XZ plane, you could also have selected local 3 as to achieve the same direction. However, due to the counterclockwise selection of nodes, the local 3 axis is oriented in the opposite direction of the Global Y. Therefore, you would use a *positive* magnitude for that case.

   c. Click **OK**.

The temperature load must be added directly to the analytical model in the STAAD.Pro interface. This is done *after* you generate the analytical model.

T.3 Generate the Analysis Model

You have now completed the majority of the modeling portion of this tutorial. You will now send the model data back to STAAD.Pro where you will add the final load case, create load combinations, add output commands, select analysis criteria, and specify post-processing print commands.

1. Change the mesh size:

a. Select the **File** ribbon tab.
   The backstage view opens.
b. Select the **Options** tab.
   The **Options** dialog opens.
c. Select the **Analysis model** tab.
d. Type `2.0 m` in the **Maximum allowed distance between nodes** field.
e. Click **OK**.

2. Either:

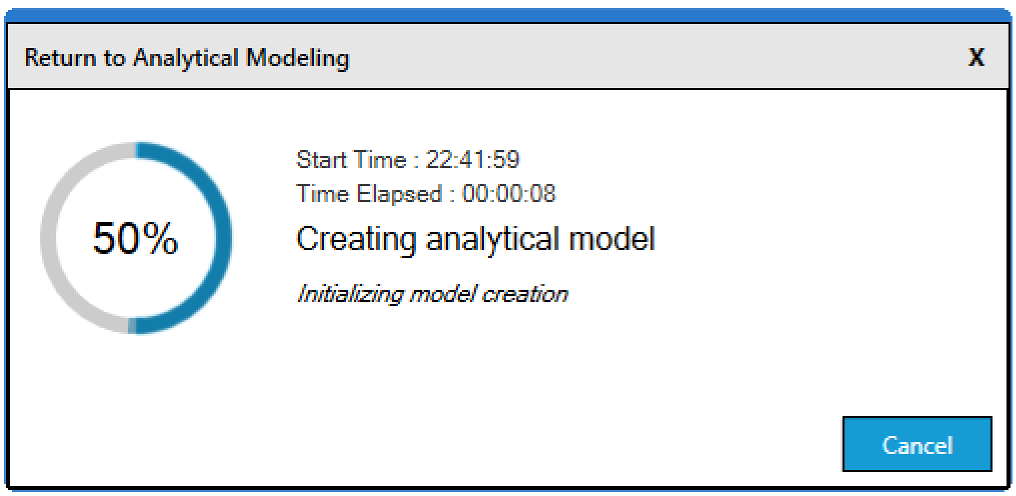
   On the **Model** ribbon tab, select the **Return to Analytical Modeling** tool in the **STAAD.Pro** group

   or

   On the **File** ribbon tab, select **Create analysis model** in the backstage tabs

   The Return to Analytical Modeling dialog opens and displays the progress of the analytical model being generated.

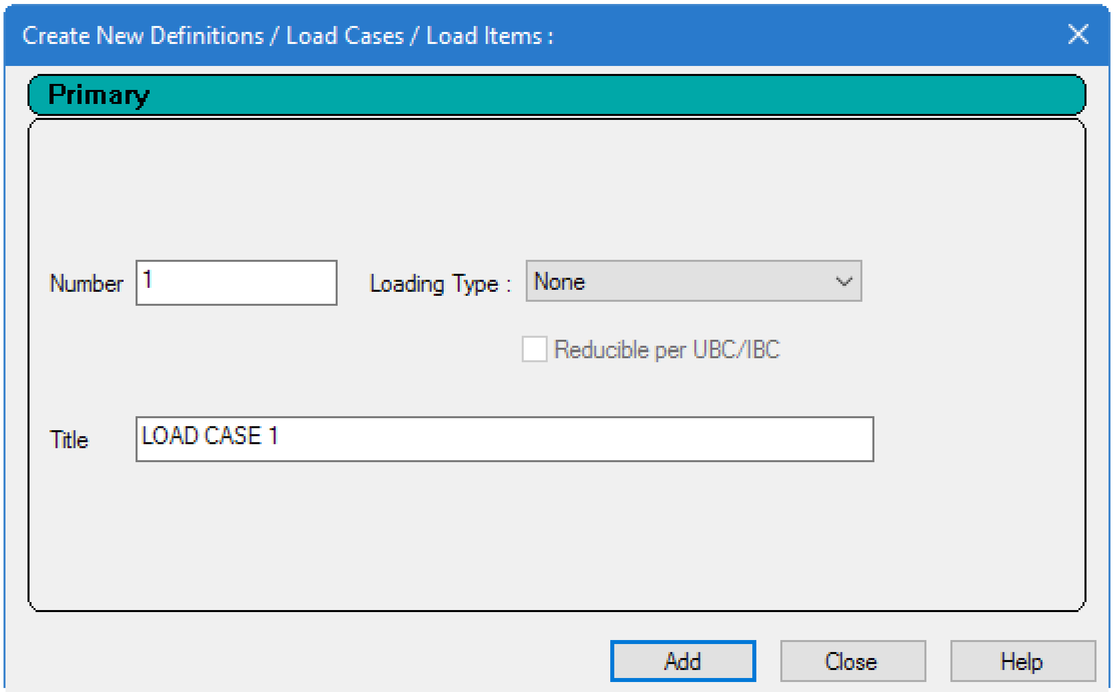


T.3 Create primary load cases

1. In STAAD.Pro, select the **Loading** page in the **Analytical Modeling** page control bar.

   The **Loading** ribbon tab is selected and the **Load & Definition** dialog opens.
2. On the **Loading** ribbon tab, select the **Primary Load Case** tool in the **Loading Specifications** group.

   
   The **Add New: Load Cases** dialog opens.



3. Create a pair of primary load cases:
   a. Type `Dead Load` as the **Title** for Load Case 1.

      Leave the **Number** as the default (1) and leave the **Loading Type** as None.
   b. Click **Add**.

      Note that the dialog stays open but the load case number is automatically incremented.
   c. Type `External Pressure Load` as the **Title**.

      Again, it is not necessary to select a **Loading Type**.
   d. Click **Add**.
   e. Click **Close**.
4. Assign the reference loads to the primary load cases:
   a. On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

      The **Add New Load Items** dialog opens.
   b. Select the **Repeat Load** > **Reference Load** tab on the left.
   c. Select **R1: "Load group 1"** in the **Available Load Cases** list.
   d. Click **>**.
      The reference load case is added to the selected loads list.
   e. Click **Add**.
   f. Click **Close**.

   The reference load case is now added included in the primary load case for analysis.
5. In the window status bar, select **2: External Pressure Load** as the current load case.
6. Repeat Step 4 to add the reference load for Load group 2 to the External Pressure Load primary load case.

T.3 Add temperature load case

1. Create a primary load case titled `Temperature Load` and then select it in the status bar.
   a. On the **Loading** ribbon tab, select the **Primary Load Case** tool in the **Loading Specifications** group.

   
   The **Add New Load Cases** dialog opens.
   b. Type `Temperature Load` as the **Title**.
   There are no load combinations used in this model, so you can leave the Loading Type as None.
   c. Click **Add**.
   d. Click **Close**.
2. In the program status bar, select **3: Temperature Load** as the current load case.
3. To generate and assign the third load type:
   a. On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

   The **Add New Load Items** dialog opens.
   b. Select the **Temperature** option under the **Temperature Loads** item.
   c. Type `40` in the **Temperature Change for Axial Elongation**field.
   d. Type `30` in the **Temperature Differential from Top to Bottom** field.
   Leave the **Temperature Differential from Side to Side (Local Z)** field as 0 (default).
   e. Click **Add** and then click **Close**.

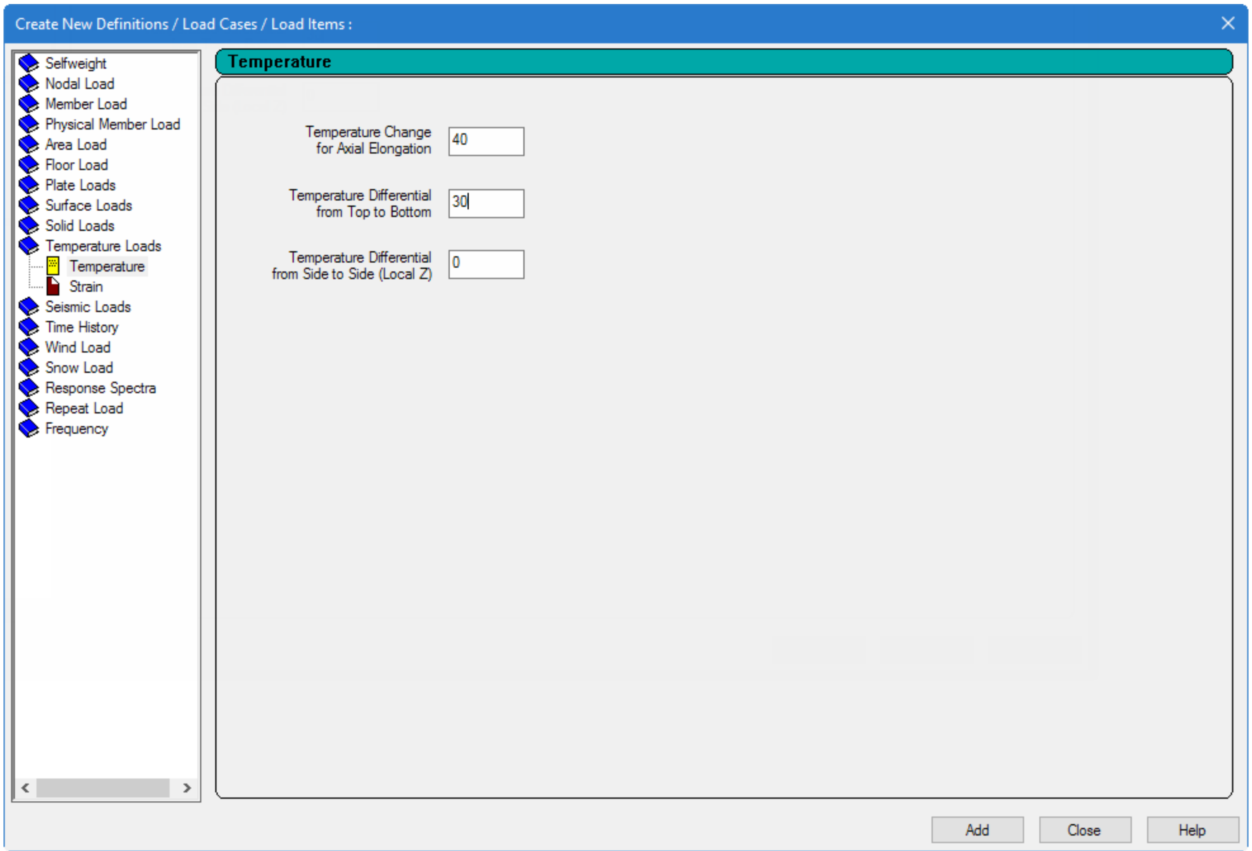


Figure 79:

4. Assign the temperature load case to all of the elements:

a. In the **Load & Definition** dialog, select **TEMP 40 30**.

This is the input command for the temperature load.

b. Select the **Assign to View** option.

c. Click **Assign**.

A message dialog opens confirming you want to make this assignment.

d. Click **Yes**.

T.3 Creating the model using the analytical user interface

The following procedures describe how to use the traditional STAAD.Pro analytical user interface to build the model. The steps and, wherever possible, the corresponding STAAD.Pro commands (the instructions which get written in the STAAD input file) are described in the following sections.

Tip: Refer to GS. Application Window Layout (on page 54) for reference on the application window.

T.3 Generating the model geometry

The structure geometry consists of joint numbers, their coordinates, member numbers, the member connectivity information, plate element numbers, etc.

The STAAD input file commands generated are:

```
JOINT COORDINATES
1 0 0 0 ; 2 2 0 0 ; 3 2 0 2 ; 4 0 0 2
5 4 0 0 ; 6 4 0 2 ; 7 6 0 0 ; 8 6 0 2
9 2 0 4 ; 10 0 0 4 ; 11 4 0 4 ; 12 6 0 4
ELEMENT INCIDENCES SHELL
1 1 2 3 4 ; 2 2 5 6 3 ; 3 5 7 8 6
4 4 3 9 10 ; 5 3 6 11 9 ; 6 6 8 12 11
```

In this tutorial, you will optionally explore four different methods to create the model:

T.3 Creating the Plates - Method 1

To create the plate elements for the slab using a mixture of drawing an element and the Copy/Paste facility, do the following steps.

T.3 Setup the Grid

1. On the **Geometry** ribbon tab, select the **Snap Grid/Plate (Quad)** tool in the **Structure** group.

   The **Snap Node/Beam** dialog closes and the **Snap Node/Plate** dialog opens.
2. On the **Snap Node/Plate** dialog, click **Create**.
   A dialog opens which will enable us to set up a grid.

   Within this dialog, there is a drop-down list from which you can select Linear, Radial, or Irregular form of grid lines.

Linear	used to place the construction lines perpendicular to one another along a "left to right - top to bottom" pattern, as in the lines of a chess board
Radial	used to place construction lines to appear in a spider-web style, which makes it is easy to create circular type models where members are modeled as piece-wise linear straight line segments
Irregular	used to create gridlines with unequal spacing that lie on the global planes or on an inclined plane

3. Select **Linear**, which is the Default Grid.

   In our structure, the segment consisting of members 1 to 3, and nodes 1 to 4, happens to lie in the X-Y plane. So, in this dialog, let us keep **X-Y** as the **Plane** of the grid. The size of the model that can be drawn at any time is controlled by the number of **Construction Lines** to the left and right of the origin of axes, and the **Spacing** between adjacent construction lines.
4. Type a **Name** of `Grid 1`.

5. Select **X-Z** as the **Plane** option.
6. Type 6 as the number of lines to the **Right** of the origin along **X** and 4 above the origin along **Z**.

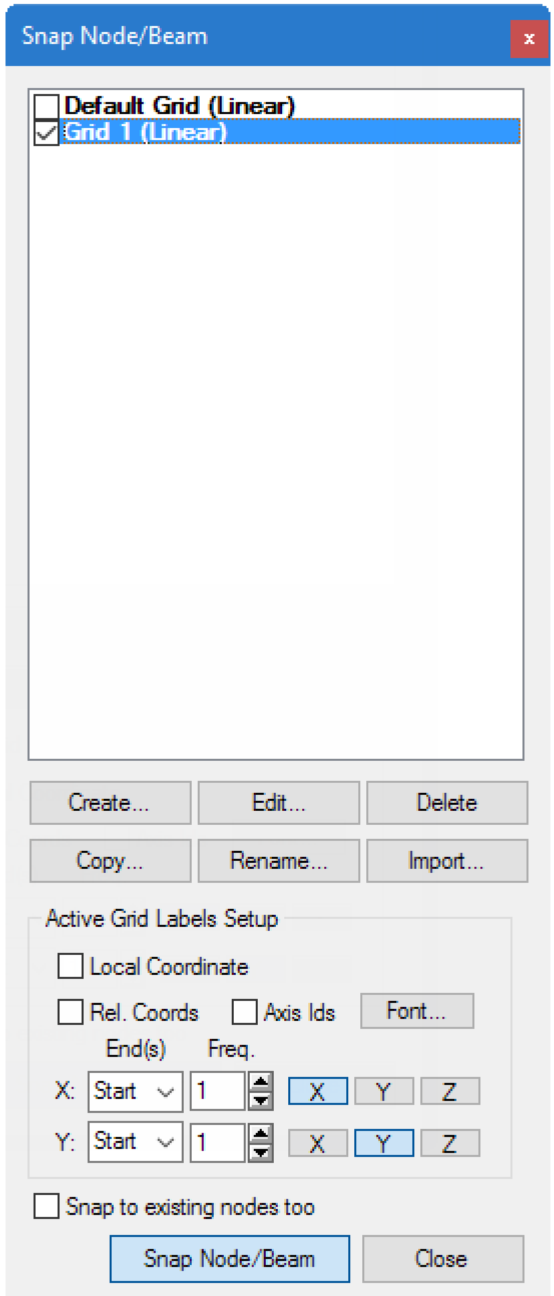
   Leave the spacing as 1 m.
7. Click **OK**.
8. In the **Snap Node/Beam** grids list, check the new **Grid 1** option.

   You can create any number of grids. By providing a name, each new grid can be identified for future reference.

   Tip: Please note that these settings are only used to generated construction lines. These construction lines enable you to easily draw the structure but do not restrict our overall model to those limits.

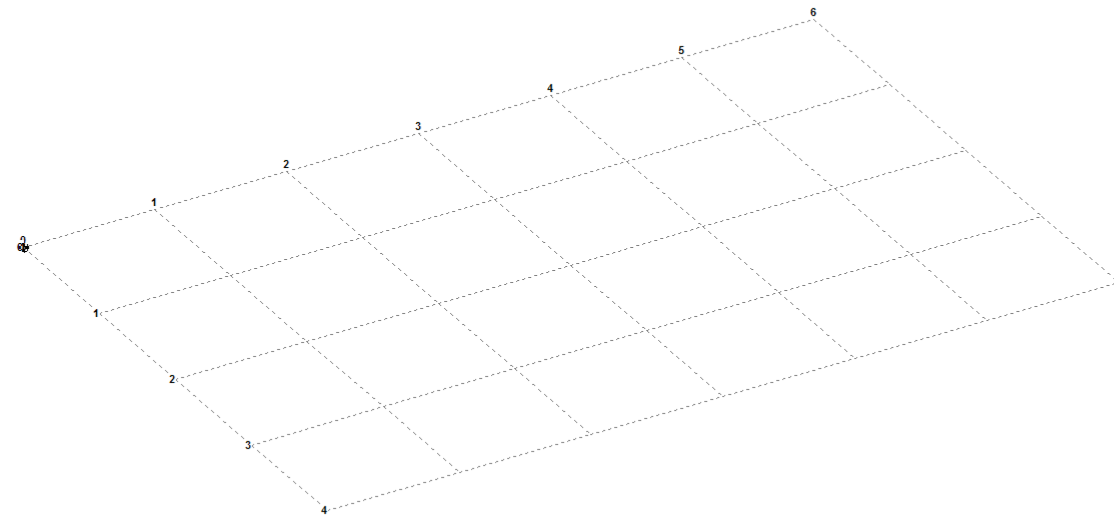
   Tip: To change the settings of this grid, select the name in the **Snap Node/Beam** dialog and then click **Edit**.

   The check by **Default Grid** is automatically cleared. STAAD.Pro will only display a single grid at a time.



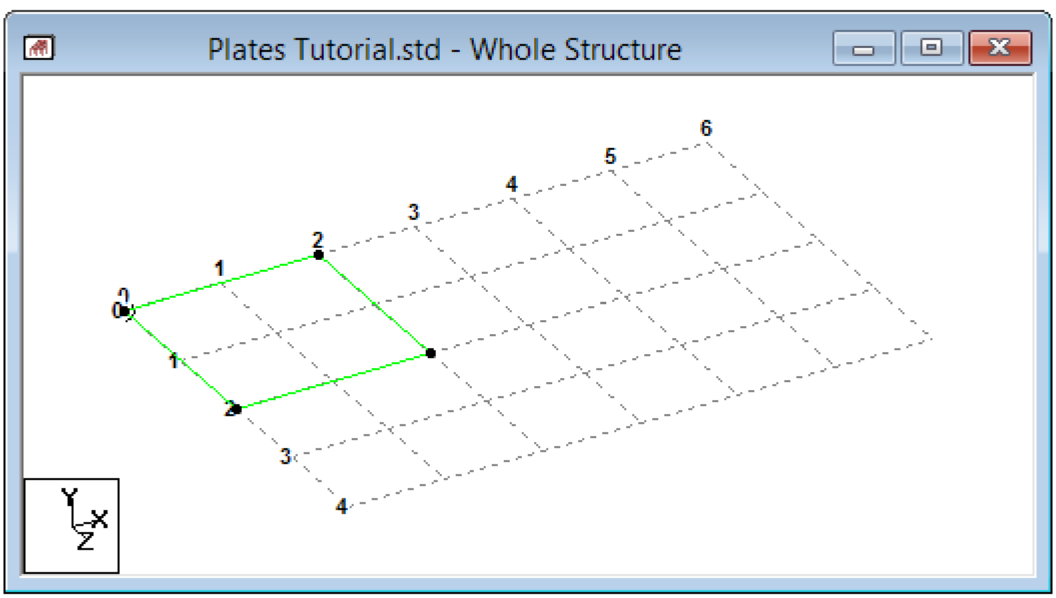
T.3 Create Plates Method 1 Element 1

1. In the View window, click at the origin (0, 0) to create the first node.
   A line is "rubber-banded" between this node and the mouse pointer, which previews the edge of the plate to placed with the next mouse click.



2. Click on the following points to create nodes and automatically join successive nodes by beam members.

   (2, 0, 0)
   (2, 0, 2)
   (0, 0, 2)



3. Click **Close** in the **Snap Node/Plate** dialog.
4. Press **<Shift+P>** to display the plate number.

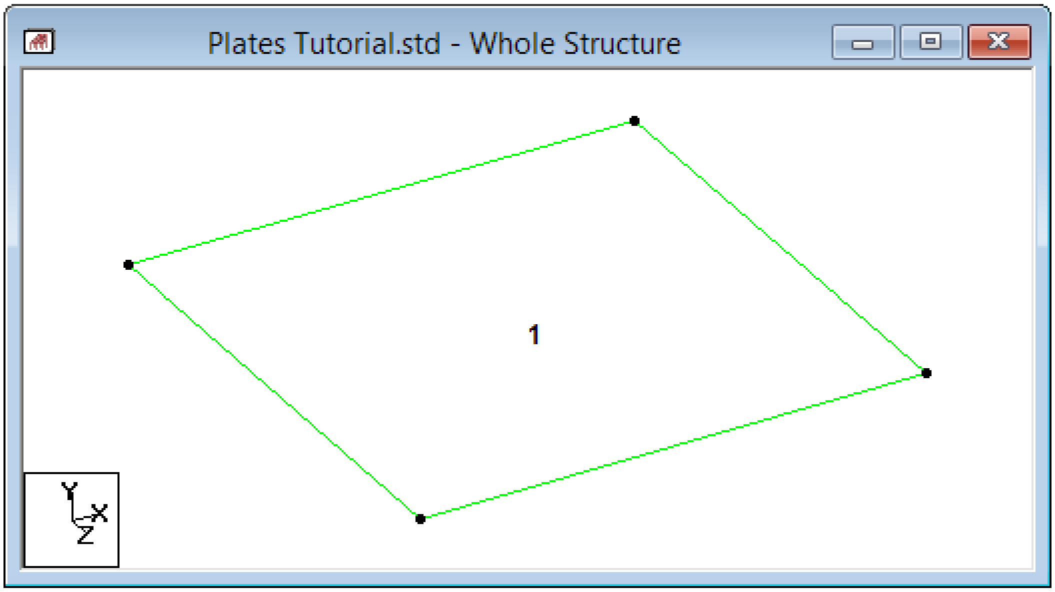


Figure 80: Plate 1 drawn

It is very important that we save our work often, to avoid loss of data and protect our investment of time and effort against power interruptions, system problems, or other unforeseen events.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.3 Create Plates Method 1 Element 2

Creating Elements by Coping and Pasting

Examining the structure shown in " T.3 Description of the tutorial problem (on page 550) " of this tutorial, it can be seen that the remaining elements can be easily generated copying the existing plate and then pasting the copied element at specific distances.

1. On the **Geometry** ribbon tab, select the **Plates Cursor** tool in the **Selection** group.

2. Select plate 1 in the View window.
3. Either:

   Right-click and select **Copy** from the pop-up menu

   or

   on the **Geometry** ribbon tab, select the **Copy** tool in the **Clipboard** group 

   or

   press **<Ctrl+C>**

4. To paste the copied plate element, either:

   Right-click and select **Paste** from the pop-up menu

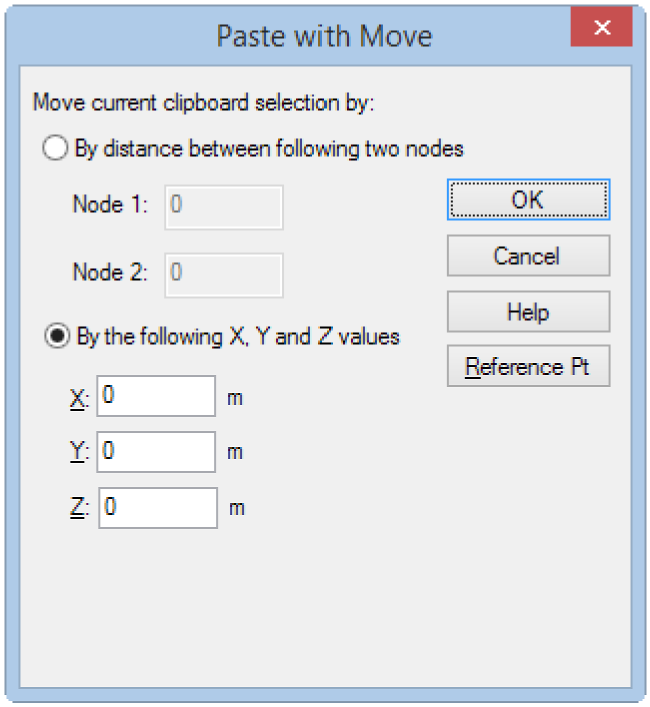
   or

   on the **Geometry** ribbon tab, select the **Paste** tool in the **Clipboard** group 

   or

   press **<Ctrl+V>**

   The **Paste with Move** dialog opens.



5. Select the **By the following X, Y and Z values** option and then type **2** (m) in the X field.

   Leave the Y and Z values as 0.
6. Click **OK**.

   The dialog closes and the plate is copied to Plate 2 at the specified X axis increment.

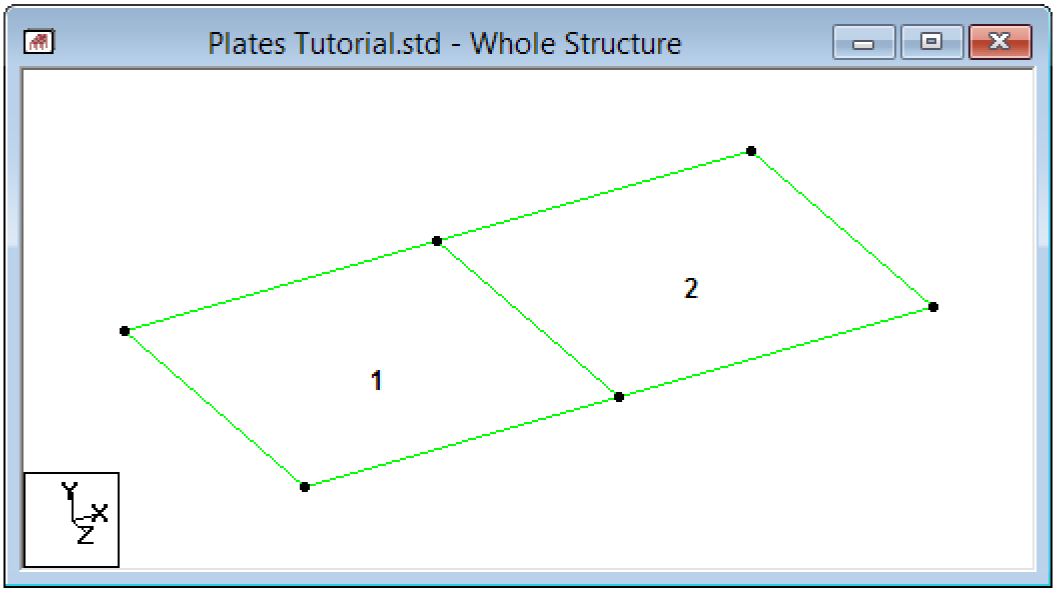


Figure 81: Plate 2 copied from plate 1

7. Repeat steps 4 through 6 except with an **X** of 4 (m) to create plate 3 from plate 1.

   You have now created one half of the symmetric set of plates. You can now copy and paste all three plates to complete the structure.

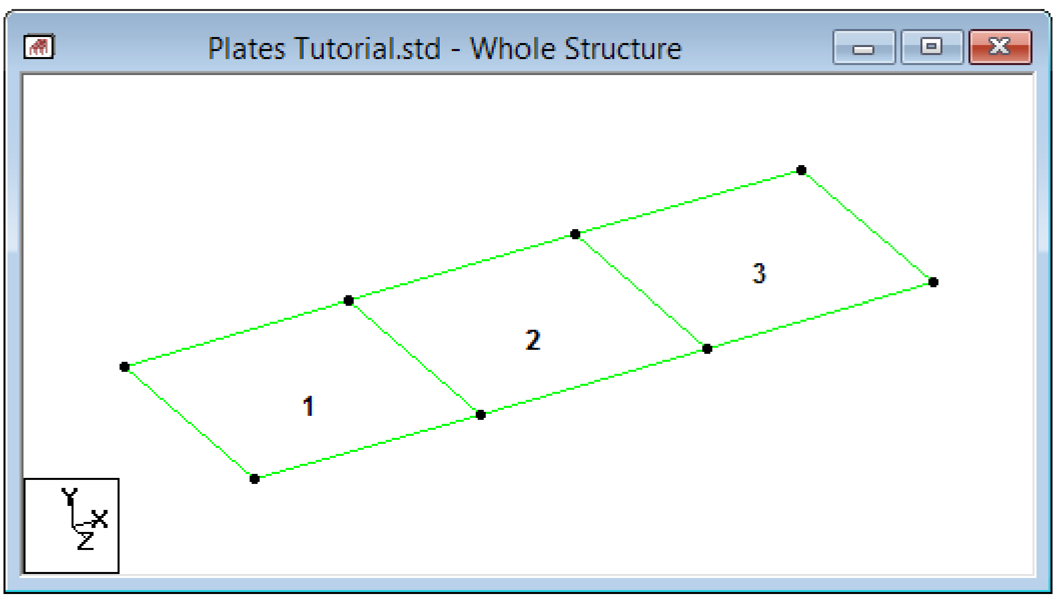

Figure 82: Plate 3 copied from plate 1

8. To select all plates, either:

   click-and-drag a window around all three plates using the **Plates Cursor** tool

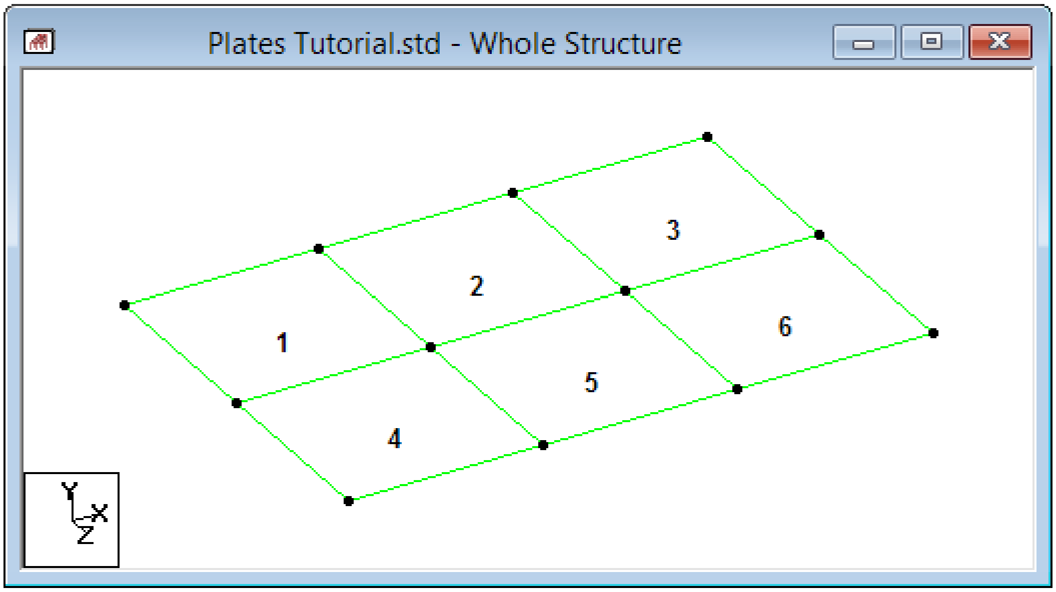
   or

   press **<Ctrl+A>**

   or

on the **Geometry** ribbon tab, select the **Plates Cursor** > **All Plates** tool in the **Selection** group.

9. Repeat steps 3 through 6 to copy and paste all the plates, except with a **Z** of 2 m (leave the X and Y values as 0).



10. Click anywhere in away from the plates to deselect them.

T.3 Create Plates Delete to Try Another Method

If you want to explore the remaining methods of creating this model, the current structure will have to be entirely deleted.

1. To select all plates, either:

   click-and-drag a window around all three plates using the **Plates Cursor** tool

   or

   press **<Ctrl+A>**

   or

   on the **Geometry** ribbon tab, select the **Plates Cursor** > **All Plates** tool in the **Selection** group.
2. Either:

   press **<Delete>**

   or

   on the **Plate Tools** ribbon tab, select the **Delete** tool in the **Clipboard** group

   A message dialog opens to confirm the deletion of the selected plates.
3. Click **OK**
   A message dialog opens indicating that orphan nodes have been created and to confirm their deletion.
4. Click **Yes**.
   The entire structure is now deleted.

T.3 Creating the Plates - Method 2

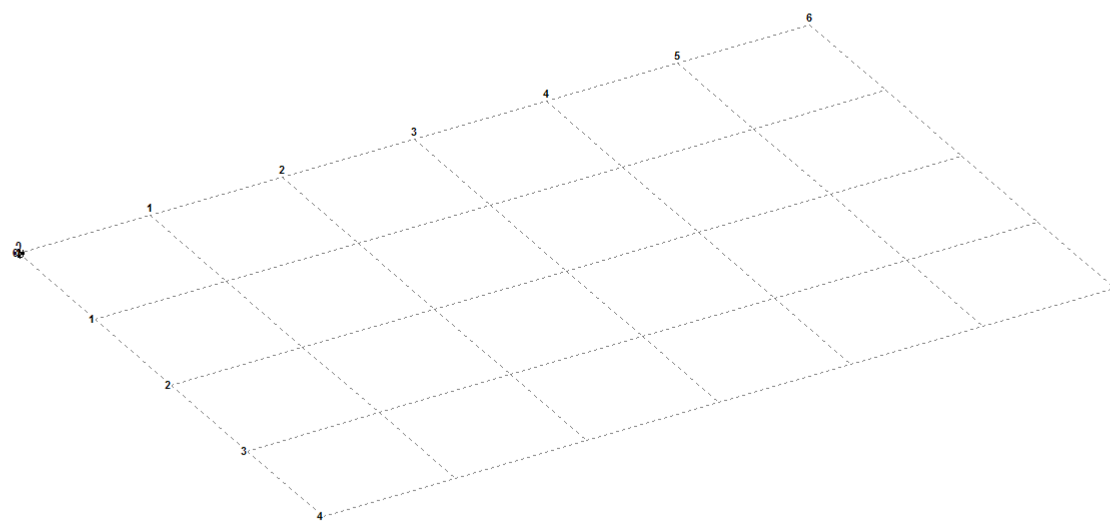
To create the plate elements using a mixture of drawing an element and the Translational Repeat facility, use the following steps.

T.3 Method 2 Creating Element 1

In this method, you will use the Translational Repeat feature in STAAD.Pro to create the model. First, you need at least one existing entity to use as the basis for the translational repeat.

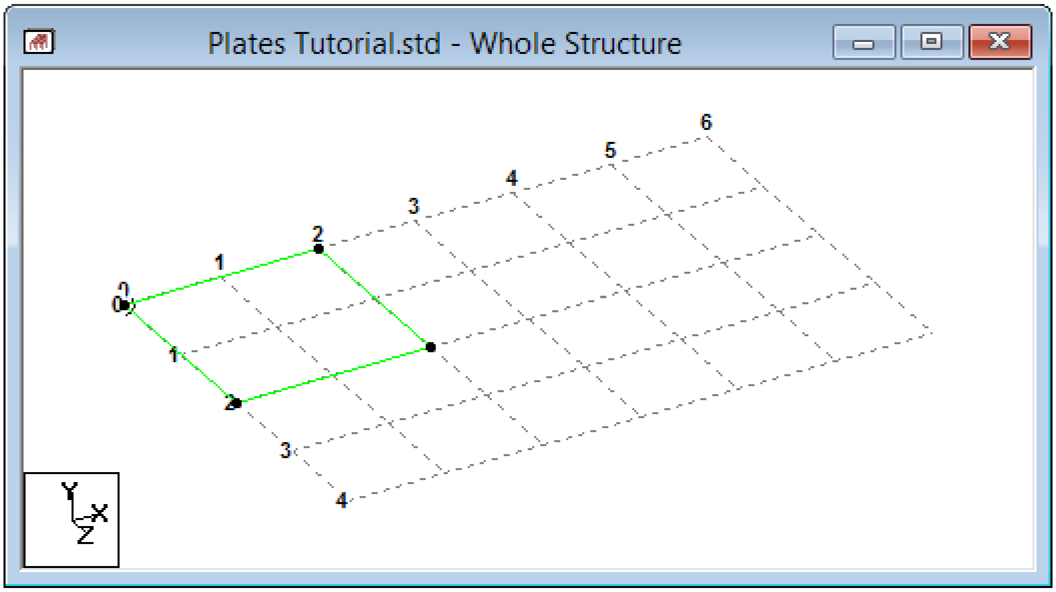
This method uses the same drawing grid from Method 1. Refer to " T.3 Setup the Grid (on page 562)."

1. In the View window, click at the origin (0, 0) to create the first node.
   A line is "rubber-banded" between this node and the mouse pointer, which previews the edge of the plate to placed with the next mouse click.



2. Click on the following points to create nodes and automatically join successive nodes by beam members.

   (2, 0, 0)
   (2, 0, 2)
   (0, 0, 2)



3. Click **Close** in the **Snap Node/Beam** dialog.
   The grid is hidden.
4. Press **<Shift+P>** to display the plate number.

T.3 Method 2 Creating Elements 2 3

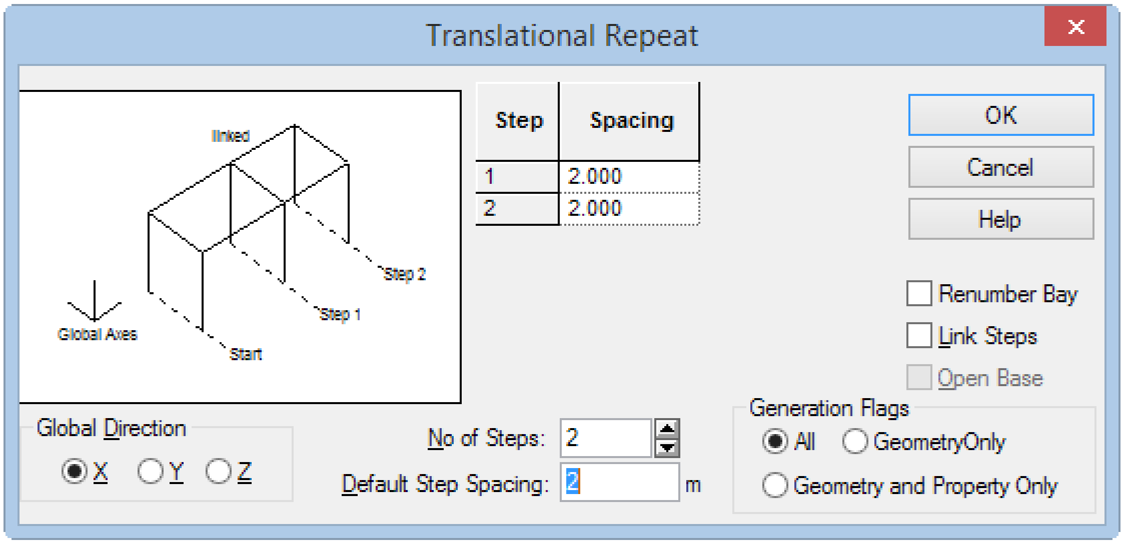
In Method 1, it required two separate executions of the Copy/Paste function to create elements 2 and 3. That is because, that feature does not contain a provision for specifying the number of copies you want to create. However, with Translational Repeat you can specify the number of copies and distances to each.

1. On the **Geometry** ribbon tab, select the **Plates Cursor** tool in the **Selection** group.

2. Select plate 1 in the View window.
3. On the **Geometry** ribbon tab, select the **Translational Repeat** tool in the **Structure** group.

   
   The **Translational Repeat** dialog opens.



4. Specify the translation repeat parameters:
   a. Select **X** as the **Global Direction** option.
   b. Type 2 (m) in the **Default Step Spacing** field.
   c. Type **2** in the **No of Steps** field and press the Tab key (or click the up arrow to increment the value to 2). The Step and Spacinng table updates to reflect two steps each at 2m spacing.

   Leave the **Renumber Bay** and **Link Steps** options unchecked and the **Generation Flags** set to **All**.

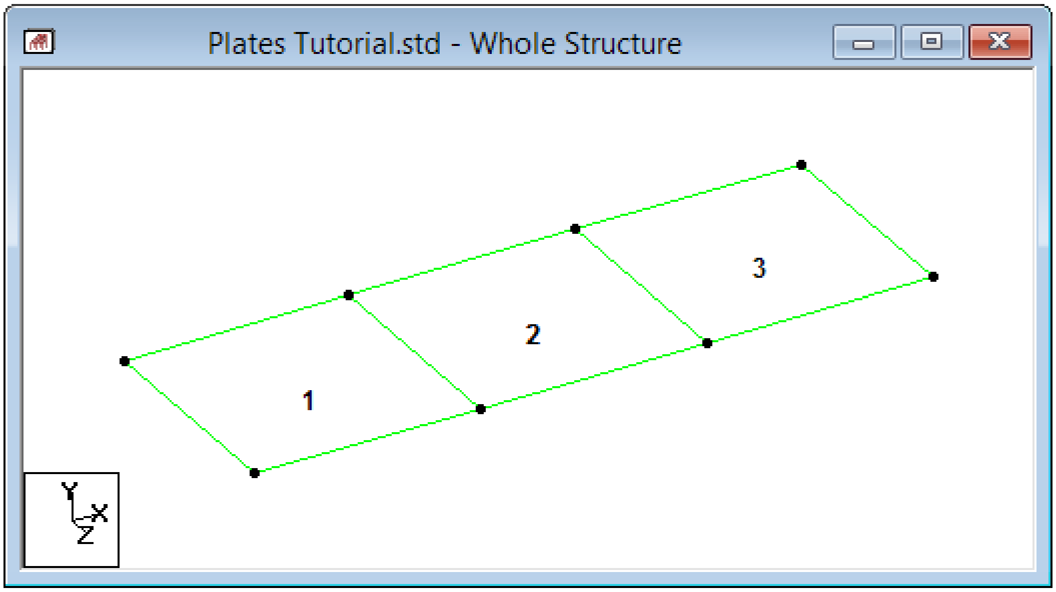
   Note:

   Using the **All** option for Generation Flags (default), all loads, properties, design parameters, member releases, etc. on the selected entities will automatically be copied along with the entities. You can limit this to geometry only or to geometry and properties only. In our example, it does not matter because no other attributes have been assigned yet.

   Renumber Bay is used to specify a custom number scheme for created entities, instead of the sequential number that the program otherwise generates. The **Linked Steps** option is used to generate linking members between new entities that have some distance separating them from the original entities.

5. Click **OK**.

   Elements 2 and 3 are created using the translational repeat parameters.



6. To select all plates, either:

   click-and-drag a window around all three plates using the **Plates Cursor** tool

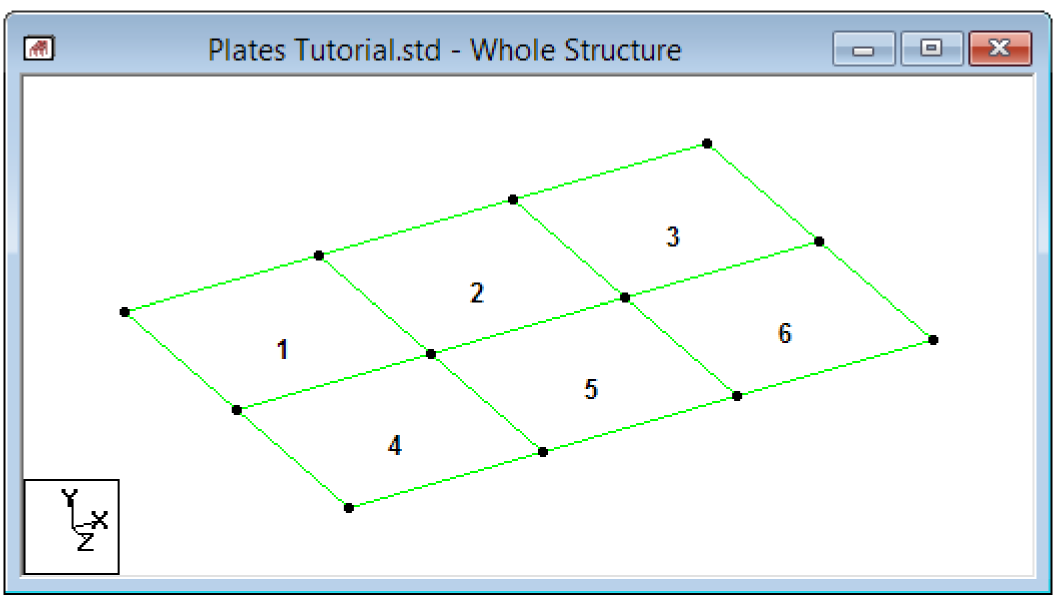
   or

   press **<Ctrl+A>**

   or

   on the **Geometry** ribbon tab, select the **Plates Cursor** > **All Plates** tool in the **Selection** group.
7. Repeat steps 3 and 4 except select **Z** as the **Global Direction** and the **No of Steps** as 1.

> **Tip:** Be sure to type 2 (m) in the **Default Step Spacing** field



8. Click anywhere in away from the plates to deselect them.

T.3 Creating the Plates - Method 3

To create the plate elements using the **Structure Wizard** program, use the following steps.

A program installed with STAAD.Pro called **Structure Wizard** offers a library of pre-defined structure templates (also referred to as “prototypes”), such as Pratt Truss, Northlight Truss, Cylindrical Frame, etc. A surface entity such as a slab or wall, which can be defined using 3-noded or 4-noded plate elements, is one such template. You can also create your own library of structure prototypes. From this wizard, a structural model may parametrically be generated, and can then be incorporated into your main structure.

1. On the **Geometry** ribbon tab, select the **Structure Wizard** tool in the **Structure** group.

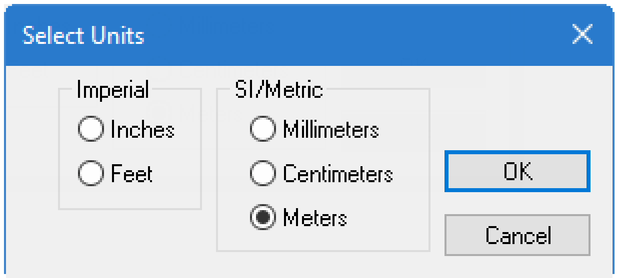
   The **Structure Wizard** window opens.

   
   *Figure 84: The **Structure Wizard** window*

> **Tip:** The **Open Structure Wizard** option in the **Where do you want to go?** dialog in the beginning stage of creating a new structure also opens this application.

2. The unit of length should be specified prior to the generation of a model.
   a. Select **File** > **Select Units**in the Structure Wizard window.

      The **Select Units** dialog opens.



b. Select **Meters**.

c. Click **OK**.

3. From the **Model Type** drop-down list, select **Surface/Plate Models**.

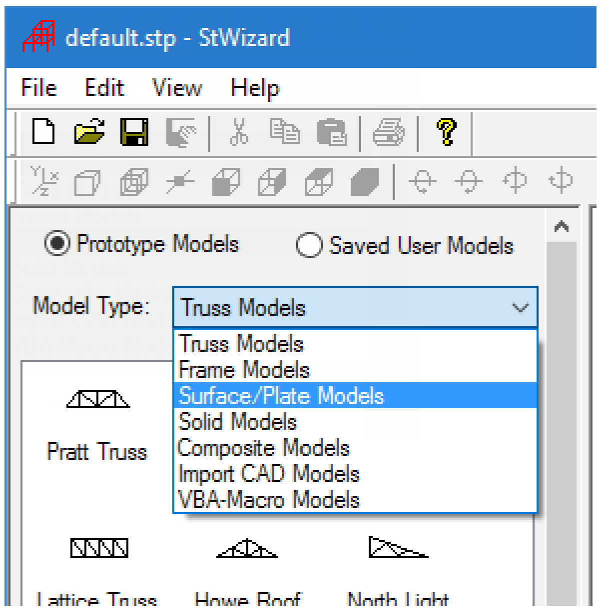


Figure 85:

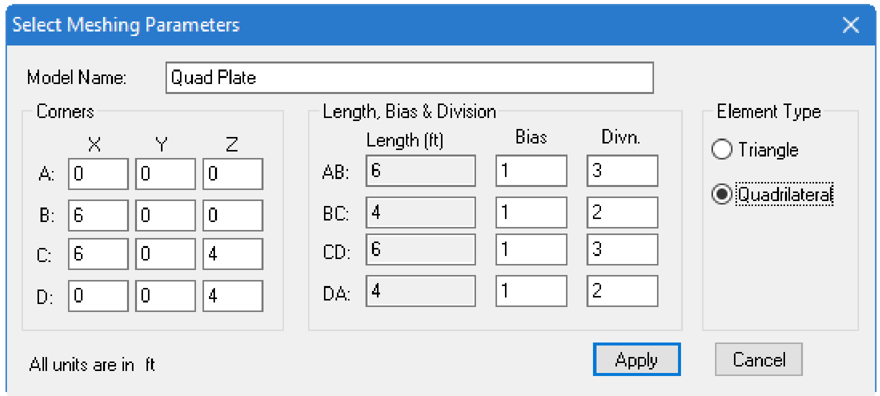
4. Either:

   double-click on the **Quad Plate** option 

   or

   drag the **Quad Plate** option to the right side of the **Structure Wizard** window

   The **Select Meshing Parameters** dialog opens.



5. Specify the meshing boundary corners and the individual element data as follows:
   a. Enter the following **Corners** data:

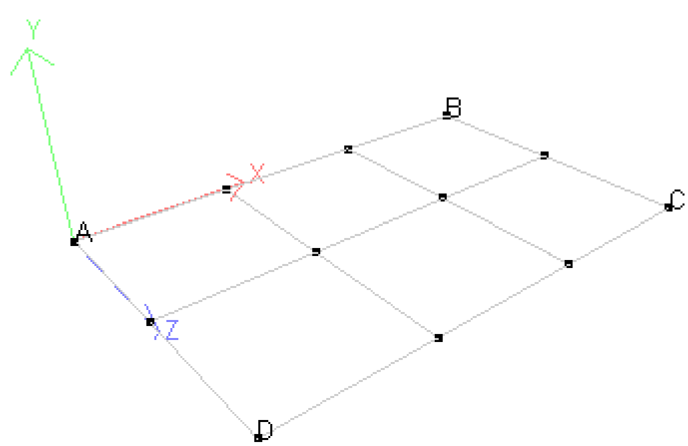
Corner	X	Y	Z
A	0	0	0
B	6	0	0
C	6	0	4
E	0	0	4

   The Length values are automatically calculated.
   b. Type 3 and the **Divisions** along AB and CD sides and 2 for the **Divisions** along BC and DA sides.

   Leave the **Bias** values all as **1**.
   c. Click **Apply**.

The mesh is generated.

Tip: If you made a mistake, right-click in the drawing area and select **Change Property** from the pop-up menu. The dialog opens and you can edit the mesh generations parameters.

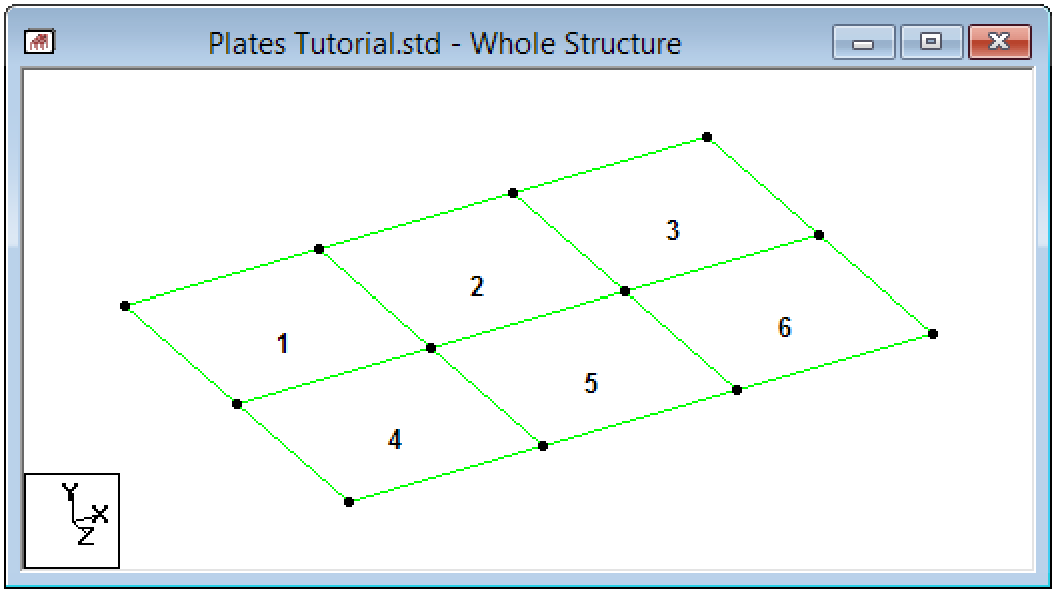


6. Select **File** > **Merge Model with STAAD.Pro Model**.
   You are prompted to confirm that you want to transfer the model data with your STAAD.Pro model.
7. Click **Yes**.

   The **Paste with Move** dialog opens.
8. Click **OK**.

   In this tutorial, there is no existing model nor is there a need to shift the model from the origin.

   The model will now be transferred to the main window.



If you want to proceed with assigning the remainder of the data, go to " T.3 Changing the input units of length (on page 580) ".

T.3 Creating the Plates - Method 4

To create the plates using the Mesh Generation facility, use the following steps.

This method uses the same drawing grid from Method 1. Refer to " T.3 Setup the Grid (on page 562)."

The STAAD.Pro GUI contains a facility for generating a mesh of elements from a boundary (or superelement) defined by a set of corner nodes. The boundary must form a closed surface and must lie within a plane, though that plane can be inclined to any of the global planes.

You define the boundary by selecting the corner nodes. If these nodes do not exist, they must be created before they can be selected.

1. Create the nodes:
   a. On the **Snap Node/Plate** dialog, click **Snap Node/Plate**.
   b. Click at the four corners of the grid at (0, 0, 0), (6, 0, 0), (6, 0, 4), and (0, 0, 4).

   Tip: If the node points are not visible, press **<SHIFT+K>**.
2. In the **Snap Node/Plate** dialog, click **Close**.
3. Use the Plates Cursor and select this plate.
4. To start a quadrilateral mesh of the existing plate element:

a. On the **Plate Tools** dialog, select the **Generate Plate Mesh** tool in the **Model** group.

The **Chose Meshing Type** dialog opens.

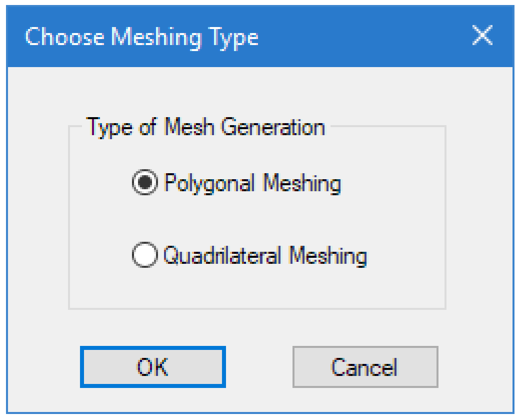


Figure 86:

b. Select the **Quadrilateral Meshing** option.

c. Click **OK**

The **Select Meshing Parameters** dialog opens.

5. Complete the meshing parameters:

   a. Type 3 and the **Divisions** along AB and CD sides and 2 for the **Divisions** along BC and DA sides.

   b. Click **Apply**.

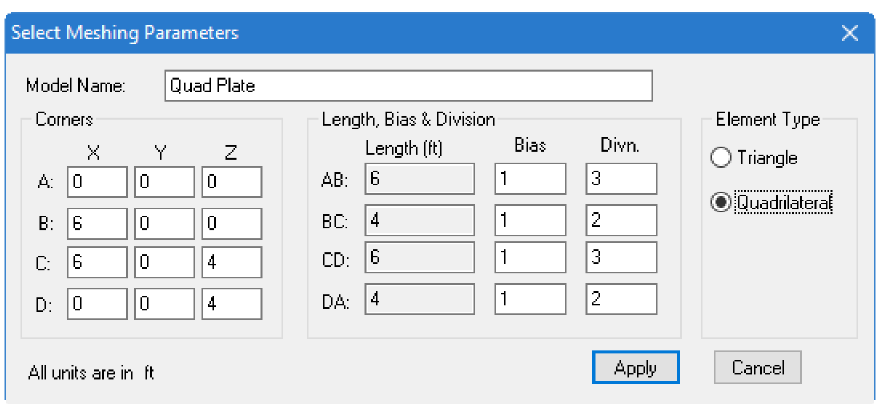

Figure 87:

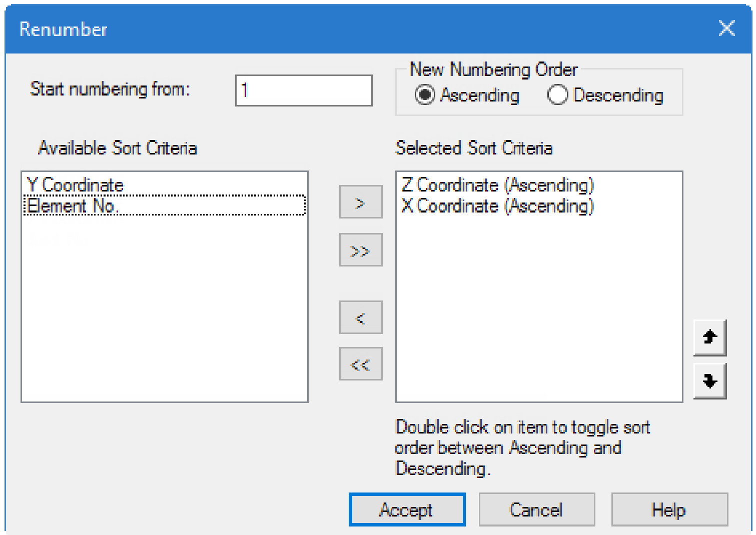
The surface is meshed.

6. Re-number the plate elements:

   a. On the **Plate Tools** ribbon tab, select the **Renumber Plates** tool in the **Model** group.

A warning message opens.

b. Click **Yes**.
The **Renumber** dialog opens.



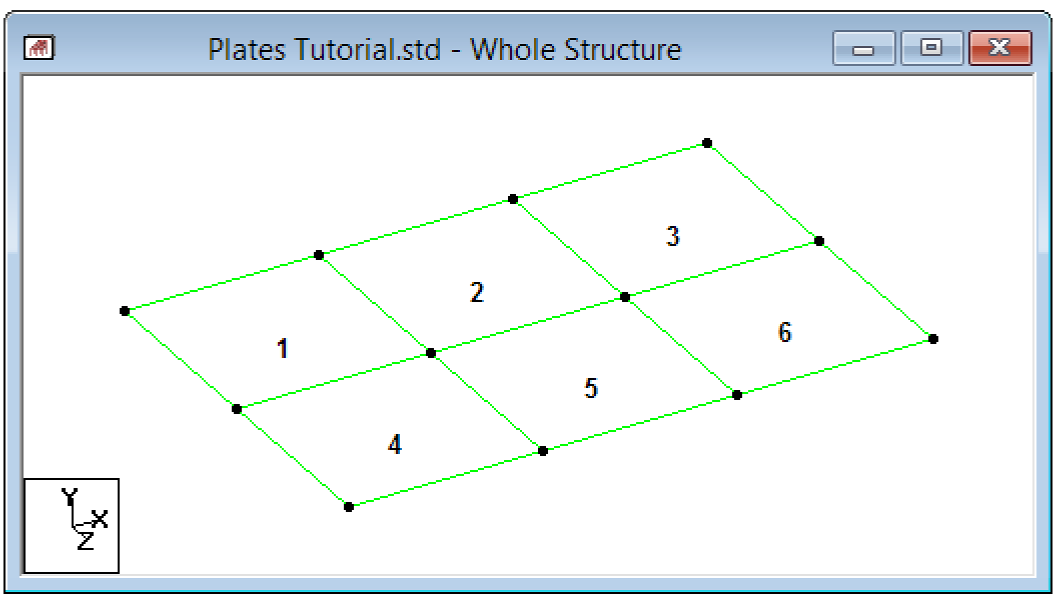
c. Double-click **Z Coordinate** in the **Available Sort Criteria** list.

d. Double-click **X Coordinate** in the **Available Sort Criteria** list.

The Z coordinate entry should appear *above* the X coordinate entry in the Selected Sort Criteria list.

e. Click **Accept**.

The six plates are re-numbered as shown below.



As an alternative in step 1, you can press and hold **<Ctrl>** to create only disconnected nodes. Then, when you can use the **Generate Mesh** > **Generate Plate Mesh** tool in the **Plate** group on the **Geometry** ribbon tab to generate the plates from those nodes, rather than re-meshing an existing plate. You then use the plate bound selection cursor  to select these corner nodes to define a meshed boundary.

Tip: Pressing the **<Ctrl>** key while clicking on grid points creates new nodes without connecting those nodes with beams or plates. If the **<Ctrl>** key is not kept pressed, the nodes become connected.

T.3 Changing the input units of length

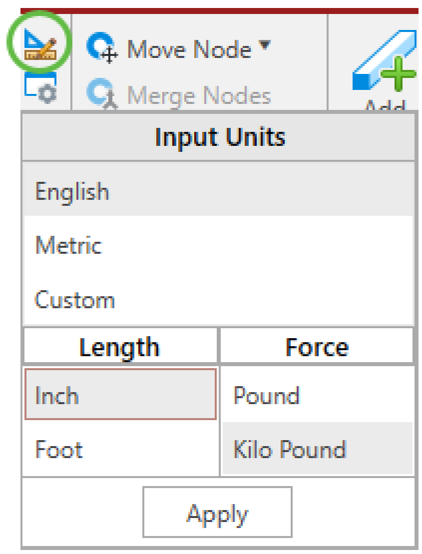
To specify element properties for the structure, it is more convenient to use length units of centimeter instead of meter. This requires changing the current length units of input.

The STAAD input file commands generated are:

```
UNIT CM KN
```

1. On the **Geometry** ribbon tab, select the **Input Units** tool in the **Structure** group.

The **Set Input Units** pop-up opens.



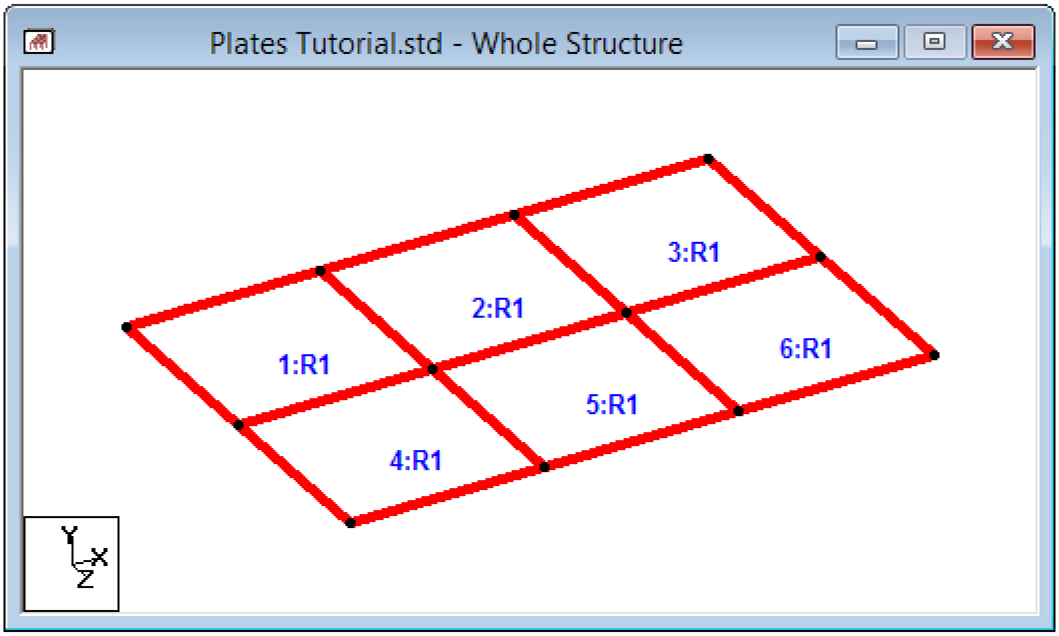
2. Select **Metric** as the **Input Units**.
3. Set the **Length** units to **Centimeter**.
   Leave the Force units as KiloNewton.
4. Click **Apply**.

T.3 Specifying Element Properties

Just as properties are assigned to members, properties must be assigned to plate elements too. The property required for plates is the plate thickness (or the thickness at each node of elements if the slab has a varying thickness).

The STAAD input file commands generated are:

```
ELEMENT PROPERTY
1 TO 6 THICKNESS 30
```



1. To select all plates, either:

   click-and-drag a window around all three plates using the **Plates Cursor** tool

   or

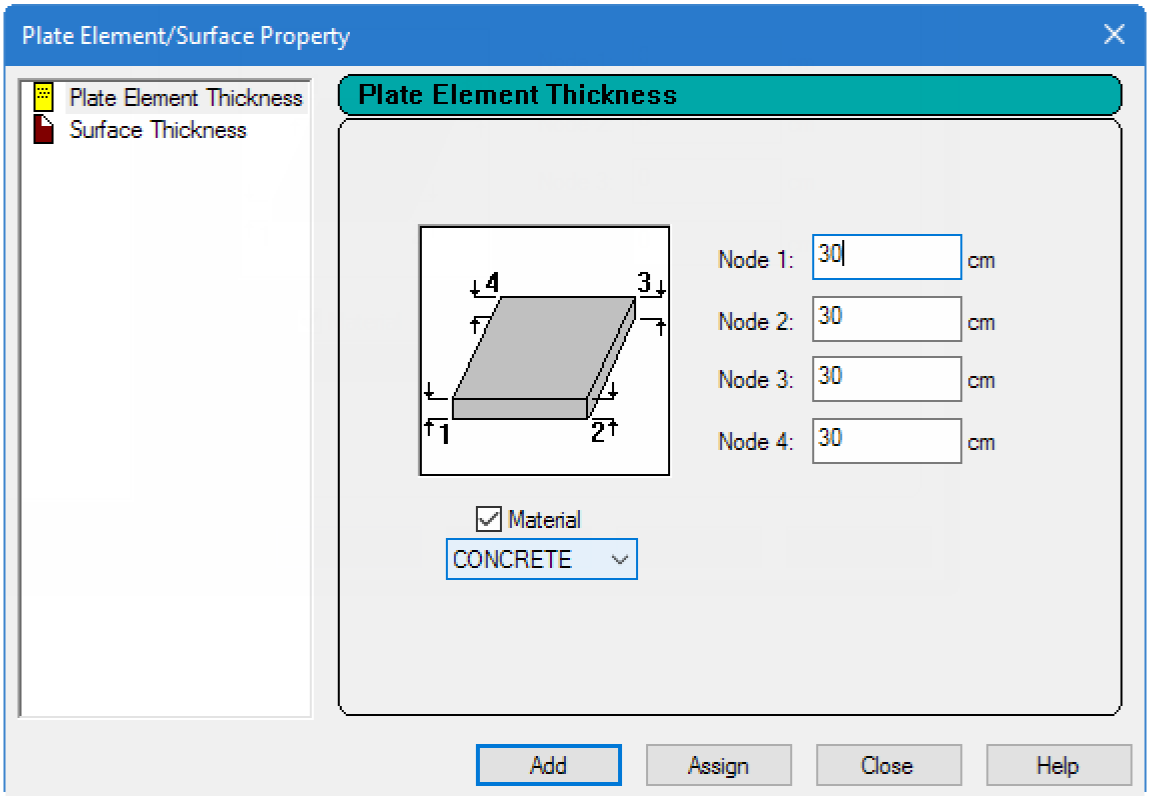
   press **<Ctrl+A>**

   or

   on the **Geometry** ribbon tab, select the **Plates Cursor** > **All Plates** tool in the **Selection** group.
2. On the **Specification** ribbon tab, select the **Plate Thickness** tool in the **Plate Profiles** group.

   The **Properties - Whole Structure** and the **Plate Element/ Surface Property** dialogs open.



3. Specify the material and thickness:
   a. Type `30` cm for the **Plate Element Thickness** at each corner.

   > **Tip:** Typing a value in the first field will automatically populate the remaining fields as a uniform thickness is typical.

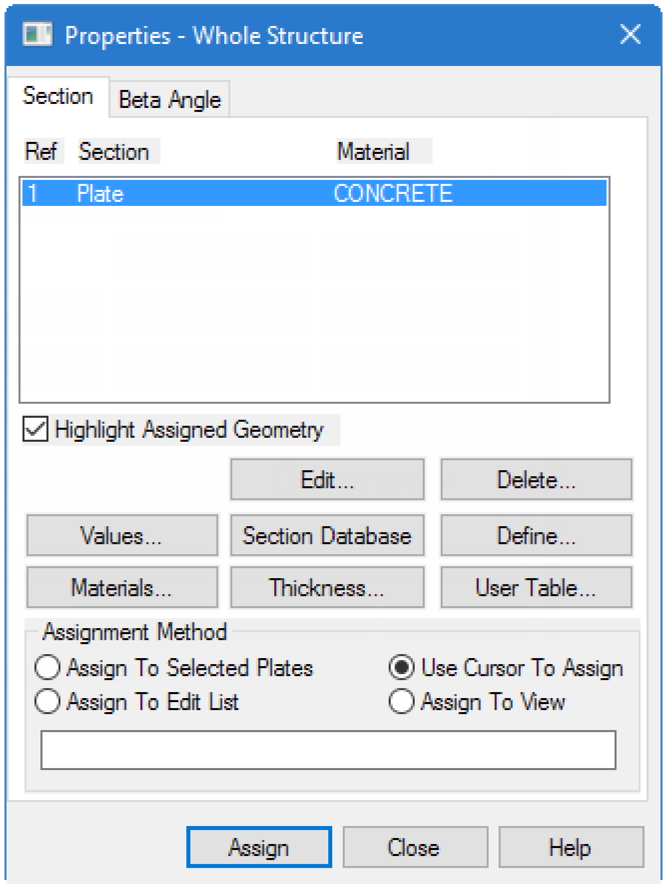
   b. Ensure that **Material** option is checked and that **CONCRETE** is selected.

   This instructs the program to assign the material properties of Concrete (E, Poisson, Density, Alpha, etc.) will be assigned along with the plate thickness.

   > **Tip:** The material property values so assigned will be the program defaults. You can review those values by clicking **Materials** in the **Properties - Whole Structure** dialog.

   c. Click **Assign**.
   d. Click **Close**.

The plate property is added to the **Properties - Whole Structure** dialog list and is assigned to the plate elements..



4. Click anywhere in the drawing area to deselect the selected entities.

> **Tip:** This is a best practice to follow when using the assignment feature. When an entity is highlighted, clicking on any Assign option is liable to cause an undesired attribute to be assigned to that entity.

T.3 Specifying Material Constants

When " T.3 Specifying Element Properties (on page 580) ", you used the **Material** option. Consequently, the material definition (E, Density, Poisson's Ratio, etc.) of concrete were assigned to the plates along with the properties

The STAAD input file commands generated are:

```
DEFINE MATERIAL START
ISOTROPIC CONCRETE
E 2171.85
POISSON 0.17
DENSITY 2.35616e-005
ALPHA 1e-005
DAMP 0.05
TYPE CONCRETE
STRENGTH FCU 2.7579
END DEFINE MATERIAL
CONSTANTS
MATERIAL CONCRETE ALL
```

Tip: However, if you had not assigned the material definition along with the thickness, you could use the **Materials** page in the **Analytical Modeling** worfklow page control to do so.

T.3 Specifying Supports

The slab is fixed-supported along the entire length of two adjacent sides. However, when modeled as plate elements, the supports can be specified only at the nodes along those edges, and not at any point between the nodes.

Tip: The finer the mesh (i.e., the larger the number of elements), then the more supported nodes you would be able to model. For this tutorial, the 2 meter mesh is used as a simple demonstration.

The STAAD input file commands generated are:

```
SUPPORTS
1 2 4 5 7 10 FIXED
```

Note: The node numbers *may be different* depending on the method of plate creation used. Regardless, the nodes should be those along the X and Z axis.

1. Press **<Shift+N>** to turn on the display of the **Node Numbers**.

   This will assist in the identification of the nodes used as supports.
2. On the **Geometry** ribbon tab, select the **Nodes Cursor** tool in the **Selection** group.

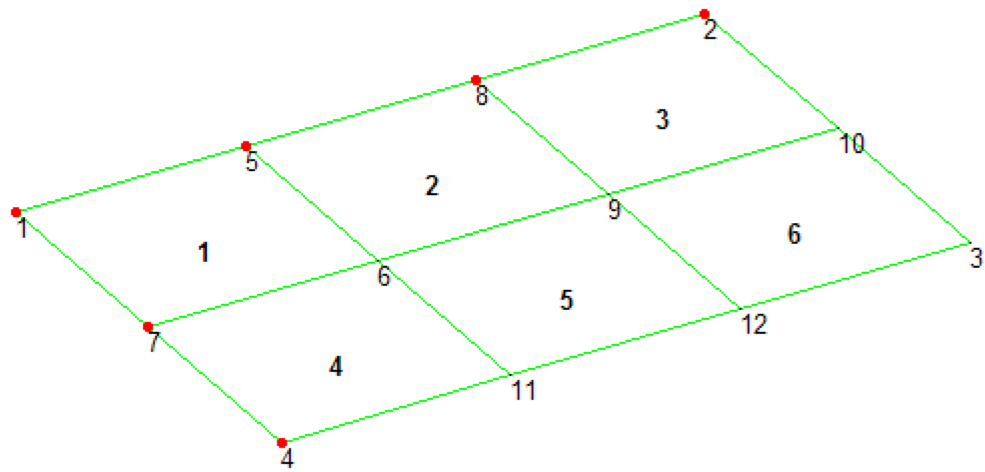
   

3. While pressing the **<Ctrl>** key, select the nodes on two adjacent edges of the plate group:

   These nodes are fixed supports in the model.

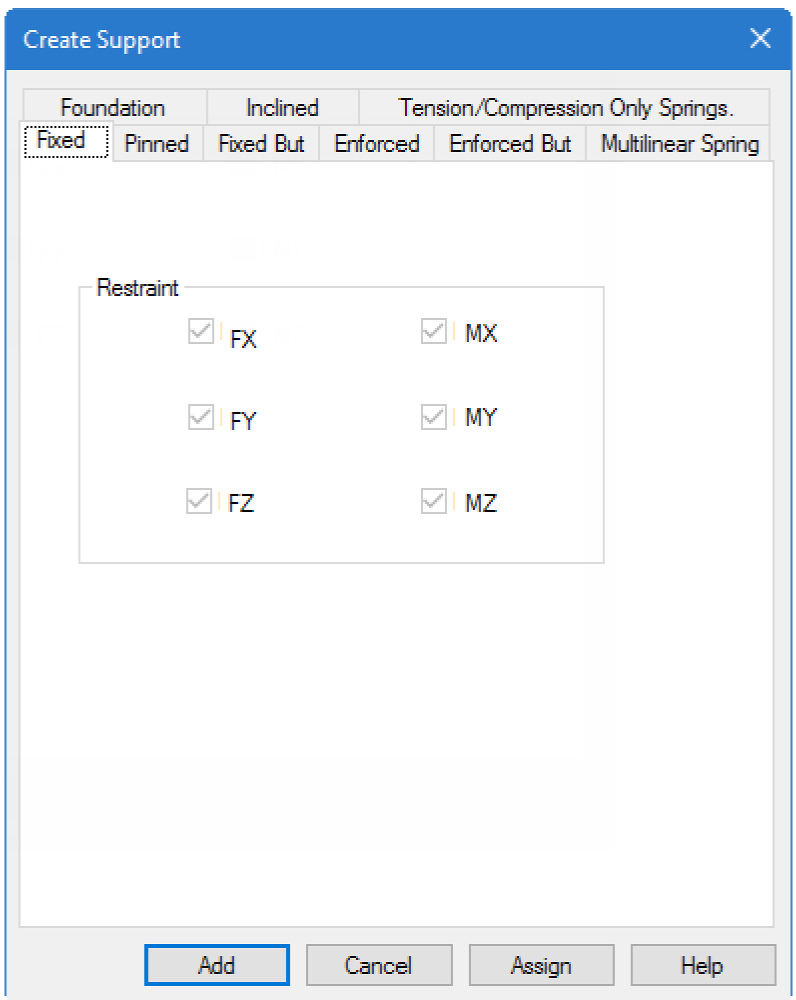
   For example, in the following figure these nodes are:

   1
   7
   4
   5
   8
   2



4. On the **Specification** ribbon tab, select the **Fixed** tool in the **Supports** group.

   The Create Support dialog opens with the **Fixed** tab selected.



5. Click **Assign**.

> **Note:** The **Assign** button is active because you selected the nodes previously.

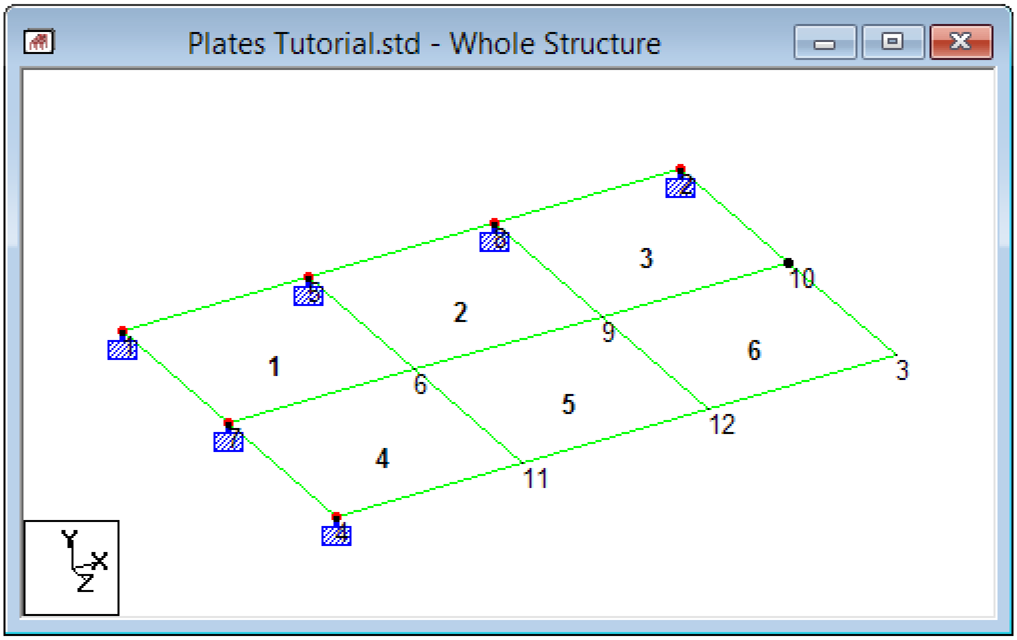


Figure 88: The structure with fixed supports along two adjacent edges

The fixed support type is also added to the **Supports - Whole Structure** dialog as S2.

T.3 Specifying Primary Load Cases

Three primary load cases are required for this structure.

The STAAD input file commands generated are:

```
UNIT METER KG
LOAD 1 DEAD LOAD
SELF Y -1.0
LOAD 2 EXTERNAL PRESSURE LOAD
ELEMENT LOAD
1 TO 6 PR GY -300
LOAD 3
TEMPERATURE LOAD
1 TO 6 TEMP 40 30
```

1. Change the units:

   > **Note:** The pressure load value listed in the beginning of this tutorial is in **KN** and **meter** units. Rather than convert that value to the current input units, this tutorial will conform to those units. The current input units, which you last set by specifying the thickness was centimeter. Therefore, you need to change the force unit to Kilogram and the length units to Meter.

   a. Click the drop-down arrow beside the current Input Units in the application window status bar.
      The **Set input Units** dialog opens.
   b. Select the length units as **Meter** and the force units as **Kilogram**.
   c. Click **Apply**.

2. Add the dead load case:
   a. On the **Loading** ribbon tab, select the **Primary Load Case** tool in the **Loading Specifications** group.

The **Add New Load Cases** dialog opens.

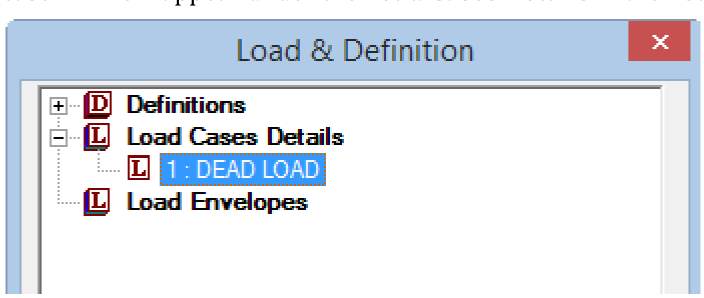
   b. Type `Dead Load` as the **Title** for Load Case 1.

   Leave the **Number** as the default (1) and leave the **Loading Type** as None.

   Note: The **Loading Type** list is used to associate the load case we are creating with any of the ACI, AISC, IBC, or other code-prescribed definitions of Dead, Live, Ice, etc. This type of association needs to be done if you intend to use the program's automatically generating load combinations in accordance with those codes. Note that there is a check box labeled **Reducible per UBC/IBC**. This feature is active only when the load case is assigned a Loading Type called **Live** when you create that load case.

   c. Click **Add**.

The newly created load case will now appear under the **Load Cases Details** in the **Load & Definition** dialog.



3. Create the selfweight load:
   a. On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

   The **Add New Load Items** dialog opens.

   b. Select the **Selfweight Load** option under the **Selfweight** item.
   c. Select the **Direction** as **Y**
   d. Type the **Factor** as `-1.0`.

   The negative number signifies that the selfweight load acts opposite to the positive direction of the global axis (Y in this case) along which it is applied.
   e. Click **Add**.
4. Assign the selfweight load to all of the elements:
   a. In the **Load & Definition** dialog, select **SELFWEIGHT Y -1**.
   b. Select the **Assign to View** option.
   c. Click **Assign**.

   A message dialog opens confirming you want to make this assignment.
   d. Click **Yes**.
5. Add the pressure load case:
   a. On the **Loading** ribbon tab, select the **Primary Load Case** tool in the **Loading Specifications** group.

The **Add New Load Cases** dialog opens.

b. Type `External Pressure Load` as the **Title**.

   Again, there is no need to associate the load case with any code based Loading Type so leave the selection as **None**.

c. Click **Add**.

6. On the **Loading** ribbon tab **Display** group, select **2: External Pressure Load** from the **Load** drop-down list.
7. Create the pressure load:

   a. On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

   The **Add New Load Items** dialog opens.

   b. Select the **Pressure on Full Plate** option under the **Plate Loads** item.

   This type enables the load to be applied on the full area of the element.

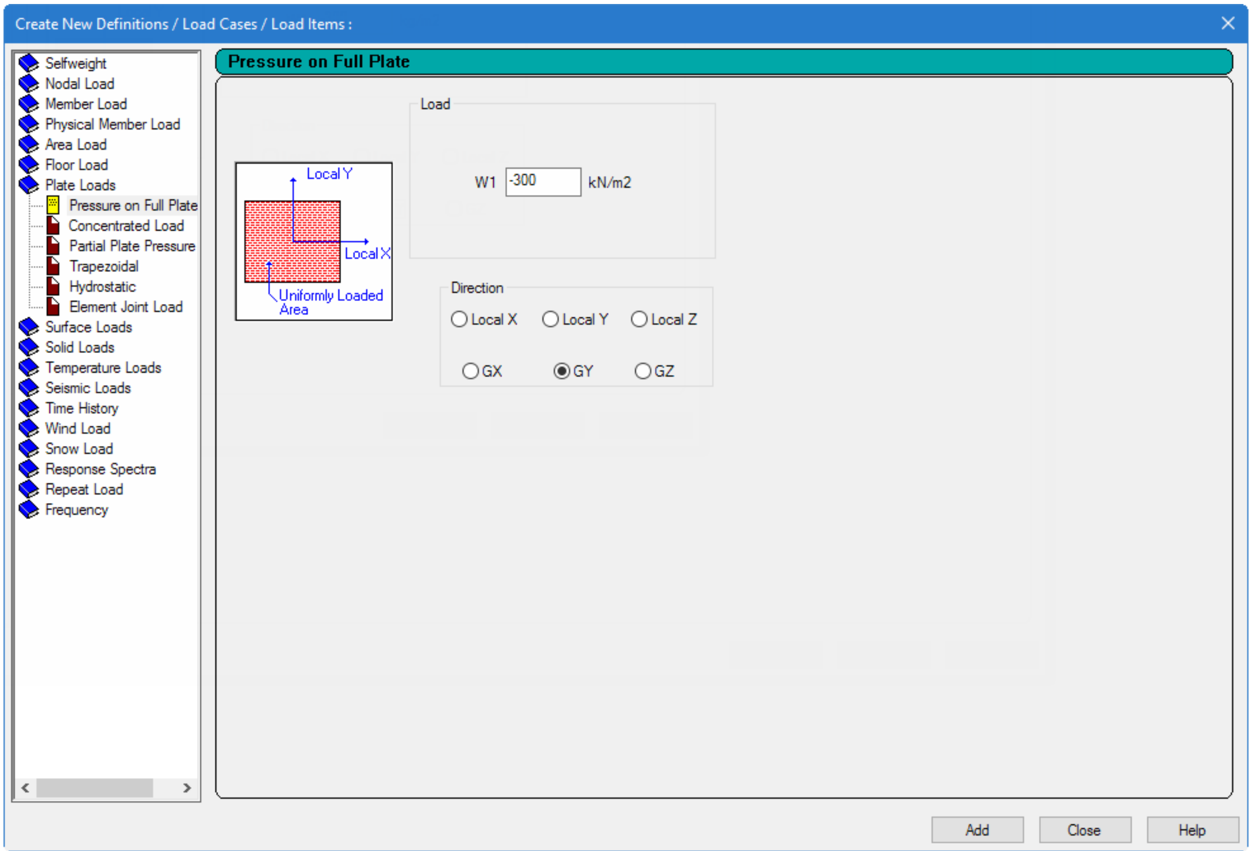
   > **Note:** The **Concentrated Load** is for applying a concentrated force on the element. The **Trapezoidal** and **Hydrostatic** options are for defining pressures with intensities varying from one point to another. The **Partial Plate Pressure Load** is useful if the load is to be applied as a “patch” on a small localized portion of an element.

   c. Type `-300` kg/m^2 in the **W1** field (force)

   d. Select **GY** as the **Direction** (global Y direction).

   e. Click **Add**.

   f. Click **Close**.



8. Repeat steps 5 and 6 to create a third load case titled `Temperature Load` and then select it on the **Loading** ribbon tab **Display** group.
9. To generate and assign the third load type:
   a. On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

      The **Add New Load Items** dialog opens.
   b. Select the **Temperature** option under the **Temperature Loads** item.
   c. Type `40` in the **Temperature Change for Axial Elongation**field.
   d. Type `30` in the **Temperature Differential from Top to Bottom** field.

      Leave the **Temperature Differential from Side to Side (Local Z)** field as 0 (default).
   e. Click **Add** and then click **Close**.

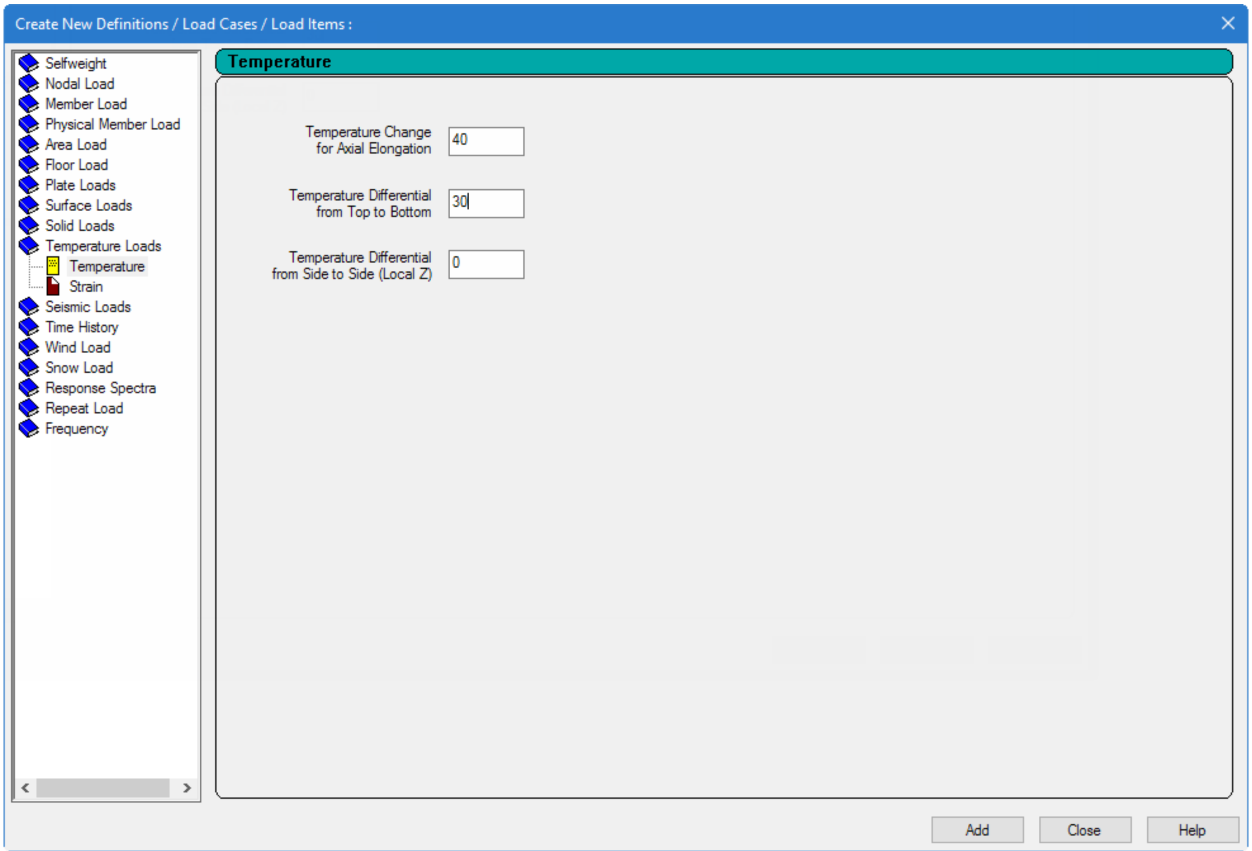


Figure 89:

10. To apply the pressure load and temperature load on all the plates, repeat step 4 for each load item.

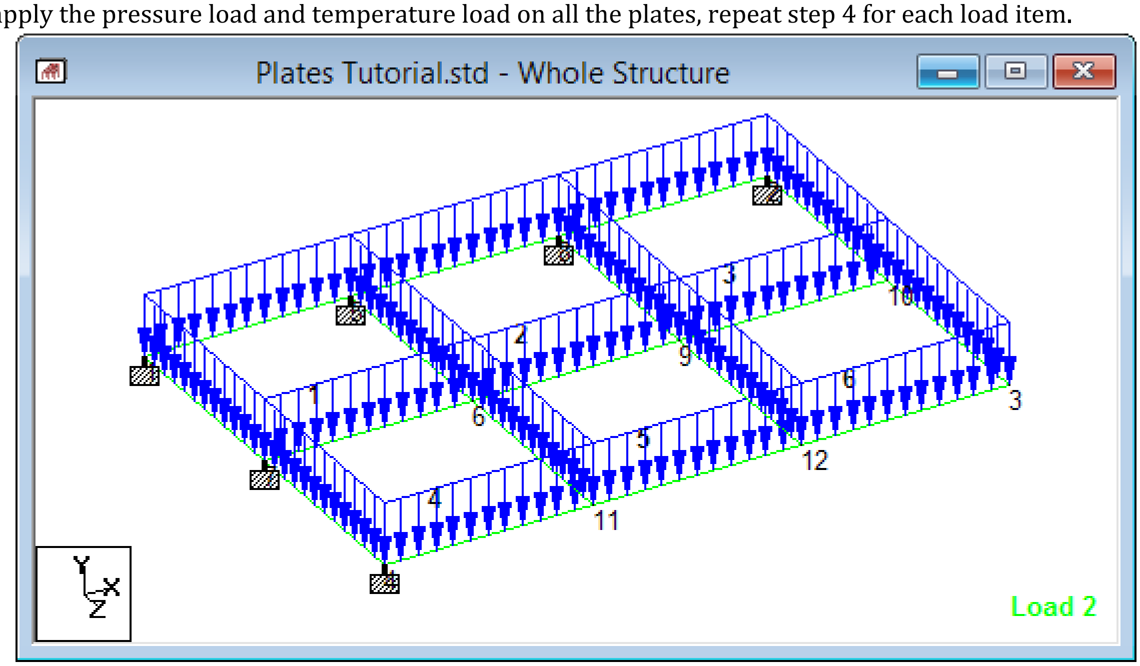

Figure 90: The pressure load applied to all plate elements

T.3 Analysis and Design

The following procedures describe how to add analysis and design commands to the STAAD input file.

Note: The analysis design commands are added using either the analytical user interface or the STAAD.Pro Editor. The STAAD.Pro Physical Modeler interface is not used to assign analysis and design commands.

T.3 Creating load combinations

This tutorial requires creating two combination cases.

The STAAD input file commands generated are:

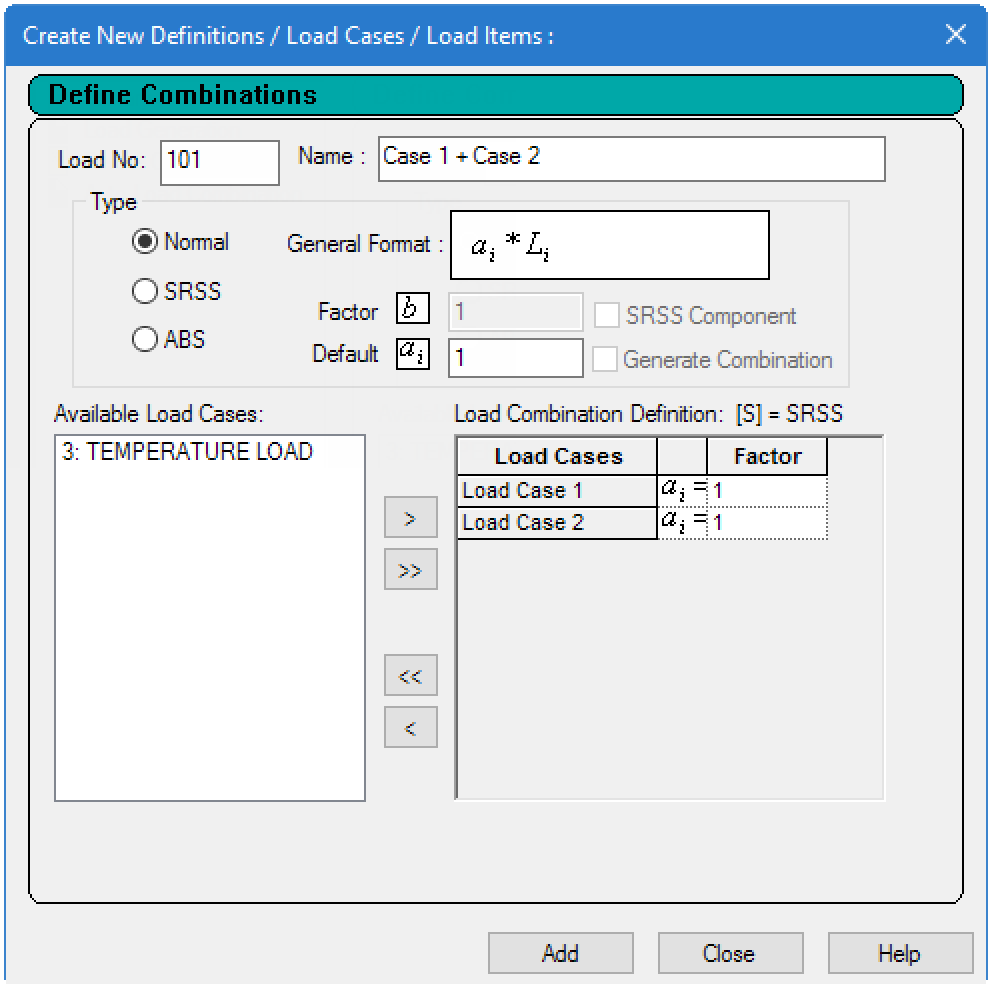
```
LOAD COMBINATION 101 CASE 1 + CASE 2
1 1.0 2 1.0
LOAD COMBINATION 102 CASE 1 + CASE 3
1 1.0 3 1.0
```

1. Define load case 4 as a load combination:
   a. On the **Loading** ribbon tab, select the **Combination Load Case** tool in the **Loading Specifications** group.

      The **Create New Load Combinations** dialog opens.
   b. Select the **Define Combinations** option from the left-hand side.
   c. Type `101` in the **Load No:** field.
   d. Type `Case 1 + Case 2` in the **Title**field.

   Leave the **Type** option as **Normal** and the **Default a1** as `1`. This uses the algebraic sum of the results for the individual load cases in the load combination. The individual results will have a multiplication factor of 1.



2. Select the load cases for the load combination:
   a. Select **1: DEAD LOAD** from Available Load List and then click **[>]**.
   b. Select **2: EXTERNAL PRESSURE LOAD** from Available Load List and then click **[>]**.
   Load cases 1 and 2 will appear in the Load Combination Definition list.
   c. Click **Add**.

   Case 101 is created.
3. To define load case 5 as a load combination, repeat step 1 but type `102` in the **Load No:** field and type `Case 1 + Case 3` in **Title**field.
4. Repeat step 2 except for selecting load cases 1 and 3 instead of cases 1 and 2.

   Tip: The load cases and combination methods used for a load combination can be changed by selecting a load combination and then clicking **Edit.**

   Load 102 is created.
5. Click **Close.**

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.3 Specifying the analysis type

A linear, static analysis is required for this model. You can also instruct STAAD.Pro to provide a static equilibrium report.

The STAAD input file commands generated are:

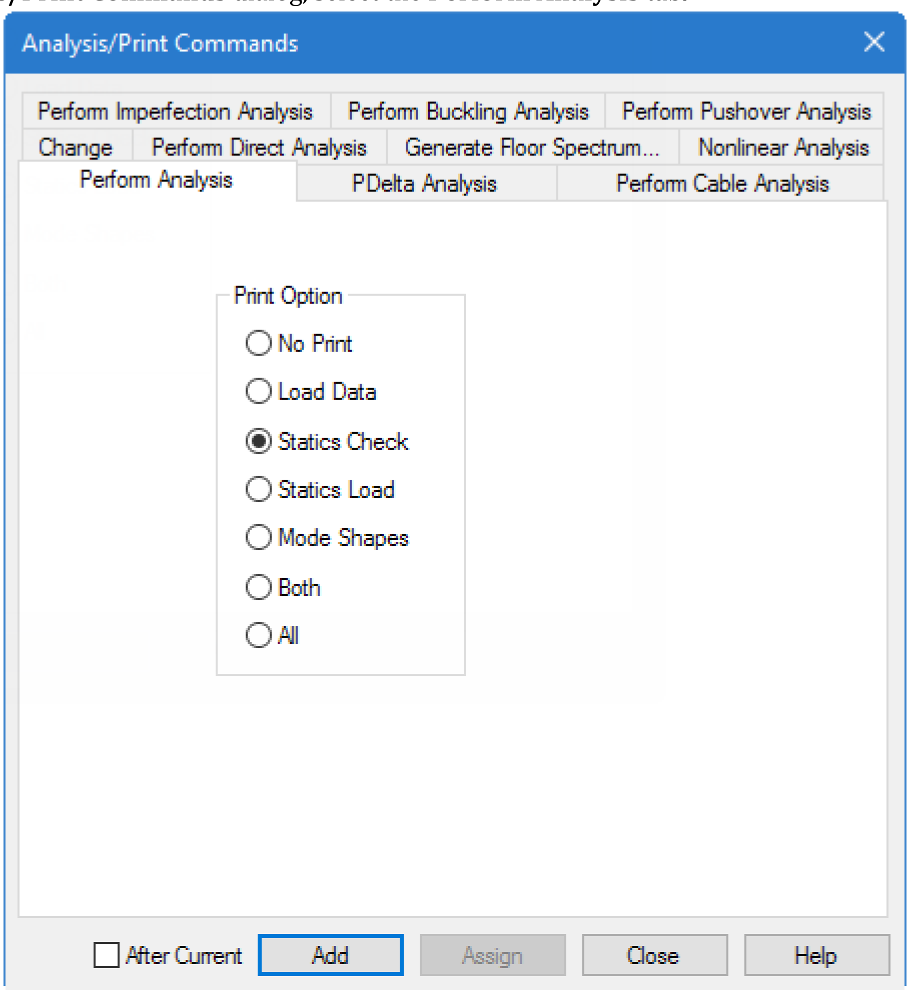
```
PERFORM ANALYSIS PRINT STATICS CHECK
```

1. On the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group.

   The **Analysis/Print Commands** dialog opens.

   Tip: If the **Analysis/Print Commands** dialog does not open automatically, then click **Define Commands** in the **Analysis - Whole Structure** dialog.

2. In the **Analysis/Print Commands** dialog, select the **Perform Analysis** tab.



3. Select the **Statics Check** print option.

 Note: In response to this option, a report consisting of the summary of applied loading and summary of support reactions, for each load case, will be produced in the STAAD output file.

4. Click **Add**
5. Click **Close**.

 The **Analysis** command is added to the **Analysis - Whole Structure** dialog.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.3 Specifying post-analysis print commands

Two types of element results can be requested:

- **a.** element stresses at the centroid or any point on the element surface which consist of stresses and moments per unit width, as explained in G.5.1 Plate and Shell Elements (on page 2099) and TR.42 Print Specifications (on page 2666).
- **b.** the element forces at the nodes which consist of the 3 forces and 3 moments at each node of the elements in the global axis system (refer to TR.42 Print Specifications (on page 2666) for details).

You will add both types of these results for this tutorial.

You will also need to set the units in which these results are printed to KN and Meter for element stresses and Kg and Meter for element forces.

The STAAD input file commands generated are:

```
UNIT METER KN
PRINT ELEMENT STRESSES LIST 3
UNIT KG METER
PRINT ELEMENT FORCE LIST 6
```

These results will be written in the STAAD output file and can be viewed using the procedure explained in " T.3 Viewing the output file (on page 605) ".

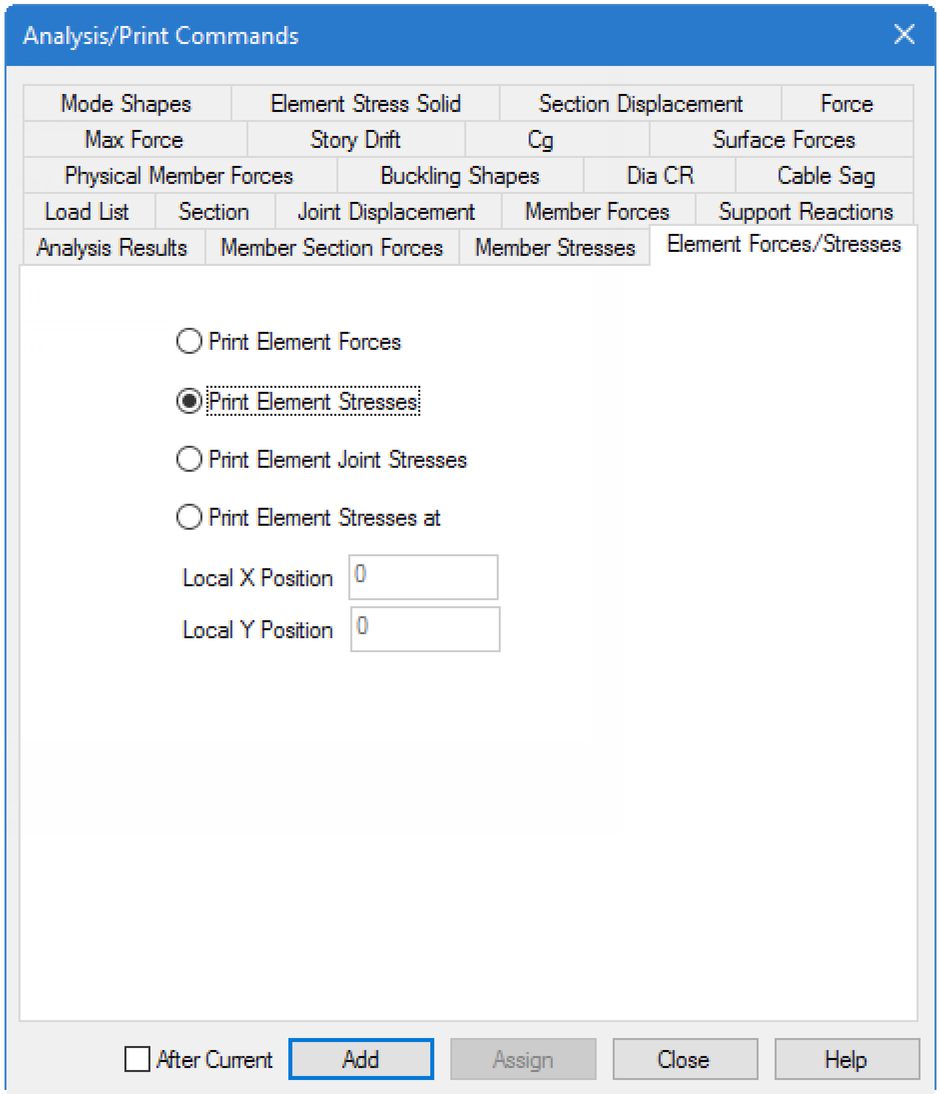
1. Set the length and force units to **Meter** and **Kilonewton** respectively.

   Refer to T.3 Changing the input units of length (on page 580) for additional information on this procedure.
2. On the **Analysis and Design** ribbon tab, select the **Post-Analysis Commands** tool in the **Analysis Data** group.

   The **Post Analysis Print - Whole Structure** dialog opens.
3. On the **Post Analysis Print - Whole Structure** dialog, click **Define Commands**.

   The **Analysis/Print Commands** dialog opens.



4. Select the **Element Forces/Stress** tab.
5. Select the **Print Element Stresses** option.
6. Click **Add** and then click **Close**.
7. Set the length and force units to **Meter**and **Kilogram** respectively.
8. Repeat steps 3 through 6 except select the **Print Element Forces** option in step 5.

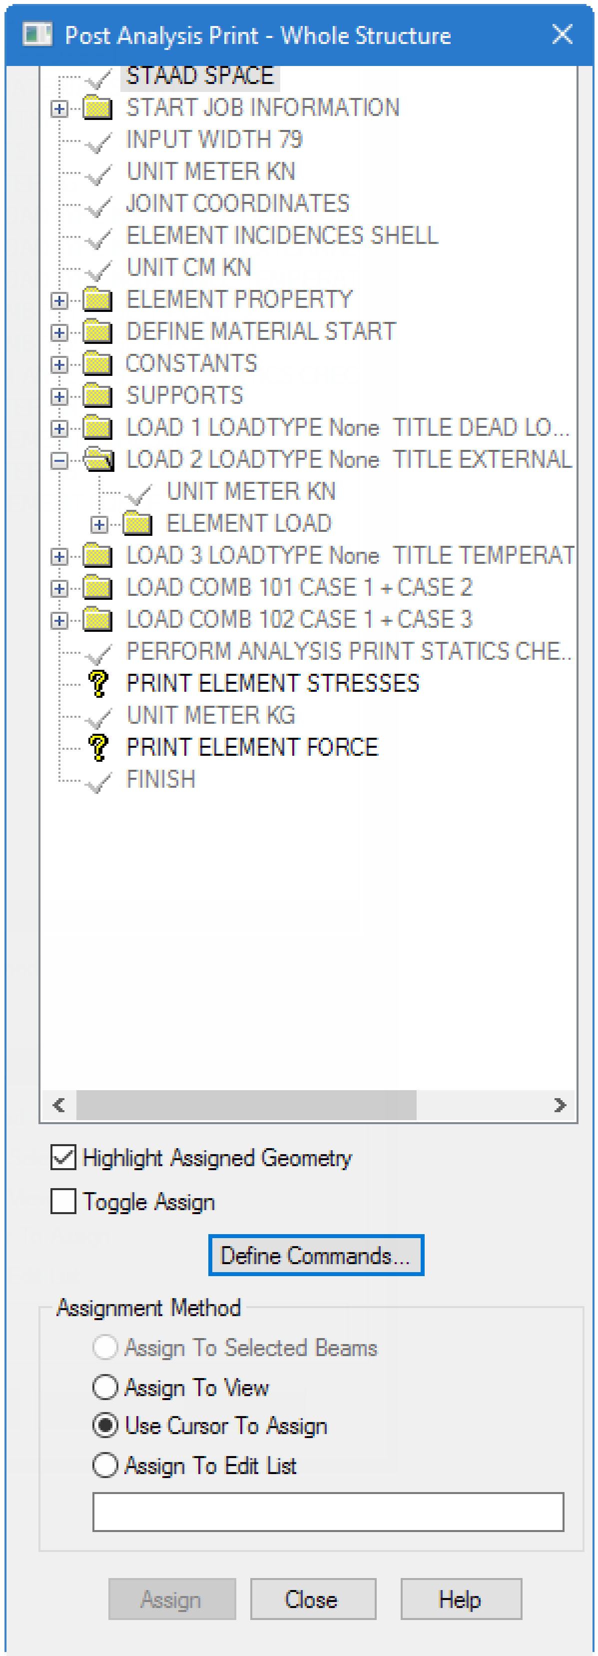


Figure 91: The dialog with unassigned commands

9. Associate the print element stresses with element 3:
   a. Select the **PRINT ELEMENT STRESSES** command in the **Post Analysis Print - Whole Structure** dialog commands list.
   b. On the **Geometry** ribbon tab, select the **Plates Cursor** tool in the **Selection** group.

   

   c. In the view window, select element no. 3.

   When you select the plate, the **Assignment Method** automatically becomes **Assign to Selected Plates**.
   d. Click **Assign**.
10. To associate the **PRINT ELEMENT FORCE** command with element 6, use a similar procedure as step 9 except for selecting element no. 6 in the place of element no. 3.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

T.3 Viewing the input command file

You can inspect the text data file created during this tutorial.

1. On the **Utilities** ribbon tab, select the **Command File** tool in the **Edit** group.

   

   The STAAD.Pro Editor opens with the contents of the input file.

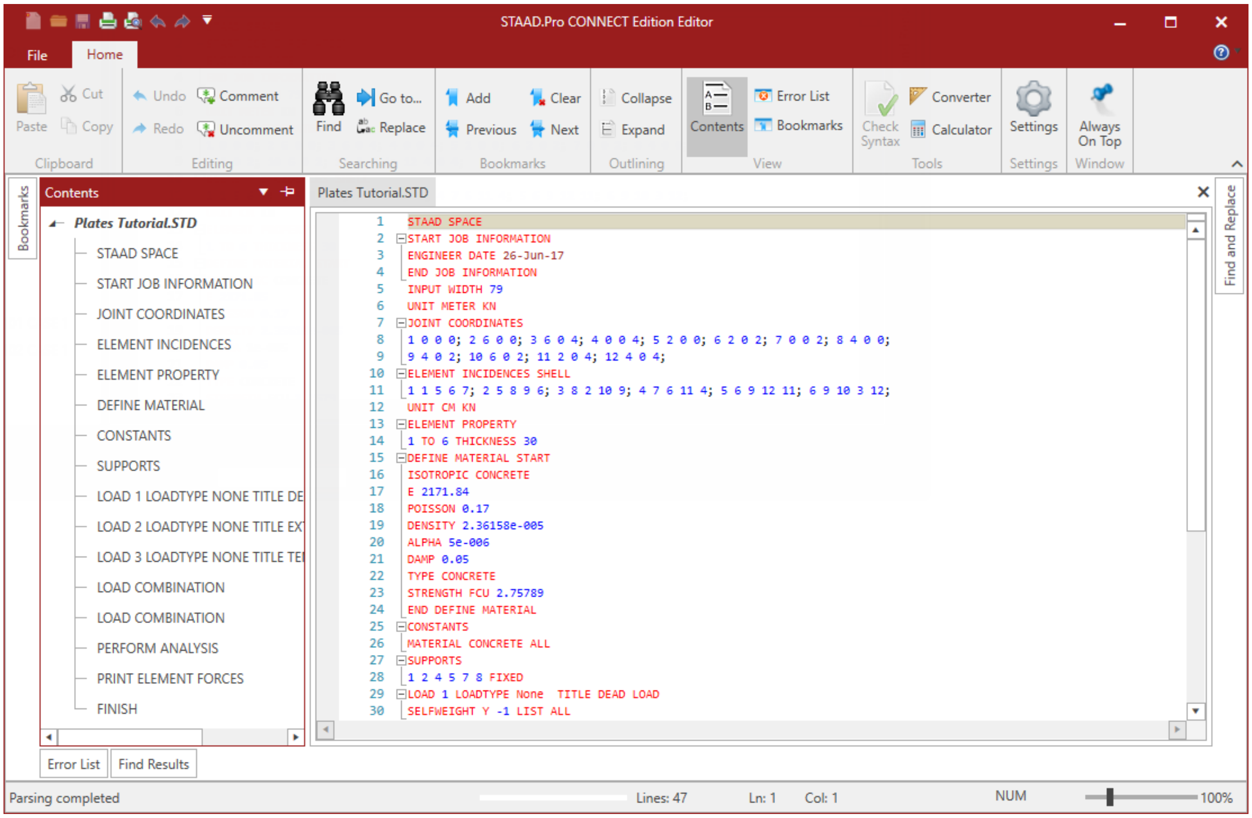

Figure 92: The STAAD.Pro Editor window

2. (Optional) You modify the data of the structure in this editor if necessary.
3. Select **File** > **Exit Editor** in the STAAD.Pro Editor window to close.

As stated in T.3 Methods of creating the model (on page 550), you could also have created the same model by typing the relevant STAAD commands into a text file using the STAAD.Pro Editor. If you would like to understand that method, proceed to the next section. If you want to skip that part, proceed to T.3 Performing the analysis and design (on page 604) where you will perform the analysis and design on this model.

T.3 Creating the model using the command file

As an alternatively to the procedures described in the proceeding tutorial, you can also create the same STAAD input file using the STAAD.Pro Editor.

To start a new STAAD input file using the STAAD.Pro Editor, follow the procedure described in T.3 Creating a new structure (on page 552). Then select the **Command File** tool in the **Edit** group on the **Utilities** ribbon tab. The STAAD.Pro Editor window opens with the basic commands for your model entered.

Note: A STAAD input file is a plain text file that uses the `.std` file extension. Therefore any standard text editor such as Notepad can also be used to create the command file. However, the STAAD.Pro Editor offers the advantage of syntax checking as you type the commands. The STAAD command syntax are highlighted by command, keyword, value, etc.

For this tutorial, delete all the command lines displayed in the editor window and type the lines shown below. While not necessary, this will allow you to learn more about the required and optional command lines for an input file.

STAAD commands are *not* case sensitive (i.e., they may be typed in upper *or* lower case letters). By convention, this and most input files use all caps, though.

For most all commands and keywords, the first three letters of a keyword are all that are needed. The rest of the letters of the word are not required, but are useful to present a user-friendly command language in mostly plain English for later reference. By convention, the required letters in a command or keyword are underlined here (“PLANE” = “PLA” = “plane” = “pla”).

```
STAAD SPACE SLAB SUPPORTED ALONG 2 EDGES
```

Every input has to start with the word STAAD. The word SPACE signifies that the structure is a space frame structure (3-D) and the geometry is defined through X, Y and Z coordinates.

```
UNIT METER KN
```

Specifies the unit to be used for data to follow.

```
JOINT COORDINATES
1 0 0 0 ; 2 2 0 0 ; 3 2 0 2 ; 4 0 0 2
5 4 0 0 ; 6 4 0 2 ; 7 6 0 0 ; 8 6 0 2
9 2 0 4 ; 10 0 0 4 ; 11 4 0 4 ; 12 6 0 4
```

Joint number followed by X, Y and Z coordinates are provided above. Semicolon signs (;) are used as line separators. That enables you to provide multiple sets of data on one line. For example, node 6 has (X, Y, Z) coordinates of (4, 0, 2).

```
ELEMENT INCIDENCES SHELL
1 1 2 3 4 ; 2 2 5 6 3 ; 3 5 7 8 6 ; 4 4 3 9 10 ;
5 3 6 11 9 ; 6 6 8 12 11
```

The incidences of elements are defined above. For example, element 3 is defined as connected between the nodes 5, 7, 8 and 6.

```
UNIT CM KN
ELEMENT PROPERTY
1 TO 6 THICKNESS 30
```

The length unit is changed from meter to centimeter. Element properties are then provided by specifying that the elements are 30 cm thick.

```
UNIT KN  METER
CONSTANTS
E 2.17185e+007 ALL
POISSON 0.17 ALL
DENSITY 23.5616 ALL
ALPHA 1e-005 ALL
```

Material constants, which are E (modulus of elasticity), Density, Poisson's Ratio and Alpha, are specified following the command CONSTANTS. Prior to this, the input units are changed to Meter and KN.

```
SUPPORTS
1 2 4 5 7 10 FIXED
```

Joints 1, 2, 4, 5, 7 and 10 are defined as fixed supported. This will cause all 6 degrees of freedom at these nodes to be restrained.

```
UNIT KG
LOAD 1 DEAD LOAD
```

Force units are changed from KN to KG to facilitate the input of loads. Load case 1 is then initiated along with an accompanying title.

```
SELFWEIGHT Y -1
```

Load case 1 consists of selfweight of the structure acting in the global Y direction with a factor of -1.0. Since global Y is vertically upward, the factor of -1.0 indicates that this load will act downwards.

```
LOAD 2 EXTERNAL PRESSURE LOAD
```

Load case 2 is initiated along with an accompanying title.

```
ELEMENT LOAD
1 TO 6 PR GY -300
```

Load 2 is a pressure load on the elements. A uniform pressure of 300Kg/m2 is applied on all the elements. GY indicates that the load is in the global Y direction. The negative sign (-300) indicates that the load acts opposite to the positive direction of global Y.

```
LOAD 3 TEMPERATURE LOAD
```

Load case 3 is initiated along with an accompanying title.

```
TEMPERATURE LOAD
1 TO 6 TEMP 40 30
```

Load 3 is a temperature load. All the 6 elements are subjected to a in-plane temperature increase of 40 degrees and a temperature variation across the thickness of 30 degrees. This increase is in the same temperature units as the Alpha value specified earlier under CONSTANTS.

```
LOAD COMB 101 CASE 1 + CASE 2
1 1.0 2 1.0
```

Load combination 101 is initiated along with an accompanying title. Load cases 1 and 2 are individually factored by a value of 1.0, and the factored values are combined algebraically.

```
LOAD COMB 102 CASE 1 + CASE 3
1 1.0 3 1.0
```

Load combination 102 is initiated along with an accompanying title. Load cases 1 and 3 are individually factored by a value of 1.0, and the factored values are combined algebraically.

```
PERFORM ANALYSIS PRINT STATICS CHECK
```

The above command instructs the program to proceed with the analysis. A static equilibrium report is also requested with the help of the words PRINT STATICS CHECK.

```
UNIT METER KN
PRINT ELEMENT STRESS LIST 3
```

The stresses and unit width moments are requested at the centroid of element 3 in KN and Meter units.

```
UNIT KG
METER
PRINT ELEMENT FORCE LIST 6
```

The forces and moments for all 6 d.o.f at the corner nodes of element 6 are requested in KG and Meter units.

```
FINISH
```

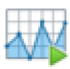
This command terminates the STAAD run.

Save the input file and close the editor. The model is opened in the STAAD.Pro interface.

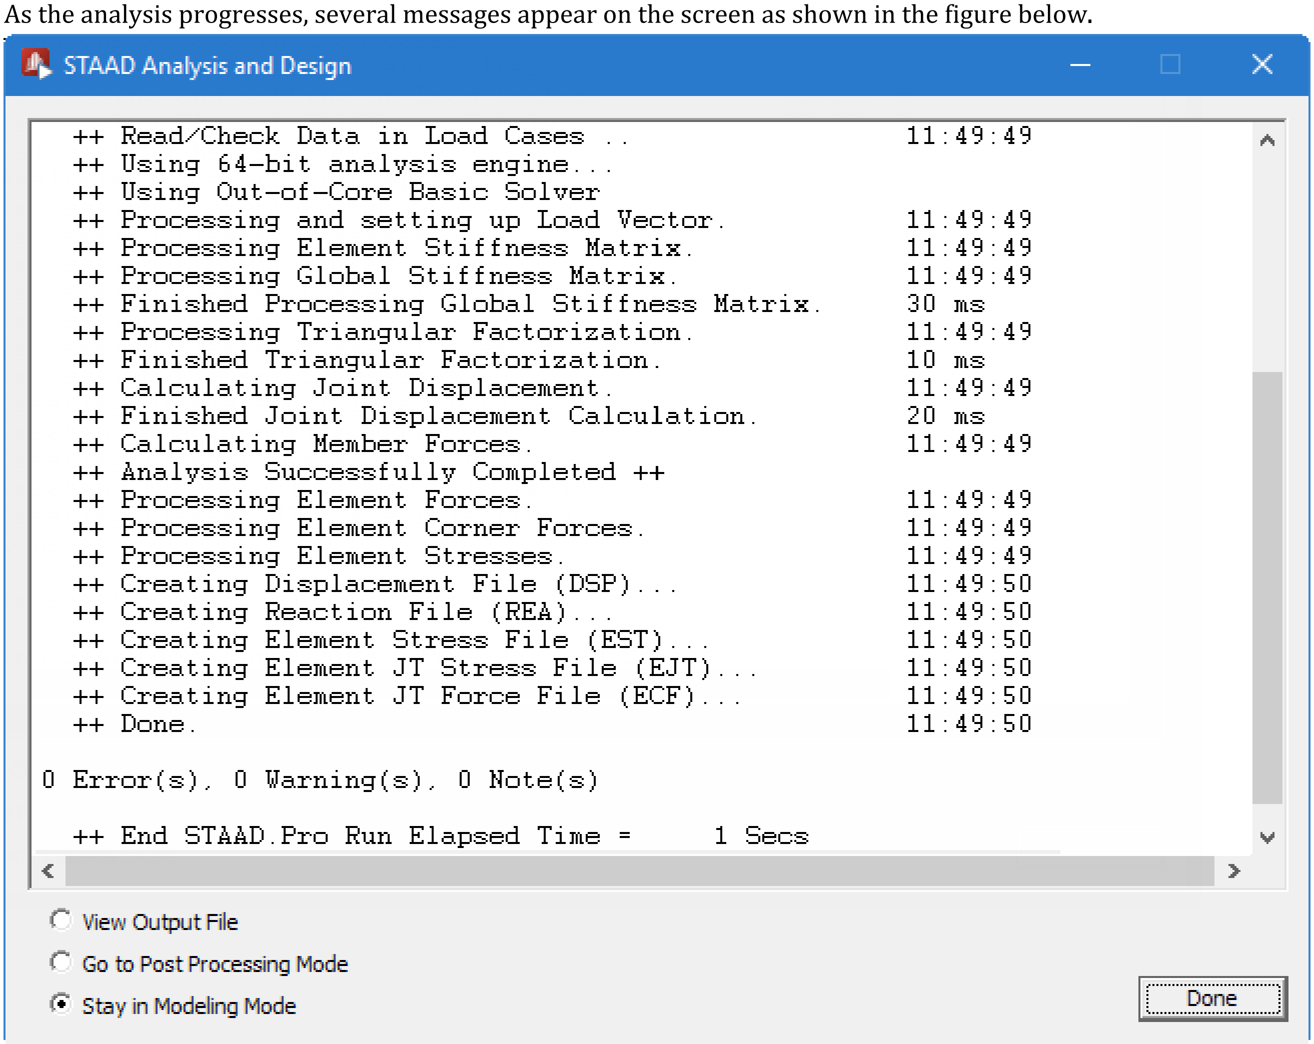
T.3 Performing the analysis and design

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab , the **Save** tool, or pressing **<CTRL +S>**.

1. On the **Analysis and Design** ribbon tab, select the **Run Analysis** tool in the **Analysis** group. .



As the analysis progresses, several messages appear on the screen as shown in the figure below.



2. Select the **View Output File** option once the analysis and design are complete.

   The three options are indicative of what will happen after you click **Done**.

View Output File	This option opens the output file created by STAAD. The output file contains the numerical results produced in response to the various input commands specified during the model generation process. It also provides you with important messages of any errors were encountered, and if so, whether the analysis and design was successfully completed or not. See T.1 Viewing the output file (on page 447) for details on viewing and understanding the contents of the output file.
Go to Post Processing Mode	This option opens the graphical Post-processor mode, which can be used to extensively review and verify the results. This mode allows you to view the results graphically, plot result diagrams, produce reports, etc. See T.1 Post-Processing (on page 455) for details on the Post processing mode.
Stay in Modeling Mode	This option closes the dialog and remains in the Model generation mode of the program, where you initiated the analysis. This is useful if you want to make further changes to the input file.

3. Click **Done**.
   The STAAD.Pro Output Viewer window opens.

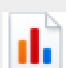
T.3 Viewing the output file

During the analysis process, STAAD.Pro creates an Output file. This file provides important information on whether the analysis was performed properly.

For example, if STAAD.Pro encounters an instability problem during the analysis process, it will be reported in the output file.

Note:

If you did not select to open the output file after running the analysis in the previous procedure, you can open it any time through the user interface. On the **Utilities** ribbon tab, select the **Analysis Output** tool in the **View** group.



Tip: By default, the output file contains a listing of the entire input also. You may choose not to print the echo of the input commands in the Output file. On the **Analysis and Design** ribbon tab, select the **Miscellaneous Commands** > **Set Echo** tool option from the menu bar and the select the **Echo Off** option in the **Set Echo** dialog.

It is *strongly recommended* that you review the entire output file to ensure that the results are reasonable and that there are no error messages or warnings reported, etc. Errors encountered during the analysis & design can disable access to the post-processing mode. The information presented in the output file is a crucial indicator of whether or not the structure satisfies the engineering requirements of safety and serviceability.

T.3 Post-Processing

If there are no errors in the input, the analysis is successfully completed. The extensive facilities of the Post-processing mode can then be used to:

- view the results graphically and numerically
- assess the suitability of the structure from the standpoint of safety, serviceability and efficiency
- create customized reports and plots

The procedure for entering the post processing mode is explained in T.2 Opening the postprocessing workflow (on page 520).

Node results such as displacements and support reactions are available for all models. The methods explained in the first two tutorials may be used to explore these. For this example, you will examine the support reactions.

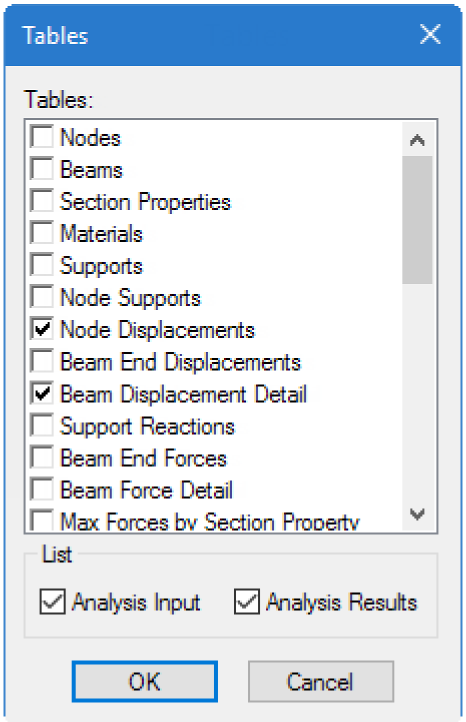
If beams are present in the model, beam results will be available too. As no beams are present in this model, this is not covered for this tutorial.

For plates, the results available are stresses, and “unit width” moments. There are several different methods for viewing these results, as explained in the next few sections.

T.3 Viewing stress values in a tabular form

1. On the **View** ribbon tab, select the **Tables** tool in the **Windows** group.

   The **Tables** dialog opens.



2. Select **Plate Center Stress** and click **OK**.

The **Plate Center Stress** table opens.

		Shear		Membrane			Bending Moment		
Plate	L/C	SQX (local) N/mm2	SQY (local) N/mm2	SX (local) N/mm2	SY (local) N/mm2	SXY (local) N/mm2	Mx kNm/m	My kNm/m	Mxy kNm/m

Figure 93:

The table has the following tabs:

Shear, Membrane and Bending — These terms are explained in G.5.1 Plate and Shell Elements (on page 2099). The individual values for each plate for each selected load case are displayed.

Summary — This tab contains the maximum for each of the 8 values listed in the Shear, Membrane and Bending tab.

Principal and Von Mises — These terms too are explained in G.5.1 Plate and Shell Elements (on page 2099). The individual values for each plate for each selected load case are displayed, for the top and bottom surfaces of the elements.

Summary — This tab contains the maximum for each of the 8 values listed in the Principal and Von Mises tab.

Global Moments — This tab provides the moments about the global X, Y and Z axes at the center of each element.

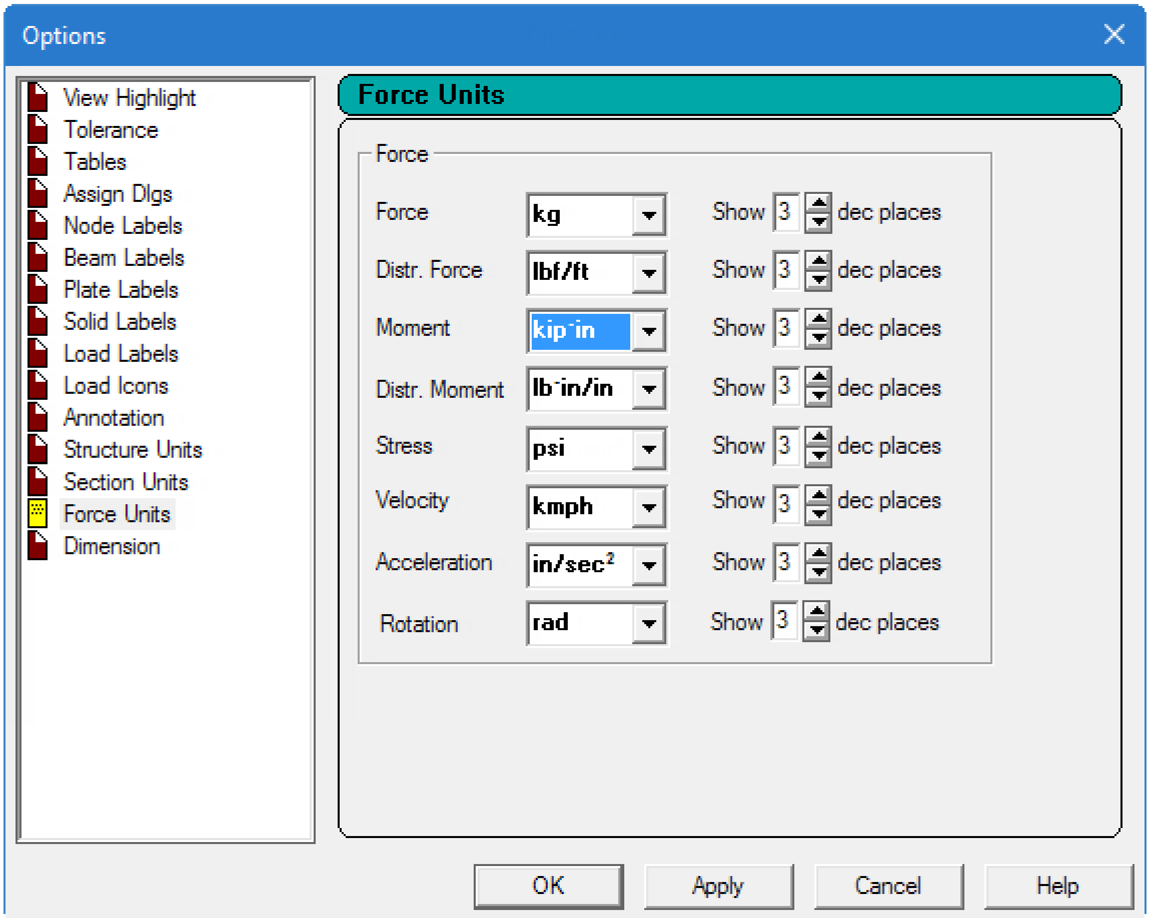
3. (Optional) Right-click in the table area and select **Print** from the pop-up menu.

T.3 Changing the units of values in the output

The length and force units of the stresses and moments are displayed alongside the individual column headings for the terms.

1. On the **File** ribbon tab, select **Display Options** on the **Settings** tab.

   The **Options** dialog opens.



2. Select the **Force Units** tab and specify the required unit from the **Stress** and **Moment** fields.
3. (Optional) Click **Apply**
4. Click **OK**.

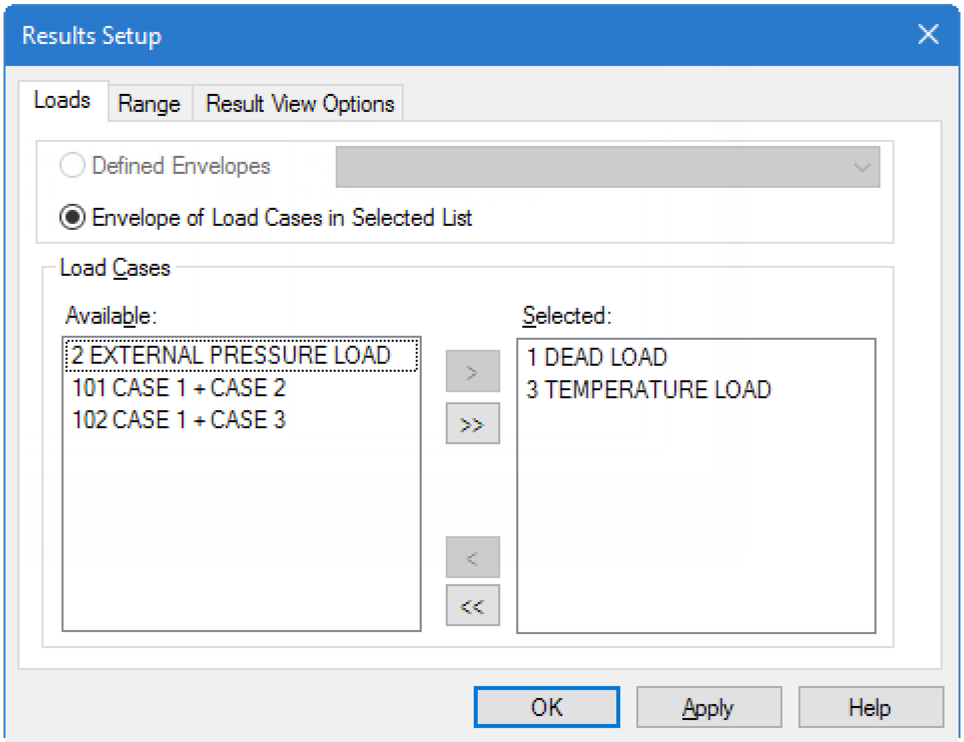
T.3 Limiting the load cases for which the results are displayed

Use the following procedure to change the load list used for present results in the Post Processing mode.

1. On the **Results** ribbon tab, select the **Select Load Case** tool in the **Configuration** group.

   
   The **Results Setup** dialog opens.
2. Click **[<<]**.

   All load cases are moved from the Selected list to the Available list.
3. Select the load cases you want from the **Available** list and the click **[>]**.
   The selected load cases are transferred from the **Available** list to the **Selected** list



4. Click **OK**.

T.3 Stress Contours

Stress contours are a color-based plot of the variation of stress or moment across the surface of the slab or a selected portion of it.

1. On the **Results** ribbon tab, select the **Plate Stress** tool in the **View Results** group.

   The **Diagrams** dialog opens to the **Plate Stress Contour** tab.
2. Select the load case number from the **Load Case** drop-down list.

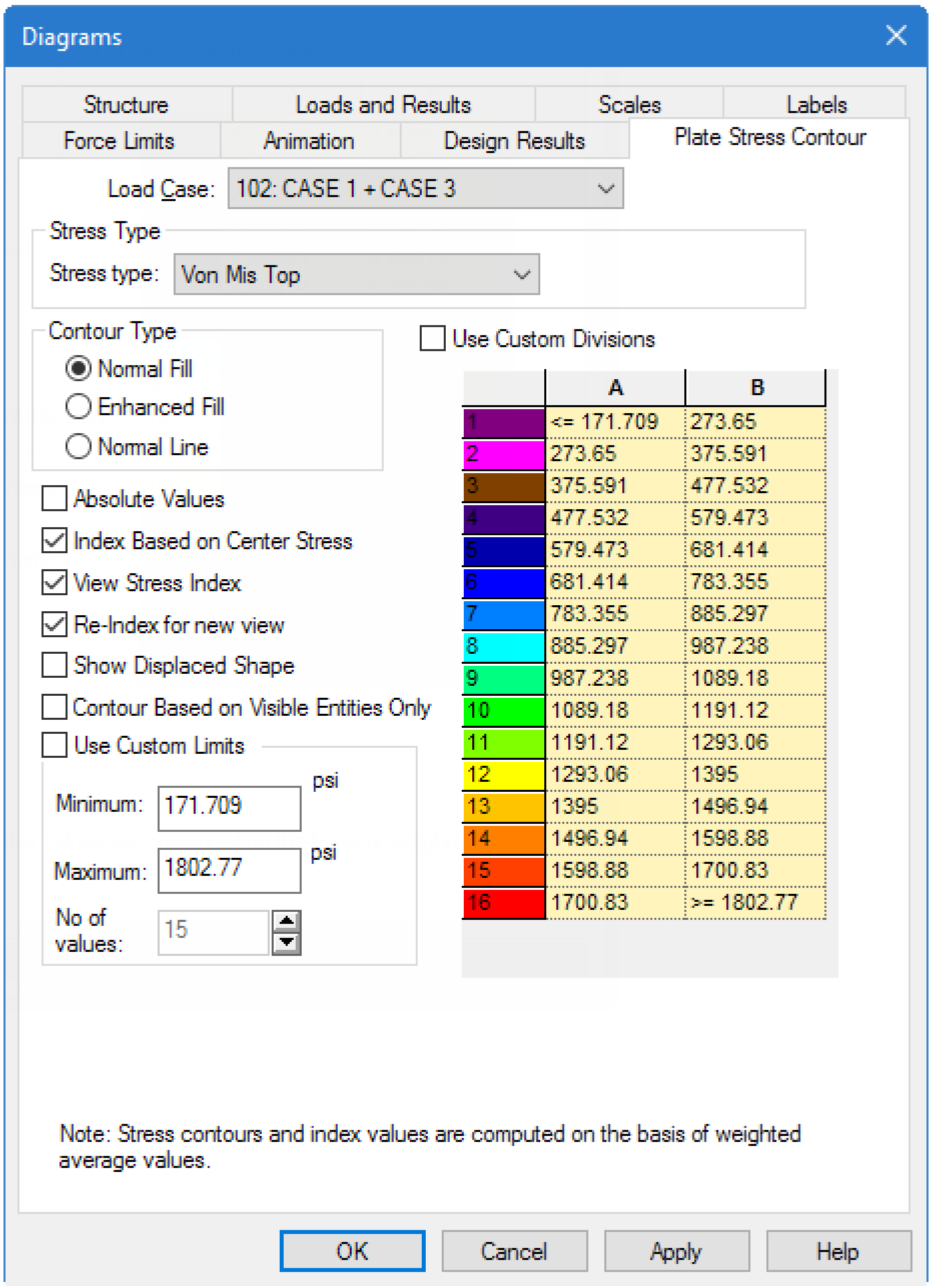
   Stress values are known exactly only at the plate centroid locations. Everywhere else, they are calculated by linear interpolation between the center point stress values of adjacent plates.

   The **Enhanced** type contour chooses a larger number of points compared to the **Normal** type contour in determining the stress variation.
3. Select the specific type of stress for which you want the contour drawn from the **Stress type** drop-down list.
4. Setting the **View Stress Index** option will display a small table consisting of the numerical range of values from smallest to largest which are represented in the plot.

   Set the following:

   Load case — 102: CASE 1 + CASE 3
   Stress Type — Von Mis Top

Contour Type — Normal Fill
Index based on Center Stress checked
View Stress Index checked
Re-Index for new view checked



5. Click **Apply**.

   The following diagram will be displayed.

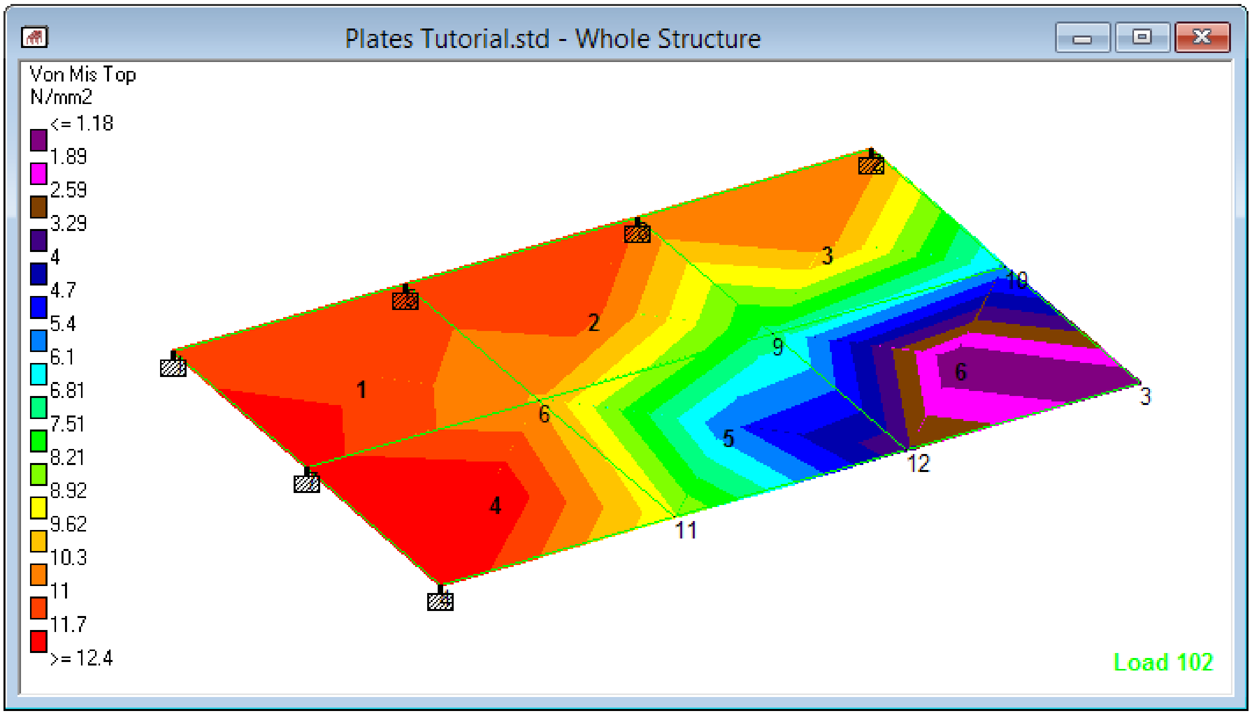


Figure 94: Plate stresses plotted for Load Case 102

6. (Optional) If some portion of the structure appears truncated, use the Zoom and Pan tools located on the View toolbar to adjust the display.

 Tip: If you mouse has a scroll wheel, you can also use that to zoom in or out (scroll up or down) or to pan the image (click-and-drag the wheel button).

Note: Leave the dialog open to explore the Animation feature explained in the next topic.

T.3 Animating stress contours

The Diagrams dialog is used to provide a dynamic animation of stress plots.

In order to animate a diagram, such as the plate stress contour, you must first have a diagram displayed. Refer to T.3 Stress Contours (on page 613) for how to plot those results on the structure.

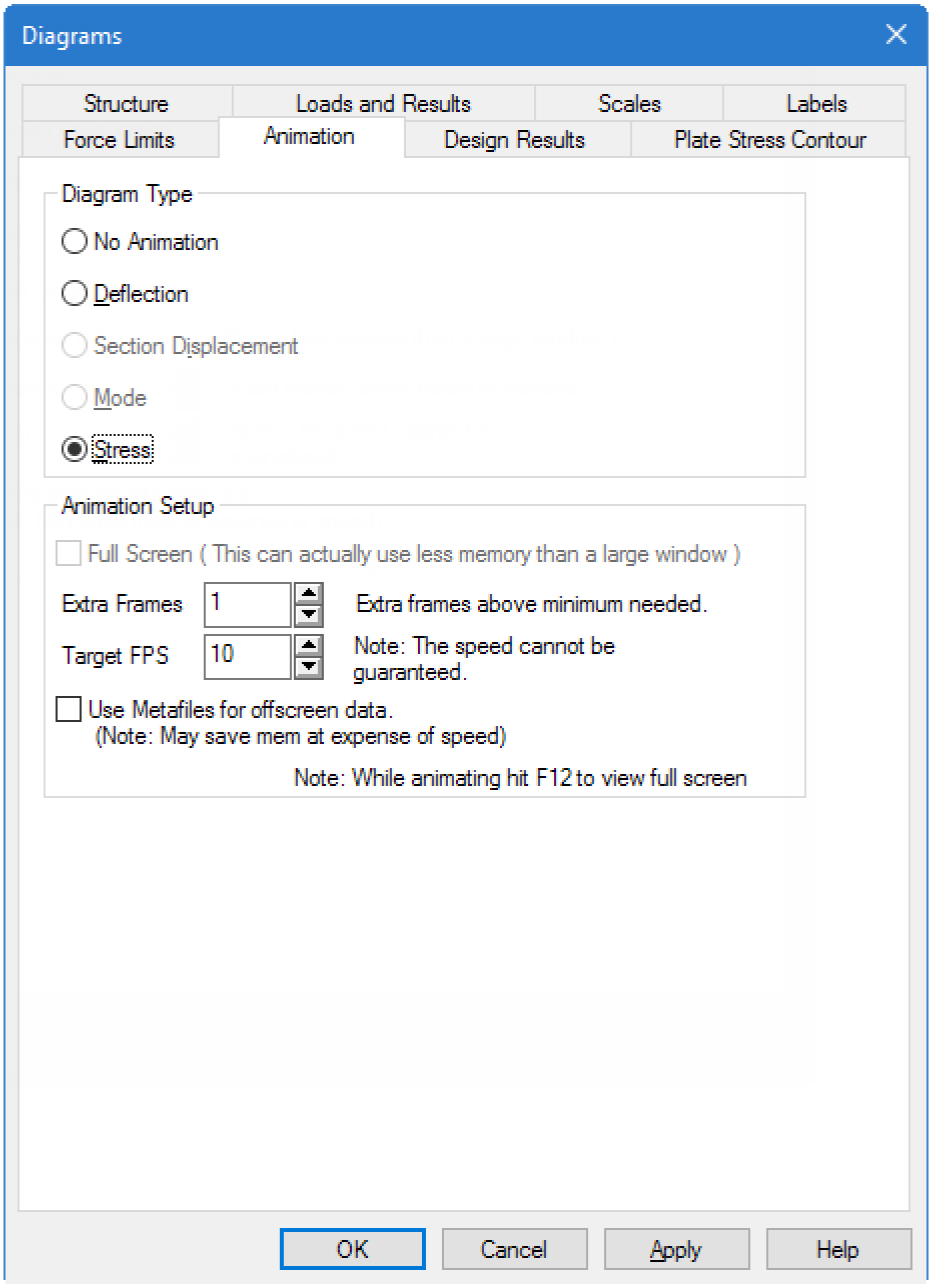
1. Either:

 on the **Results** ribbon tab, select the **Animation** tool in the **Animation** group

 or

 if the **Diagrams** dialog is still open from the previous procedure, select the **Animation** tab
2. Select the **Stress** option.

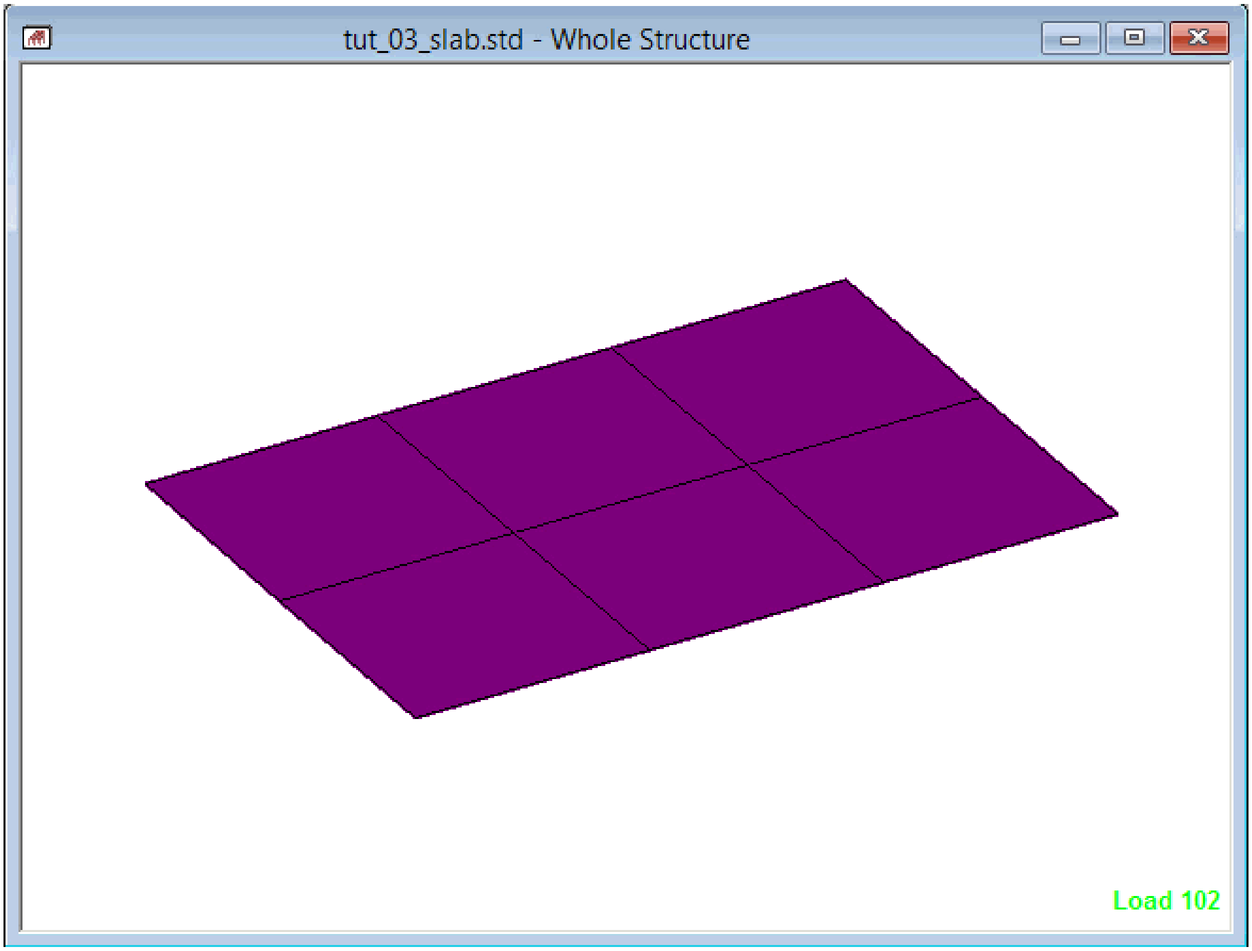


3. (Optional) Set the **Target FPS** 5

Tip: This will slow the animation down to make it easier to distinguish the frames.

4. Click **Apply**.

The plate stress contours are animated loading and unloading.



5. To stop the animation, select the **No Animation** option and click **Apply** again.

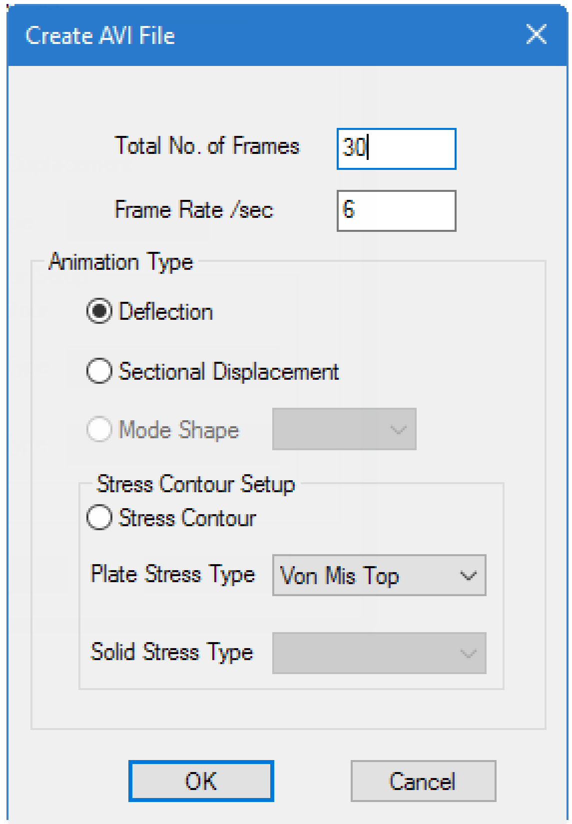
T.3 Creating AVI Files

You can save dynamic result, such as a deflection diagram in animation, to a video file.

This feature is available in STAAD.Pro for node deflection, beam section displacement, mode shape and plate stress contour diagrams. These files can then be viewed using video player programs such as the Windows Media Player.

1. On the **Utilities** ribbon tab, select the **Create AVI File** tool in the **Utilities** group.

The **Create AVI File** dialog opens.



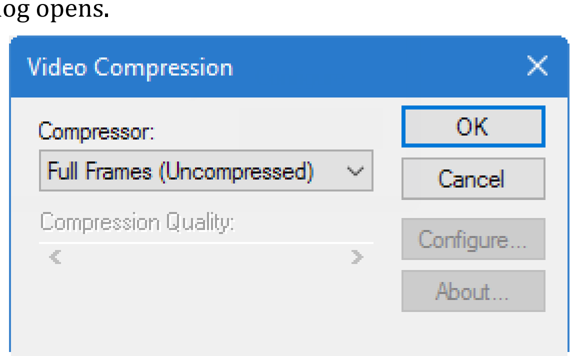
Total No. of Frames Sets the number of frames used to capture the movement. In an animated view, the movement from one extremity to the other is captured as several frames.

Frame Rate /sec sets the speed of the motion

The rest of the options in the above dialog are for the type of diagram from which the video file is to be created. Certain items such as Mode Shape and Plate Stress contour are disabled if the required data of that type are not present in the STAAD file, such as a modal extraction, or finite elements.

2. Select the **Stress Contour** option for Animation Type and then select **Von Mis Top** from the Plate Stress Type drop-down list.
3. Click **OK.**
   A dialog opens to specify the file name.
4. Type a file name and location for the video file and then click **OK**.

   The **Video Compression** dialog opens.



5. (Optional) Select a Compressor option and set the Compression Quality value.

   Note: Video files can be quite large, and compression is a technique used reduce the size of these files, though some video smoothness is lost in this process.
6. Click **OK** to begin creating the video file.

   When the file has been generated, a message opens indicating that the operation was successful.
7. Click **OK** to dismiss.
   The file with the extension `.AVI` is saved in the same folder where the STAAD input file is located.

T.3 Viewing plate results using element query

Element Query is a facility where several results for a specific element can be viewed at the same time from a single dialog.

1. On the **Results** tab, select the **Plate Cursor** tool in the **Selection** group.

   
2. Either:

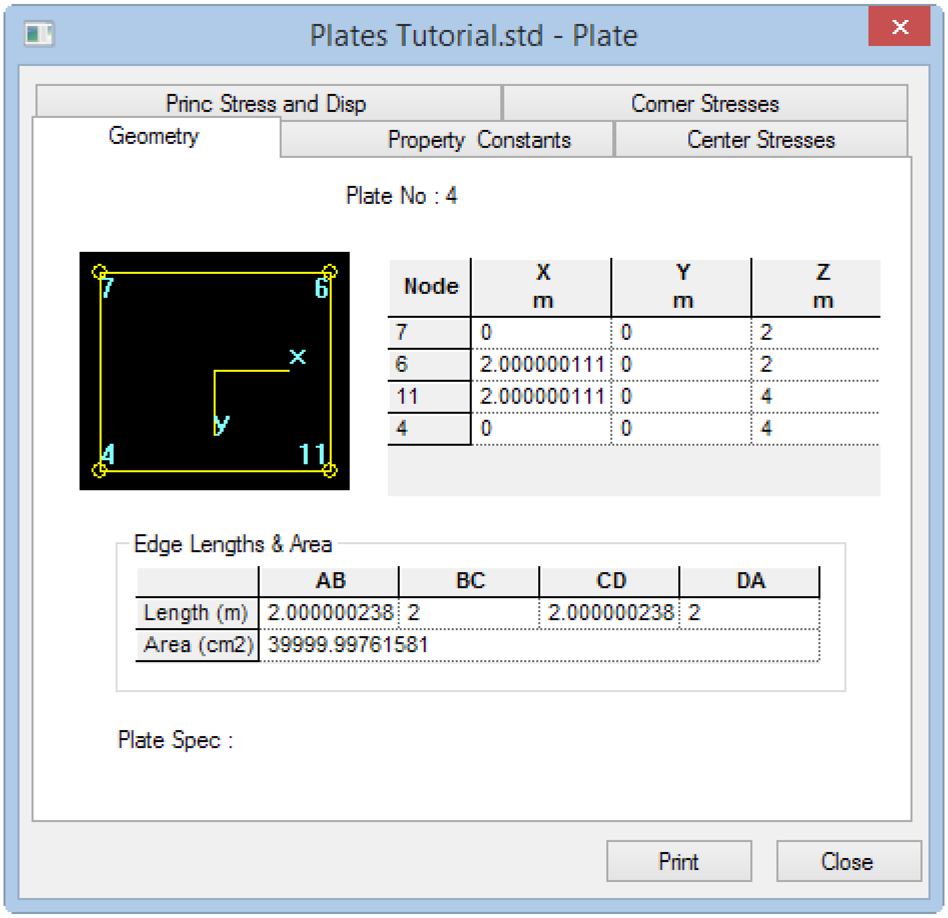
   Double-click on element 4

   or

   select element 4 and then select the **Properties** tool in the **Model** group on the **Plate Tools** ribbon tab.

   Tip: Press **<Shift+P>** to display the plate numbers.

   The **Plate** dialog opens.



The various tabs of the query box enable one to view various types of information such as the plate geometry, property constants, stresses, etc., for various load cases, as well as print those values.

Some example tabs of this dialog are shown in the following figures.

T.3 Producing a report

Produce a report consisting of the plate principal stresses, for all plates, sorted in the order from Low to High of the Principal Maximum Stress (SMAX) for load cases 101 and 102.

Occasionally, you will need to obtain results conforming to certain restrictions, such as, say, the resultant node displacements for a few selected nodes, for a few selected load cases, sorted in the order from low to high, with the values reported in a tabular form.

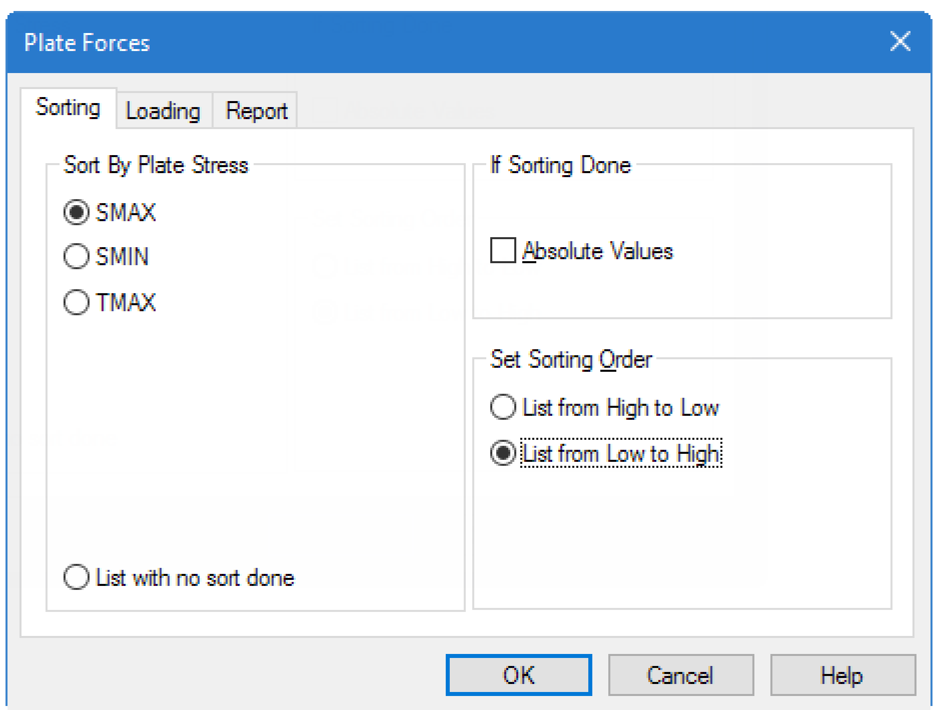
1. On the **Results** tab, select the **Plate Cursor** tool in the **Selection** group.

2. Select the all the plate elements.

Tip: Drag a window around all the elements in the view area or press **<Ctrl+A>**.

3. On the **Results** ribbon tab, select the **Reports** > **Principal Stresses** tool in the **Reports** group.

The **Plate Forces** dialog opens.



4. Specify the report contents:
   a. Select the **Sorting** tab.
   b. Select the **SMAX** option in the **Sort By Plate Stress** group.

   c. Select **List from Low to High** option in the **Set Sorting Order** group.
   d. Clear the **Absolute Values** check box in the **If Sorting done** group.
5. Select the load cases to use:
   a. Select the **Loading** tab.

   b. Select load cases `101` and `102` in the **Available** list and click **[>]** to add them to the **Selected** list.
6. (Optional) You can save this report for future use,
   a. Select the **Report** tab
   b. Type a **Title** for the report.
   c. Set the **Save Report** check box.
7. Click **OK**.

   The Plate Forces table opens to display the table of maximum principal stress with SMAX values sorted from Low to High.

tut_03_slab.std - Plate Forces

Plate	L/C		SMAX psi	SMIN psi	TMAX psi	Angle
1	102	Top	-1116.735	-1932.408	407.837	-39.107
2	102	Top	-433.175	-1818.515	692.670	-25.667
4	102	Top	-418.965	-1975.360	778.197	-41.610
3	102	Top	-133.907	-1606.236	736.164	-37.347
6	102	Top	-75.538	-196.529	60.496	-34.905
5	102	Top	-65.322	-836.845	385.761	-18.993
3	101	Top	-45.261	-288.561	121.650	78.932
1	101	Top	-15.983	-94.019	39.018	45.073
4	101	Top	-11.390	-199.786	94.198	26.436

5	101	Top	113.895	-116.089	114.992	54.271
5	101	Bottom	116.089	-113.895	114.992	54.271
4	102	Bottom	138.902	-935.369	537.136	-47.958
6	102	Bottom	182.676	-2.348	92.512	-44.681
2	101	Bottom	188.779	-8.528	98.654	69.878
4	101	Bottom	199.786	11.390	94.198	26.436
3	102	Bottom	268.146	-661.351	464.748	-32.091
3	101	Bottom	288.561	45.261	121.650	78.932
2	102	Bottom	512.208	-715.830	614.019	-24.059

8. (Optional) To print this table, right-click anywhere within the table and select **Print**

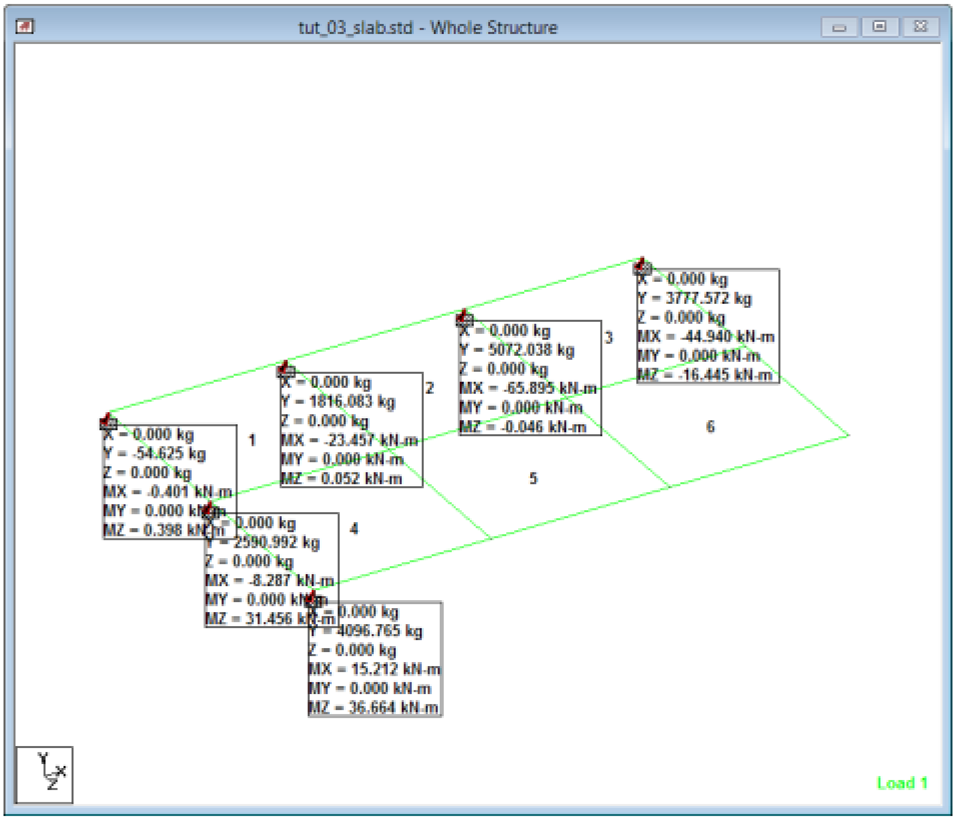
To transfer the contents of this table to a Microsoft Excel file, click the **Plate** label in the top-left corner of the table. The entire table is selected. Right-click and select **Copy** from the pop-up menu. You can now paste the table contents into a Microsoft Office Excel spreadsheet or other spreadsheet file.

T.3 Viewing Support Reactions

Use the nodal results page to obtain support reaction results.

1. Select the **Reactions** page in the **Postprocessing** page control bar.

   The reactions at the supports will be displayed on the drawing and the Support Reactions table is displayed on the right side of the program window.



The six values — namely, the three forces along global X, Y and Z, and the three moments Mx, My and Mz, in the global axis system — are displayed in a box for each support node.

tut_03_slab.std - Support Reactions:

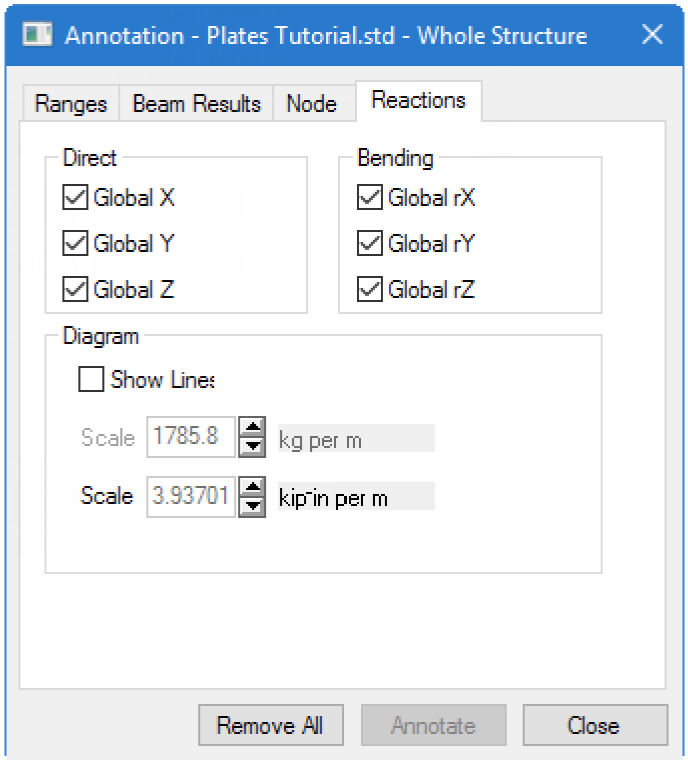
All | Summary | Envelope

		Horizontal	Vertical	Horizontal	Moment		
Node	L/C	Fx kg	Fy kg	Fz kg	Mx kN-m	My kN-m	Mz kN-m
1	1 DEAD LOA	0.000	-54.625	0.000	-0.401	0.000	0.398
	2 EXTERNAL	0.000	-22.736	0.000	-0.167	0.000	0.166
	3 TEMPERAT	167.55337E	2409.264	147.88130E	-71.280	68.375	71.263
	101 CASE 1	0.000	-77.361	0.000	-0.567	0.000	0.564
	102 CASE 1	167.55337E	2354.639	147.88130E	-71.681	68.375	71.661
2	1 DEAD LOA	0.000	1816.083	0.000	-23.457	0.000	0.052
	2 EXTERNAL	0.000	755.878	0.000	-9.763	0.000	0.022
	3 TEMPERAT	-201.83948E	5020.928	171.82707E	-134.655	350.875	25.587
	101 CASE 1	0.000	2571.961	0.000	-33.221	0.000	0.074
	102 CASE 1	-201.83948E	6837.011	171.82707E	-158.112	350.875	25.639
4	1 DEAD LOA	0.000	2590.992	0.000	-8.287	0.000	31.456
	2 EXTERNAL	0.000	1078.405	0.000	-3.449	0.000	13.093
	3 TEMPERAT	287.00058E	2777.288	-234.57780E	16.530	-37.619	97.175
	101 CASE 1	0.000	3669.398	0.000	-11.736	0.000	44.549

2. Display of one or more of the six terms of each support node may be toggled off in the following manner.

a. On the **Results** ribbon tab, select the **Annotate** tool in the **Configuration** group.

The **Annotation** dialog opens.



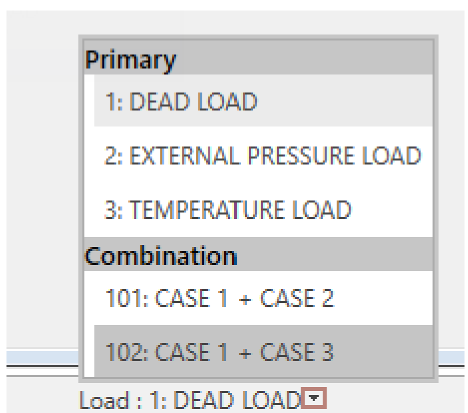
b. Select the **Reactions** tab.

c. Clear the degree of freedom check boxes in the **Direct** or **Bending** groups you want to hide from display.

d. Click **Annotate** and then **Close**.

The drawing will now contain only the selected items.

3. (Optional) To change the load case for which the reactions are displayed, select the desired case from the **Load** drop-down in the program status bar.



4. On the **Support Reactions** table, select the **Summary** tab.

Tip: You can also open this table by selecting **Tables** > **Reactions** tool in the **View Results** group on the **Results** ribbon tab.

The summary tab contains the maximum value for each of the 6 degrees of freedom along with the load case number responsible for it.

			Horizontal	Vertical	Horizontal	Moment	
	Node	L/C	Fx kg	Fy kg	Fz kg	Mx kN-m	My kN-m
Max Fx	10	3 TEMPERAT	329.13190E	-7060.589	-356.61441E	21.307	31.088
Min Fx	7	3 TEMPERAT	-322.52367E	-6908.630	230.46947E	22.255	-253.619
Max Fy	5	102 CASE 1	-259.32270E	8833.778	41014.389	-142.543	-159.100
Min Fy	10	3 TEMPERAT	329.13190E	-7060.589	-356.61441E	21.307	31.088
Max Fz	7	3 TEMPERAT	-322.52367E	-6908.630	230.46947E	22.255	-253.619
Min Fz	10	3 TEMPERAT	329.13190E	-7060.589	-356.61441E	21.307	31.088
Max Mx	10	102 CASE 1	329.13190E	-2963.825	-356.61441E	36.520	31.088

Refer to T.3 Changing the units of values in the output (on page 611) to change the units in which these values are displayed.

This brings us to the conclusion of this tutorial.

4
Modeling

This section of the help describes methods used to model your structure in STAAD.Pro.

This section begins by detailing how to model analytical elements using the Analytical Modeling workflow. Following that are sections on how to model the structure using other workflows and utilities in STAAD.Pro.

M. Navigating the Graphical View Window

This section describes how to control the graphical display of your model.

M. To select a center of rotation at a node

Used to select an node as the center of rotation. When toggled on, pressing **<Ctrl+Shift>** and clicking a node will set that node as the center of rotation.

1. Either:

   On the **View** ribbon tab, select the **Toggle View Rotation Mode** tool in the **Rotation** group.

   or

   On the **View** ribbon tab, select the **Always Fit in Current Window** tool in the **Rotation** group.

   > **Note:** The icon for the Toggle View Rotation Mode is depressed when in this mode (and there is no check on the View > Always Fit in Current Window menu item).

   A message dialog appears to remind you how to next select a center of rotation.
2. Hold down the **<Ctrl+Shift>** keys and click on a node.

   A reticle  is placed on this node to indicate it is the center of rotation.
3. Either:

   Use the rotate tools found in the Rotate toolbar or the arrow keys to rotate the structure about this node.

   or

   Hold down the right mouse button while dragging the pointer to free rotate the model about this node.
4. Repeat steps 3 and 4 to re-center and rotate the structure.
5. To return the center of rotation to the center of the structural model:

   select the **Toggle View Rotation Mode** tool

   or

select the **Always Fit in Current Window** tool such that a check mark appears

or

select the **Use Center of the structure as rotational Center** option in the **Orientation** dialog.

Tip: You may specify the exact center of rotation coordinates at any point using the **Orientation** dialog.

M. To view a 3D rendering of your model

To display the model with full 3D sections and lighting, use the following procedure.

Depending on the material used (steel, concrete, etc.), an appropriate texture will be applied to the structure. A property or material must be assigned to the entities of the model before this feature can be used. This is for visual and presentation purposes only.

Note: The 3D rendering is used to display the model only. You cannot select model objects or otherwise manipulate the model in this view.

1. On the **View** ribbon tab, select the **3D Rendering** tool in the **Windows** group.

   A new view window opens with the model displayed as a 3D rendering.
2. Navigate the rendering view as follows:

To...	Do this...
rotate the structure	left-click in the view and drag the mouse in any direction
pan the structure	click-and-drag the middle mouse button (typically the scroll wheel)
zoom in/out	scroll the mouse wheel up or down

3. (Optional) To generate a picture for inclusion in reports:
   a. Right-click and select **Take Picture** from the pop-up menu.
      The **Picture #** dialog opens.
   b. Type a picture **ID** and **Caption**.
   c. Click **OK**.
4. Click the **[X]** in the top, right-hand corner of the window to close the view.

M. 3D Rendering View Right-click View Menu

Menu item	Description
View Axes	Toggles the display of the global axes.
Perspective	Toggles the perspective lens for the rendered window.
Wireframe View	When selected, solid rendering is turned off. Only the outline of shapes are shown.

Menu item	Description
Enable Lighting	Toggles the light source. Turning this feature off removes any reflection.
Lights (list)	Select the light color from the list.
Change Light Color	The lighting is by default gray to resemble the color of steel. This can be changed to any other color.
Enable Texture Mapping	The structure will be displayed with a unique texture.
Change Entity Color…	Opens the Change Entity Color dialog, which is used change the color of structure entities by class.
Change Background Color…	Opens a color selector dialog, so the default background color can be changed.
Change Font…	Opens a font selection dialog, so the text display can be changed.
Model View Details	Opens the Structure Diagram Info dialog, which contains a summary of the entity counts in the structure.
Take Picture	Takes a STAAD image of the rendered view for inclusion in reports. A picture ID dialog opens to name the image.

M. Labels

STAAD.Pro has numerous options for displaying labels in the view window.

M. To switch on labels for nodes, beams, plates, etc.

Labels are a way of identifying the entities we have drawn on the screen.

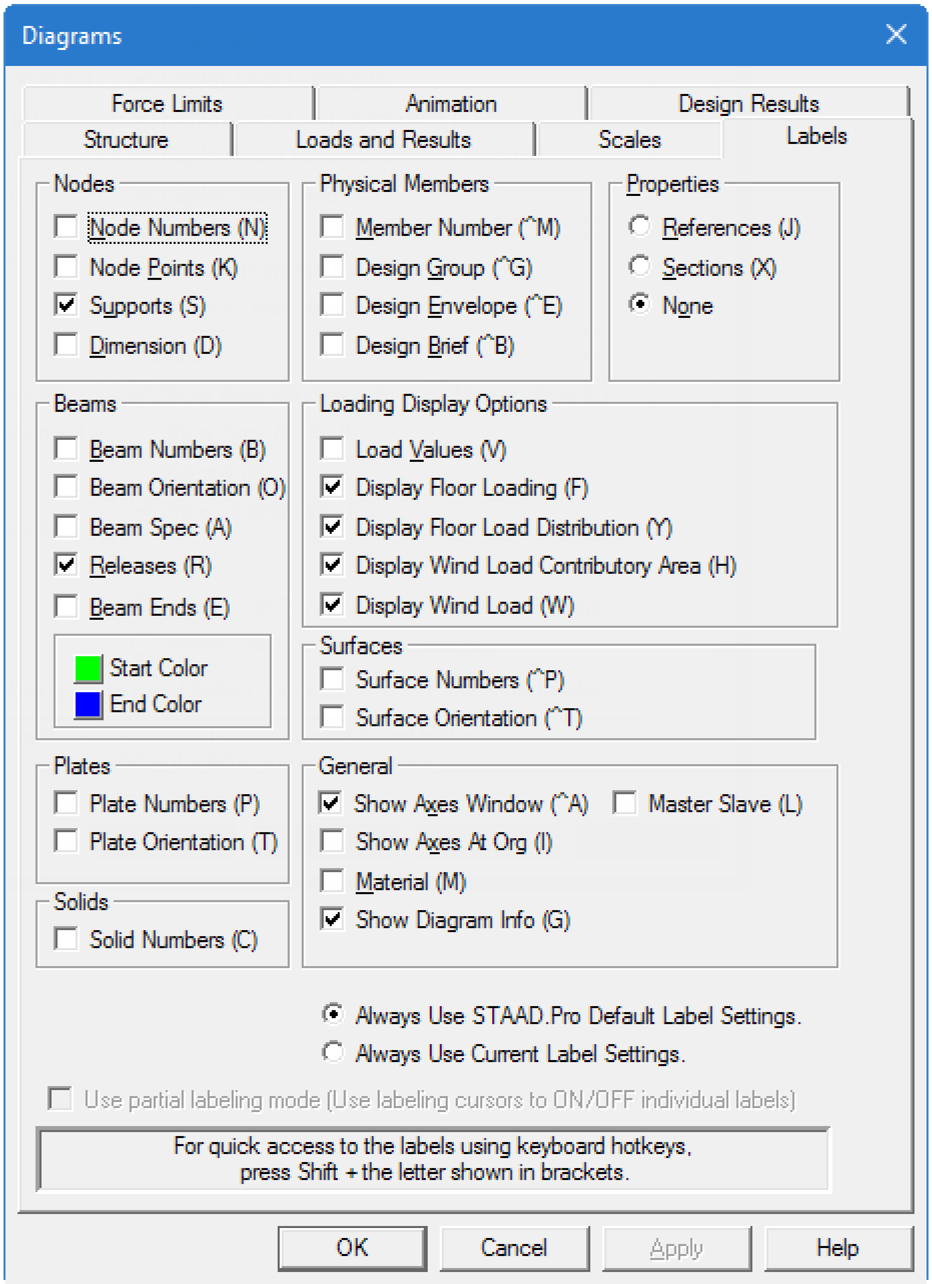
1. Either:

   Select the **Labels** tool 

   or

   Right-click anywhere in the View area and select **Labels** from the pop-up menu.

   The **Diagrams** dialog opens.
2. Select the **Labels** tab and then select the options for the appropriate labels (examples shown in the following figure).



Diagrams
Force Limits
Animation
Design Results
Structure
Loads and Results
Scales
Labels
Nodes
Node Numbers (N)
Node Points (K)

Always Use STAAD.Pro Default Label Settings.
Always Use Current Label Settings.
Use partial labeling mode (Use labeling cursors to ON/OFF individual labels)
For quick access to the labels using keyboard hotkeys,
press Shift + the letter shown in brackets.
OK
Cancel
Apply
Help

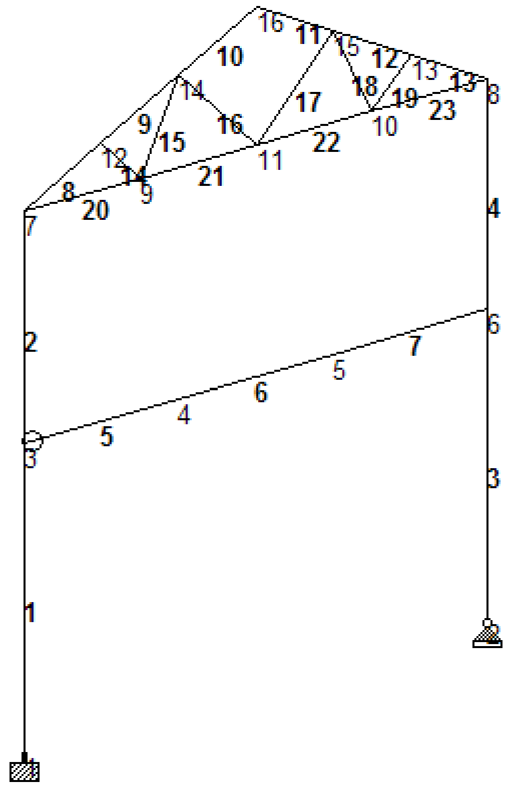

Figure 95: `US.1. Plane Frame with Steel Design.std` *with the beam and node labels displayed*

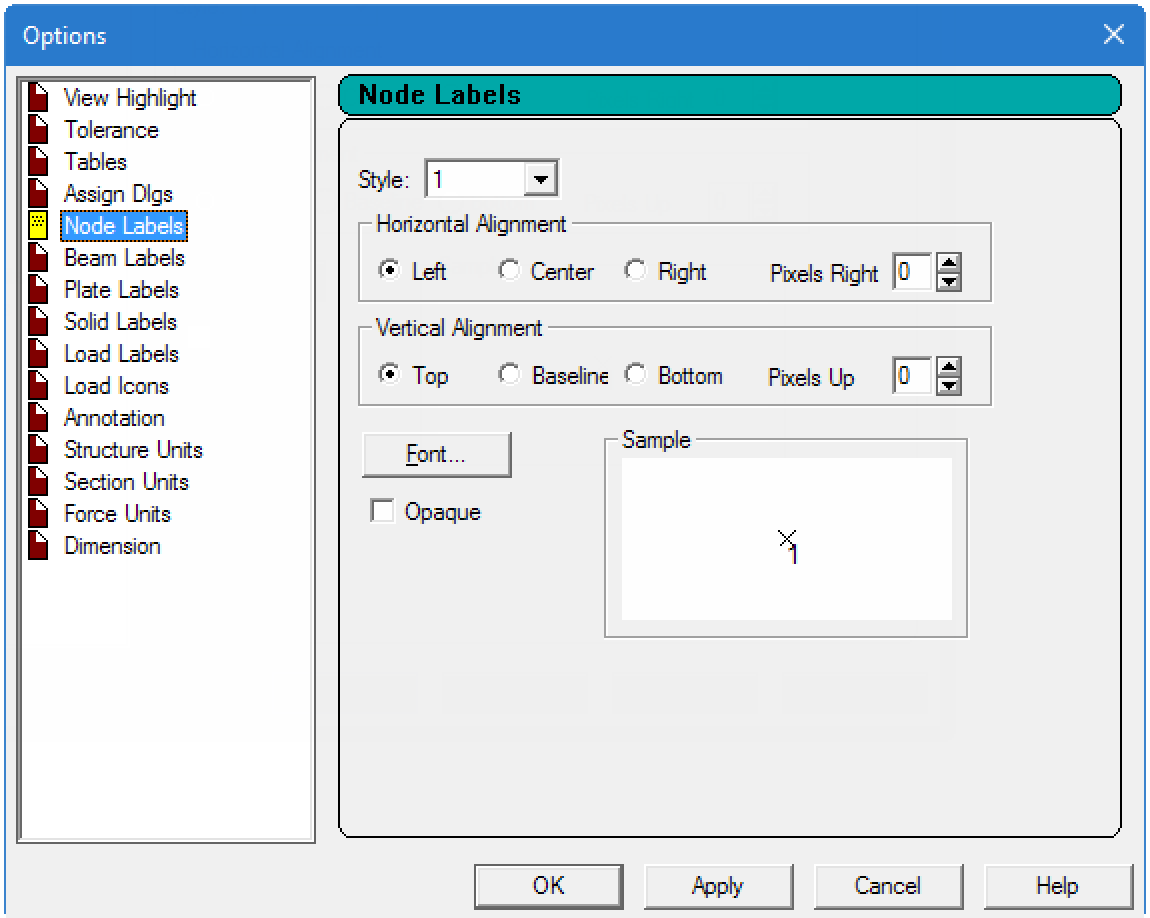
3. Click **OK** to update the View window and close the dialog.
4. To change the font of the node/beam labels, select **View** > **Options**.
    a. Select the **File** ribbon tab.
    The STAAD.Pro Backstage view opens.
    b. On the **Settings** tab, select **Display Options**.

    The **Options** dialog opens.
    c. Select the appropriate tab (Node Labels / Beam labels) and then click **Font** to make the desired changes.



d. Click **OK** to close the **Font** dialog.

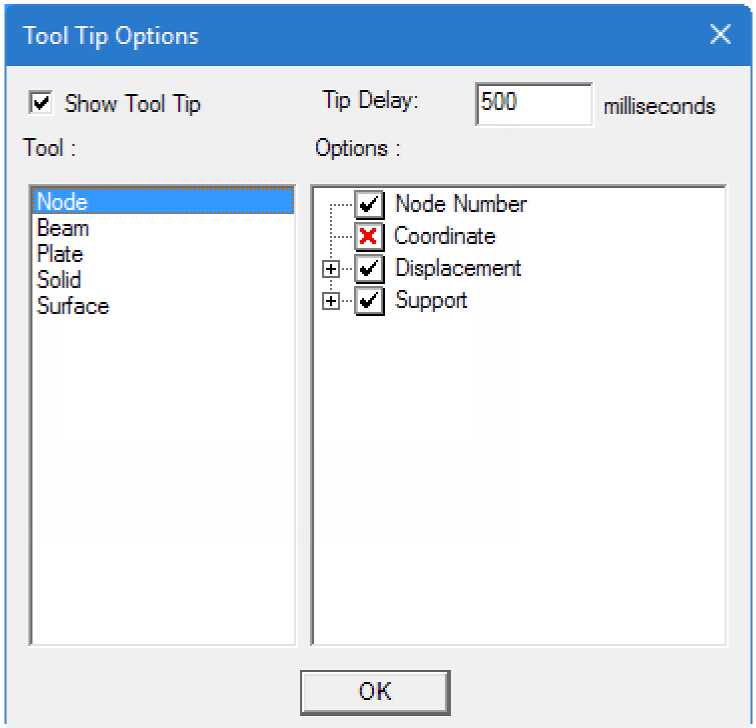
e. Click **OK** to close the **Options** dialog.

M. To change the structural tool tip options

Structural tool tips offer a facility for displaying any customized input or output information about a node, beam, plate or solid element when the mouse cursor is placed over the structural entity. The tool tips are similar to the ones displayed when the mouse cursor hovers over a toolbar icon.

1. Select the **File** ribbon tab.
   The STAAD.Pro Backstage view opens.
2. On the **Settings** tab, select **Structural Tooltip Options**.

   The **Tool Tip Options** dialog opens.



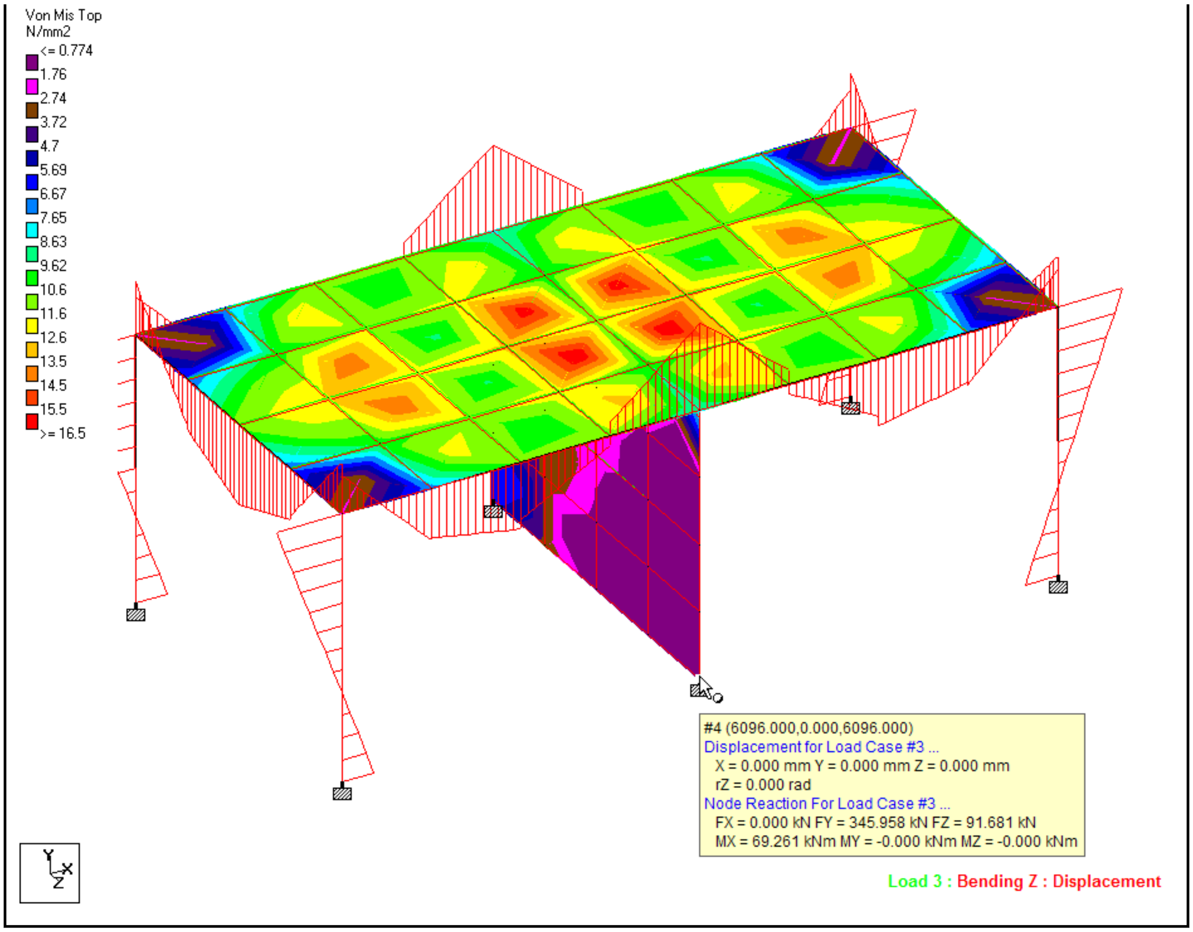
3. Check the **Show Tool Tip** option.
4. (Optional) Change the **Tip Delay**

   This number is expressed in milliseconds (i.e., 1,000 = 1 second).
5. For a selected model entity (Node, Beam, etc. in the left list), set the information and results you want to display in the tool tip in the right list.

   The options (items that can be displayed) for each entity are shown under the **Options** list. A check mark signifies that the particular data item will be displayed in the tool tip. An option with a "+" next to it signifies that further options can be enabled or disabled. A red "X" indicates the data will not be shown in the tool tip. Simply click on the check box to turn an option on or off.
6. Click **OK**.

Example

Structural tool tips can be configured to display a wide variety of information by hovering over a model entity, as shown in the following figure.



Note: The tool tips automatically display the results for the active load case. All values are reported in the current display units.

M. To switch individual object label display

To control the display of individual node, beam, plate, or solid labels, use the following procedure.

These tools activate the Partial Labeling Mode, which allows you to control the display of individual object labels in STAAD.Pro.

1. On the **View** ribbon tab, select one of the following tools in the **Labels** group:

   Individual Nodel Label

   or

   Individual Beam Label

or

Individual Plate Label

or

Individual Solid Label

2. Select the model object that you want to switch the label state.

   The model object must be of the same type as the selected tool.

   If this is the first time you are switching individual labels, you will be prompted that the program will turn on Partial Labeling Mode. Click **Yes** to proceed.

M. Views

You can navitage the view, control the display of model objects, and save named views in STAAD.Pro.

M. Displaying a Portion of the Model

Sometimes, the large number of entities that are drawn on the screen may make it difficult to clearly see the details at any particular region of the structure. In such cases, one is confronted with the task of decluttering the screen or looking at specific regions or entities while removing the rest of the structure from the view.

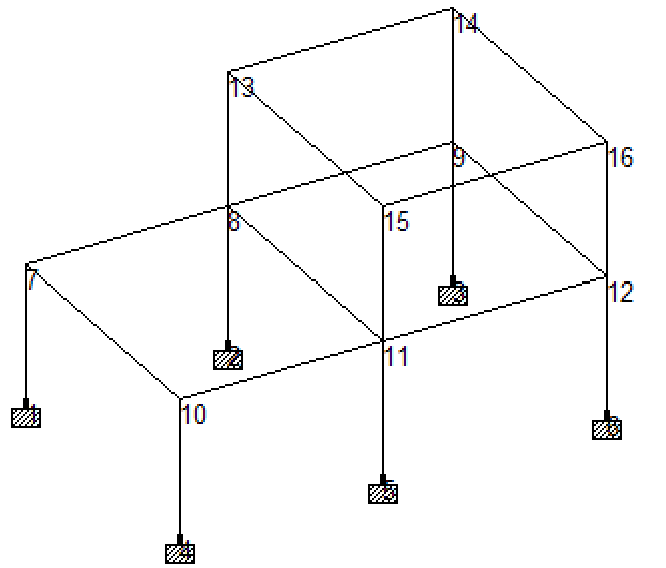
There are different methods in STAAD.Pro by which you can view a portion of the structure.

M. To cut a section of a model

The file `US.8. Concrete Design for a Space Frame.STD` is used to demonstrate this feature.

1. (Optional) Press **<Shift+N>** to display the node numbers.

   This will aide in specifying a node number in the following step.



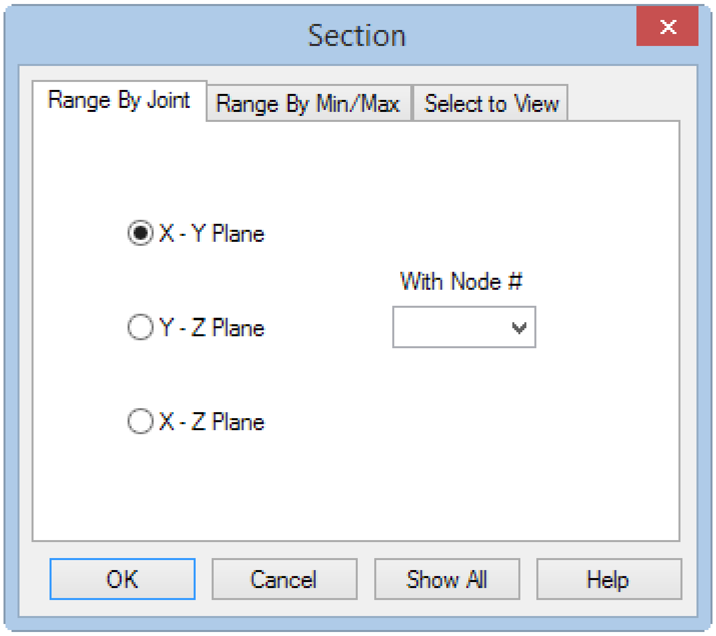
2. Use the cut section tool:
   a. On the **Utilities** ribbon tab, select the **Structure Tools** tool in the **Geometry Tools** group.

   b. Select the **Cut Section** tool from the drop-down list.

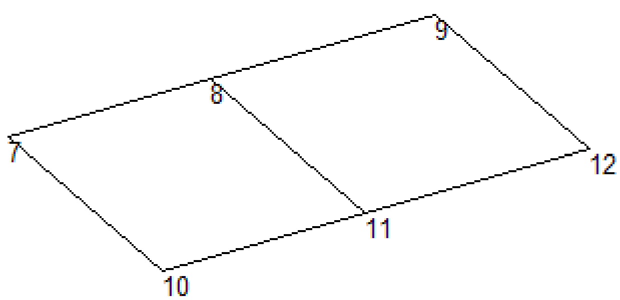
   The **Section** dialog opens.



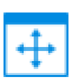
3. Specify a cut plane by joint and plane orientation (range by joint method):
   a. Select the **Range By Joint** tab.
   b. Select the **X - Z Plane** option.
   c. Select **10** from the **With Node #** drop-down list (which contains all node numbers in the model).

   Tip: You can select any node with in this same plane to achieve the same result.

   d. Click **OK**.



4. To restore the original view, select the **Whole Structure** tool in the **Tools** group on the **View** ribbon tab.



Tip: Alternatively, you can click **Show All** on the **Section** dialog.

5. Specify a cut plane by minimum and maximum distances and plane orientation (the range by min/max method):
   a. Repeat step 2 to open the Section dialog.
   b. Select the **Range By Min/Max** tab.

c. Select the **X-Z Plane** option.
d. Type `10` in the **Minimum** field and type `14` in the **Maximum** field.

The **Minimum** and **Maximum** values are the boundary distances along the axis perpendicular to the sectional plane. Every object lying entirely between these two distances will be displayed.

Note: When using this method, make sure that the current input units of length are in the intended units.

6. Repeat step 4 to restore original view.
7. Display only the nodes for quick selection (the Select to View method):

a. Select the **Select To View** tab.

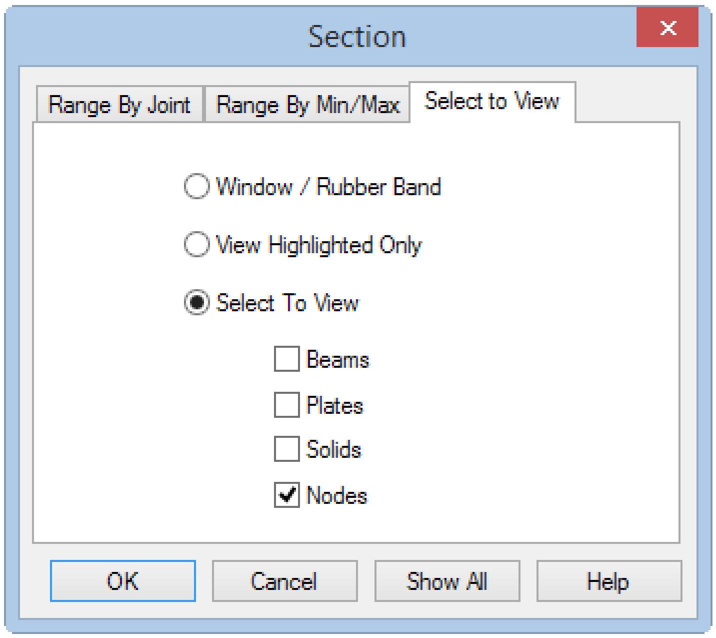


Figure 96:

b. Select the **Select To View** option.
c. Check the **Node** option.
d. Click **OK**.

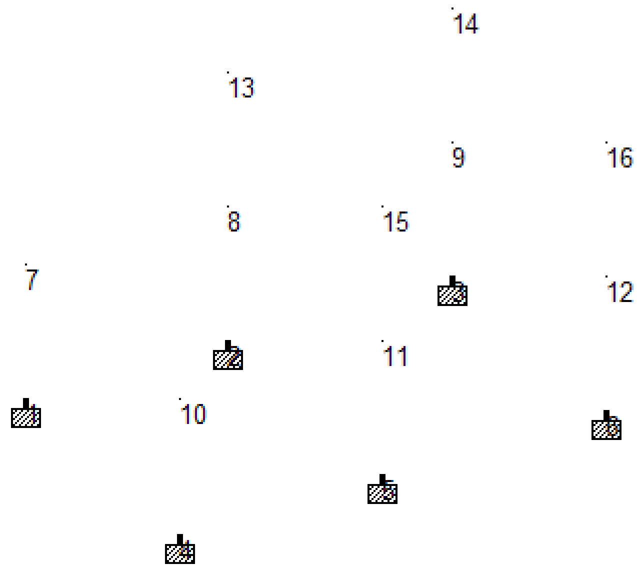

Figure 97: The nodes only displayed for

8. Select the **Whole Structure** tool to restore original view.

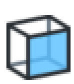
Note: You can save these views by selecting the **View Management** > **Save View** tool in the **Views** group on the **View** ribbon tab. Provide a title for the new view. These saved views may later be opened by selecting the **Open View** tool in the **Views** group on the **View** ribbon tab.

M. To create a new view

The file `US.8. Concrete Design for a Space Frame.STD` is used to demonstrate this feature.

New view windows are helpful for performing such operations as adding and deleting members, assigning properties, loads, supports, and more. A new view of a selected portion offers the advantage of de-cluttering the screen and limiting the displayed objects to just a few chosen entities.

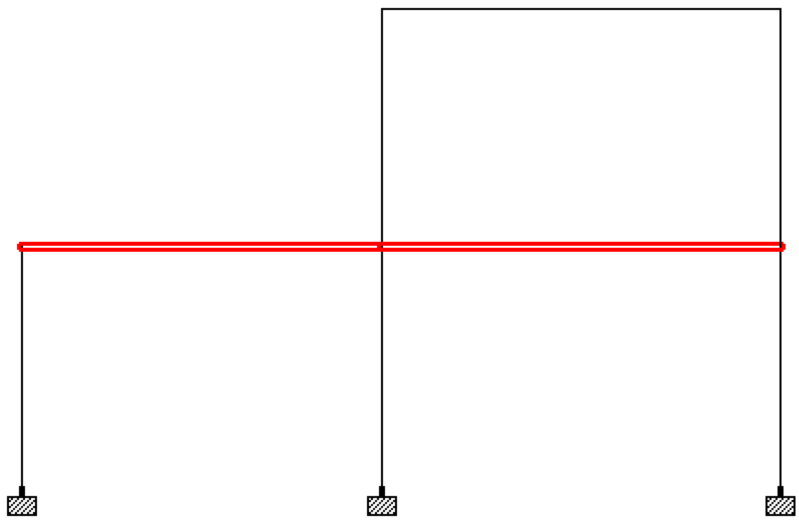
1. On the **View** ribbon tab, select the **Front View** tool in the **Tools** group.



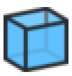
2. In the view window, drag a window area around the middle level of beams to select them.

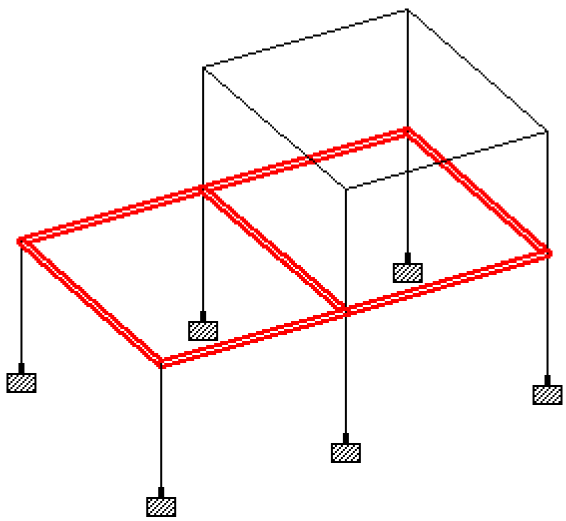
Tip: Make sure that the **Beam Cursor** tool  is the active selection tool on the **Select** ribbon tab in the **Cursors** group.

The selected members are highlighted.



3. (Optional) On the **View** ribbon tab, select the **Isometric View** in the **Tools** group.





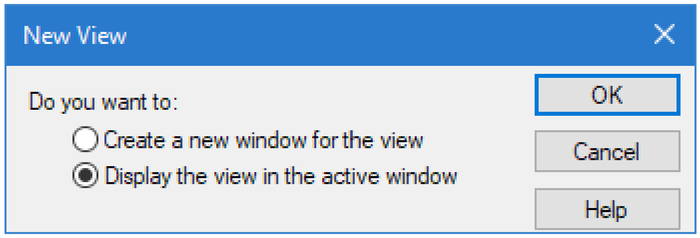
4. Either:

   On the **View** ribbon tab, select the **New View** tool in the **Views** group.

   
   or

   Right-click anywhere in the current view window and select **New View** from the pop-up menu.

The **New View** dialog opens.



The dialog includes options open the new view in a new (child) window or to replace the current (parent) view window.

5. Select the **Create a new window for the view** option and then click **OK.**

   The portion of the structure that we selected is displayed in a new window.

Tip: Multiple child view windows may be created in this way.

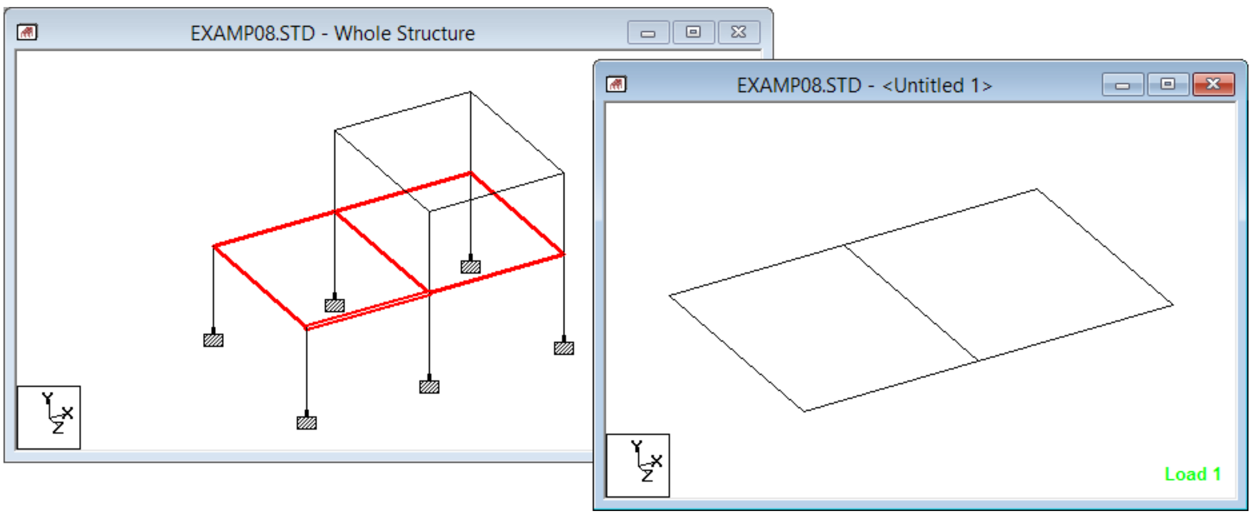


Figure 98:

6. Save the view for later use:
   a. On the **Views** ribbon tab, select the **View Management Save View** tool in the **Views** group.

   The **Save View As** dialog opens.
   b. Type a name for the view.
   c. Click **OK.**

   The view window is titled with the view name. You can
7. Close the new view window by clicking close **[X]** in the top-right corner.
8. Repeat steps 2 through 4 to start another New View.
9. Select the **Display the view in the active window** option and click **OK.**
   The full structure is hidden and the selected portion is displayed in the View window.
10. To restore the original view, select the **Whole Structure** tool in the **Tools** group on the **View** ribbon tab.

Note: You can save these views by selecting the **View Management** > **Save View** tool in the **Views** group on the **View** ribbon tab. Provide a title for the new view. These saved views may later be opened by selecting the **Open View** tool in the **Views** group on the **View** ribbon tab.

M. To restore the window layout

To restore the window arrangement for the current workflow page, use the following procedure.

If you have closed some of the layout tables, dialogs, or view windows you can quickly restore the default layout.

1. On the right-hand side of the page control bar, select the **Restore View** tool.
   The default window layout is opened.

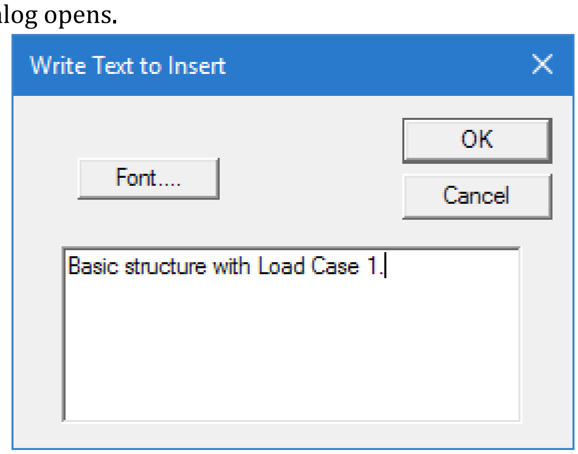
M. To insert custom text in a view

To add custom text to the view window and, subsequently, pictures taken for reports, use the following procedure.

The text can serve as comments or titles to pictures and result diagrams. The added text can be plotted too.

1. Select the **Insert Text** tool in the **Display** group on the **Utilities** ribbon tab.

   The mouse pointer changes to the text cursor ( ).
2. Click in the view window where you want to insert the text.
   The **Write Text to Insert** dialog opens.



3. (Optional) Click **Font** to set the type display.
4. Type the text into the text field and then click **OK**.
5. Either:

   Repeat steps 2 through 4 to insert additional text items.

   or

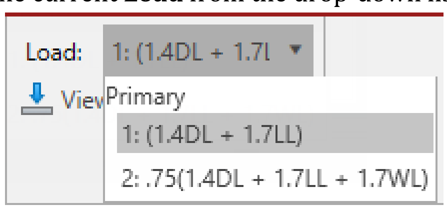
   Repeat step 1 to turn off the insert text tool.

6. (Optional) To modify previously inserted text:
   a. Select the **Text Cursor** tool in the Selection group on the **Geometry**, **Results**, or **Member Design** ribbon tabs.
   b. Double-click on the text you want to modify.
      An edit dialog opens with the existing text.
   c. Make changes and then click **OK**.
   d. Click-and-hold the left mouse button on the text to move it to another location in the view window.
7. (Optional) To delete previously inserted text:
   a. Select the **Text Cursor** tool in the Selection group on the **Geometry**, **Results**, or **Member Design** ribbon tabs.
   b. Click on the text you want to delete.
   c. Press **<Delete>**.

M. To display loads graphically

You can display the load diagrams and load values on the model.

1. On the **Loading** ribbon tab, select the current **Load** from the drop-down list in the **Display** group.



> **Tip:** The current load case number is displayed in the lower, right-hand side of the view window as well as in the application status bar.

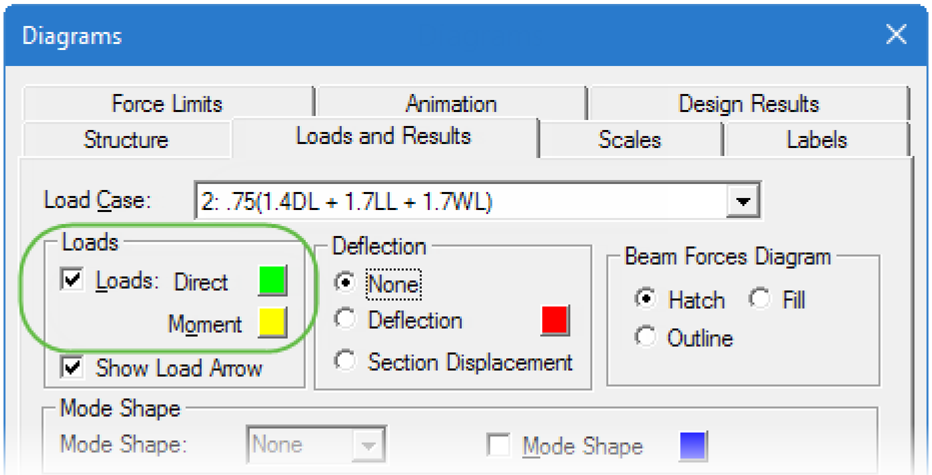
2. Either:

   Select the **Labels** tool 

   or

   Right-click anywhere in the View area and select **Labels** from the pop-up menu.

   The **Diagrams** dialog opens.
3. Either:
   a. select the **Loads and Results** tab.
   b. Check the **Loads** option.



c. (Optional) Click the color squares for Direct or Moment to change the load pattern colors.

d. Click **Apply**.
The loads are graphically displayed on the model.

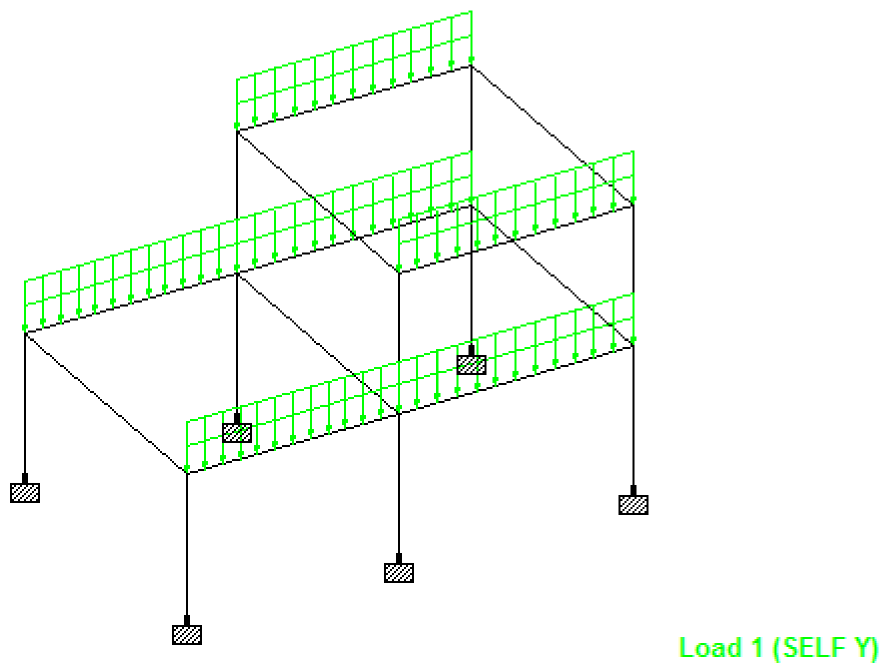


Figure 99: Load case 1 displayed on `US.8. Concrete Design for a Space Frame.std`

4. a. Select the **Labels** tab.
   b. Set the **Load Values** check box in the **Loading Display Options** group.
   c. Click **OK**.

The load values are displayed for the current load case, as seen here for the file `US.8. Concrete Design for a Space Frame.STD`.

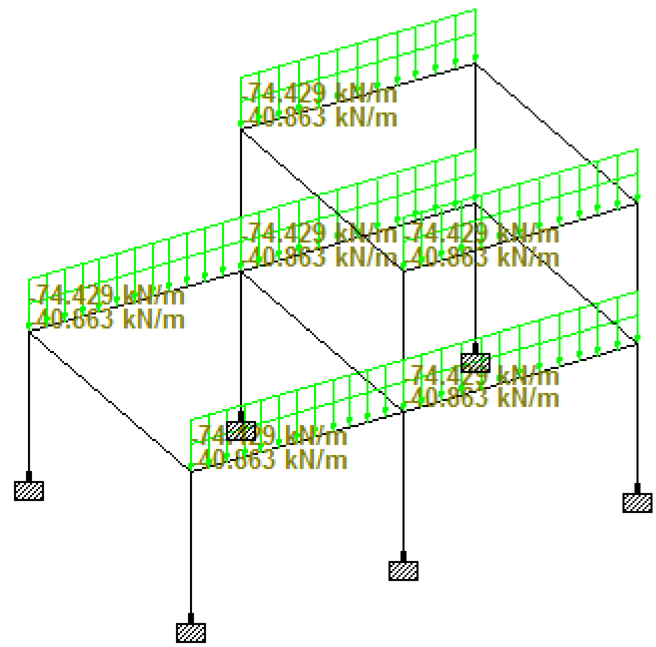

Figure 100:

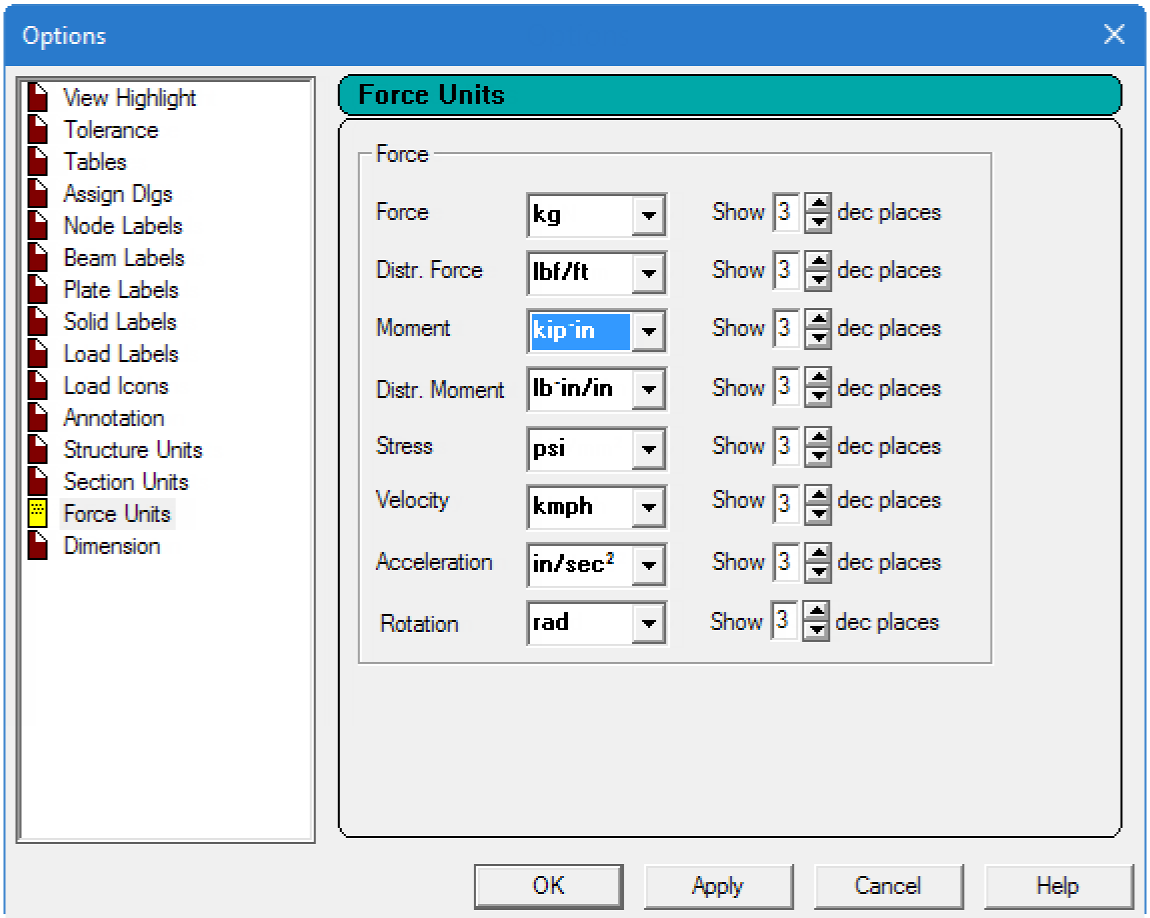
5. (Optional) To change the units displayed:
   a. Select the **File** ribbon tab.
      The STAAD.Pro Backstage view opens.
   b. On the **Settings** tab, select **Display Options**.

      The **Options** dialog opens.
   c. Select the **Force Units** tab.

      The **Options** dialog opens.



d. Select the **Force** and **Distributed Force** values as needed.

e. Click **OK**.

The values are updated with the new units.

M. To identifying beam start and end

Beam ends can be colored to easily identify the start and end joints of a beam. By default, the start (i) joint is colored green and the end (j) joint is colored blue.

1. Either:

   Select the **Labels** tool 

   or

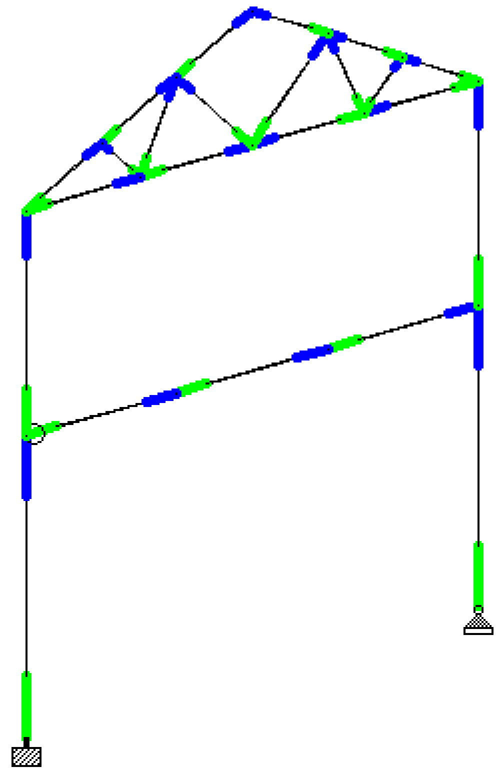
   Right-click anywhere in the View area and select **Labels** from the pop-up menu.

   The **Diagrams** dialog opens.
2. Check the **Beam Ends** option in the **Beams** group.
3. Click **OK**.

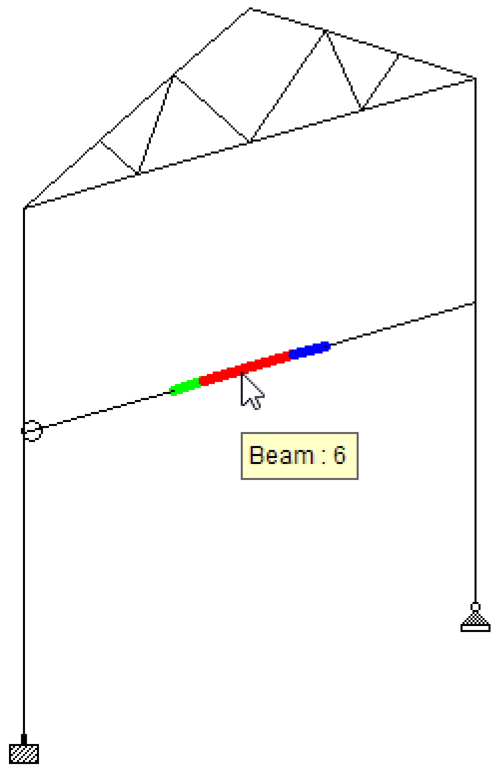
Tip: Alternatively, you can press **<Shift+E>** to toggle the beam end colors.

The beam ends are colored for the entire structure.

The file `US.1. Plane Frame with Steel Design.STD` is used to demonstrate this feature.



Alternatively, you can hover your mouse over any beam momentarily and the beam ends for that member are displayed using the same colors.



M. Rotation tools

These tools found on the **View** ribbon tab can rotate your model to a predefined orientation.

Tool name	Description	Example
 **Isometric View**	Displays the structure in the isometric view. The angle which defines isometric view is generally X = 30, Y = 30, Z = 0	
Tool name	Description	Example
 **Front View**	Displays the structure as seen from the positive Z axis. When the global Y axis is vertical, this is the elevation view, as looking towards the negative direction of the Z-axis.	 **Back View**	Displays the structure as seen from the negative Z axis. When the global Y axis is vertical, this is the elevation view, as seen looking towards the positive direction of the Z-axis.	 **Left View**	Displays the structure as seen from the negative X axis. When the global Y axis is vertical, this is the side elevation, as seen looking towards the positive direction of the X-axis.	 **Right View**	Displays the structure as seen from the positive X axis. When the global Y axis is vertical, this is the side elevation, as seen looking towards the negative direction of the X-axis.	
Tool name	Description	Example
 **Top View**	Displays the structure as seen from the top looking down (positive Y axis). When the global Y axis is vertical, this is the plan view, as seen from the sky looking down.	 **Bottom View**	Displays the structure as seen from the bottom looking up (negative Y axis). When the global Y axis is vertical, this is as if one is looking up skywards.	
M. To display control nodes

To highlight control nodes in a model that contains control/dependent joints, use the following procedure.

Tip: Open example 26 to demonstrate this procedure for yourself.

1. Either:

   on the **View** ribbon tab, select the **Label Settings** tool in the **Labels** group

   

   or

   in the view window, right-click and select **Labels** from the pop-up menu

   The **Diagrams** dialog opens to the Labels tab.
2. Check the option from **Control/Dependent** in the General group.
3. Click **Apply**.

   Tip: Press **<Shift+L>** to highlight control nodes quickly.

   The control nodes are highlighted with green cubes.

4. Click **OK**.

Related Links

M. Creating Model Objects

This section describes the tools used in STAAD.Pro to model your structure.

M. Drawing Aids

M. To add a grid for drawing objects

To add a grid for drawing beams or plates, use the following procedure.

Only one grid may be displayed at a time. However, you may have multiple grids associated with your model.

Note: Grids added to the model will be available to use in both the **Snap Node/Beam**, **Snap Node/Plate**, and **Snap Node/Solid** dialogs.

1. Either:

   On the **Geometry** ribbon tab, select the **Grids** > **Beam Grid** tool in the **Structure** group.

   
   or

   On the **Geometry** ribbon tab, select the **Grids** > **Triangular Plate Grid** tool in the **Structure** group.

   

   or

   On the **Geometry** ribbon tab, select the **Grids** > **Quad Plate Grid** tool in the **Structure** group.

   

   or

   On the **Geometry** ribbon tab, select the **Grids** > **Solid Grid** tool in the **Structure** group.

The corresponding **Snap Node/Beam**, **Snap Node/Plate**, or **Snap Node/Solid** dialog opens. If an existing grid is selected in this dialog, this grid is displayed in the view window.

2. Click **Create**.
   A pop-up dialog opens for defining grid details.
3. Select the type of grid from the drop-down list.

Grid type	Description
Linear	a Cartesian grid with even spaces along both of the axis.
Radial	a polar grid with even spaces between rays and radial lines.
Irregular	a Cartesian grid with irregular spaces along both of the axis.

   The pop-up dialog fields update with the grid type selection.
4. Type a grid **Name** to identify the grid in the Snap Node/Beam dialog.
5. Specify the location of the grid with respect to the global axes:
   a. Select the parallel global **Plane** for alignment (or reference when an angle is specified).
   b. (Optional) Select a global axis and then type an **Angle of Plane** to incline the grid with respect to that axis.
   c. (Optional) (For Irregular grids) Set the option to Use Arbitrary Plane and then type the vectors of the grid X and Y axis.
      This method can be used instead of specifying the Plane and Angle of Plane.
   d. Type global coordinates from the global origin to the **Grid Origin**.

> **Tip:** Click the node selection tool () and then click on an existing node in the model to use as the grid origin.

6. Specify the **Construction Lines** for the grid:

Grid type	Description
Linear	For both grid X and Y, type the number of grids spaces to the **Left** and **Right** of the origin, the **Spacing** (in current units) between each grid line, and (optionally) a **Skew** angle.
Radial	Type the **Start Angle** and **Sweep** to specify the beginning and end of the radial lines along with the number of bays (spaces between radial lines). Type the inner-most and outer-most radius in the **Radius 1** and **Radius 2**, respectively, along with the number of **Bays** (spaces between arcs).
Irregular	Type the distance between each consecutive grid line in the current units along each axis.

7. Click **OK**.
   The pop-up dialog closes and the new grid name is added to the list.
8. Check the name of the grid in the list that you want displayed in the view window.

Click **Edit** to make changes to the currently selected grid in the list. You can change the grid orientation and construction lines but the type of grid cannot be changed.

- *Irregular grid dialog* (on page 2722)

M. To import a STAAD.Pro grid file

To import a STAAD.Pro grid file which was contains grids used in another model, use the following procedure.

Any time you save a model with custom grids, the grid data is saved into a STAAD.Pro grid file (file extension `.grd`) with the same file name and location as the STAAD input file.

1. Either:

   On the **Geometry** ribbon tab, select the **Grids** > **Beam Grid** tool in the **Structure** group.

   
   or

   On the **Geometry** ribbon tab, select the **Grids** > **Triangular Plate Grid** tool in the **Structure** group.

   or

   On the **Geometry** ribbon tab, select the **Grids** > **Quad Plate Grid** tool in the **Structure** group.

   or

   On the **Geometry** ribbon tab, select the **Grids** > **Solid Grid** tool in the **Structure** group.

   The corresponding **Snap Node/Beam**, **Snap Node/Plate**, or **Snap Node/Solid** dialog opens. If an existing grid is selected in this dialog, this grid is displayed in the view window.
2. Click **Import**.
   The **Import Options** dialog opens.
3. Select **STAAD.Pro Grid (.grd)** and then click **OK**.
   An Windows **Open** dialog opens.
4. Select the STAAD.Pro grid file and then click **Open**.
   The grids in the file are added to the Snap Node/Beam dialog.

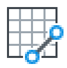
M. To import a DXF file as a grid

To import an AutoCAD® DXF file to use as a drawing grid, use the following procedure.

The straight lines within a DXF file can be imported as a grid. Complex shapes and curved lines will not be imported.

1. Either:

   On the **Geometry** ribbon tab, select the **Grids** > **Beam Grid** tool in the **Structure** group.



or

On the **Geometry** ribbon tab, select the **Grids** > **Triangular Plate Grid** tool in the **Structure** group.

or

On the **Geometry** ribbon tab, select the **Grids** > **Quad Plate Grid** tool in the **Structure** group.

or

On the **Geometry** ribbon tab, select the **Grids** > **Solid Grid** tool in the **Structure** group.

The corresponding **Snap Node/Beam**, **Snap Node/Plate**, or **Snap Node/Solid** dialog opens. If an existing grid is selected in this dialog, this grid is displayed in the view window.

2. Click **Import**.
   The **Import Options** dialog opens.
3. Select the **DXF** option and click **OK**.
   The **DXF Import** dialog opens.
4. In the File Name field, either:

   type the file path and file name of the DXF file

   or

   click **[...]** locate the file using the **Open DXF File** dialog

   The layers and line data is read and displayed graphically.
5. Select the layer number containing the line data you want to use from the **Layers** drop-down list.
   The lines are displayed in the list view and graphically.
6. (Optional) Uncheck any lines you do not want to include in the imported grid.
   The lines are hidden in the view window.
7. (Optional) Type a **Name** for the imported grid.

   By default, the name of the DXF file is used.
8. Select the **Unit** to use for the grid.

   Tip: The drop-down list contains most common length units. Use the up or down arrows to navigate through the options.

9. Click **OK**.
   The Imported Grid pop-up dialog opens.
10. (Optional) Specify the **Angle of Plane** and **Grid Origin** to orient the grid.
11. Click **OK**.

When you save your model, the imported DXF grid will be saved to the corresponding STAAD.Pro grid file (file extension `.grd`).

M. Beams

M. To set attributes for new beams

To specify a set of attributes to automatically assign to new beams, use the following procedure.

For member profiles and member end releases, you will need to add the corresponding specification to your model before you can select it for most attribute sets.

Tip: The predefined attribute sets have some pre-populated values that will be added to your model automatically, though.

In STAAD.Pro, you will often assign attributes (beta angle, end offsets, material, profile, etc.) after you have placed a member. However, you can also assign attribute sets when creating new members by defining these ahead of time. STAAD.Pro allows you to create and edit named attribute sets so you can easily change between attribute sets.

Note: This feature is not active by default so new members will not have any attributes assigned initially.

1. On the **Geometry** ribbon tab, select **Add Beam** > **Set New Beam Attributes** in the **Beam** group.
   The **Define Member Attributes** dialog opens.
2. Select an attribute set in the list.

   Tip: There are several named sets which can be used or you can simply use the default “(None)” set.
3. Check the box for each attribute you want assigned.

   You can check multiple items. Each item has one or more options to select once you have checked to assign it.

Attribute	Description
Member Property	Check to **Assign Profile with Material** and then select the profile and associated material from the drop-down list.
Beta Angle	Check to **Assign Member Rotation** and then select the option for rotation from the list. Type in the **Angle in Degrees** if you select that option.
Member Release	Check to **Assign to Member Start** and **Assign to Member End** as needed. Select a end release specification from the drop-down list for each end you have added a member release.
4. Click **Save**.
   The attribute set is updated with the new specification selections.
5. Check the option to **Assign these attributes when creating members**.

   Note: This option can only be checked for one attribute set.
6. Click **OK**.

- *Define Member Attributes dialog* (on page 2729)

M. To add beams by drawing on a grid

1. On the **Geometry** ribbon tab, select the **Grids** > **Snap Grid Beam** tool in the **Structure** group.

   The Snap Node-Beam dialog (on page 2719) opens and the current grid is displayed in the active View window.

   Tip: The dialog and grid are automatically opened if you select Start adding beams in the New model wizard.
2. (Optional) Either:

   click **Edit** to edit the currently selected grid

   or

   click **Create** to create a new custom grid (radial and irregular grids must be custom)
3. (Optional) Set the **Snap to existing nodes too**

   Note: Existing nodes have precedence over grid intersections, in order to prevent creating M. To check for and remove duplicate entities (on page 914).
4. If it is not already active, click **Snap Node/Beam** in the Snap Node/Beam dialog.
5. In the Active view window, click any grid intersection or existing node (if the option was set) to select the start point of a new beam member.

   A cross icon "snaps" to the nearest grid line intersection or existing node to the mouse pointer. This indicates the tentative point for placing a beam end. Once the start end is selected, a red circle indicates the start point and a line is rubber-banded to the snap point nearest the mouse pointer.
6. Click the end point of the beam.
7. Repeat steps 5 and 6 until you are finished drawing beams.
8. To stop drawing beams, either:

   press **<Esc>**

   or

   click **Snap Node/Beam** in the Snap Node/Beam dialog

M. To add beams with new nodes

To add beams between existing nodes or along beams by generating new nodes, use the following procedure.

1. On the **Geometry** ribbon tab, **Add Beam** tool in the **Beam** group.

   The mouse pointer changes to the Add Beams cursor ().
2. Click on any point along the first beam where the starting node of the new beam will lie.

   If the program detects you are clicking on an existing node, skip to Step 6.

   If an existing node is not present at that point, a dialog box will prompt for a new node to be created.

3. Click **Yes**.
The **Insert Nodes into Beam #** dialog opens. The value in the **Distance** edit box is the exact location clicked on from the start of the beam.
4. (Optional) Edit the **Distance** value as necessary.

> **Tip:** Other nodes can also be generated along the beam as well. For more information on how to use the **Insert Node** dialog box, please refer to M. To insert a node in a single member (on page 682).

5. Click **OK**

   A new node is created on the selected beam and a the new beam member is “rubber banded” to this point.

> **Tip:** If the new node input is not within a close proximity of the point clicked on the screen (that which resulted in the dialog opening), no “rubber band” line will be shown. In this case, simply click on the new node to start the creation of the beam.

6. Click a point along another beam or an existing node to specify the end point of the new beam.

   If this is not at an existing node, refer to steps 2 through 5 for inserting a new node into a beam.
7. To stop adding beams:

   Press **<Esc>**

   or

   select any tool

Related Links
- *TR.12 Member Incidences Specification* (on page 2221)

M. To add beams from mid-points

1. On the **Geometry** ribbon tab, select the **Add Beam** > **Add Beam Between Mid-Points** tool in the Beams group.

   The mouse pointer changes to the Add Beams cursor ().
2. Click on any point along the first beam where the starting node of the new beam will lie.
A new beam member is "rubber banded" to this point.
3. Click on any point along the second beam where the end node of the new beam will lie.

   New nodes are created on the selected beams at their mid-points and a the new beam member connects these two new points.
4. Repeat steps 1 through 3 to continue adding beams.
5. To stop adding beams:

   Press **<Esc>**

   or

   select any tool

M. To add beams perpendicular to existing beams

1. On the **Geometry** ribbon tab, select the **Add Beam by Perpendicular Intersection** tool in the **Beam** group.

   
   The mouse pointer changes to the Add Beams cursor ().
2. Click on any point along the first beam where the starting node of the new beam will lie.
   A new beam member is "rubber banded" to this point.
3. Click on any point along the second beam where the end node of the new beam will lie.
   A new node is created on the selected beam at the at the calculated perpendicular point and a the new beam member is added.
4. Repeat steps 2 and 3 to continue adding beams.
5. To stop adding beams:

   Press **<Esc>**

   or

   select any tool

M. To add a curved beam

To add a curved beam between two existing nodes, use the following procedure.

Curved members may only be created between two existing nodes. Any non-tapered cross-section is permitted for curved members. The internal angle subtended by the arc must be less than 180 degrees.

Note: The design of curved members is *not* supported.

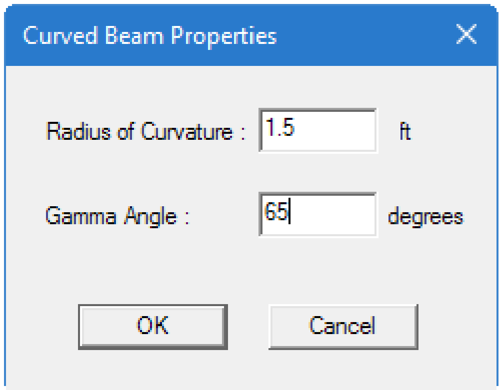
1. On the **Geometry** ribbon tab, select the **Add Beam** > **Add Curved Beam** tool in the **Beam** group.

   Tip: This tool is contained on a drop-down list below the **Add Beam** tool.

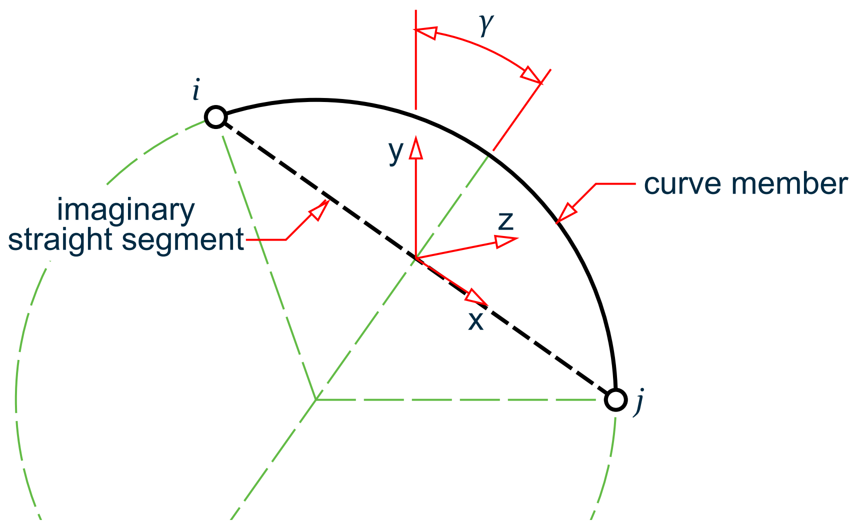
   The pointer changes to the Add Curved Beam cursor ().
2. Click on the start and end nodes, respectively.

   The **Curve Beam Properties** dialog opens.



3. Type the **Radius of Curvature** (in current units of length) and the **Gamma Angle** (in degrees) values.

   The gamma angle, γ , is the angle between the member local Y axis and the plane of the circular arc of the member.



4. Click **OK**.
   The curved beam will is added to the model.
5. Repeat steps 2 through 4 to add more curved beams.
6. To stop adding beams:

   Press **<Esc>**

   or

   select any tool

Related Links

- *G.6.8 Curved Members* (on page 2120)
- *TR.20.8 Curved Member Specification* (on page 2273)

M. To split a beam at selected node(s)

1. Select one or more nodes located along a beam.
2. On the **Geometry** ribbon tab, select the **Break Beams at Selected Nodes** tool in the **Beam** group.

A message box appears which displays the number of new beams created.

3. Click **OK**
   The dialog closes.

M. To stretch a member

1. Select one or more members which are to be extended.
2. On the **Geometry** ribbon tab, select the **Geometry** > **Stretch Selected Member(s)** tool in the **Beam** group.

the Stretch Member(s) dialog (on page 2732) opens.

3. (Optional) Click the drop-down list in the **Select member(s)** and then uncheck any members you do not wish included in the stretch operation.
4. Specify the method of stretch and required parameters:

   Select **To a point** and then type the coordinates of an arbitrary point

   or

   Select **Through a distance** and then select the member end and distance to extend to

   or

   Select **To an existing node** and then select the node number

   Tip: Click the tool to graphically select a node.

   or

   Select **To an existing member** and then select the member number

   Tip: Click the tool to graphically select a member.
5. Click **OK**.

Related Links

- *Stretch Member(s) dialog* (on page 2732)

M. To merge two or more members

To merge two or more members into a single member, user the following procedure.

1. Select the beams to be merged.
2. On the **Geometry** ribbon tab, select the **Merge Selected Beams** tool in the **Beam** group.

The **Merge Selected Beams** dialog opens.
3. Specify the member properties the merged member will have.
4. Click **Merge**.

Related Links
- *Merge Selected Beams dialog* (on page 2733)

M. To renumber selected beams

To renumber the currently selected members, use the following procedure.

1. Select the beams to be renumbered.
2. On the **Geometry** ribbon tab, select the **Renumber Beams** tool in the **Beam** group.

A message dialog opens to warn you that renumbering may not be undone.
3. Click **Yes** to confirm you wish to proceed.
The **Renumber** dialog opens.
4. (Optional) Specify a **Start number from**
5. (Optional) Select the **New Numbering Order**
6. (Optional) Select the sort criteria to be used and add them to the **Selected Sort Criteria**
7. (Optional) Reorder the items in the **Selected Sort Criteria**
For example, select the Z Coordinate and click **Move Up** twice so the order from top to bottom is: Z Coordinate, X Coordinate, Y Coordinate. This instructs the program to renumber beams parallel to the Y axis until no more beams are in that line. It then skips to the next selected entity along the X axis and renumbers those, again along the Y axis. Once it has reached the end of selected beams parallel to the X axis, it then skips to the next selected entity parallel to the Z axis and repeats the previous procedures.
8. Click **Accept**.
A message dialog opens with the status of the renumbering operation.
9. Click **OK** to dismiss the message dialog.
The selected beams are renumbered following the indicated pattern.

- *Renumber dialog* (on page 2728)

M. Physical Members

Physical members are composites of one or more analytical members which represent the true physical geometry of a member in a structure.

Note: Physical members use the nomenclature `PMEMBER` in the STAAD input file.

About Physical Members

Beam objects connecting two nodes in a structural model are referred to as analytical beams as they are the fundamental, one-dimensional object processed by the STAAD engine during analysis. While necessary for this purpose, they are often difficult elements to use for design as they do not possess the same geometry of a physical structural element. For example, a girder is not physically broken where a beam frames, but a node must be placed to represent the connection in the model. The design of this girder is then complicated as the bracing conditions and other parameters of design can not be directly interpreted by the program.

In this case, STAAD.Pro has the facility to use group one or more analytical beam objects into physical members for the purpose of design. This concept is used in both the Steel Design and Concrete Design workflows. Additionally, physical members can be created in the modeling mode for the purpose of integrated steel design.

Related Links

- *TR.16.2 Physical Members* (on page 2238)
- *M. To assign catalog section to physical members* (on page 718)

M. To manually form physical members

To form a physical member for a selected set of analytical members, use the following procedure.

The following are required to form a physical member:

- analytical members must be interconnected
- analytical members are collinear
- the local axes of the component members should be identical (i.e., the x, y, and z are respectively parallel and in the same sense)
- a single analytical member may not be in more than one physical member

1. Select one or more beams which represent a single physical member.

   Note: Component analytical members must meet the criteria for physical members.

2. Either

   on the **Beam** ribbon tab, select the **Form Member** tool in the **Model** group

   or

   on the **Geometry** ribbon tab, select the **Form Member** tool in the **Physical Member** group (Analytical Modeling workflow)

   or

   on the **Member Design** ribbon tab, select the **Form Member** tool in the **Physical Member** group (Steel Design workflow)

   or

   right-click and select **Form Member** from the pop-up menu.

   The physical member (i.e., M#) number is displayed on each component analytical member and the physical member is added to the **Physical Member** table.

M. To automatically form physical members

To have the program automatically detect and form physical members within a selected set of members, use the following procedure.

1. Select a set of beams that you want formed into physical members.
2. Either:

   on the **Geometry** ribbon tab, select the **AutoForm Member** tool in the **Physical Members** group (Analytical Modeling workflow)

   or

   on the **Member Design** ribbon tab, select the **AutoForm Member** tool in the **Physical Members** group (Steel Design workflow)

The program applies the rules of forming physical members to detect which members should be grouped to a single physical member.

M. To automatically generate physical member restraints

Used the following procedure to automatically generate top and bottom flange restraint conditions for the selected physical members.

Note: The PBRACE command generated by this menu item is valid only for D2.B.12 Physical Member Design (on page 1372) .

1. Create a STAAD.Pro model with steel members.
2. Either:

   on the **Analysis and Design** ribbon tab, select the **Design** > **Steel Design** tool in the **Design** group

   or

   select the **Design** page

   The **Steel Design - Whole Structure** dialog opens.
3. Form one or more physical members in the model.
4. Select **AS4100** as the **Current Code**.
5. Select one or more of the physical members.
6. On the Utilities ribbon tab, select the **Physical Member Restraints** tool in the **Geometry Tools** group.

   The PBRACE commands are added for the current design parameter set with the tag (Physical).

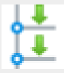
   Note: Only top or bottom flange restraints can be described using a single PBRACE command. Therefore, this command generates to lines of PBRACE commands for each physical member.

M. To manually add physical member restraints

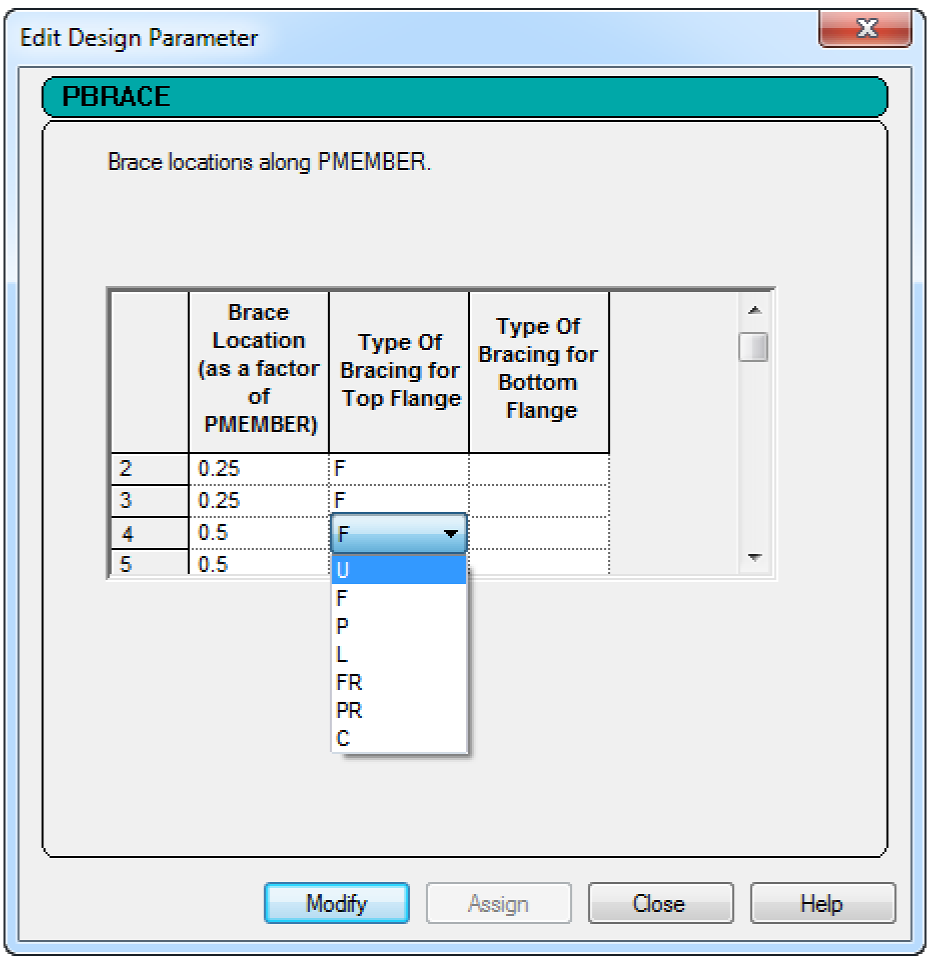
To manually add physical member restraints for assignment to physical members, use the following procedure.

Manual restraints apply to steel physical members which will be designed per AS 4100.

Tip: The restraint details can be automatically generated using a new **Member Restraints** item found in the **Utilities** ribbon tab in the **Geometry Tools** group.



1. In the Analytical Modeling workflow page controls, select the Design page.
2. Select **AS4100** as the **Current Code** in the **Steel Design - Whole Structure** dialog.
3. Click **Define Parameters.**
   The **Design Parameters** dialog opens.
4. Select the **PBRACE** parameter.
5. For each brace point, specify a fraction of the total physical member length in the **Brace Location** cell.



6. Select the type of restraint present for the top or bottom flange.

> **Note:** Only top or bottom flange restraints can be described using a single PBRACE command. If both top and bottom bracing is added in the Design Parameters dialog, this will generate two new command lines in the input file.

7. Click **Add**.
   The new command appears in the tree as a child element of the current design parameter set.
8. Click **Close**.
   The design parameters are marked with an icon. This indicates that the need to be assigned to members.
9. Use one of the STAAD.Pro assignment methods to assign each parameter to the applicable members.

The PBRACE specification is tagged as (Physical), and therefore can only be assigned to physical members (PMEMBER groups).

Related Links

- *D2.B.12.6 Physical Member Restraints Specification* (on page 1376)

M. To delete a physical member

1. Select the **Member Number ID** or any component Beam Number ID in the **Physical Member Table**.
2. Right click to display the pop-up menu.
3. Select **Delete**.
   A confirmation dialog opens.
4. Select **Yes**.

> **Note:** Only the physical member group assignment is removed. The component analytical beams are not deleted.

> **Caution:** This cannot be undone.

M. Plates

M. To set new plate attributes

To specify a set of attributes to automatically assign to new beams, use the following procedure.

1. On the **Geometry** ribbon tab, select the **Add Plate** > **Set New Plate Attributes** tool in the **Plate** group.
   The **Define Plate Object Property** dialog opens.
2. Select the check box for each of the plate object properties you want to use and then select the property value you want to use from the drop-down list:

Option	Description
Property	Check the **Use Property** option and then select a defined plate or surface thickness property from the drop-down list.
Material	Check the **Use Material** option and then select a material definition name from the drop-down list.
Release	Check the **Use Release** option and then select a plate release specification from the drop-down list.

3. (Optional) To create a new specification to use, click the associated Create button with the use option checked.
   The corresponding dialog opens to add a property, material, or release. Once you add this specification, the new specification is available from that drop-down list for use.
4. Check the option to **Assign these attribute when creating new plates**.
5. Click **OK**.

M. To draw plates connecting existing nodes

To draw triangular or quadrilateral plate elements connecting existing nodes, use the following procedure.

This procedure is used to manually add plate elements to your model. STAAD.Pro also has tools to automatically generate a finite element mesh with a surface area.

1. On the **Geometry** ribbon tab, select one of the following tools in the **Plates** group:

Use this tool...	To...
 **Add Quad Plate**	create four-node plate elements
 **Add Triangle Plate**	create three-node plate elements

   The mouse pointer changes to either the Add Quad Plate cursor () or Add Triangle Plate cursor (), respectively.
2. Click on any node that will form the first corner of the plate element.
   A line is "rubber banded" to the cursor from this node. This represents the first edge of the surface.
3. Click on the subsequent nodes to form the plate vertices in either a clockwise or counterclockwise order.

   The plate shape is "rubber banded" to the cursor as you move the mouse pointer to give you a preview of the plate shape.

   Note: Plate vertices should lie within a flat plane. Refer to " M. To check for warped plates (on page 912) " to verify that plates are planar.

   The plate is added to the model.
4. Repeat steps 2 and 3 to add more plates.
5. To stop adding plates:

   press **<Esc>**

   or

select any tool

Related Links

- *TR.13.1 Plate and Shell Element Incidence Specification* (on page 2224)

M. To add a plate bounded by beams

To create an “infill” plate by selecting exiting members as plate edges, use the following procedure.

Note: The beams to be used as bounding edges of an “infill” plate must meet the following requirements:

- three or four beams that form a closed polygon
- the beams cannot extend past the vertex nodes of the closed polygon
- the beams must lie within a plane

1. Select the beams you want to use as bounding edges of the plate.
   You must select three or more beams.

   Note: Use the **Beam Cursor** tool in the **Selection** group on the **Geometry** ribbon tab.
2. On the Geometry ribbon tab, select the **Add Plate** > **Create Infill Plates** tool in the **Plates** group.

   
   A message dialog indicates that the plate was successfully generated.

M. To generate plate mesh from corner nodes

To generate a finite element mesh by selecting corner nodes, use the following procedure.

You must have three or more existing nodes that lie in a plane in your analytical model.

This procedure is used to immediately generate a mesh within a selection of vertices. If you would like to investigate changing parameters prior to generating a mesh or to add openings with the mesh, then you may want to use the procedure a M. Parametric Models (on page 670) instead.

1. On the **Geometry** ribbon tab, select the **Generate Mesh** > **Create Mesh** tool in the **Plate** group.

   The mouse pointer changes to a mesh cursor.
2. Click the nodes that will form the vertices of the mesh area, in either a clockwise or counter clockwise order.

   Notes:

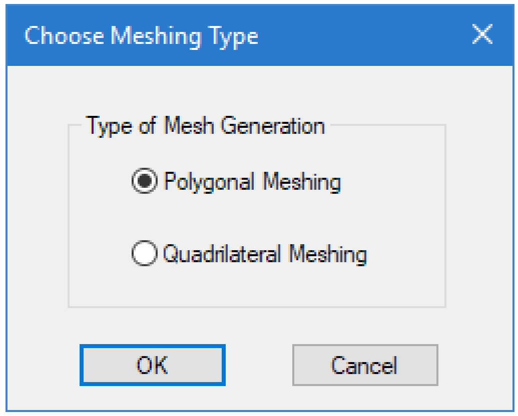
   - The order of the nodes should be in either a clockwise or counterclockwise direction.
   - The nodes must for a polygonal area (i.e., they edges cannot cross).
   - The nodes must lie in the same plane.
3. When you have select the corner nodes, either:

select the first node again

or

press **<Esc>**

The **Choose Meshing Type** dialog opens.



4. Select the type of meshing to use and then click **OK**.

Polygonal Meshing	Only triangular elements will be created
Quadrilateral Meshing	This will create principally four sided elements, but where the geometry dictates, some places may require triangular elements.

   The **Define Mesh Region** dialog opens.
5. Review the mesh vertices:
   a. Click the Add New Row tool to add a new vertex.
   b. Click the Delete Row tool to remove the currently selected row.
   c. Select the Holes tree entry to add openings to the mesh.
6. Click **OK**.
   The specified area within the vertices is meshed.

M. Parametric Models

STAAD.Pro allows you to model surfaces by automatically generating a mesh from a set of parameters. You can preview the final meshed state of the wall, slab, or panel before deploying the meshed entity into the remainder of the model. This way you can visually examine several trials or prototypes to find the most suitable alternative.

Tip: In past versions of STAAD.Pro, facilities for mesh generation have been available through the Geometry menu of the main program window and through the Structure Wizard utility which too is accessible through the Geometry menu. While these facilities continue to be available, an enhanced mesh generation tool has been added to the Geometry page.

This method offers some advantages over other methods of mesh generation in STAAD.Pro:

a. It enables you to preview the final meshed state of the wall, slab or panel before deploying the meshed entity into the remainder of the model. Several trials or prototypes can visually examined before committing to the most suitable one. This greatly minimizes the inconvenience of ending up with an undesirable meshed panel.
b. During the process of meshing, the program will automatically take into consideration existing nodes that lie within the boundary of the panel, but are not chosen as corner nodes of the panel. You simply have to define the panel boundary. The remainder of the nodes will be automatically considered by the program as “control

points" which is to say that elements will be created in such a manner that some of those elements will have these nodes in their incidence list. Control points might be panel points of a truss which supports a multi-span slab, or a foundation slab that supports several columns.

c. It allows for the definition of lines on the surface along which nodes should be created. Thus, if for a continuous slab over a wall, a line only needs to be drawn to define the intersection. Nodes will then be created along that line, and they will automatically become control points for the wall when it is meshed later. The problem of correctly modeling the monolithic connection between the 2 panels is now easier to handle as a result of this feature.

M. To create a parametric surface model

To create a parametric surface model for generating a finite element mesh, use the following procedure.

1. Select the **Parametric Models** tool in the Plate group on the **Geometry** ribbon tab.

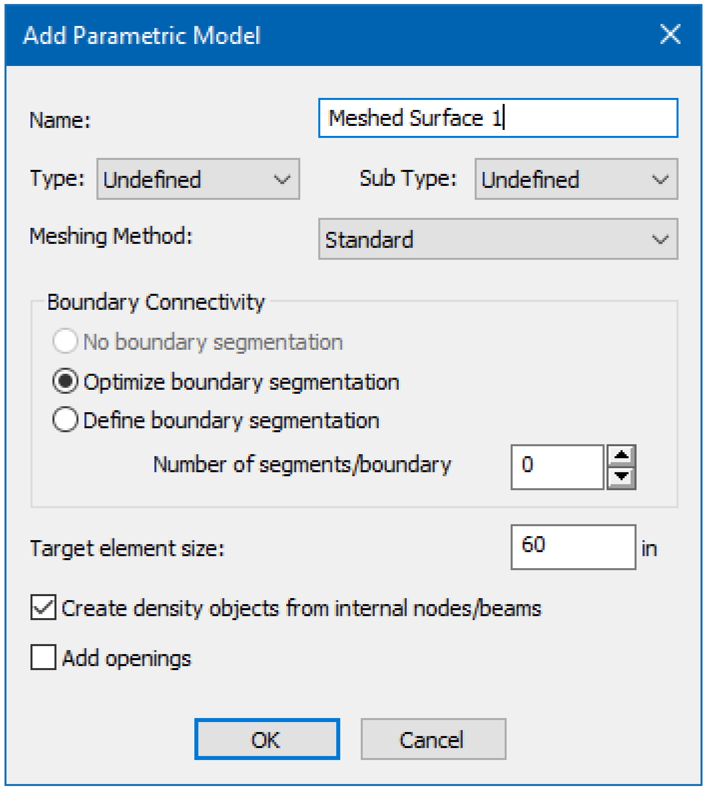
   The **Parametric Models** dialog opens. The structure is displayed as a series of dashed lines to signify this mode can be used to experiment with various settings.
2. Click **Add** in the **Parametric Models** dialog.

   The mouse pointer changes to the add surface cursor .
3. Click on the points that form the corners of the panel boundary.

   Note: Click the points in either a clockwise or counter-clockwise order.

   Tip: If you choose the option for including nodes and beams in the boundary area in the subsequent steps, then you can skip over intermediate points lying and a straight line segment, as the program will detect these and add them as mesh nodes automatically.

   When the first point is clicked a second time to close the loop, the **Add Parametric Model** dialog opens.



4. Specify the desired meshing parameters:
   a. Type a **Name** for the meshed surface.

      The default name is incremented.
   b. (Optional) Select a **Type** and **Sub Type** to identify the surface use.
   c. Select the **Meshing Method**.

      Selecting the **Standard** method will use quadrilateral elements where as the **Basic** method will use triangular elements.
   d. Select the **Boundary Connectivity** to identify the number of divisions along each surface boundary.
   e. Type a **Target element size** in the specified units of length.
   f. Check the **Create density objects from internal nodes/beams** to generate additional nodes along any members or defined nodes that lie in the surface plane.
5. (Optional) If the surface will have openings, check the **Add openings** option to specify those in the next dialog.

> **Tip:** Openings can be added later from the **Parametric Models** dialog if needed.

6. Specify the desired meshing parameters and click **OK**.
   If you selected to add openings, the dialog to define those opens.
7. (Optional) Select an opening shape and then click **OK** to draw the opening on the meshed surface.

   Refer to the following tasks for additional information on adding openings.

   The new mesh model is displayed as an overlay on the structure with control points highlighted. The details of the mesh parameters are available in the Parametric Models dialog.

Note: You may edit and refine your mesh by varying the parameters as necessary until the resulting finite element is satisfactory for your model requirements.

8. Once you are satisfied with the surface mesh, click **Merge Mesh**. in the Parametric Models dialog to commit it to the STAAD.Pro input file.

Tip: To delete a parametric mesh, opening, density line, or density point, select that entry within the **Parametric Models** dialog and click **Delete**.

Related Links

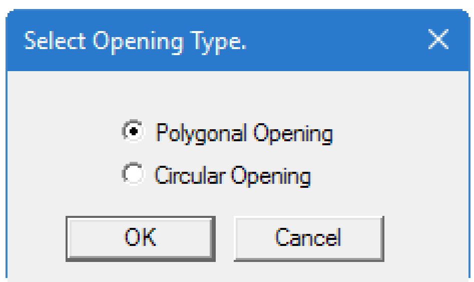
- *New Mesh Model dialog* (on page 2736)

M. To create a polygonal opening in a mesh model

1. In the **Parametric Models** dialog Mesh Models list, select the leaf called **Openings** under the mesh model to which you wish to add an opening.
2. Click **Add**.

   The **Select Opening Type** dialog opens.

3. Select the **Polygonal Opening** option and then click **OK**.

   The drawing will change to display just the mesh region. The right hand side of the screen will display a grid with the grid line settings and spacing.

   Tip: The various viewing options and zoom options on top of the screen can be used to obtain a convenient view of the panel.

4. (Optional) Edit the grid positions using the **Snap Node/Panel**
5. Click the points inside the panel to define the corners of the polygonal hole.

   Note: The cursor displays a blinking cross (+) at grid intersections. This blinking cross marks the point on the grid at which nodes of the hole boundary may be set. Click points around the mesh boundary in either a clockwise or counter-clockwise order, clicking on the first point a second time to close the loop.

   The mesh is regenerated taking into consideration the hole.

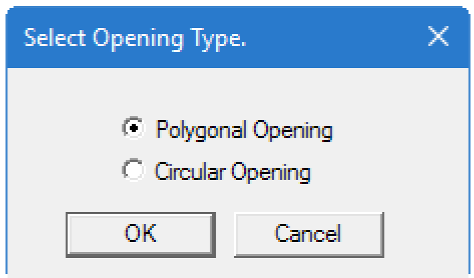
Tip: To delete a parametric mesh, opening, density line, or density point, select that entry within the **Parametric Models** dialog and click **Delete**.

M. To create a circular opening in a mesh model

Note: In case an opening is required on a part of the structure that is already meshed with plate elements, the existing plates have to be deleted first, and then, the plates with the opening can be modeled as a whole using this feature.

1. In the **Parametric Models** dialog Mesh Models list, select the leaf called **Openings** under the mesh model to which you wish to add an opening.
2. Click **Add**.

   The **Select Opening Type** dialog opens.

3. Select the **Circular Opening** option and then click **OK**.

   The drawing will change to display just the mesh region. The right hand side of the screen will display a grid with the grid line settings and spacing.

   Tip: The various viewing options and zoom options on top of the screen can be used to obtain a convenient view of the panel.

4. (Optional) Edit the grid positions using the **Snap Node/Panel**
5. Click the point which will be the center of the circular opening.
   The cursor displays a blinking cross (+) at grid intersections. This blinking cross marks the point on the grid at which nodes of the hole boundary may be set.
6. Click a second point to define the radius of the circle.

   A dialog opens for defining the number of divisions around the circular opening.
7. (Optional) Change the number of divisions used around the circumference of the circular opening.
8. Click the **OK** button.
   The mesh is regenerated taking into consideration the hole.

Tip: To delete a parametric mesh, opening, density line, or density point, select that entry within the **Parametric Models** dialog and click **Delete**.

M. To add a density line or point

1. In the Parametric Models dialog Mesh Models list, click on the leaf called **Density Lines** or **Density Points** under the mesh model to which you wish to add an opening.
2. Click **Add**.

   The drawing will change to display just the mesh region. The right hand side of the screen will display a grid with the grid line settings and spacing.

> **Tip:** The various viewing options and zoom options on top of the screen can be used to obtain a convenient view of the panel.

3. (Optional) Edit the grid positions using the **Snap Node/Panel**
4. Either:

   Click the start and points of a density line.

   or

   Click a density point.

   The mesh is regenerated to account for the new density line or point
5. Repeat step 4 as many times as needed.
6. To stop adding density points or density lines, press the **<Esc>** key.

> **Tip:** To delete a parametric mesh, opening, density line, or density point, select that entry within the **Parametric Models** dialog and click **Delete**.

M. To define a slab/wall connection

Use the following procedure to generate a mesh for a wall super-element when compatibility with a connected slab super-element is required.

A slab mesh must first be created. The slab mesh should include a density line representing the connecting edge of the wall.

> **Tip:** Using beam elements is fast way to help generate meshed surfaces and ensure that the density line edge for the slab/wall connection is included when the slab is generated. These "construction" beams can be deleted once the surface elements have been successfully generated.

1. On the **Geometry** ribbon tab, select the **Generate Slab/Wall Connection** tool in the **Structure** group.

   The mouse pointer changes to the add surface cursor .
2. In the Active view window, click the corner nodes of the wall super-element in either a clockwise or counterclockwise order.

   > **Note:** The first and second nodes must be the corner nodes which form the slab/wall connection. Failure to do so will open a warning dialog.
3. Continue clicking the remaining corner nodes to for the wall super-element. Close the polygon by clicking on the first node again.

   The **Division Along Wall** dialog opens.

   > **Note:** The divisions along the horizontal side of the wall have already been decided as the number of points created along the wall base in the previously mesh slab.
4. (Optional) Specify a **No. of divisions in extrusion direction**

> **Note:** The divisions along the horizontal side of the wall have already been decided as the number of points created along the wall base in the previously mesh slab.

5. Click **OK**.
   The wall is meshed.

> **Tip:** To verify the compatibility between plates, select the **Plate Tools** > **Check Improperly Connected Plates** tool in the **Geometry Tools** on the **Utilities** ribbon tab.

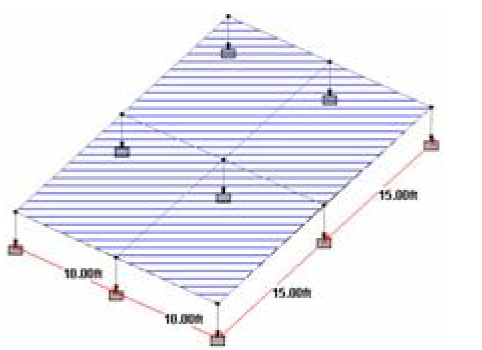
M. Composite Decks

STAAD.Pro can model composite steel deck systems for design.

An important feature to note is that when the structure is modified, the deck automatically gets modified with it. Note that when the dimension of the structure is changed along the length from 30 ft to 40 ft, the deck gets modified with the structure and there is no need to redefine the deck all over again. The deck loading is also revised automatically.

Original structure	Modified structure
	


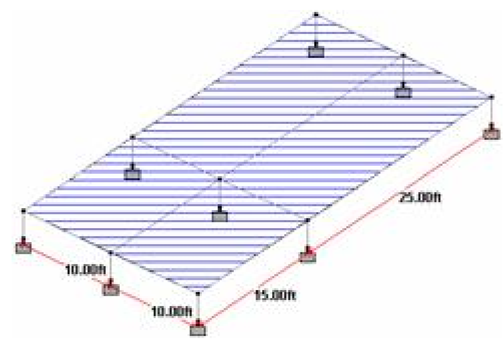


Figure 101: Composite deck and load update with structure changes

The design parameters for the composite deck are already defined through the interface. Few additional design parameters like `TRACK` can be assigned, if so desired, and finally, design commands like `CHECK CODE` has to be assigned to the composite deck.

- *P. To generate a floor vibration report* (on page 1996)
- *P. Floor Vibrations Engineering Theory* (on page 1998)

M. To create a new composite deck from perimeter beams

1. Select the **Composite Deck Layout** tool in the **Composite Deck** group on the **Geometry** ribbon tab.

The **Composite Deck** dialog opens.

2. Select the perimeter beams:
   a. Select the **Clicking on Nodes** option.
   b. Click **Create New Deck**.

      The mouse pointer changes to the Add Composite Deck cursor ().
   c. Click on the end nodes defining the corners of the perimeter beam area.
   d. Click on the first node a second time to close the decking area.

   Alternatively, you can select the perimeter beams in the view window first. Then select the **Use Selected Beam** option and click **Create New Deck**.

   The **New Composite Deck** dialog opens.
3. Type a **New Composite Deck Name** and then click **OK**.

The deck name is added to the list of composite decks with all the perimeter and interior beams listed.

Note: You can delete a composite deck definition by selecting in within the list in the **Composite Deck** dialog and then pressing **<Delete>**. Confirm you want to delete the deck in the dialog. Only the deck definition is deleted. Constituent members will remain in the model.

Related Links

- *Composite Deck dialog* (on page 2741)

M. To specify a direction for the composite deck ribs

To specify the orientation of the deck ribs, use the following procedure.

The program will automatically assign a rib direction parallel to the detected shortest span in the deck area. However, you will often need to edit the orientation.

1. Select a composite deck name in the **Composite Deck** dialog list.
2. Select a pair of parallel beams.

   The deck ribs will run perpendicular to these two beams.
3. Click **Create Direction.**
   If you have previously assigned a deck rib direction, you will be prompted to confirm you want to update this direction.

The deck span direction arrow is updated to reflect the change in direction.
Related Links

- *Composite Deck dialog* (on page 2741)

M. To assign composite deck properties

To define the concrete, rib, and connectivity details of a composite deck, use the following procedure.

1. Select a composite deck name in the **Composite Deck** dialog list.
2. Type values to use for the concrete in the current units:

Concrete thickness above flutes
Unit Wt. of Concrete
Concrete Grade

3. Specify the steel deck rib properties:

To...	Do the following...
use a catalog value	select the deck name from the **Use Database** drop-down list
specify a custom value	type values for **Rib Width** and **Rib Height**.

> **Note:** The program includes three standard catalogs: ASC™, Vulcraft™, and VERCO™.

4. Specify the **Stud Diameter** by either:

   selecting a predefined diameter from the drop-down list

   or

   selecting **Custom** in the drop-down list and then typing the diameter in the current units
5. Type the **Stud Length** in the current units.
6. Select if the composite deck is **Shored** (i.e., propped) or **Unshored** during construction.
7. Click **Update Deck Property**.

Related Links

- *Composite Deck dialog* (on page 2741)

M. To modify composite steel beam properties

To change the steel beam profile or effective flange width, use the following procedure.

The program will use the assigned steel sections for beams and also automatically calculate the effective flange width of the composite section. However, you can update steel sections from the **Composite Decks** dialog as well as specify a value for the effective flange width.

1. Select a beam in the **Composite Decks** dialog within a composite deck name.
   The beam options are displayed in the dialog.
2. (Optional) Click **Add/Change Property** to open the **Section Profile Tables** dialog.

   From there, you can select a different beam or beam properties.

> **Note:** You should *not* specify a composite section type specification for these beams. The use of the composite deck definition allows the program to calculate all the necessary composite section parameters automatically. Refer to G.6.7 Composite Beams and Composite Decks (on page 2119) for details.

3. (Optional) Type an **Effective Width** in the current units and then click **Update** to change the effective width of the composite deck for the beam.

M. Solids

M. To draw a solid connecting existing nodes

To draw a solid with 4 to 8 nodes connecting existing nodes, use the following procedure.

You model must have at least four nodes which do *not* all lie in the same plane.

The basic solid element consists of 8 nodes. However, by collapsing nodes together progressively, different three-dimensional solid shapes can be formed. The minimal number of nodes is a four-noded, pyramidal shape.

1. On the **Geometry** ribbon tab, select one of the tools in the **Add Solid** menu in the **Solid** group.

   

Use this tool...	To...
	create eight-noded solid elements (i.e., a cuboid)
	create seven-noded solid elements
	create six-noded solid elements (i.e., a triangular prism)
	create five-noded solid elements (i.e., a rectangular pyramid)
	create four-noded solid elements (i.e., a triangular pyramid, or tetrahedron)

   The mouse pointer changes to either the Add Solid cursor ().
2. Click on any node that will form the first corner of the solid element.
   A line is “rubber banded” to the cursor from this node. This represents the first edge of the solid.
3. Continue clicking on nodes up to the number corresponding to the tool selected in step 1.

   It is important that you click the nodes in an order which does not result in a negative volume.

   a. Click on the node counter-clockwise to the first node on the same face.
   b. Click the subsequent nodes on the same face in a counter-clockwise order.
   c. Click on a node on the opposing face.
   d. Click on the node counter-clockwise to the first opposing face node.
   e. Click the subsequent nodes on the opposing face in a counter-clockwise order.

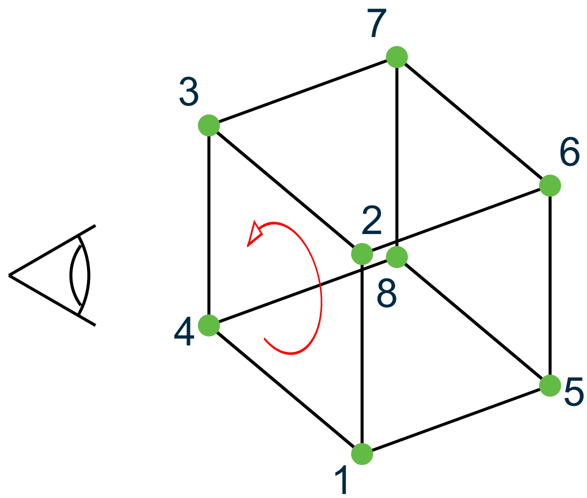

Figure 102: Select nodes in a counter-clockwise order from an outside view perspective on one face and then repeat on the opposing face.

The solid element is added to the model.

Tip: It is recommended to use the **Solid Tools** > **Negative Volume** tool in the **Geometry Tools** group on the **Utilities** ribbon tab to verify the solid incidences are correctly specified. The 3D rendering is also a useful tool in identifying negative volumes.

M. Nodes

M. To insert a node in a single member

Used to insert nodes in an existing member(s). The member is split into the corresponding number of segments with automatic generation of node numbers, member numbers, member properties, and loads.

1. On the **Geometry** ribbon tab, select the **Insert Node** tool in the **Beam** group.

   
   The mouse pointer changes to the **Insert Node** pointer .
2. Select a beam member.
   The Insert Nodes into Beam # dialog (on page 2730) opens.
3. Either:

Specify a **Distance** or **Proportion** value and click **Add New Point**.

or

Click **Add Mid Point** to add a new node halfway along the length of the beam.

or

Specify an integer number of new nodes in the **n =** box and click **Add n Points** to divide the beam into n+1 number of equal divisions.

The new node point is listed in the **Insertion Points** list.

4. Repeat Step 3 as many times as needed.

Tip: Click **Remove** to remove the selected node point from the Insertion Points list if you make an error.

5. Click **OK**.
The dialog closes and the specified nodes are inserted into the beam.

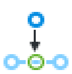
Related Links

- *Insert Nodes into Beam # dialog* (on page 2730)

M. To insert a node in multiple members

Used to insert nodes in an existing member(s). The member is split into the corresponding number of segments with automatic generation of node numbers, member numbers, member properties, and loads.

1. Select two or more beam elements.
2. On the **Geometry** ribbon tab, select the **Insert Node** tool in the **Beam** group.



The Insert Node / Nodes dialog (on page 2731) opens.

3. Either:

Select the **New point by distance** option and then type a **Distance** value.

or

Select the **New point by proportion** option and then type a **Proportion** value.

or

Select the **Add Mid Point** option.

or

Select the **Add 'n' Points** option and then type an integer number of new nodes in the **n =** box to divide the beam into n+1 number of equal divisions.

4. Click **OK**.
The dialog closes and the specified nodes are inserted into the beams.

Related Links

- *Insert Node / Nodes dialog* (on page 2731)

M. To add a node at overlapping beams

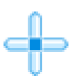
To connect to overlapping beams with a node at that location, use the following procedure.

You can manually select beams that are overlapping or the program can automatically detect these for you using the optional first step below.

1. (Optional) Automatically select overlapping beams:
   a. On the **Geometry** ribbon tab, select the **Intersecting Beams** > **Highlight Intersecting Beams** tool in the **Beam** group.

   
   The **Intersect Members** dialog opens.
   b. In the **Enter Tolerance** field, type a tolerance used for how close members should pass before the program considers them to be overlapping.
   c. Click **OK**.

   The program automatically selects all overlapping beam sets.
2. On the **Beam Tools** ribbon tab, select the **Intersect Beams** tool in the **Model** group.

3. Type a tolerance to use in the **Intersect Members** dialog and then click **OK**.
   A message dialog opens to indicate that new beams have been created.

M. To merge two nodes

1. Select the nodes to be merged using the Nodes Cursor.
2. On the **Geometry** ribbon tab, select the **Merge Selected Nodes** tool in the **Node** group.

   The **Select Node** dialog opens.
3. Select the **Node To Keep** from the list of selected nodes.
   The remaining nodes will be removed. All members and elements which were connected to those nodes will be reconnected to the selected node to keep.
4. Click **OK**.

M. Modify Your Model

The following procedures are used to manipulate existing model geometry.

M. To move selected objects

You must have one or more objects selected.

Refer to GS. Selecting Objects in STAAD.Pro (on page 40) for details.

1. On the **Geometry** ribbon tab, select one of the following tools:

   the **Move Node** tool in the **Node** group

   or

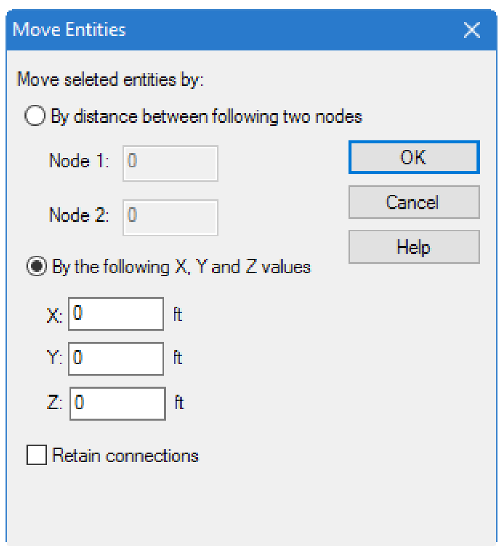
   the **Move Beam** tool in the **Beam** group

   or

   the **Move Plate** tool in the **Plate** group

   or

   the **Move Solid** tool in the **Solid** group
   The **Move Entities** dialog opens.



> **Note:** This dialog has a different title depending on the object type being moved but the functionality is similar.

2. Select the method by which the objects are to be moved:

   By distance between following nodes uses two node numbers and determines the vector between them. The selected entities are moved along a parallel vector of the same distance.

   or

   By the following X, Y and Z values uses the Cartesian coordinates specified to create a vector.

3. Specify node numbers or vector component values.
4. (Optional) Check the **Retain connections** option to retain connections between entities.

   Note: The model geometry will be adjusted to some degree, even if this is not selected, when nodes are the entities being moved as they member, plate, surface, and solid geometry is defined by node location. However, if you are moving a member, plate, surface, or solid, then selecting this option will move the associated nodes and thus retain the connection with adjacent entities (though their geometry will stretch, warp, or shift as a result of the move).
5. Click **OK**.
   A message dialog opens asking if you would like new nodes created where any moved entities cross other existing entities.
6. Click **Yes** to create new nodes or **No** to ignore intersections.
   The model is updated with the moved geometry.

Related Links

- *Move Entities dialog* (on page 2726)

M. To move the model origin

To shift the translate the entire model by shifting the origin location along a vector, use the following procedure.

Tip: You can use the **Generate Rotate** tool to rotate the entire model about the origin as well.

1. On the Geometry ribbon tab, select the **Move Node** > **Move Origin** tool in the **Node** group.

   The **Move Origin** dialog opens.
2. Specify the origin offset vector method:

Vector method	Do the following...
two nodes	select the **By distance between following two nodes** and then type the node numbers in the corresponding fields.
global axes components	select the **By the following X, Y and Z values** and then type the global axes component distances in the corresponding fields.

   Either method generates a vector by which the origin is shifted.

   Note: A positive value in the coordinates (or resulting positive value resulting the from the selected nodes) will move the origin in a positive direction along the corresponding global axis. Thus, the resulting coordinate of each node is therefore reduced by that same magnitude.

   For example, providing a origin shift along the X axis of 5 units, means that a node previously located at the origin now has an X coordinate of -5 units.
3. Click **OK**.

The coordinates of each node are modified in the STAAD input file to reflect the change in distance to the new origin.

Related Links

- *Move Origin dialog* (on page 2727)

M. To rotate selected entities

You must have one or more objects selected.

Refer to GS. Selecting Objects in STAAD.Pro (on page 40) for details.

1. On the **Geometry** ribbon tab, select the **Rotate** tool in the **Structure** group.

   The **Rotate** dialog opens.
2. Specify an **Angle** of rotation.
3. Provide to points used to define the axis of rotation by either:

   selecting two **Nodes**

   or

   typing coordinates of two arbitrary **Points**
4. Select if the selected geometry is to be copied of moved and, if copied, if linking members are to be created.
5. Click **OK**.

Related Links
- *Rotate dialog* (on page 2719)

M. To generate copies of geometry along a line

To generate copies of selected geometry along a path parallel to a global axis, use the following procedure.

1. Select the structure geometry (beams, plates, solids, etc.) that you want to copy.

   Tip: You do not need to select the nodes, as they will be copied along with the other model entities.
2. On the **Geometry** ribbon tab, select the **Translational Repeat** tool in the **Structure** group.

   
   The **Translational Repeat** dialog opens.
3. Select the **Global Direction** along which the copies will be generated.
4. Specify the **No. of Steps** to generate.

   Tip: By setting the **Default Spacing** value first, the entries will update with the new value for each step.
5. (Optional) Edit the **Spacing** values for each step (copy) if the steps are irregular or if the desired **Default Spacing** was not first specified.
6. (Optional) Set the option to **Renumber Bay** and specify a **Number from** value (start number of that copy) if needed.
7. (Optional) Set the **Link Steps** option to generate additional members between copies, parallel to the **Global Direction**.

You may also set the **Open Base** option, which will prevent links from being generated between nodes with the lowest Y coordinates (when Y is vertical/up).

8. (Optional) Set the **Generation Flags** to the level of geometry, properties, or specifications to be copied to the new, generated members.
9. Click **OK**.

   The new members are generated using the specified parameters.

Related Links

- *Translational Repeat dialog* (on page 2716)

M. To generate copies of geometry along an arc

To create copies of selected geometry along a arc about a global axis, use the following procedure.

1. Select the structure geometry (beams, plates, solids, etc.) that you want to copy.

   Tip: You do not need to select the nodes, as they will be copied along with the other model entities.
2. On the **Geometry** ribbon tab, select the **Circular Repeat** tool in the **Structure** group.

   The **3D Circular** dialog opens.
3. Select the global **Axis of Rotation** about which the copies will be generated.
4. Specify the **Total Angle** of the arc.

   This is measured in a positive (right-hand rule) direction about the selected **Axis of Rotation** between the original selection and the last copy.
5. Specify the **No. of Steps** to generate.

   The copies will be equally distributed about the specified arc.
6. Specify a center of rotation by either:

   typing a Node number. You may also click the Node Selection tool to graphically select a node.

   or

   planar coordinates for an arbitrary point (i.e., not at a node)

   Note: The axis of rotation for the circular copy will pass through this selected node or point, parallel to the selected global axis of rotation.
7. (Optional) Check the **Use this as Reference Point for Beta angle generation** option to orient the copies towards the central axis of rotation.
8. (Optional) Set the **Link Steps** option to generate additional members between copies.

   You may also set the **Open Base** option, which will prevent links from being generated between nodes with the lowest Y coordinates (when Y is vertical/up).
9. (Optional) Set the **Geometry Only** option to generate only nodes, members, elements, etc. with no properties assigned.
10. Click **OK**.

    The new members are generated using the specified parameters.

Related Links

- *3D Circular dialog* (on page 2717)

M. To generate mirror copies of model entities

To generate symmetric copies of the model selection about a plane, use the following procedure.

1. Select the geometry to copy or move.

   Note: Refer to the discussion on the Select menu for details on the selection procedure.
2. On the **Geometry** ribbon tab, select the **Mirror** tool in the **Structure** group.

   The **Mirror** dialog opens.
3. Specify an mirror plane.
4. Specify a Plane position.
5. Select if the selected geometry is to be copied of moved and, if copied, if linking members are to be created.
6. (Optional) Set the option to mirror members if their orientation is also to be mirrored.
7. Click **OK**.

Related Links

- *Mirror dialog* (on page 2725)

M. Groups

A group is a way to collect a series of objects together for selection, loading, or design purposes.

M. To create a group from a selection

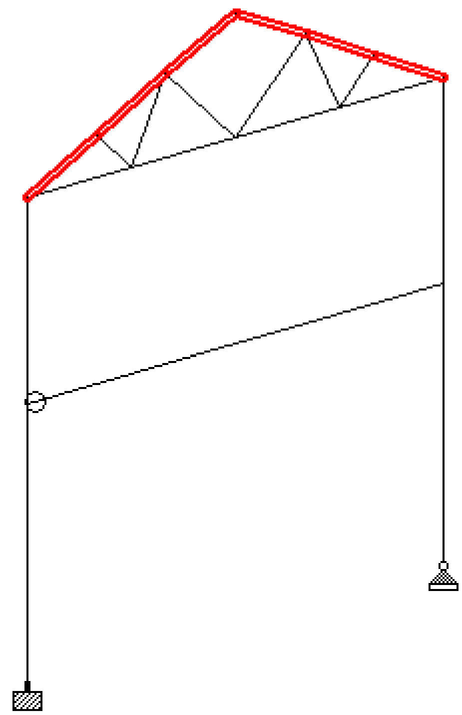
To create a new group using a selection of model objects, use the following procedure.

Group names are a means for easily identifying a collection of entities like Beams, Plates or Solids using a single moniker. By grouping these entities, we need to assign attributes such as member properties and material constants just to the group, a simple process, compared to the task of assigning them to the individual members.

The file EX. US-1 Plane Frame with Steel Design (on page 6256) is used to demonstrate this feature.

Consider the members which form the truss as being in one of three groups: Top Chords, Bottom Chords, and Web Members.

1. Select the top chord members:
   With the model open, use the **Beam Cursor** tool to select the members forming the top chords (i.e., members 8 through 13).



Tip: Press and hold the **<Ctrl>** key and then click the members in the View window.

2. Either:

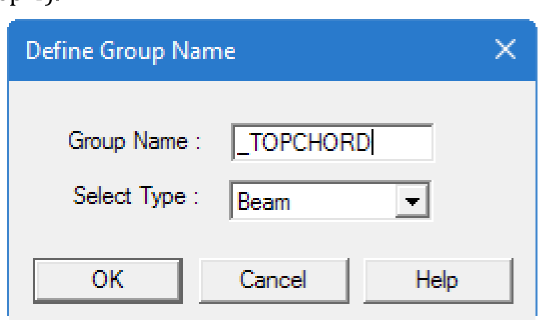
   On the **Utilities** ribbon tab, select the **Groups** tool in the **Geometry Tools** group

   or

   press **<Ctrl+G>**

   If you have not previously defined any groups, the **Define Group Name** dialog opens. Otherwise, the **Create Group** dialog opens (skip to step 4).



3. Specify the group details:
   a. Type a name in the **Group Name** field.

Note: Group Names must begin with the underscore "_" character.

A group name such as _TOPCHORD can be used for this example.

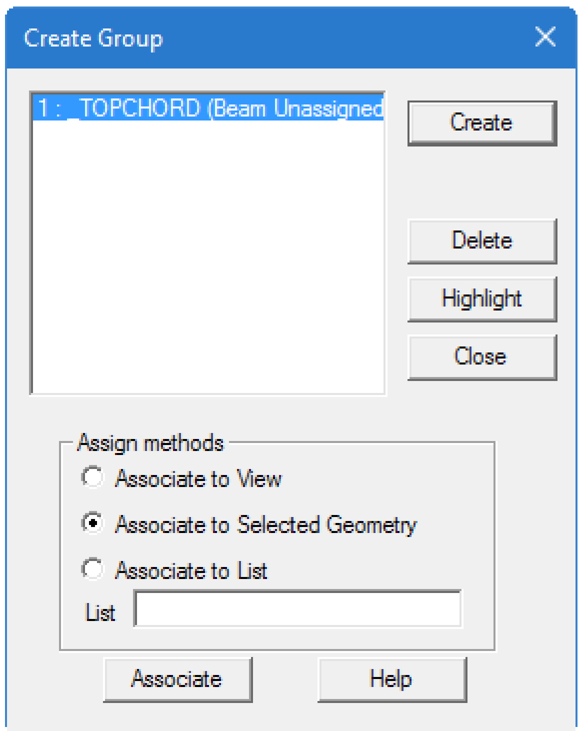
b. Select the object type from the **Select Type** drop-down list.

Groups can consist of nodes, beams, plates, solids, and a general category called geometry. Geometry can be used to associated objects of mixed types.

Select **Beam** for the top chords example.

c. Click **OK**.

The **Create Group** dialog opens. At this point, you have created a group name but it does not yet contain any objects.

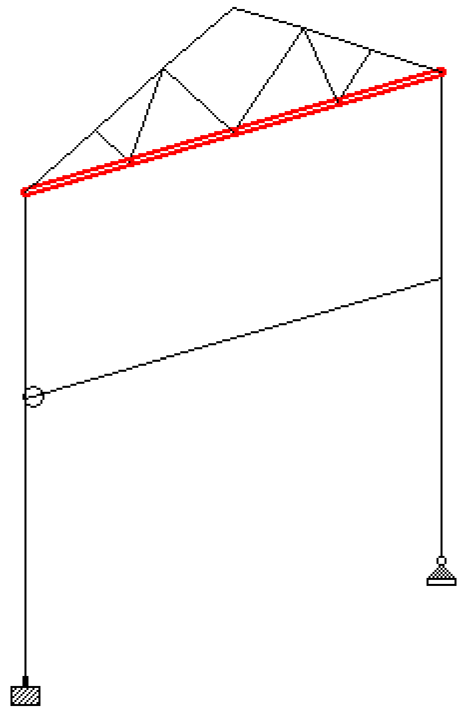


4. Select **Associate to Selected Geometry** and then click **Associate**.

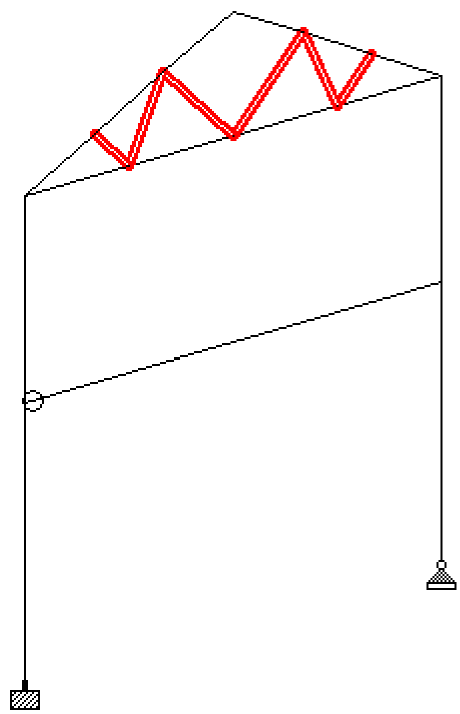
   The selected members are added to the group.
5. Select other model objects.

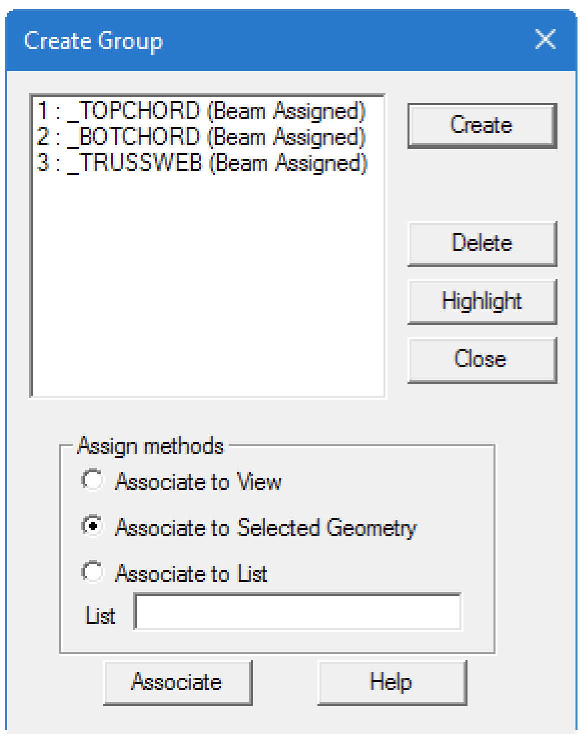
Tip: The **Create Group** dialog can remain open while you change selection tools and select objects in the View window.

For the example file, the members forming the bottom chord (members 20, 21, 22, and 23).



6. **Associated these members with a new group:**
   - **a.** Click **Create** in the **Create Group** dialog.
   - **b.** Follow steps 4 and 5 and assign the **Group Name** and objects type as the **Select Type**.
     For the example file `US-1 Plane Frame with Steel Design.std`, use the name `_BOTCHORD` for the bottom chord members.
7. Repeat steps 5 and 6 to create additional groups as needed.
   For the example file `US-1 Plane Frame with Steel Design.std`, you can select the truss web members (members 14, 15, 16, 17, 18, and 19) and add them to a group named `_TRUSSWEB`





8. Click **Close** in the **Create Group** dialog.

Select the **Group Selection** tool in the **Selection** group on the **Selection** ribbon tab to open the **Select Groups** dialog, which can be used to select a named group.

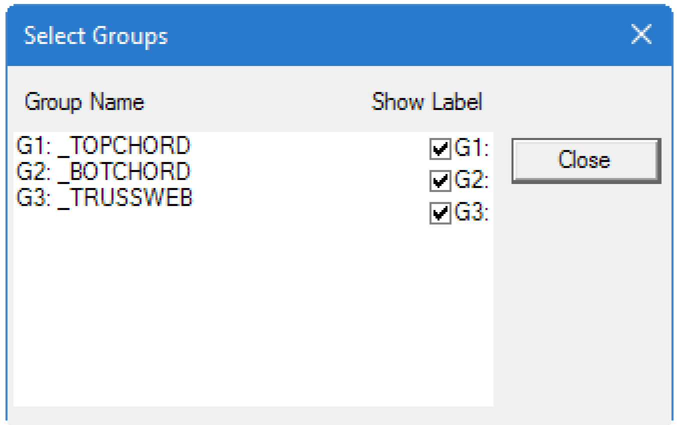


Figure 103:

Note: If the option for **Show Label** are unchecked, labels such as beam numbers will not be displayed for these specific members, even if the beam numbering icon is switched on for the entire structure.

Related Links

- *Create Group dialog* (on page 2950)
- *TR.16.1 Listing of Entities by Specifying Groups* (on page 2235)

M. To add objects to an existing group

To add more objects to an existing group, use the following procedure.

It is important to select the current objects in a group along with the additional objects so that the current objects are not removed. When associating objects to a group, *only* the current selection (or other association method) will be included in the group.

1. On the Utilities ribbon tab, select the Groups tool in the Geometry Tools group.

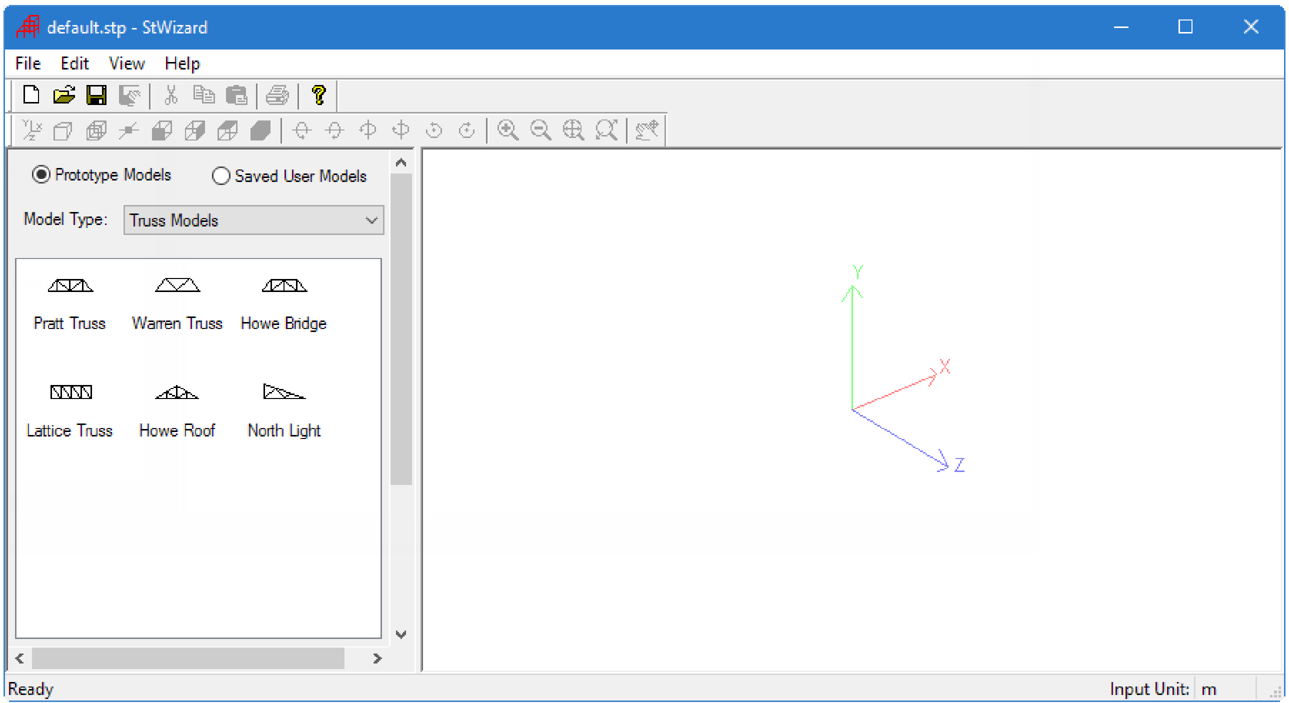
   The **Create Groups** dialog opens.
2. Select the group name to which you want to add objects.
3. Click **Highlight**.
   The current objects in the group are selected in the view window.
4. In the view window, use the selection cursors to select the additional geometry.

   Note: Hold the **<Ctrl>** key in order to select additional objects without unselecting the current group contents.
5. Select the **Associated to Selected Geometry** option.
6. Click **Associate**.

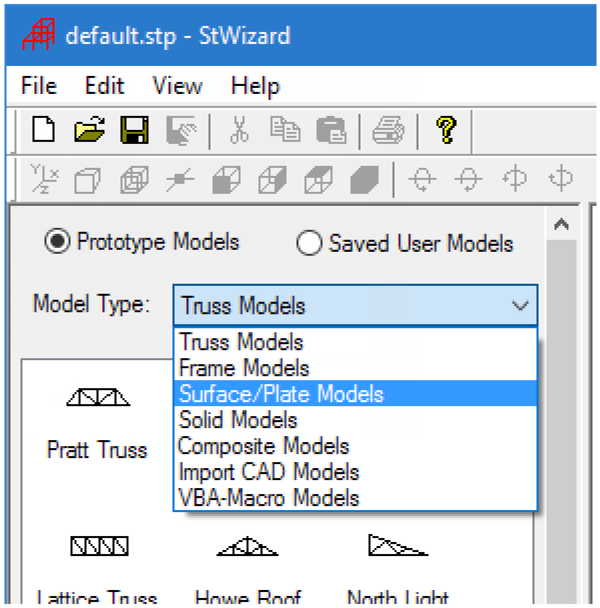
M. Structure Wizard

Used to parametrically generate a structural model and then transfer and superimpose it on the current structure in STAAD.Pro.

Opens when **Geometry** > **Run Structure Wizard** is selected in the STAAD.Pro window.



The **Prototype Models** and **Saved User Models** options appear on the top of the left side of the screen. If the **Prototype Models** option is selected, the **Model Type** will list the types of prototype structures available (such as Trusses, Frames, Plates, Solids, etc.) as shown below. If the **Saved User Models** option is selected, the **Model Type** will display the list previously done and saved models by the user.



M. To set units

To set the units of length used in the parametric model types, use the following procedure.

The current units of length are displayed in the Structure Wizard status bar.

1. Select **File** > **Select Units**.
   The **Select Units** dialog opens
2. Select one of the units of length.

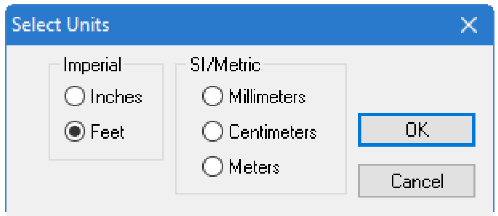
   Inches
   Feet
   Millimeters
   Centimeters
   Meters
3. Click **OK**.

M. Generation of Structure from Models

In this section, the process of generating a structural model and combining it with the existing STAAD.Pro structure will be explained using a Howe Roof truss. Follow these steps to create the other truss types also.

Selection of Units

The unit of length should be specified prior to the generation of a model. Select **File** > **Select Unit** and the **Select Unit** dialog opens. You can select any unit of length from Imperial (inch, feet) or SI/Metric (millimeter, centimeter, meter) system of units.



M. To create a truss model

To create a parametric truss model, use the following procedure.

1. Select **Truss Models** from the **Model Type** drop-down list.
2. Select one of the parametric truss types by either:

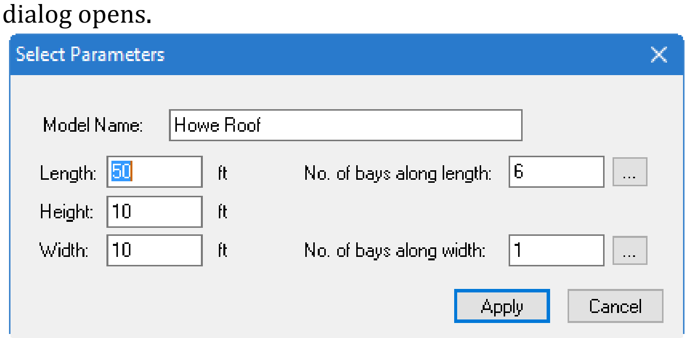
   double-click on the type of model

   or

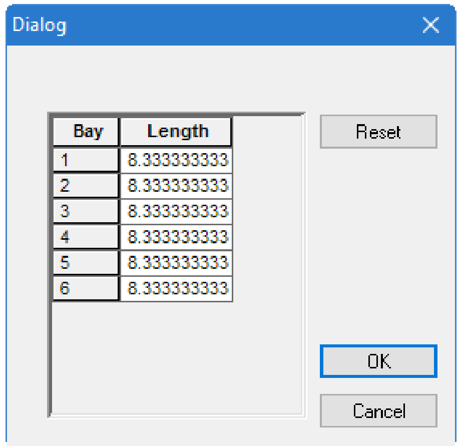
   click-and-drag the model icon into the view window

   Pratt Truss
   Warren Truss
   Howe Bridge
   Lattice Truss
   Howe Roof
   North Light

   The **Select Parameters** dialog opens.



3. (Optional) Type a **Model Name**.
4. Type the overall truss **Length**, **Height**, and **Width** distances.
5. Type the **No. of bays along length** to define the number of equally spaced bay along the length of the truss.
6. (Optional) To use unequaly length bays:
   a. Click the **[...]** adjacent to the **No. of bays along length** field.
      A dialog opens with the length of each bay.



b. Type the length of the different bays in the corresponding **Length** cells.

> **Note:** The total length of the bays must add to the overall length specified in the **Select Parameters** dialog. The precision should be to about 3 decimal places (e.g., 11.333).

c. Click **OK**.

7. Type the **No. of bays along width** to define the number of transverse bays.
8. (Optional) To use unequaly length transverse bays:

   a. Click the **[...]** adjacent to the **No. of bays along width** field.
   A dialog opens with the length of each bay.

   b. Type the length of the different bays in the corresponding **Length** cells.

   > **Note:** The total length of the bays must add to the overall width specified in the **Select Parameters** dialog. The precision should be to about 3 decimal places (e.g., 11.333).

   c. Click **OK**.
9. Click **Apply**.

M. Frame Models

The process of generating a Frame structural model and combining it with the existing STAAD.Pro structure is the same as for Trusses (see the above description).

M. To create a frame or continuous beam model

To create a continuous beam, bay frame, grid frame, or floor grid model, use the following procedure.

1. Select **Frame Models** from the **Model Type** drop-down list.
2. Select one of the rectangular frame or beam types by either:

   double-clicking the icon

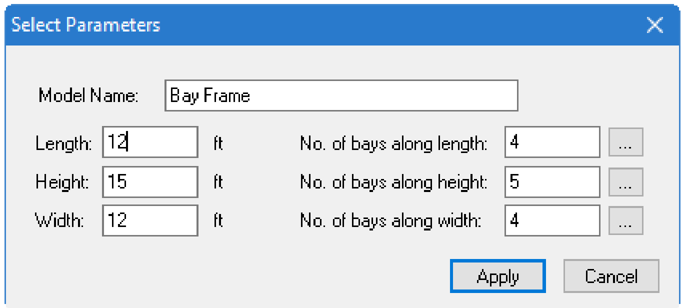
   or

   click-and-drag the icon to the view window

   Bay Frame – a 3D frame with no horizontal connecting members at the base
   Grid Frame – a 3D frame that has horizontal connecting members at all levels
   Floor Grid – a 2D frame in the XZ plane

Continuous Beam – a linear beam continuous over internal supports (i.e., the bay length)

The **Select Parameters** dialog opens.



3. (Optional) Type a **Model Name**.
4. Type the overall dimensions of the frame or beam:
   - **a.** Type the **Length**.
   - **b.** For bay frames and grid frames, type the **Height**.
   - **c.** For frames, type the **Width.**
5. Type the number of bays in each dimension:
   - **a.** Type the **No of bays along the length**.
   - **b.** For bay frames and grid frames, type the **No of bays along the height**.
   - **c.** For frames, type the **No of bays along the width**.
6. (Optional) To use unequal length division in any direction:
   - **a.** Click the **[...]** button adjacent to that field.
     A dialog opens.
   - **b.** Type the length of each bay.
   - **c.** Click **OK**.

> **Note:** The total length of the bays must add to the overall length specified in the **Select Parameters** dialog. The precision should be to about 3 decimal places (e.g., 11.333).

7. Click **Apply**.

M. To create a cylindrical frame or beam

To create a cylindrical frame or circular beam, use the following procedure.

1. Select **Frame Models** from the **Model Type** drop-down list.
2. Select one of the cylindrical frames or beam types by either:

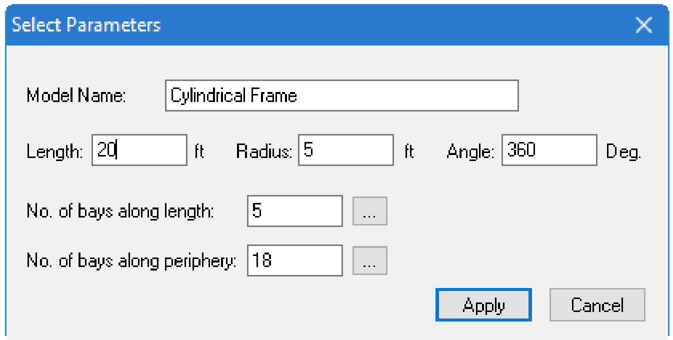
   double-clicking the icon

   or

   click-and-drag the icon to the view window

   Cylindrical Frame — a cylindrical frame with the cylinder height along the Z axis
   Reverse Cylindrical Frame — a cylindrical frame with the cylinder height along the Y axis
   Circular Beam – a single layer of coordinates which form a beam along a circular arc (i.e., polar coordinates)

   The **Select Parameters** dialog opens.



3. (Optional) Type a **Model Name**.
4. For frames, type the total **Length** along the central axis of the cylinder.
5. Type the **Radius** and the sweep **Angle** of the frame.

Tip: For a full circular frame or beam, leave the Angle 360.

6. For frames, type the **No. of bays along length**.
7. (Optional) For frames with irregular spaced bays along the length:
   a. Click the **[...]** button adjacent to the **No. of bays along length** field.
      A dialog opens.
   b. Type the length of each bay.
   c. Click **OK**.

Note: The total length of the bays must add to the overall length specified in the **Select Parameters** dialog. The precision should be to about 3 decimal places (e.g., 11.333).

8. Type the **No of bays along periphery** to specify the number of spaces along the circumference of the circle.
9. (Optional) For frames with irregular spaced bays along the length:
   a. Click the **[...]** button adjacent to the **No. of bays along periphery** field.
      A dialog opens.
   b. Type the angle subtended by each bay.
   c. Click **OK**.

Note: The total of the angles of all the bays must sum to equal the total Angle given in the **Select Parameters** dialog.

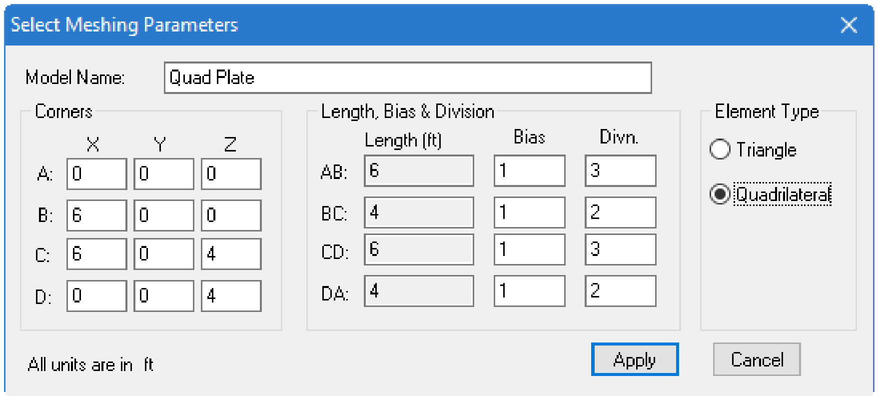
10. Click **Apply**.

M. Surface or Plate Models

The surfaces like Quadrilateral Plate, Cylindrical Surface, Hyperbolic Paraboloid Shell, Polygonal plate with Holes and Circular plate with Holes can be created and meshed with the given parametric values.

M. Quadrilateral Plate

The Quadrilateral prototype can be used to mesh a quadrilateral surface into small plate elements. Select the **Quadrilateral** prototype under the model type **Surfaces**. Drag the item into the right-side window and release the button. The **Select Meshing Parameters** dialog box will appear to specify the parameters.



Corners Provide the relative coordinates of the corners of the Quadrilateral Surface or region you want to mesh.

Bias & Divisions Specify the number of divisions you want along all the edges and the respective biasing. The minimum and maximum limits of number of divisions of each side are 1 and 100 respectively. Two opposite sides may have different numbers of divisions. When the number of divisions for two opposite sides are different, the sum of all divisions must be an even number for quadrilateral elements.

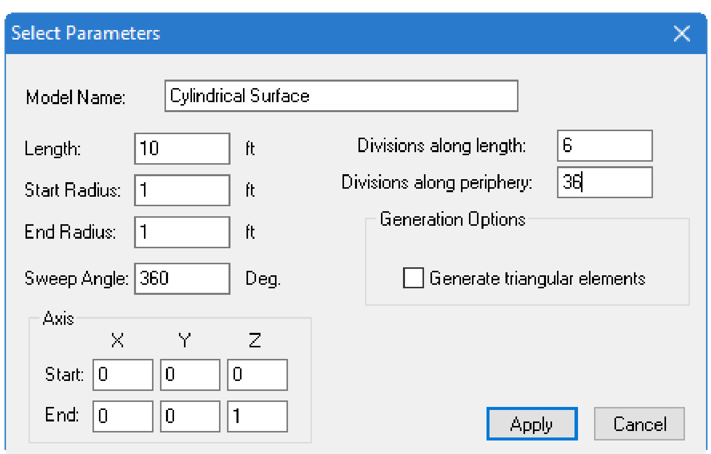
Bias If you want equal divisions along the length of a side, keep the Bias as 1. If your intention is to divide a side in such a way that the length of the last division is five times the length of the first division, specify Bias for that side as 5 along with the number of divisions.

Biasing may be negative. When negative Biasing has been specified, the side is divided so that the first division length is the value of the Biasing times the last division length.

Element Type Select the appropriate radio button depending on whether you want to mesh the region in smaller **Triangular Elements** or **Quadrilateral Elements**.

M. Cylindrical Surface

Select the **Cylindrical Surface** prototype under the model type **Surfaces.** Drag the item into the right-side window and release the button. The **Select Parameters** dialog box will appear to specify the parameters as shown in the next figure.



The Cylindrical Surface can be generated by providing the basic geometrical parameters **Length**, **Start Radius**, **End Radius** and **Sweep Angle**. You can generate a tapered cylinder by providing unequal values at **Start** and **End radius**. Entering a **Sweep Angle** less than 360 degree can also generate a longitudinally cut cylinder.

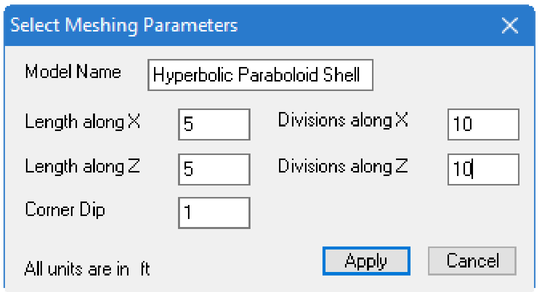
The **Axis** of the cylinder can also be controlled by entering the values of **Start -** X, Y, Z values and **End -** X, Y, Z values. The direction of the line joining the points gives the axis of the cylinder.

Providing the number of **Divisions along Length** and **Divisions along periphery**, the mesh can be generated. The option, **Generate open cylinder** will keep the ends open and **Generate triangular element** will generate triangles instead of quadrilaterals.

M. Hyperbolic Paraboloid Shell

Select the **Hyperbolic Paraboloid Shell** prototype under the model type **Surfaces.** Drag the item into the right-side window and release the button. The **Select Meshing Parameters** dialog box will appear to specify the parameters.

The basic geometrical parameters for generating a Hyperbolic Paraboloid Surface are the length of the two adjacent sides and the **Corner Dips**. The meshing parameters are the divisions along the adjacent edges. Click **Apply** after specifying all the parameters to generate the model.



M. Spherical Surface

A Spherical Surface can be generated and meshed with this feature. Three types of Spherical Surfaces may be generated, viz., **Spherical Cap**, **Spherical Surface** and **Spherical Region**. The **Diameter of Sphere** is required for all those cases. **Base Diameter** is required for Cap and Region only. **Top Diameter** is required for Spherical Region only. For Spherical Surface you have to define the **Start Angle** and **End Angle** in degrees for both the directions **- Latitude** and **Longitude.**

For the purpose of mesh generation, the number of **Divisions** in both the directions is to be specified. Click **Apply** after specifying all these parameters to generate the model.

The **Select Meshing Parameters** dialog box is shown below in the case of a Spherical Surface.

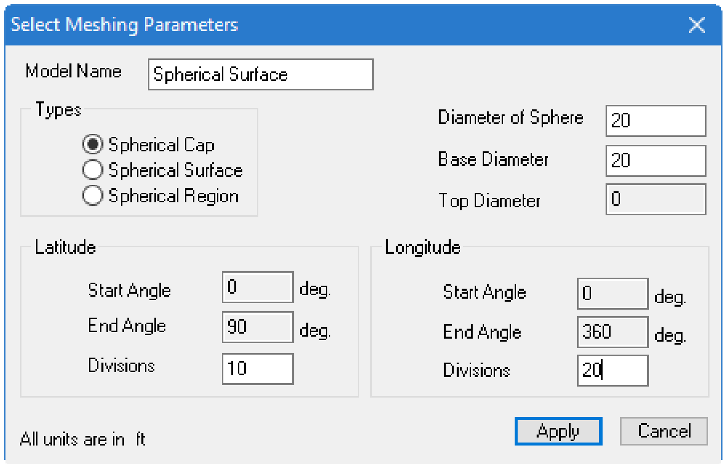


Figure 104:

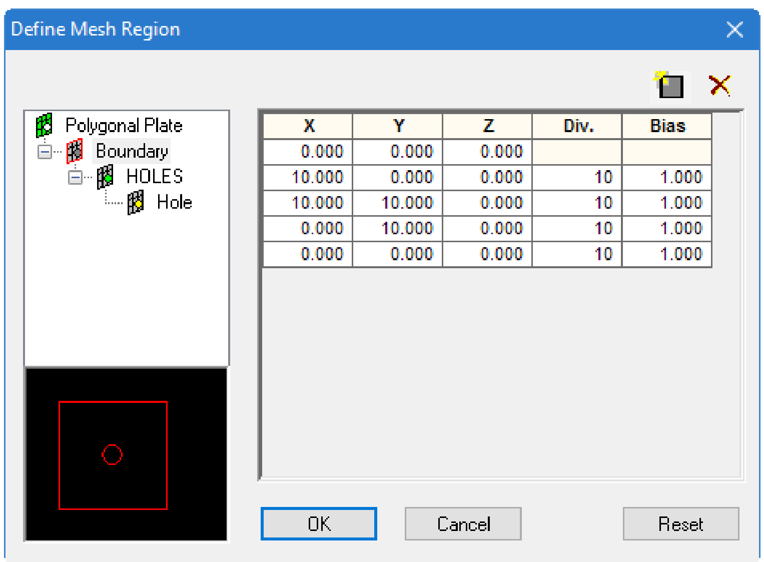
M. Polygonal Plate with Holes

Select the **Polygonal Plate with Hole** prototype under the model type **Surfaces/Plates**. Drag the item into the right-side window and release the button. The **Define Meshing Region** dialog box will appear as shown below.

The Polygonal prototype allows us to mesh a polygonal surface, with or without different kinds of holes inside the boundary, into small triangular plate elements.



Boundary

The Boundary tab as shown above in the **Define Mesh Region** dialog box provides us an option to specify the **location of Corners, Number of Divisions** of each side and Bias of each side's division for the Boundary to mesh the surface.

X, Y, Z are the coordinates of the various corners of the surfaces. The sides will be defined as joining the various corners. **Div.** option is to define the divisions of various sides of the polygonal surface to be considered for generating the surface meshing. The **Bias** option helps the user to create divisions having unequal spacings among them.

On the top of the right side of this dialog box there are two icons namely, **Add New Row** and **Delete Row**. Clicking on the first icon will add a new row enabling us to specify the coordinates of the corner of the polygonal surface. Clicking on the second icon will enable us to delete an existing row.

Holes

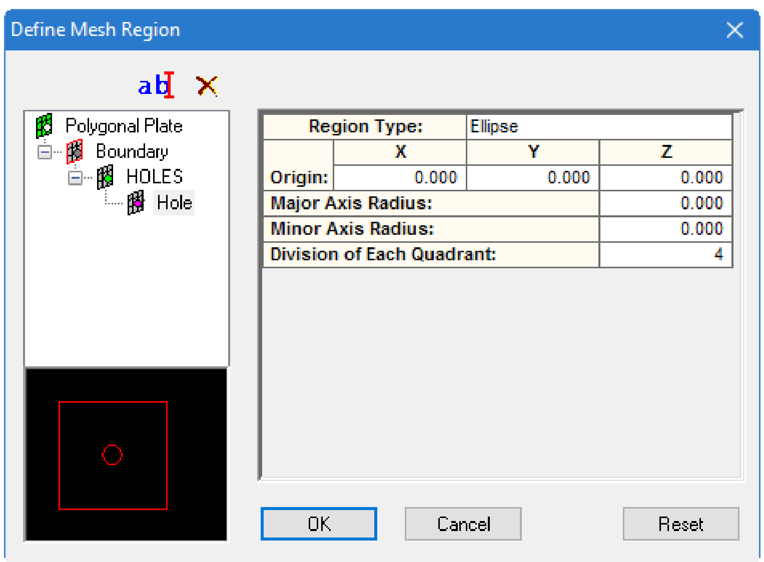
After creating the boundary, the user can start introducing the holes in the plate. In STAAD, we may create circular, elliptical as well as polygonal holes.

When we click on the **HOLES** option, two icons appear as shown below namely, **Add New Hole** and **Delete All Holes**.

Add New Hole	This icon allows us to add new holes to the surface.
Delete All Holes	This icon allows us to remove all the existing holes from the surface. Once a new hole is added, the name of the that hole appears under **HOLES** in a tree view. A new icon titled **Rename** Hole will now appear which will enable us to rename the newly created hole.

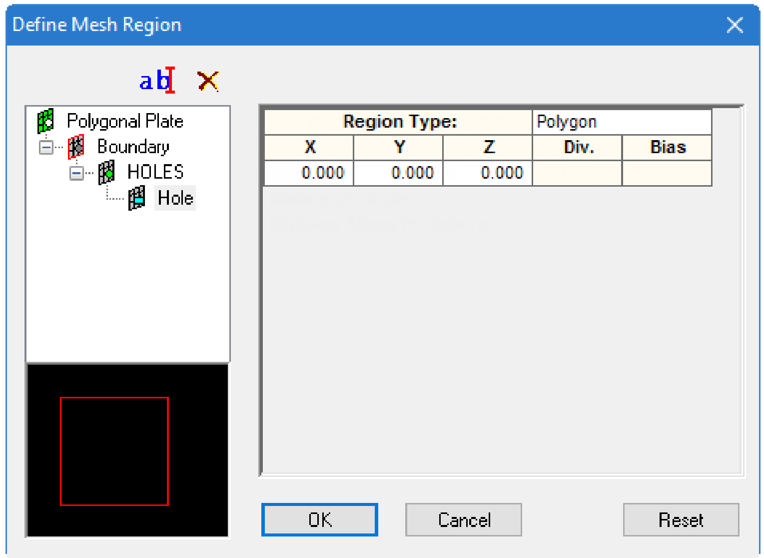
Hole

To create a hole within the boundary, click this option. This is the default name of the hole. When we click on Hole, a table will be displayed on the right side of the dialog box, where we can define the geometry of the hole. Specify what kind of hole we want to create from among the three available options namely Polygon, Circle and Ellipse, in the **Region Type**, as shown in the next figure. For each hole, one tab will be created automatically in the **Define Meshing Region** dialog box to allow us to specify different parameters for that hole.

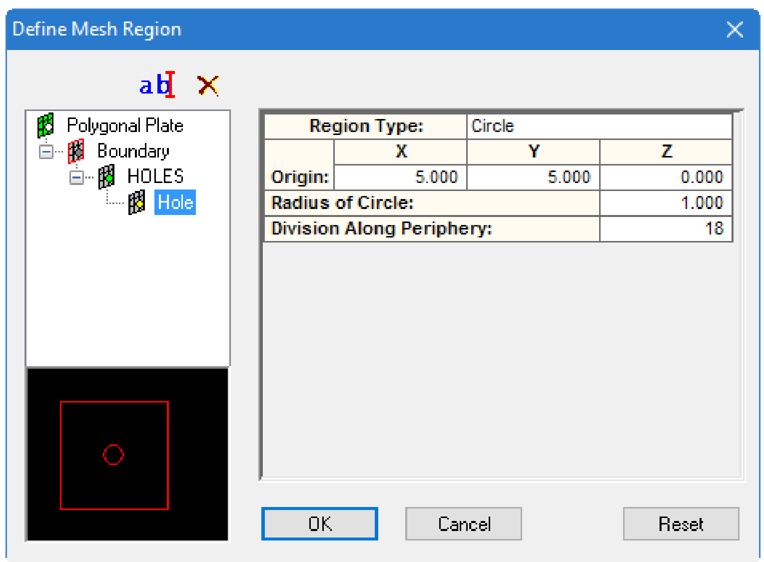


The creation and editing of the region types are explained below.

Polygon	This option is used to define polygonal holes. The geometry of the polygonal holes is generated in the same way as the geometry of the polygonal. Please refer to the description under polygonal surfaces for details on defining the geometry of polygonal holes.



Circle This option is used to define circular holes. The parameters for defining the geometry of circular holes are described below:

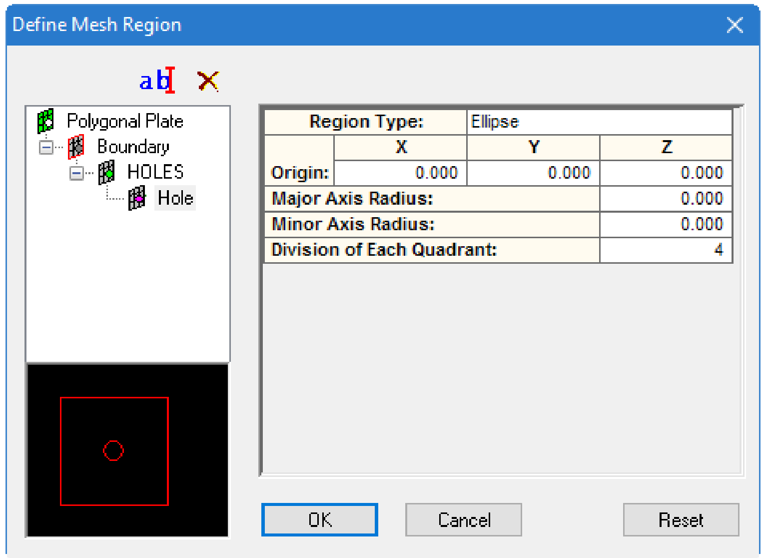


Origin We have to specify the X, Y, and Z coordinates in its proper places to define the position of the center of the circular hole.

Radius of circle The value in this box will define the radius of the circular hole.

Division Along Periphery The value in this box defines the number of divisions to be done along the circumference of the circular hole. This information will be considered in mesh generation of the surface

Ellipse This option is used to generate ellipsoidal holes. The parameters to define the geometry of ellipsoidal holes are as follows:



Origin	We have to specify the X, Y, and Z coordinates in its proper places to define the position of the center of the ellipsoidal holes.
Major Axis Radius, Minor Axis Radius	The values in these boxes will define the major axis and the minor axis of the ellipsoidal holes.
Division of each Quadrant	The values specified in this box specifies the number of divisions of each quadrant. This information will be used for the mesh generation of the surface.

Once all the parameters have been specified, clicking on **OK** to carry out the mesh generation operation of the surface. Clicking on **Cancel** will cancel the mesh generation operation. Clicking on Reset will reset the parameters provided at the beginning.

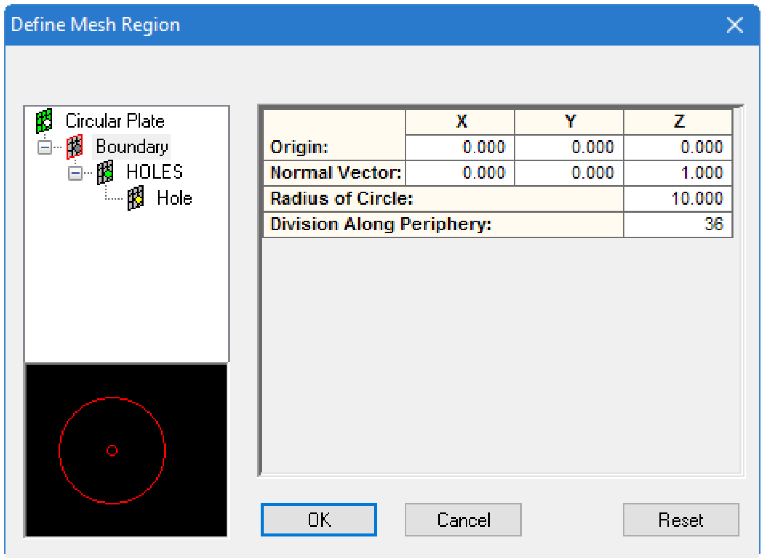
Note: The one limitation of the Polygonal Surface Meshing is that the total number of nodes must not exceed 15000.

M. Circular Plate with Hole

Circular Plate with hole is a special case of Polygonal Plate with Hole, where the Boundary is circular, keeping the other parameters unaltered.

Select the **Circular Plate with Holes** prototype under the model type **Surfaces/Plates**. Drag the item into the right-side window and release the button. The **Define Meshing Region** dialog box will appear as shown in the next figure.

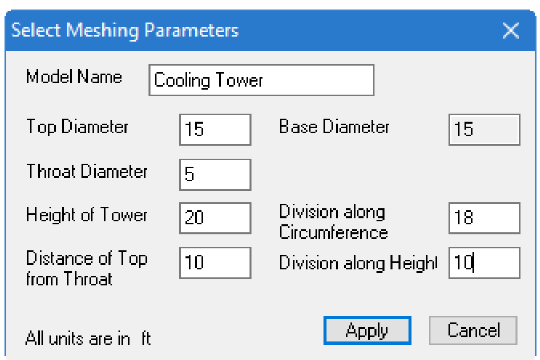
The basic parameters required to define the circular plate geometrically are the location of the center (**Origin**) and **Radius**. To specify the plane of the circular plate the **Normal Vector** can also be defined. As the meshing parameter, **Number of Division along Periphery** is required.



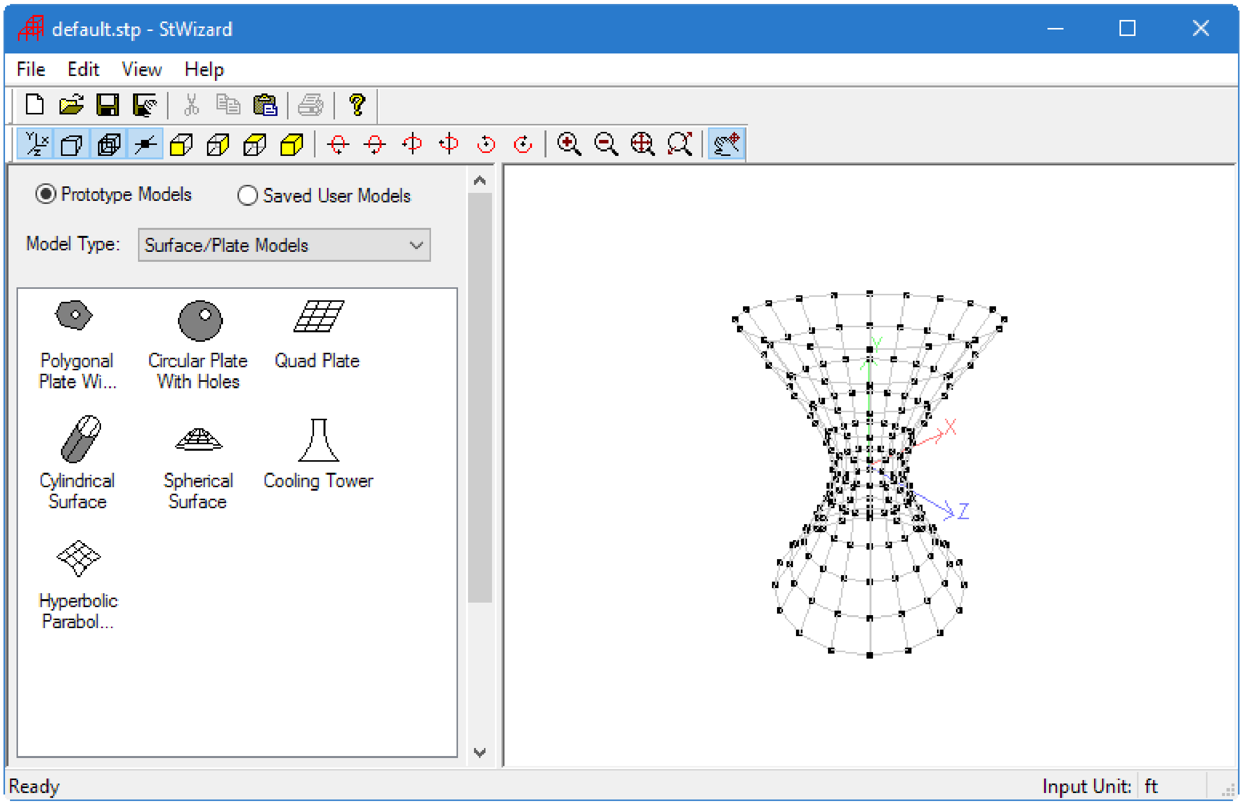
M. Cooling Tower

A hyperbolic paraboloid shaped Cooling Tower may be generated and meshed with the parameters displayed in the **Select Meshing Parameters** dialog box as shown in the next figure.

The basic geometrical parameters required to model such a structure are Top Diameter, Throat Diameter, Height of Tower and Distance of Top from Throat. The Base Diameter is internally calculated and displayed to the user. For the purpose of mesh generation, the number of Division along Circumference and Division along Height is to be specified.



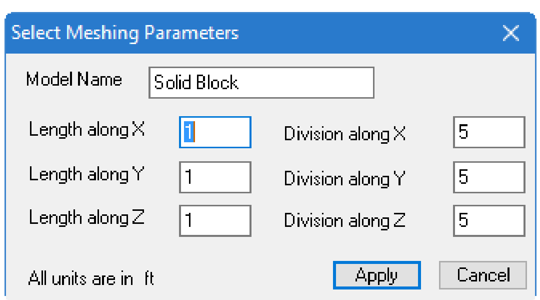
A complete model of a Cooling Tower is shown below.



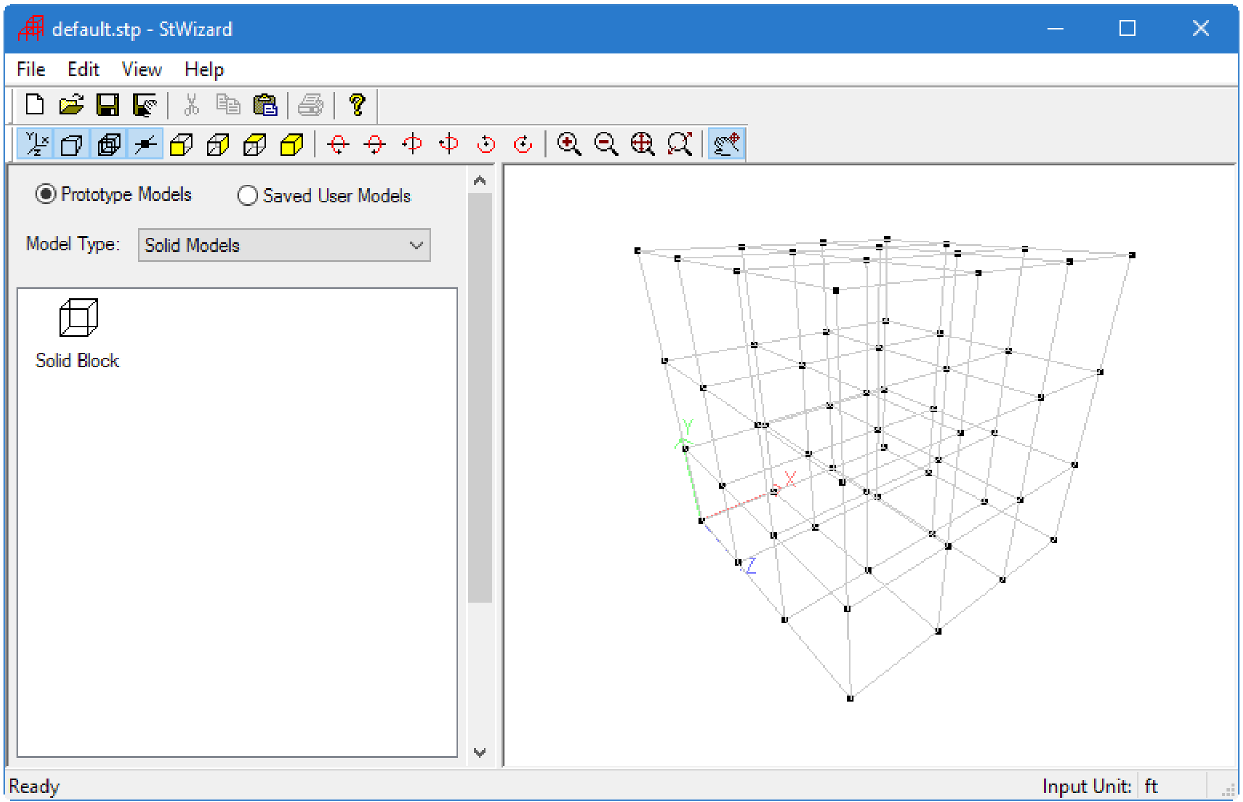
M. Solid

A Solid rectangular block can be generated and meshed with the parameters displayed in the **Select Meshing Parameters** dialog box as shown below.

The required parameters are the **Lengths along X**, **Y** and **Z** directions and the corresponding **Number of Divisions** along those edges.



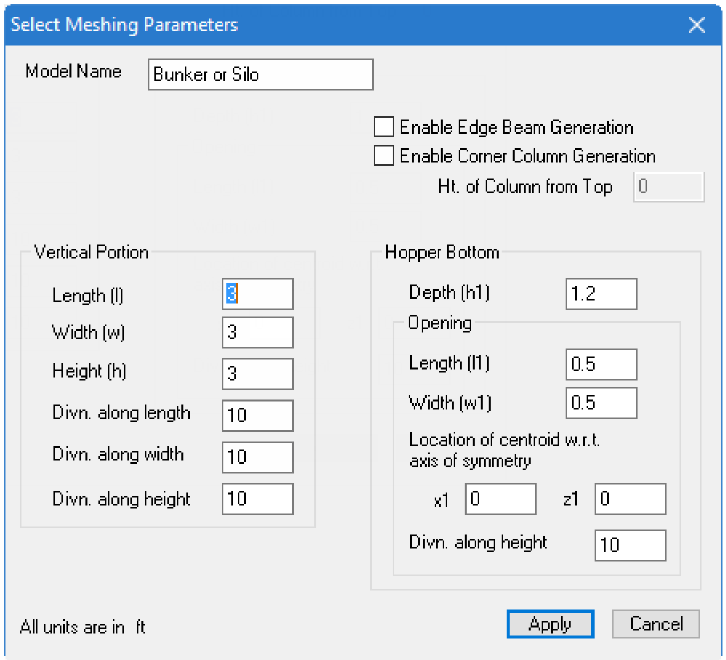
A Solid rectangular block is shown below.



M. Composite Model: Bunker or Silo

A Bunker or Silo can be modeled parametrically and meshed with this feature.

Select the **Bunker or Silo** prototype under the model type **Composite Models**. Drag the item into the right-side window and release the button. The **Select Meshing Parameters** dialog box will appear as shown below.



To define the geometry of the Vertical Portion, you have to define the **Length**, **Width** and **Height** of that portion along-with the number of **Divisions** along them for the purpose of mesh generation.

The **Depth of the Hopper Bottom** is required with the number of Divisions along depth. The **Length** and **Width** of the opening at the bottom is required and to locate this opening the **shift of Centroid** of the opening w.r.t. the axis of symmetry of the Silo is required.

Checking the box **Enable Edge Beam Generation** can generate edge beams and also checking the box **Enable Corner Column Generation** can generate Corner Columns, for which the **Height of Column from Top** is to be provided.

M. Import CAD Model

This feature, Import CAD Model, has two separate utilities, Scan DXF and STAAD Models.

M. To generate geometry from a DXF file

This is a utility which allows the geometry (nodes, members, plates, etc.) of a previously created model to be imported and altered.

This feature supports a limited number of CAD entities like Line, 3D-Polyline, and 3D-Face.

If the geometry of a model is created using a drawing program like AutoCAD and saved in a DXF file, it can be imported into STAAD using this utility.

1. Select **Import CAD Models** from the **Model Type** drop-down list.
2. Either:

   Drag-and-drop the **Scan DXF** icon into the view window. 

   or

Double-click the **Scan DXF** icon.

The **Open** dialog opens.

3. Select the DXF file you want to use and click **Open**.
The drawing geometry is opened in Structure Wizard.

M. To generate geometry from a STAAD model

This feature can be used to import an existing model which can then be quickly scaled up or down in the Structure Wizard.

1. Select **Import CAD Models** from the **Model Type** drop-down list.
2. Either:

   Drag-and-drop the **STAAD Model** icon into the view window. 

   or

   Double-click the **STAAD Model** icon.

   The **Open** dialog opens.
3. Select the STAAD input file (`.std`) you want to use and click **Open**.
The model geometry is opened in Structure Wizard.

M. VBA Macro Models

This feature allows you to parametrically define models using a VBA Macro.

Two sample files are supplied with the program.

Tip: Select **File** > **Set as Top Most** to turn *off* that feature before launching a macro. Otherwise, the macro form may be hidden beneath the **Structure Wizard** application window.

- Dragging a macro icon from the left side of the window to the right to launch the macro.
- Double-click an icon on the left-hand side to open the code in the VBA editor. You can then make changes and save the file to suit your needs.

Related Links

- *EX. Structure Wizard Macro Example Files* (on page 6253)

M. To add a new plugin

1. Either:

   Select **File** > **Add Plugin**

   or

   Right-click in the model types list and select **Add Plugin** from the pop-up menu.

   The **Select an existing Macro** dialog opens.
2. Select the Visual Basic Macro file (file extension `.vbs`) you want to add and click **Open**.
The new macro is added to the list of plugins in the model types list.

M. To edit model parameters

1. Either:

   Right-click in the view window and select **Change Property** from the pop-up menu.

   or

   Select **Edit** > **Change Property**.

   or

   Double-click on the model view window.
   The **Select Parameters** dialog opens.
2. Change one or more parameters as needed..
3. Click **Apply**.

M. To rescale a model

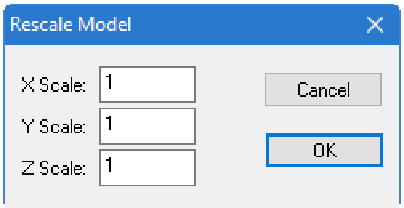
1. Either:

   Right-click in the view window and select **Scale** from the pop-up menu.

   or

   Select **Edit** > **Scale**.

   The **Rescale Model** dialog opens.



2. Type in corresponding Z, Y, and Z scale factors in the fields.
3. Click **OK**.

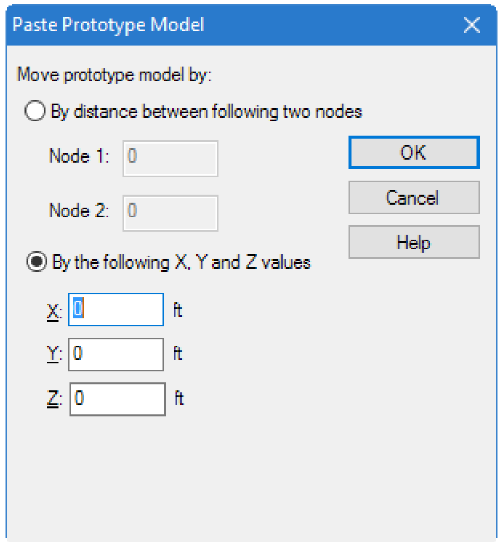
M. To delete an entire model

Right-click in the view window and select **Delete** from the pop-up menu

M. To transfer the generated model to STAAD.Pro

1. Select **File** > **Merge Model with STAAD.Pro Model**.
   A dialog prompts you to confirm you want to merge this prototype with your current STAAD.Pro model.
2. Click **Yes**.

   The **Paste Prototype Model** dialog opens.



3. (Optional) Specify the method of offset:

Tip: This is useful, for example, to place a prototype truss model at the top of already modeled columns.

Move option	Do the following
By distance between following two nodes	Type the node numbers
By the following X, Y and Z values	Type the coordinates (in the indicated units) where to place the prototype origin in the global coordinates of the STAAD model.

4. Click **OK**.
   The model is placed.

In the event that nodes, members, or elements overlap existing similar objects in the STAAD model, a message dialog opens indicating that the duplicate objects have been ignored. Click **OK** to proceed.

M. To add items to the library

You can customize the list of model types using the following procedure.

1. Select the **Model Type** from the drop-down list.
2. Either:

   Select **File** > **Add Plugin**

   or

   right-click in the model type list and select **Add Plugin** from the pop-up menu
   The **Open** dialog opens.
3. Select the library file (file extension `.dll`) for the plugin and click **Open**.
4. (Optional) To rename a selected model generator, do the following:
   a. Select a model generator and either:

      Select **Edit** > **Rename Model Generator**

or

right-click on the model generator and select **Rename Model Generator** from the pop-up menu

The **Select Name** dialog opens.

b. Type a new name.

c. Click **OK**.

5. (Optional) Save the library of prototypes to a new file:
   a. Select **File** > **Save As**.
      The **Save As** dialog opens.
   b. Type a new file name for the StWizard Model Files (file extension `.stp`) and click **Save**.
   c. You can now open this file again by selecting **File** > **Open**.

M. Pages in the Analytical Modeling Workflow

- Geometry – used to layout your structure, including nodes, beams, plates, and solids

> **Note:** If you are using the Physical Modeling workflow, the majority of the tools on this page will be disabled. Model geometry for physical models must be updated in the STAAD.Pro Physical Modeler interface.

- Properties
- Specifications
- Supports
- Loading
- Analysis
- Design

Nodes table

Used to display a table of nodes with coordinates for adding and editing nodes. The table may also be used to highlight the node on the graphical view of the structure.

The *Nodes* table lists the node numbers and their coordinates. This table can be used to define new nodes and edit existing node-coordinates. If we click on a node number in this table, the node gets highlighted in the table as well as in the structure view..

Opens when the **Geometry** page is selected in the **Analytical Modeling** workflow.

Node	Lists the node numbers in numerical order.
X	The X coordinates of the nodes in the currently selected unit. Changing this immediately changes the X-coordinate of the node in the graphical display also.
Y	The Y coordinates of the nodes in the currently selected unit. Changing this immediately changes the Y-coordinate of the node in the graphical display also.
Z	The Z coordinates of the nodes in the currently selected unit. Changing this immediately changes the Z-coordinate of the node in the graphical display also.

Goto <object> dialog

Used to go to a specific node within the **Nodes**, **Beams**, etc. table.

Opens when **Go To** is selected from the right-click pop-up menu on many tables.

Type the number of a node, beam, etc. and then click **OK**. The table will highlight that entry.

Node Supports

Lists all nodes for which supports have been defined along with the type of support.

M. Properties and Specifications

M. Section Profiles

Beam members must have a section profile assigned for analysis.

STAAD.Pro supports a wide variety of section profiles, including catalog sections, prismatic sections, tapered member sections, and so on.

M. Section Database Profiles

STAAD.Pro comes with an extensive, built-in database of common catalog sections for many countries.

- *TR.20.1 Assigning Properties from Steel Tables* (on page 2257)

M. To add a new table section property

To add a table section property from a standard catalogs for steel, cold-formed steel, timber, or aluminum, use the following procedure.

These are also referred to as the “built-in” tables of sections in STAAD.Pro.

1. Either:

   select the **Database** tool in the **Specifications** group on the **Specifications** ribbon tab

   

   or

   select the **Properties** page and then click **Section Database** on the **Properties - Whole Structure** dialog

   Tip: Selecting the country from the **Database** tool drop-down list first results in a faster dialog load time.

   The **Section Profile Tables** dialog opens.
2. Select the appropriate table:
   a. Select the material tab at the top of the dialog:

      Steel
      Coldformed Steel

Timber
Aluminium

b. Select the country catalog and shape profile on the left-hand side of the dialog.

> **Tip:** If you selected the material and country using the **Database** tool drop-down, then only that material and country tables are shown in the dialog.

3. Select the shape profile on the left-hand side of the dialog.
4. Either:

   select the specific shape (i.e., beam, profile, shape, section, etc.) in the list

   or

   select to define a shape for some (i.e., pipes)

> **Note:** Refer to related codes in the Design (on page 969) for information on section nomenclature.

5. Select the appropriate **Type Specification** for some shapes.
   Some type specifications require additional input (such as cover plate dimensions, spacing, composite slab data, etc.).
6. (Optional) Select an associated **Material**.
   This feature allows you to use material definitions for steel, stainless steel, concrete, aluminum, or any previously specified, custom material definitions.
7. Either:

To...	Do the following...
add the section to the model for later assignment	click **Add**.
add the section to the model and assign to the current member selection	click **Asign**.

8. (Optional) Repeat steps 2 through 7 as needed to add more sections to the model.
9. Click **Close**.

The section and, if selected, associated material, is added to the **Properties - Whole Structure** dialog.

If you did not assign the section to a selection set, you must select the section label in the **Properties - Whole Structure** dialog and assign it using one of the assignment methods.

M. To add an American steel joist section

To add an American steel joist section and, optionally, have it sized by span and load, use the following procedure.

STAAD.Pro includes the facilities for specifying steel joists and joist girders. The basis for this implementation is the information contained in the 1994 publication of the American Steel Joist Institute called “Fortieth edition standard specifications, load tables and weight tables for steel joist and joist girders.” Member properties can be assigned by specifying a joist designation contained in tables supplied with the program, including the following joists and joist girder types:

Open web steel joists – K series and KCS joists
Longspan steel joists – LH series
Deep Longspan steel joists – DLH series
Joist Girders – G series

Tip: It is recommend that use the default selection of **Steel** material definition with joists.

1. Either:

   select the **Database** tool in the **Specifications** group on the **Specifications** ribbon tab

   

   or

   select the **Properties** page and then click **Section Database** on the **Properties - Whole Structure** dialog

   Tip: Selecting the country from the **Database** tool drop-down list first results in a faster dialog load time.

   The **Section Profile Tables** dialog opens.
2. Select the **Steel** tab and then the **American Steel Joist** entry on the left-hand side.
3. Select the series of joists you want to use.
4. (Optional) To have the program select a least-weight option of joist for you, do the following:
   a. Type the search criteria (differs by joist series) in the **Find suitable joist section** fields.
   b. Click **Find Section.**

   For example, if you select the LH series of joists and then specify a Clear Span of 35 ft, a Depth Limit of 24 in (2ft), a Total Load of 750 lbs/ft (0.75k/ft), a Live Load of 500 lbs/ft (0.5k/ft), and a Deflection Limit of L/360, the program will select a **24LH09** when you click **Find Section.**
   The least weight suitable joist in the joist series will be selected. If not suitable joist can be found in the series, a message dialog opens.
5. Either:

To...	Do the following...
add the section to the model for later assignment	click **Add.**
add the section to the model and assign to the current member selection	click **Asign.**

6. Click **Close.**

Example Input

An example of a structure with joist:

```
STAAD SPACE EXAMPLE FOR JOIST GIRDER
UNIT FEET KIP
JOINT COORDINATES
1 0 0 0; 2 0 10 0
3 30 10 0; 4 30 0 0
MEMBER INCIDENCES
```

```
1 1 2; 2 2 3; 3 3 4;

M. To assign catalog section to physical members

To select and assign a catalog section to physical members, use the following procedures.

Note: For a physical member whose physical member property is already assigned, the individual analytical members in that Physical member will adopt the same member property that of the physical member. However, in case, where the analytical member property is assigned to any member in that physical member, then this analytical member property will supersede physical member property.

1. Select the Properties page.
   The **Properties - Whole Structure** dialog opens.
2. On the **Geometry** ribbon tab, select the **Toggle Physical Member Mode** tool in the **Physical Members** group.

   
   The tool is highlighted to indicate the mode is active.
3. Either:

   select the **Database** tool in the **Specifications** group on the **Specifications** ribbon tab

   

or

select the **Properties** page and then click **Section Database** on the **Properties - Whole Structure** dialog

Tip: Selecting the country from the **Database** tool drop-down list first results in a faster dialog load time.

The **Section Profile Tables** dialog opens.

4. Select the appropriate table:
   a. Select the material tab at the top of the dialog:

      Steel
      Coldformed Steel
      Timber
      Aluminium
   b. Select the country catalog and shape profile on the left-hand side of the dialog.

Tip: If you selected the material and country using the **Database** tool drop-down, then only that material and country tables are shown in the dialog.

5. Select the shape profile on the left-hand side of the dialog.
6. Either:

   select the specific shape (i.e., beam, profile, shape, section, etc.) in the list

   or

   select to define a shape for some (i.e., pipes)

Note: Refer to related codes in the Design (on page 969) for information on section nomenclature.

7. Select the appropriate **Type Specification** for some shapes.
   Some type specifications require additional input (such as cover plate dimensions, spacing, composite slab data, etc.).
8. (Optional) Select an associated **Material**.
   This feature allows you to use material definitions for steel, stainless steel, concrete, aluminum, or any previously specified, custom material definitions.
9. Click **Add**.
   The new member property is added to the list as a Physical member property in the **Properties - Whole Structure** dialog. Such properties are designated with the word "Physical".

Note: Only the Physical Member properties can be assigned to a physical member, and no analytical member property can be assigned to a physical member.

10. Click **Close**.

You must assign the physical member properties to physical members using one of the standard assignment methods from the **Properties - Whole Structure** dialog.

M. Section Database Manager

This utility application is used to manage the section catalog databases used in STAAD.Pro.

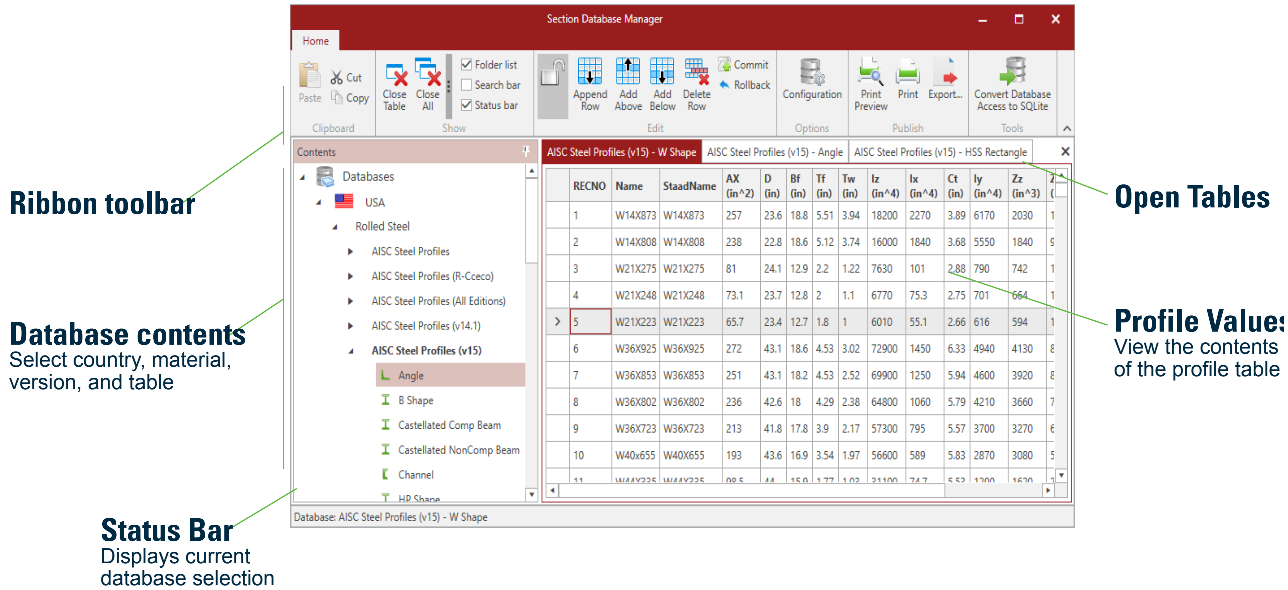

Figure 105: Section Database Manager Window Overview

M. To change a default section database

To change the section database used the default for a particular country and material combination, use the following procedure.

The latest edition of each country's database is selected as the default value. However, to use older editions of catalogs (e.g., when historical sections in the AISC database are needed), you may want to change the default catalog used. Please note that some catalogs are significantly larger, such as the “AISC Steel Profiles (All Editions)” and this can slow dialog loading times.

This procedure is also used if your organization has developed a custom section database.

1. Select the **Section Database** tool in the **Tools** group on the **Specifications** ribbon tab.

   

   The **Section Database Manager** application opens.
2. On the **Home** ribbon tab, select the **Configuration** tool in the **Options** group.

   

   The **Default Database Configuration** dialog opens.
3. (Optional) Select the **Default Country** from the drop-down list.

   This will be the first country expanded when the **Section Profiles Tables** dialog open is opened.
4. Select the tab corresponding to the material type.
5. For a particular **Country**, select a default database from the drop-down list in the **Selected Database** field.
6. Repeat steps 4 and 5 to change additional default databases.
7. Click **Save**.

8. Click **Close**.

Tip: Alternatively, you can navigate to the database you want to use as the default for a particular country and material combination in the Contents panel. Then, right-click and select **Set as Default Database** from the pop-up menu.

M. To add a custom table section property

To edit the section database tables to include custom sections, use the following procedure.

Warning: It is strongly recommended that you do not modify the database files that are installed with STAAD.Pro. These files are typically overwritten when the program is updated. Instead, you can create your own custom copy and modify that database file.

Adding a section to a database table is useful if you need to commonly use that custom section in many models or projects.

This procedure is not the same as adding a user-defined (UPT) section or catalog. This should only be performed if you need to make edits to the standard shape catalogs that are included with STAAD.Pro. Using a UPT section allows you to enter dimensions and, for many sections, have the program calculate section values.

1. Select the **Section Database** tool in the **Tools** group on the **Specifications** ribbon tab.

   

   The **Section Database Manager** application opens.
2. In the Databases list, double-click on the country, material, catalog, and table you want to edit.
   The selected table opens in read-only mode.
3. Select the **Lock** tool.
   The table is unlocked for editing.
4. Either:

To...	Do the following...
add a row to the end of the table	select the **Append Row** tool
add a row above the current table row	select the **Add Above** tool
add a row below the current table row	select the **Add Below** tool

   The order of the table here is how it will also be presented in the **Section Profile Tables** dialog in STAAD.Pro.

   An empty row is added to the table.
5. Type a record number (RECNO), name, STAAD.Pro nomenclature name (StaadName), and then the section values for each column in the table.

   You can press **<Tab>** to move to the next column within a row when entering values.
6. (Optional) Repeat steps 4 and 5 as many times as needed to add additional shapes.
7. Click **Commit** to save the changes to the database.
8. Select the **Unlock** tool.
   The database is now locked against further editing.
9. Close the SectionDBManager program.

You can now use this section just as you would any default catalog section in STAAD.Pro.

Note: You can use the **Delete Row** tool to remove the current selected table row. Exercise caution when using this tool!

M. To add a custom section database

To create a custom section database for use in STAAD.Pro, use the following procedure.

Note: This procedure involves editing SQLite files and requires third-party software and a basic understanding of updating SQL queries.

Warning: It is strongly recommended that you do not modify the database files that are installed with STAAD.Pro. These files are typically overwritten when the program is updated. Instead, you can create your own custom copy and modify that database file.

The database files used in STAAD.Pro have a specific structure. Therefore, you should start by copying an existing section database file. Attempting to create a new section database file from scratch is strongly discouraged.

The best practice is to identify the section database that includes tables *most similar* to your custom table requirements. You can change the country of the section database, but it is recommended to start with a source database from the same country you intend to use as your custom database.

1. Copy an existing section database file:
   - a. In Windows Explorer, navigate to `C:\ProgramData\Bentley\Engineering\STAAD.Pro CONNECT Edition\Sections` (typical installation location).
   - b. Copy the appropriate section database file (extension `.db3`) to a convenient location.
   - c. Give this copied file a new file name.
2. Use a SQLite database editor program to update the database values:

   You must use a third-party SQLite database editor such as SQLiteStudio or SQLite Administrator. Details on the use of these products is beyond the scope of this documentation.
   - a. **Required:** Update the sections database name to something unique.

     This will be used to identify the sections database in STAAD.Pro so it must be different from existing databases, both those installed with the program and other custom databases. The section database files contain a table named “DBInfo” that contains the name used in STAAD.Pro.

     Typically, this can be done by running the SQL query: `UPDATE 'DBInfo' SET name='`*`custom database name`*`'`, where *`custom database name`* is the unique name you want to use.
   - b. (Optional) Update the field units if necessary.

     The units for each section value are maintained outside of the section tables in a table named “Field Units”. If these need to be changed (e.g., you are creating a metric version of an imperial table), then these must also be updated using a SQLite editor application.
   - c. If you need to add additional field (columns) to a table, then this must be done in an SQLite editor.
   - d. Save the database if necessary.

     Typically, SQL queries such as UPDATE write the changes to the database and do not require saving.

     You can use the SQL query `SELECT * FROM 'DBInfo'` to view all the field values in that table to verify the name has been updated.
3. Select the **Section Database** tool in the **Tools** group on the **Specifications** ribbon tab.

The **Section Database Manager** application opens.

4. On the **Home** ribbon tab, select the **Configuration** tool in the **Options** group.

   

   The **Default Database Configuration** dialog opens.
5. Select and add your custom database:
   a. Click **Browse** and then navigate to where you saved your custom database file.
   b. Select the file and click **OK**.

   > **Note:** Alternately, you can copy and paste the full file path to the database file.

   c. Click **Add**.
   An information dialog opens to confirm the database was added.
   d. Click **OK**.
   e. Click **Save**.
   An information dialog opens to confirm the Database INI file was updated.

The database is added and can now be edited.

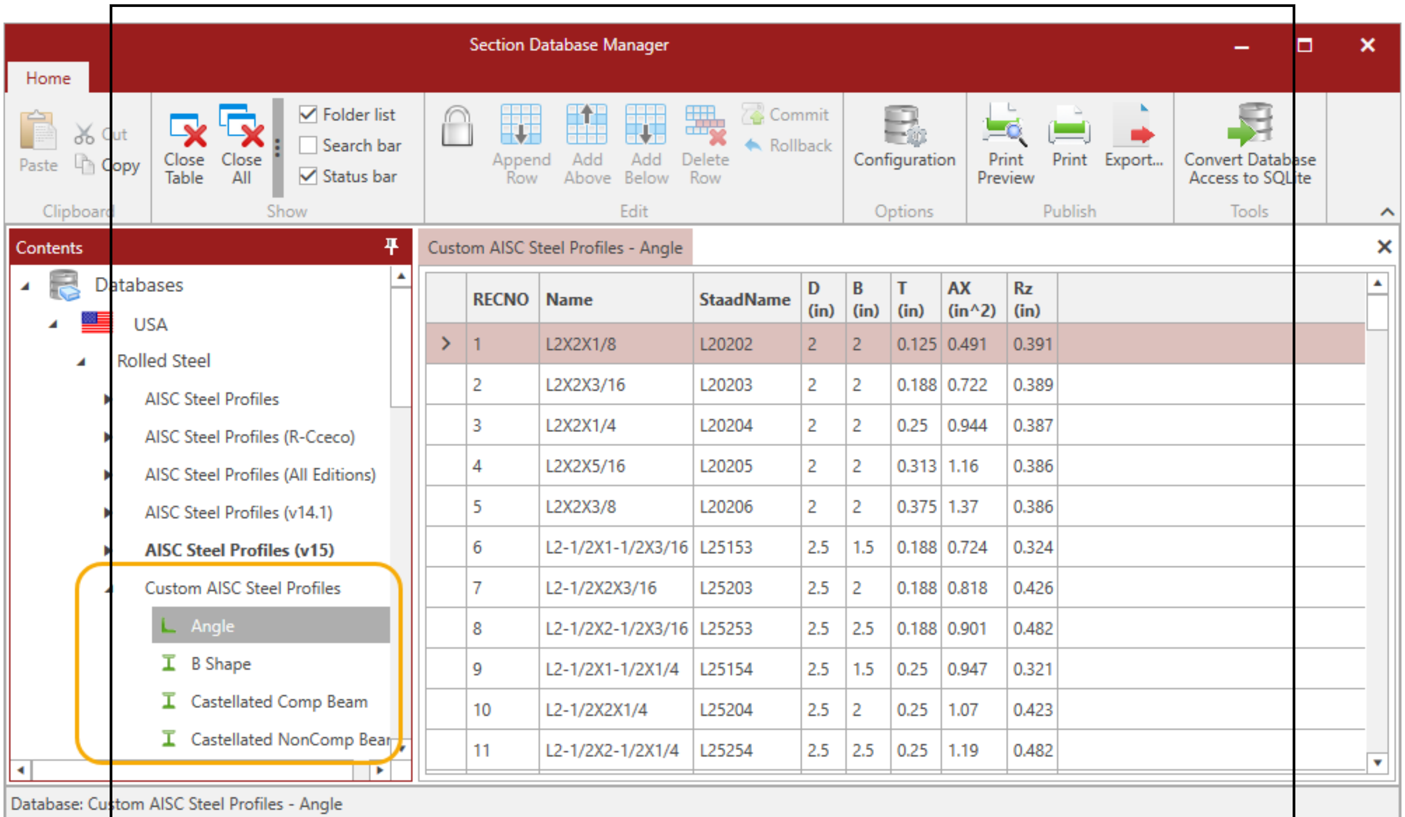

Figure 106: A custom database has been added to the Section Database Manager

M. To convert a legacy database

To migrate custom databases of shapes to the SQLite format, use the following procedure.

You can convert legacy Microsoft Access database files (file extension `.mdb` or `.accdb`) to SQLite database files.

1. Select the **Section Database** tool in the **Tools** group on the **Specifications** ribbon tab.

   The **Section Database Manager** application opens.
2. On the **Home** ribbon tab, select the **Convert Database Access to SQLite** tool in the **Tools** group.

   The **Convert Access Database to SQLite Database** dialog opens.
3. Either:

   type the complete path to your existing Access database file in the **Source** field

   or

click the **Browse** button to navigate to and select the existing Access database file

4. Either:

   type the complete path to and file name of the new SQLite database file in the **Destination** field

   or

   click the **Browse** button to navigate to and type a file name for the new SQLite database file
5. Click **Convert**.

You now have an SQLite database you can utilize add as a custom database for use in STAAD.Pro CONNECT Edition.

Section Database Manager Ribbon toolbar

Table 24: Section Database Manager Home ribbon tab

Tool Name	Description	Shortcut
 **Paste**	Paste clipboard contents into the table.	**<Ctrl+V>**
 **Cut**	Copy the selection to the clipboard and delete the original.	**<Ctrl+X>**
 **Copy**	Copy the selection to the clipboard.	**<Ctrl+C>**
 **Close Table**	Closes the currently selected table.	
 **Close All**	Closes all open tables.	

Tool Name	Description	Shortcut
 **Unlock** / Lock	Unlocks the current table for editing. Once unlocked, the same tool re-locks the table to prevent further changes.	
 **Append Row**	Adds a new table row at the end of the table.	
 **Add Above**	Adds a new table row before the current selection.	
 **Add Below**	Adds a new table row after the current selection.	
 **Delete Row**	Deletes the currently selected row from the table.	**<Delete>**
 **Commit**	Saves all changes to the current table.	
 **Rollback**	Undoes all uncommitted changes made to the current table.	

Tool Name	Description	Shortcut
 **Configuration**	Opens the **Default Database Configuration** dialog, which is used to select the default country and section databases to use in the **Section Profiles Table** dialog.	
 **Print Preview**	Opens a print preview of the currently selected table.	
 **Print**	Prints the currently selected table contents.	**<Ctrl+P>**
 **Export**	Opens a Save As dialog, where you can choose a location and file format for exporting the current table contents to an external file.	
 **Convert Database Access to SQLite**	Opens the **Convert Access Database to SQLite Database** dialog, which is used to convert legacy section database files in Microsoft Access database format to SQLite database files.	

Default Database Configuration dialog
Used to select the default country and section databases to use in the **Section Profiles Table** dialog.

Opens when the **Configuration** tool is selected on the **Home** tab in the **Section Database Manager** application.

When an existing STAAD.Pro model is opened, the program reads the contents of the file, and checks the validity of data in that file. One of those data items validated is names of sections assigned from steel tables. Since steel sections are country-specific, such as British, German, etc., the program needs to know the country or organization whose steel table is the underlying database for validating the sections being read in from the file. Normally, the input file contains the name of the database as part of the member property command. In the absence of an explicit name, STAAD.Pro uses a default. That default is set using this facility.

Section Profile Table tab

Default Country	Select the default country to display when the **Section Profiles Table** dialog opens.
Tables Selection	The materials are organized as tabs along the top of the table. For each material, the countries are listed along with the default catalog to use for each. Select the catalog from the drop-down list for each as needed.
Custom Profile Table	Used to associate a user-defined section table with STAAD.Pro. STAAD.Pro profile table files are Microsoft Office Access® database files (file extension `.mdb`). **Category** Select the profile category (typically material and/or country) with which the profile database is to be associated. **Table** Type the name of the STAAD.Pro profile table file (file extension `.mdb`) to add or click **[...]** to browse for a file. **Add** Adds the selected custom profile table to the program.

M. Prismatic and Tapered Sections

You can define parametric sections for use your model.

M. To assign a prismatic section

To define and assign a prismatic section, use the following procedure.

Prismatic sections such as circle, rectangle, tee, and trapezoidal can be used for concrete members used in design.

Circle prismatic sections can also be used to represent steel rods for analysis.

> **Tip:** If you need to perform design for a steel rod, you can closely approximate a solid steel rod by creating a circular hollow section with a very small inside diameter. Alternately, you can select a steel library section from a catalog that contains solid rods or create your own.

1. Either:

   select the **Database** tool in the **Specifications** group on the **Specifications** ribbon tab

   or

   select the **Properties** page and then click **Section Database** on the **Properties - Whole Structure** dialog

   > **Tip:** Selecting the country from the **Database** tool drop-down list first results in a faster dialog load time.

   The **Section Profile Tables** dialog opens.
2. Either:

select the Properties page and then click **Define** on the **Properties - Whole Structure** dialog

or

on the **Specifications** ribbon tab, select the **Prismatic** tool in the **Beam Profiles** group

The **Property** dialog opens.

3. Select the tab corresponding to the profile shape you want to use.

Notes:

The geometric shapes circle, rectangle, tee, trapezoidal, and general are typically used for concrete members.
Tapered I and tapered tube are typically used for steel members.
The Assign Profile tab is used to assign a profile shape for steel design for later member selection.

4. Type the profile dimensions for the selected shape.
5. (Optional) Select an associated **Material**.

   This feature allows you to use material definitions for steel, stainless steel, concrete, aluminum, or any previously specified, custom material definitions.
6. Either:

To…	Do the following…
add the section to the model for later assignment	click **Add**.
add the section to the model and assign to the current member selection	click **Asign**.

7. Click **Close**.

Related Links

- *G.6.1 Prismatic Properties* (on page 2114)
- *Property dialog* (on page 2794)
- *TR.20.2 Prismatic Property Specification* (on page 2263)
- *TR.20.2.1 Prismatic Tapered Tube Property Specification* (on page 2264)

M. To assign a tapered I section

To define and assign a web-tapered I section, use the following procedure.

Note: *f1* (Depth of section at start node) should always be greater than *f3* (Depth of section at end node). You must provide the member incidences accordingly.

If the tapered section requires a composite slab, then M.To create an I shape user table section (on page 739) instead.

Tapered I-sections have constant flange dimensions and a linearly varying web depth along the length of the member.

Shear deformation is not considered for tapered I-Beams and tapered poles. This means that the `SET SHEAR` command has no effect on the deformation computed for members with these cross sections.

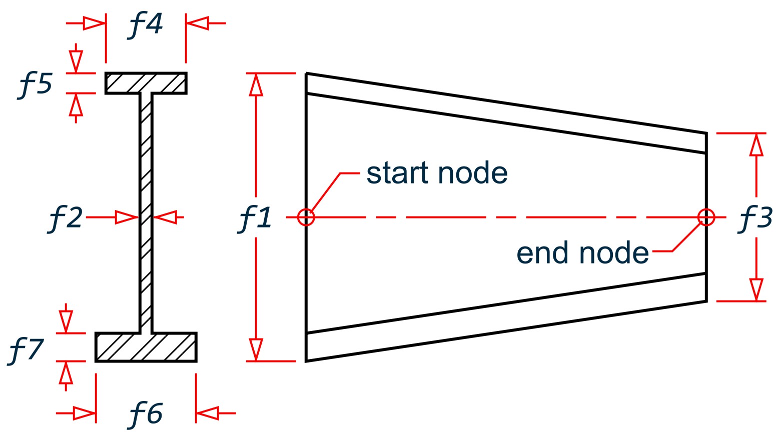
1. On the **Specification** ribbon tab, select the **Tapered** tool in the **Beam Profiles** group.

   The **Tapered I** dialog opens.
2. Select an associated **Material**.

   This feature allows you to use material definitions for steel, stainless steel, concrete, aluminum, or any previously specified, custom material definitions.

   Note: Tapered I sections are typically steel or aluminum members.
3. Specify the profile dimensions for the shape.

4. Either:

To...	Do the following...
add the section to the model for later assignment	click **Add**.
add the section to the model and assign to the current member selection	click **Asign**.

5. Repeat steps 2 through 4 as needed to add more tapered I sections to the model.
6. Click **Close**.

The section and, if selected, associated material, is added to the **Properties - Whole Structure** dialog.

If you did not assign the section to a selection set, you must select the section label in the **Properties - Whole Structure** dialog and assign it using one of the assignment methods.

M. User Table Sections

User-provided tables (UPT) give you a means to specify many different types of parametric sections, including general properties, polygonal sections, and complex sections generated in Section Wizard.

M.To create a wide-flange user table section

To create a user-provided table section with a wide flange profile, including those with composite flanges or additional bottom plates, use the following procedure.

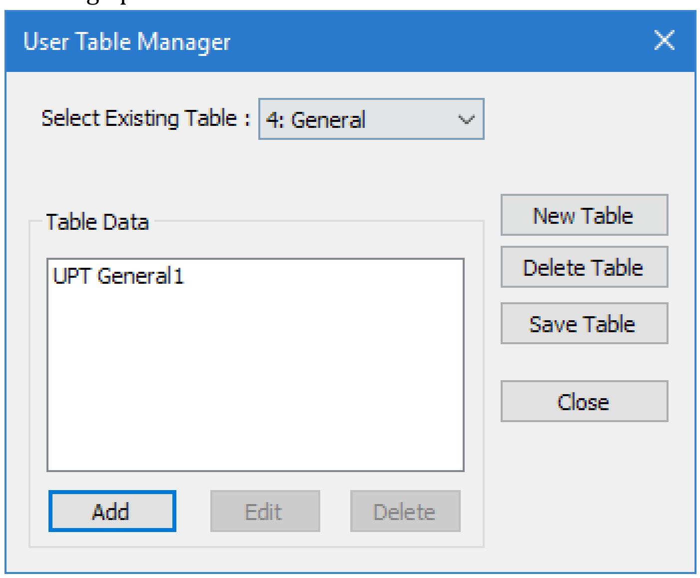
You may want to change the input dimensions prior to creating user provided table sections. Select **Tools** > **Set Current Input Unit** to do so.

1. On the **Specification** ribbon tab, select the **User Table** > **User Table Manager** tool in the **Beam Profiles** group.

   If no User Defined Table exists, you will be prompted to create one.

   The **User Table Manager** dialog opens.

2. Click **New Table**.
   The **New User Table** dialog opens.
3. the **Select Section Type** list, select **WIDE FALNGE** and then click **OK**.
   The dialog closes and the **Table Data** list in the **User Table Manager** dialog now has at least one entry.
4. Click **Add**.
   The **Wide Flange** dialog opens.
5. Type a **Section Name**.
6. **Required:** Enter the following wide flange section parameters:

D	Depth of the section
TF	Thickness of top flange (or both flanges when `WF1` is not specified)
WF	Width of the top flange (or both flanges when `WF1` is not specified)
TW	Thickness of web

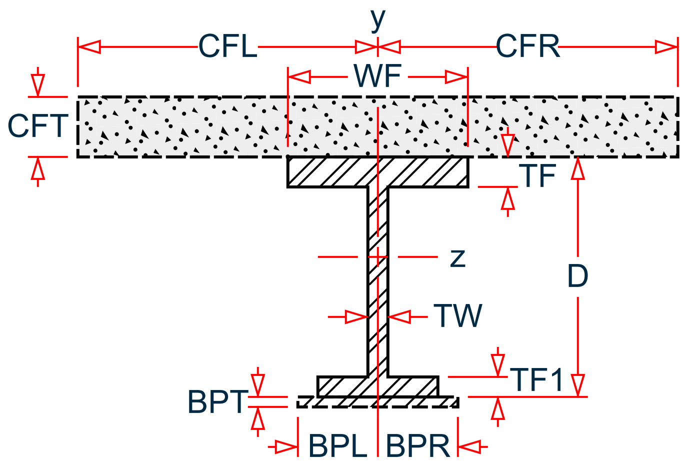


Figure 107: Wide flange section

7. (Optional) If the bottom flange has different dimensions, also specify:

WF1	(Optional) Width of the bottom flange. The width of the top flange will be used if this value is not specified.
TF1	(Optional) Thickness of bottom flange. The thickness of the top flange will be used if this value is not specified.

8. (Optional) To specify a composite top flange:
   a. Check the **Additional Composite Flange** option.
   The Additional Composite Flange Specifications become active.
   b. Specify the following values:

B(left)	Width of the composite slab to the left of the web center line
B(right)	Thickness of the composite slab
Thickness	Width of the composite slab to the right of the web center line
Modular Ratio	Modular ratio of the concrete in the composite slab with respect to the steel section material

9. (Optional) To specify an additional bottom flange plate:
   a. Check the **Additional Bottom Steel Plate** option.
   The Additional Bottom Steel Plate Specifications become active.
   b. Specify the following values:

B(left)	Width of the additional bottom flange plate to the left of the web center line
B(right)	Width of the additional bottom flange plate to the right of the web center line
Thickness	Thickness of the additional bottom flange plate

10. Specify the section properties by either:

Options	Description
To automatically have the program calculate the section properties...	Click **Calculate**

Options	Description
To manually specify the section properties...	Type values for **Cross Section Area (Ax)**, **Inertia about local z (Iz)**, **Inertia about local y (Iy)**, **Torsional Constant (Ix)**, **Shear Area in Y (Ay)**, and **Shear Area in Z (Az)**

11. Click **OK**.
12. (Optional) Repeat steps 4 through 11 to add more wide flange sections.

> **Tip:** The wide flange sections in the same user table can have different options for composite flanges or additional bottom steel plates.

13. Click **Close**.

The section can now be added for use in the Properties - Whole Strucutre dialog (on page 2793) by selecting it in the **User Property Table** dialog.

Refer to EX. US-17 User-Provided Tables (on page 6443) and EX. UK-17 User-Provided Tables (on page 6730) for examples of wide flange user-provided tables.

M.To create a channel user table section

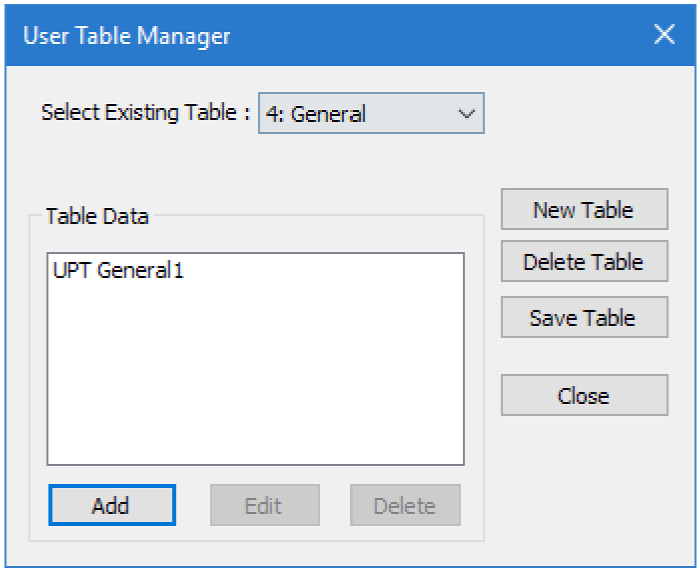
To create a user-provided table section with a channel profile, use the following procedure.

You may want to change the input dimensions prior to creating user provided table sections. Select **Tools** > **Set Current Input Unit** to do so.

1. On the **Specification** ribbon tab, select the **User Table** > **User Table Manager** tool in the **Beam Profiles** group.

   
   If no User Defined Table exists, you will be prompted to create one.

   The **User Table Manager** dialog opens.



2. Click **New Table**.
   The **New User Table** dialog opens.
3. the **Select Section Type** list, select **CHANNEL** and then click **OK**.
   The dialog closes and the **Table Data** list in the **User Table Manager** dialog now has at least one entry.
4. Click **Add**.
   The **Channel** dialog opens.
5. Type a **Section Name**.
6. **Required:** Enter the following channel section parameters:

D	Depth of the section
TW	Thickness of web
WF	Width of flange
TF	Thickness of flange

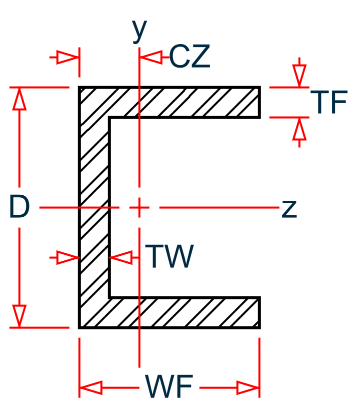


Figure 108: Channel section

7. Specify the section properties by either:

Options	Description
To automatically have the program calculate the section properties...	Click **Calculate**
To manually specify the section properties...	Type values for **Cross Section Area (Ax)**, **Inertia about local z (Iz)**, **Inertia about local y (Iy)**, **Torsional Constant (Ix)**, **C.G. Along local Z (Cz)**, **Shear Area in Y (Ay)**, and **Shear Area in Z (Az)**

8. Click **OK**.
9. (Optional) Repeat steps 4 through 8 to add more channel sections.
10. Click **Close**.

The section can now be added for use in the Properties - Whole Strucutre dialog (on page 2793) by selecting it in the **User Property Table** dialog.

M.To create an angle user table section

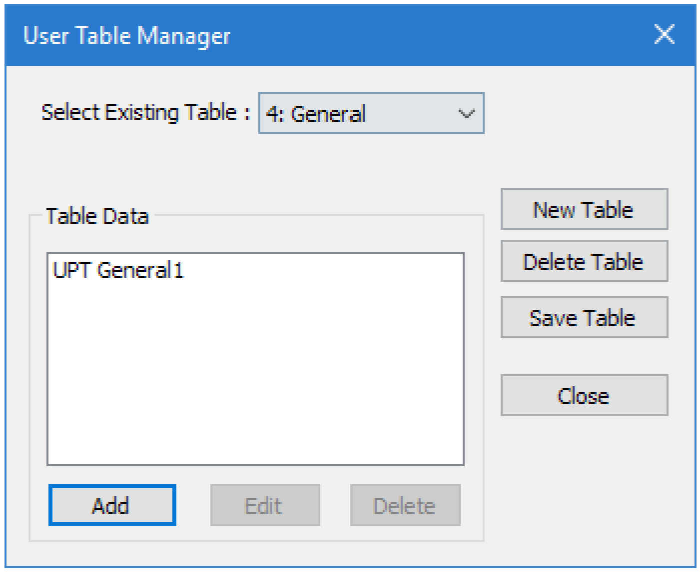
To create a user-provided table section with a single angle profile, use the following procedure.

You may want to change the input dimensions prior to creating user provided table sections. Select **Tools** > **Set Current Input Unit** to do so.

1. On the **Specification** ribbon tab, select the **User Table** > **User Table Manager** tool in the **Beam Profiles** group.

   
   If no User Defined Table exists, you will be prompted to create one.

   The **User Table Manager** dialog opens.



2. Click **New Table**.
   The **New User Table** dialog opens.
3. the **Select Section Type** list, select **ANGLE** and then click **OK**.
   The dialog closes and the **Table Data** list in the **User Table Manager** dialog now has at least one entry.
4. Click **Add**.
   The **Angle** dialog opens.
5. Type a **Section Name**.
6. **Required:** Enter the following angle section parameters:

D	Depth of angle (i.e., length of the leg along the local y-axis)
WF	Width of angle (i.e., length of the leg along the local z-axis)
TF	Thickness of angle leg

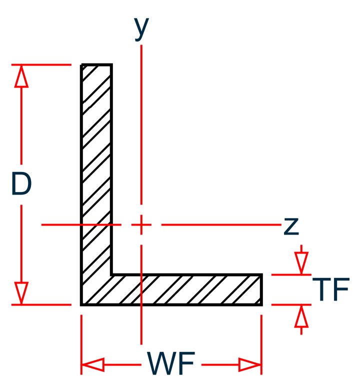


Figure 109: Angle section

7. Specify the section properties by either:

Options	Description
To automatically have the program calculate the section properties...	Click **Calculate**

Options	Description
To manually specify the section properties...	Type values for **Rad. of Gyration about Principal Axis (R)**, **Shear Area in Y (Ay)**, and **Shear Area in Z (Az)**

8. Click **OK**.
9. (Optional) Repeat steps 4 through 8 to add more angle sections.
10. Click **Close**.

The section can now be added for use in the Properties - Whole Strucutre dialog (on page 2793) by selecting it in the **User Property Table** dialog.

> Refer to EX. US-17 User-Provided Tables (on page 6443) and EX. UK-17 User-Provided Tables (on page 6730) for examples of angle user-provided tables.

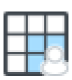
M.To create a double angle user table section

To create a user-provided table section with a double angle profile, use the following procedure.

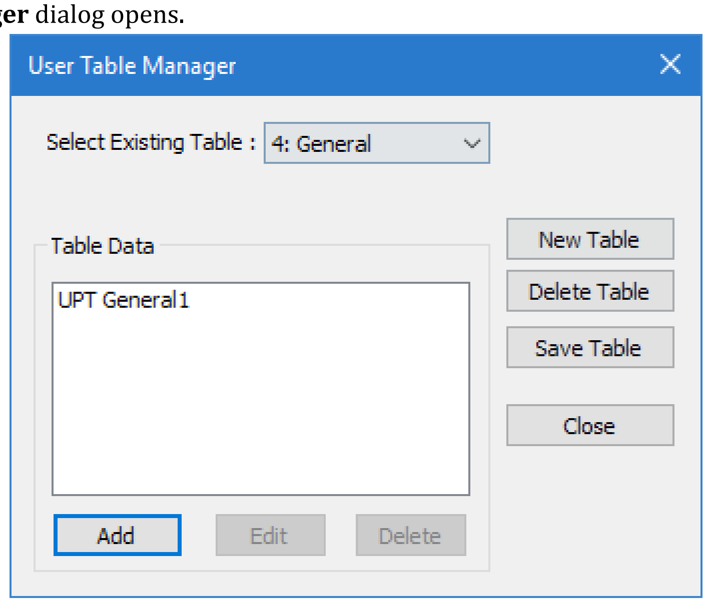
You may want to change the input dimensions prior to creating user provided table sections. Select **Tools** > **Set Current Input Unit** to do so.

1. On the **Specification** ribbon tab, select the **User Table** > **User Table Manager** tool in the **Beam Profiles** group.



If no User Defined Table exists, you will be prompted to create one.

The **User Table Manager** dialog opens.



2. Click **New Table**.
   The **New User Table** dialog opens.
3. the **Select Section Type** list, select **DOUBLE ANGLE** and then click **OK**.
   The dialog closes and the **Table Data** list in the **User Table Manager** dialog now has at least one entry.
4. Click **Add**.
   The **Double Angle** dialog opens.
5. Type a **Section Name**.
6. **Required:** Enter the following angle section parameters:

D	Depth of angle (i.e., length of the leg along the local y-axis)
WF	Width of angle (i.e., length of the leg along the local z-axis)
TF	Thickness of angle leg
SP	Space between angles.

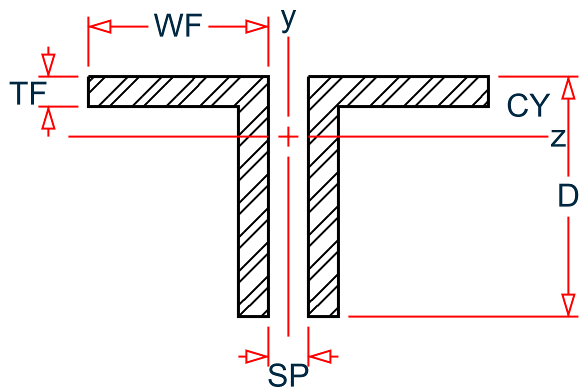


Figure 110: Double angle section

7. Specify the section properties by either:

Options	**Description**
To automatically have the program calculate the section properties...	Click **Calculate**
To manually specify the section properties...	Type values for **Inertia about local z (Iz)**, **Inertia about local y (Iy)**, **Torsional Constant (Ix)**, **C.G. Along local Y (Cy)**, **Shear Area in Y (Ay)**, and **Shear Area in Z (Az)**

8. Specify the Single Angle (rvv) value.
   This is the radius of gyration about the minor principal axis for one of the angles taken as a single angle.
9. Click **OK**.
10. (Optional) Repeat steps 4 through 9 to add more angle sections.
11. Click **Close**.

The section can now be added for use in the Properties - Whole Strucutre dialog (on page 2793) by selecting it in the **User Property Table** dialog.

> Refer to EX. US-17 User-Provided Tables (on page 6443) and EX. UK-17 User-Provided Tables (on page 6730) for examples of angle user-provided tables.

Related Links

- *Double Angle dialog* (on page 2804)

M.To create an I shape user table section

To create a user-provided table section with an I section profile, including those with composite flanges or tapered web depth, use the following procedure.

You may want to change the input dimensions prior to creating user provided table sections. Select **Tools** > **Set Current Input Unit** to do so.

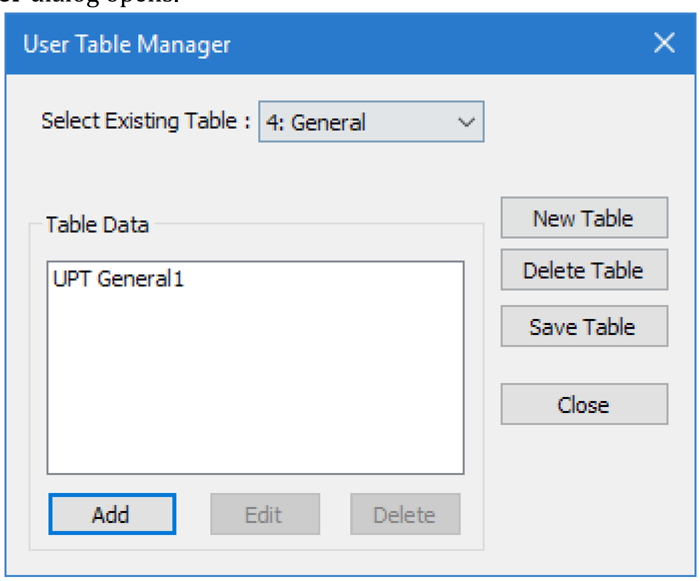
This user-provided section allows you to specify a tapered I-Section with an optional composite top flange. For I sections with a bottom steel plates, you must M.To create a wide-flange user table section (on page 731). Alternatively, you may M. To assign a tapered I section (on page 729) when a non-composite section is required.

1. On the **Specification** ribbon tab, select the **User Table** > **User Table Manager** tool in the **Beam Profiles** group.

   If no User Defined Table exists, you will be prompted to create one.

   The **User Table Manager** dialog opens.

2. Click **New Table**.
   The **New User Table** dialog opens.
3. the **Select Section Type** list, select **ISECTION** and then click **OK.**
   The dialog closes and the **Table Data** list in the **User Table Manager** dialog now has at least one entry.
4. Click **Add.**
   The **ISection** dialog opens.
5. Type a **Section Name.**
6. **Required:** Enter the following wide flange section parameters:

TWW	Thickness of web

TFF	Thickness of top flange
BFF	Width of top flange
TFF1	Thickness of bottom flange
BFF1	Width of bottom flange
Depth at Start Node	The overall depth of the section at the starting node.
Depth at End Node	The overall depth of the section at the ending node. **Note:** This must be less than or equal to the depth at the start node (i.e., the section depth must taper *down* from start to end nodes or remain constant depth).

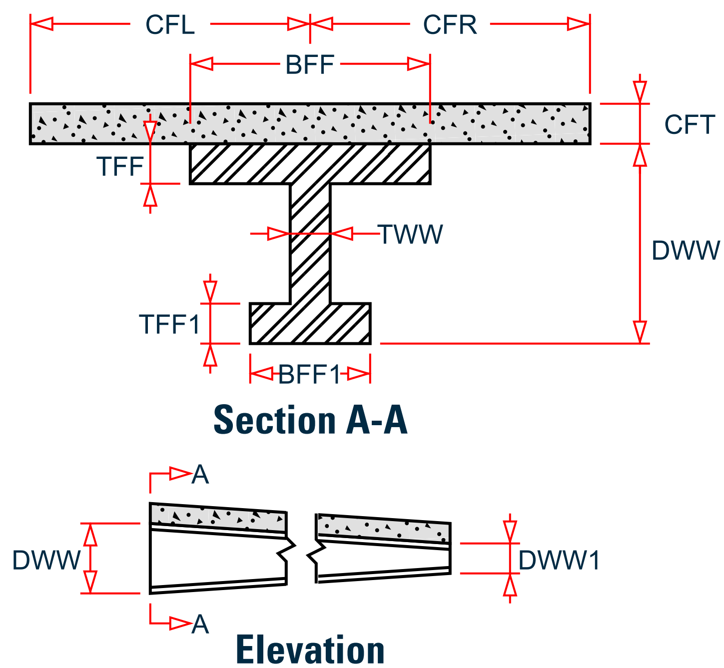


Figure 111: I section and tapered web

7. (Optional) To specify a composite top flange:
   a. Check the **Additional Composite Flange** option.
   The Additional Composite Flange Specifications become active.
   b. Specify the following values:

B(left)	Width of the composite slab to the left of the web center line
B(right)	Thickness of the composite slab
Thickness	Width of the composite slab to the right of the web center line
Modular Ratio	Modular ratio of the concrete in the composite slab with respect to the steel section material

8. (Optional) Specify the section properties **Torsional Constant (Ix)**, **Shear Area in Y (Ay)**, and **Shear Area in Z (Az)**.

If positive values are entered, then those values are used for each of these section properties. If a zero is entered, then the program will calculate these values. If a negative value is used, then the absolute value of each is applied as a factor for that section property.

The remaining section properties are calculated at finite points along the section for use in the analysis.

9. Click **OK**.
10. (Optional) Repeat steps 4 through 9 to add more I sections.

    Tip: The I sections in the same user table can have different options for composite flanges or section depths.

11. Click **Close**.

The section can now be added for use in the Properties - Whole Strucutre dialog (on page 2793) by selecting it in the **User Property Table** dialog.

Related Links

- *TR.19.9 I Section* (on page 2252)
- *I Section dialog* (on page 2808)

M.To create an prismatic user table section

To create a generic user-provided table section providing only cross section properties, use the following procedure.

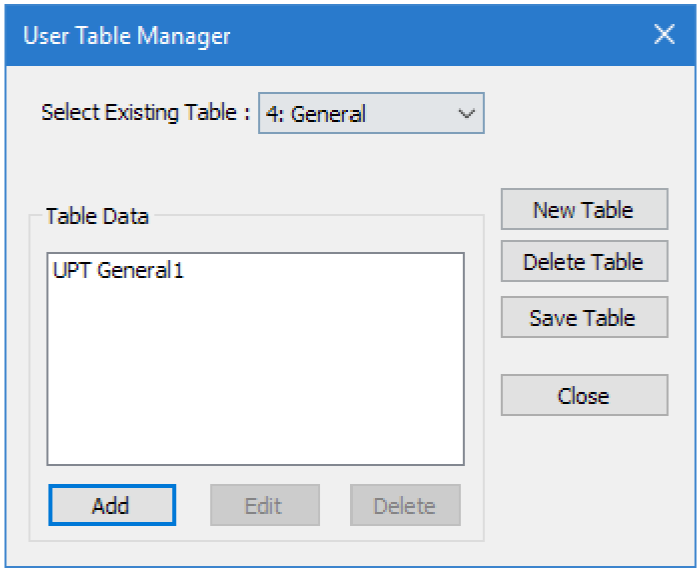
You may want to change the input dimensions prior to creating user provided table sections. Select **Tools** > **Set Current Input Unit** to do so.

This section type is useful when you only have cross-section property values or if the necessary section shape does not classify as any of the other user-provided section types.

1. On the **Specification** ribbon tab, select the **User Table** > **User Table Manager** tool in the **Beam Profiles** group.

   
   If no User Defined Table exists, you will be prompted to create one.

   The **User Table Manager** dialog opens.



2. Click **New Table**.
   The **New User Table** dialog opens.
3. the **Select Section Type** list, select **PRISMATIC** and then click **OK**.
   The dialog closes and the **Table Data** list in the **User Table Manager** dialog now has at least one entry.
4. Click **Add**.
   The **Prismatic** dialog opens.
5. Type a **Section Name**.
6. **Required:** Enter the following angle section parameters:

YD	Depth of the section in the direction of the local y-axis.
ZD	Depth of the section in the direction of the local z-axis

7. Specify the section properties:

Cros Section Area (Ax)	Cross-section area
Inertia about local z (Iz)	Moment of inertia about the local z-axis
Inertia about local y (Iy)	Moment of inertia about the local y-axis
Torstional Constant (Ix)	Torsional constant
Shear Area in Y (Ay)	Shear area for shear parallel to local y-axis.
Shear Area in Z (Az)	Shear area for shear parallel to local z-axis.

8. Click **OK**.
9. (Optional) Repeat steps 4 through 8 to add more prismatic sections.
10. Click **Close**.

The section can now be added for use in the Properties - Whole Strucutre dialog (on page 2793) by selecting it in the **User Property Table** dialog.

> Refer to EX. US-17 User-Provided Tables (on page 6443) and EX. UK-17 User-Provided Tables (on page 6730) for examples of angle user-provided tables.

Related Links

- *TR.19.10 Prismatic* (on page 2253)
- *Prismatic dialog* (on page 2809)

M. To create a general section

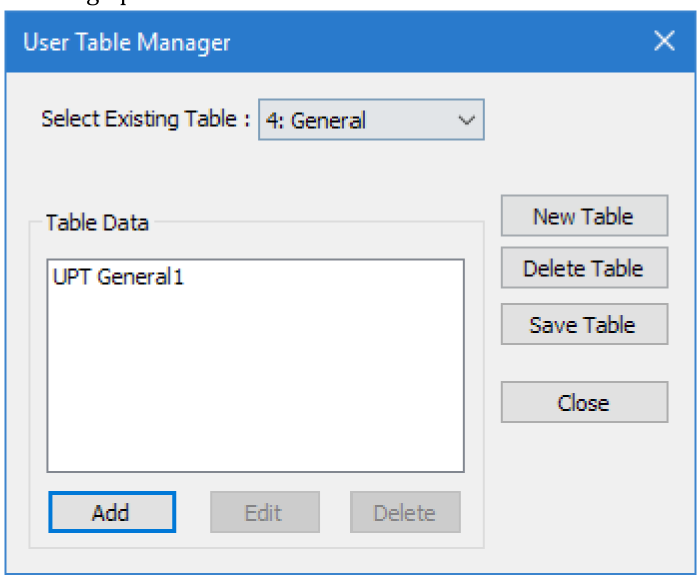
To create a user provided table section with a general profile, use the following steps.

You may want to change the input dimensions prior to creating user provided table sections. Select **Tools** > **Set Current Input Unit** to do so.

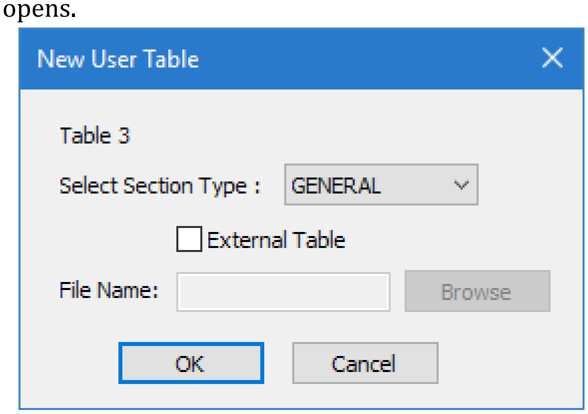
1. On the **Specification** ribbon tab, select the **User Table** > **User Table Manager** tool in the **Beam Profiles** group.

   If no User Defined Table exists, you will be prompted to create one.
   The **User Table Manager** dialog opens.

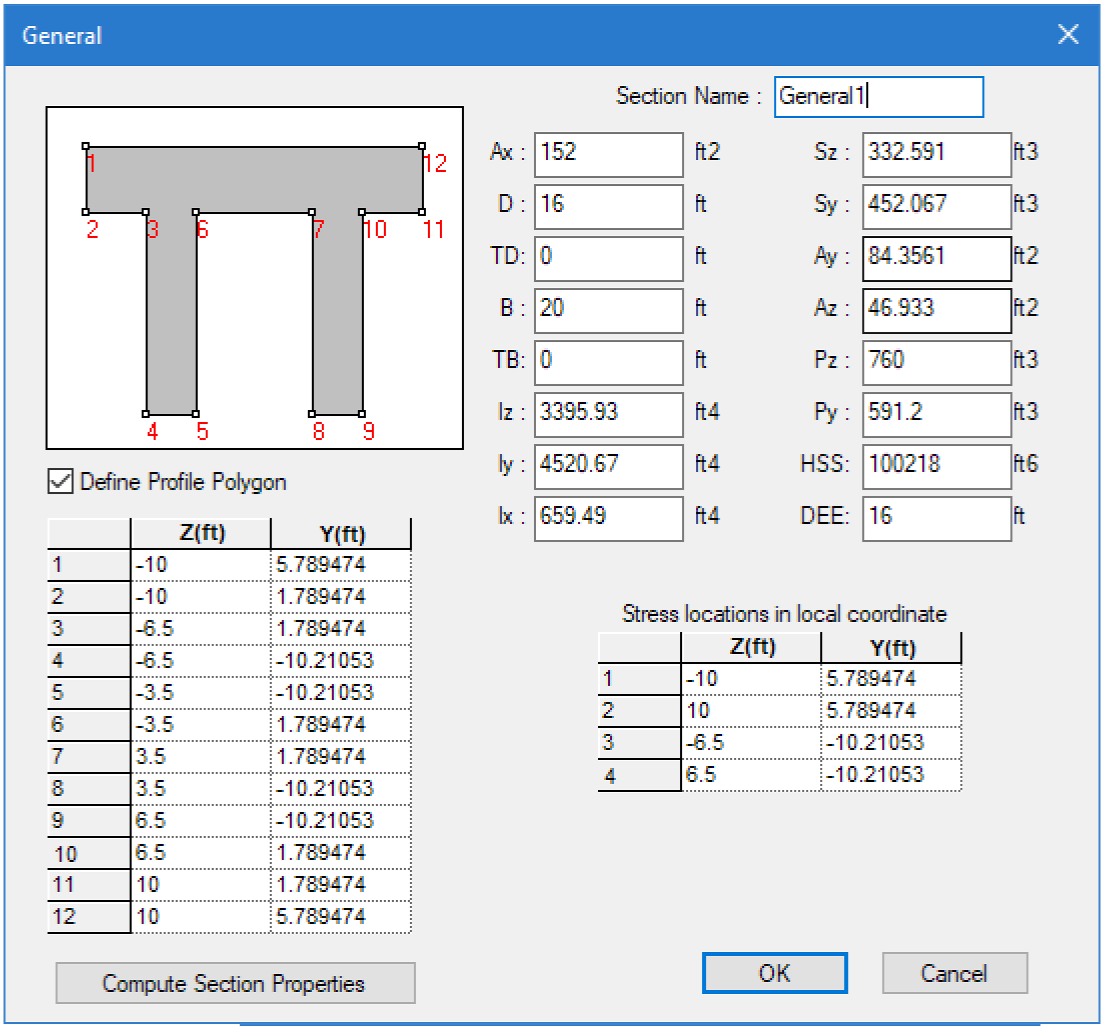
   


2. Click **New Table**.
   The **New User Table** dialog opens.

3. In the **Select Section Type** list, select **GENERAL** and then click **OK**.
   The dialog closes and the **Select Existing Table** list in the **User Table Manager** dialog now has at least one entry.
4. Click **Add**.

   The **General** dialog opens.



5. Type a **Section Name**.
6. Either:

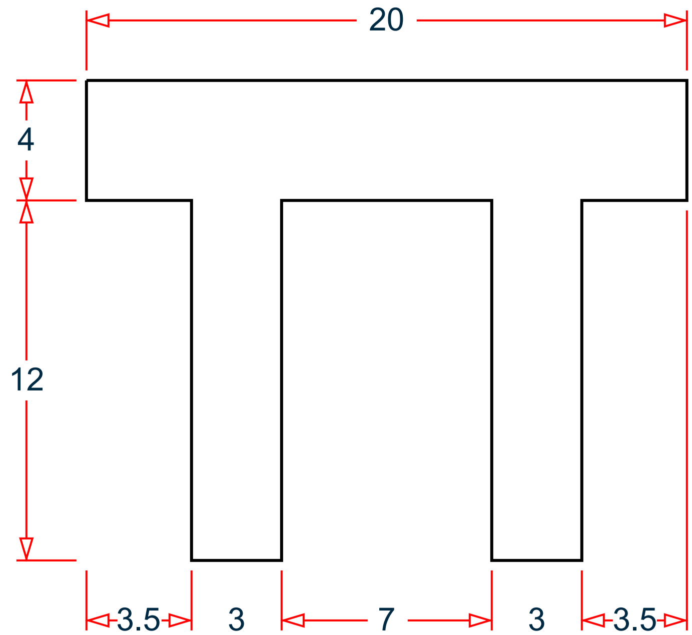
   Type the section properties if these are available in the corresponding fields

   or

   Set the **Define Profile Polygon** and enter in Z,Y coordinates of the section apexes.

Tip: These values may be copied and pasted from a spreadsheet.

The following is an example cross section, with corresponding Z,Y coordinates which can be copy/pasted directly into the table.



Coordinate Number	Z (units)	Y (units)
1	0	0
2	0	-4
3	3.5	-4
4	3.5	-16
5	6.5	-16
6	6.5	-4
7	13.5	-4
8	13.5	-16
9	16.5	-16
10	16.5	-4
11	20	-4
12	20	0

7. (Optional) If you entered in section corner coordinates, click **Compute Section Properties**

   The section properties are calculated and the fields are updated. The coordinates are also updated from an arbitrary origin to the an origin at the center of gravity of the cross section.

Tip: You can manually overwrite any of these values if necessary.

8. (Optional) If you want to have section stress calculated, enter Y,Z coordinates in the **Stress locations in local coordinates**

   Tip: The coordinate locations for stresses should be based on the center of gravity of the section, rather than an arbitrary data point. These may be copied/pasted from the re-centered apex coordinates table.

9. Click **OK**.
   The section is added to the list in the **Create User Property Table** dialog.
10. (Optional) Repeat steps 4 through 9 to add more General sections.
11. Click **Close**.

The section can now be added for use in the Properties - Whole Strucutre dialog (on page 2793) by selecting it in the **User Property Table** dialog.

Example

The example given in 6 above creates the following lines in a STAAD input file:

```
…
TABLE 1
UNIT INCHES KIP

- *User Table Manager dialog* (on page 2798)
- *User Provided Table dialog* (on page 2798)

M. To use a general shape created in Section Wizard

To use a general shape created in Section Wizard as a user provided shape table in STAAD.Pro, doe the following.

You must create a profile outline in Section Wizard and export it as a General Shape (file extension `.upt`) for use in STAAD.Pro. Refer to TR.20.10 Member Property Reduction Factors (on page 2282) for details.

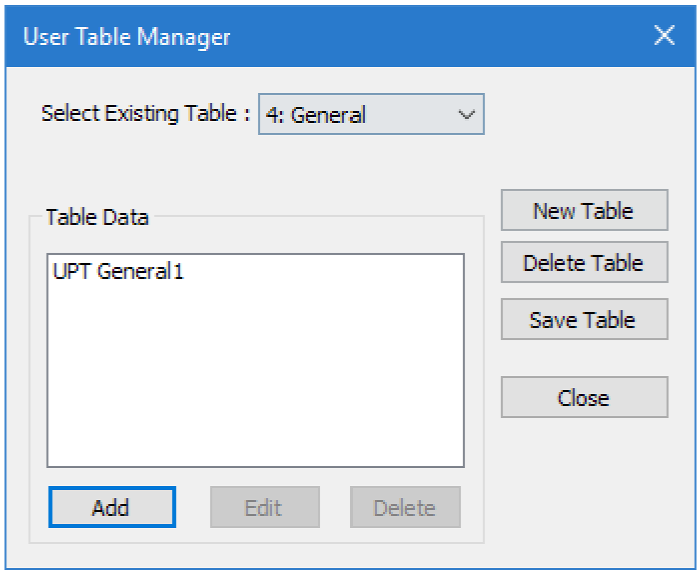
Note: This profile shape should consist of only an outer contour. Any internal voids such as internal contours or openings will be ignored, though section properties calculated by Section Wizard based on sections with voids will be used.

1. On the **Specification** ribbon tab, select the **User Table** > **User Table Manager** tool in the **Beam Profiles** group.

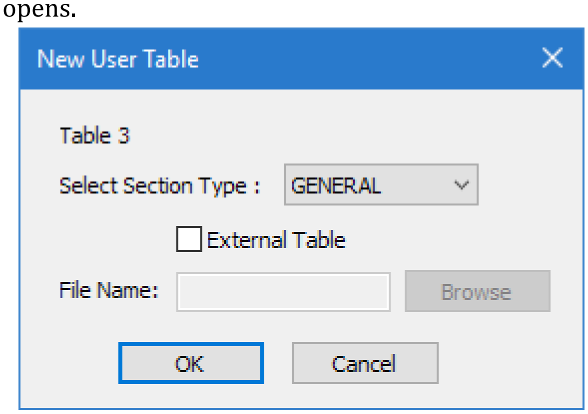
   

   If no User Defined Table exists, you will be prompted to create one.

   The **User Table Manager** dialog opens.

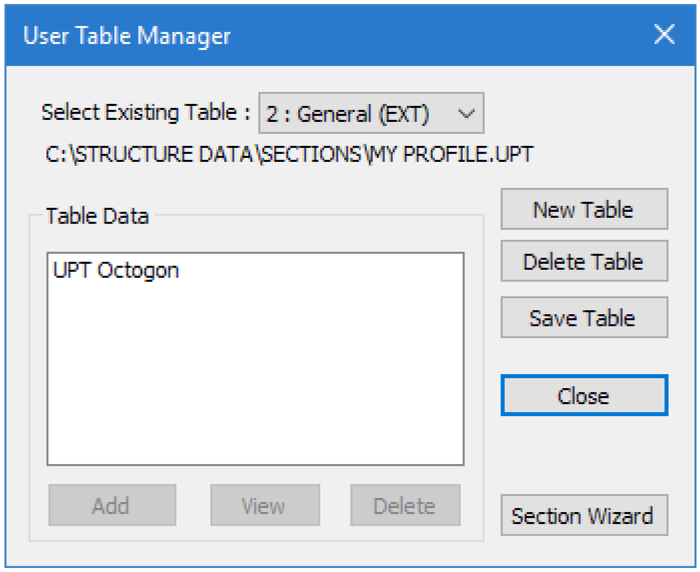
   


2. Click **New Table**.
   The **New User Table** dialog opens.

3. Specify the new external table:
   a. In the **Select Section Type** list, select **GENERAL**.
   b. Check the **External Table** option.
   c. Click **Browse**.
   d. Navigate to and select the `.upt` file exported from Section Wizard and the click **OK**.

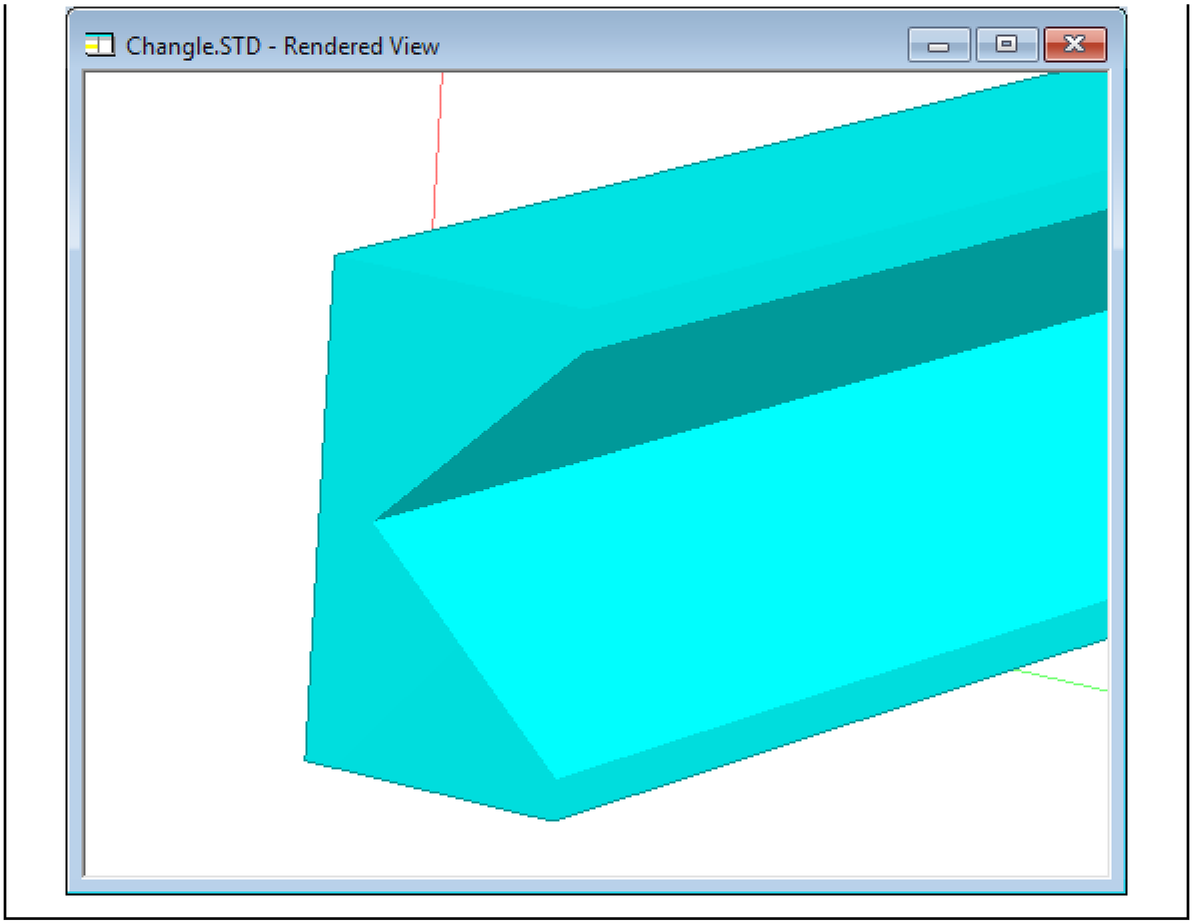
   The dialog closes and the **Table Data** in the **User Table Manager** dialog shows the name of the profile read from the `.upt` file.



4. (Optional) To view the calculated section properties, select the profile entry in the **User Table Manager** dialog and then click **View**.
   The **General** dialog opens.
5. Click **Close**.

The section can now be added for use in the Properties - Whole Strucutre dialog (on page 2793) by selecting it in the **User Property Table** dialog.

> **Tip:** Changing the structure diagram to display 3D rendering types for Full Sections or Sections Outline will display the shape profile. Similarly, 3D renderings of the structure will also display the shape profile.



M. Section Wizard Help

M. To start Section Wizard

Section Wizard consists a set of utility programs used to generate custom sections for use in STAAD.Pro.

1. Open a model in the STAAD.Pro Analytical Modeling workflow.
2. On the **Specifications** ribbon tab, select **Section Wizard** tool in the **Tools** group.

   The **Section Wizard** program opens.

Alternatively, you can locate the file `\SectionWizard\Section.exe` in the folder where STAAD.Pro was installed on your computer.

M. Section Builder

The Section Builder module is used to calculate the properties of sections built up from an arrangement of cross sections taken from a number of standard tables. This module is composed of two windows. The main **Section Builder** window, which displays the composite section along with a number of tools to manipulate the sections and the **Section Element** dialog box which is used to select the sections to be used and method of locating them onto the current overall section.

M. Application Window Layout

The main Section Builder window displays the current composite section. All of the primary commands are activated through the menus along the top of the window. There is also a status bar along the bottom of the window which displays the overall dimensions of the composite section and the location of the cursor when it lies over the main workspace. Additionally a dimension value will be displayed in the status bar by clicking and dragging the mouse across the window.

Sections created in the Section Dialog box can be located onto a composite section relative to the nodes of the 'current section.' A section is made into the current section simply by clicking on it so that it is shown in yellow. Note how the nodes of the current section are identified as potential locating points for the addition of new sections.

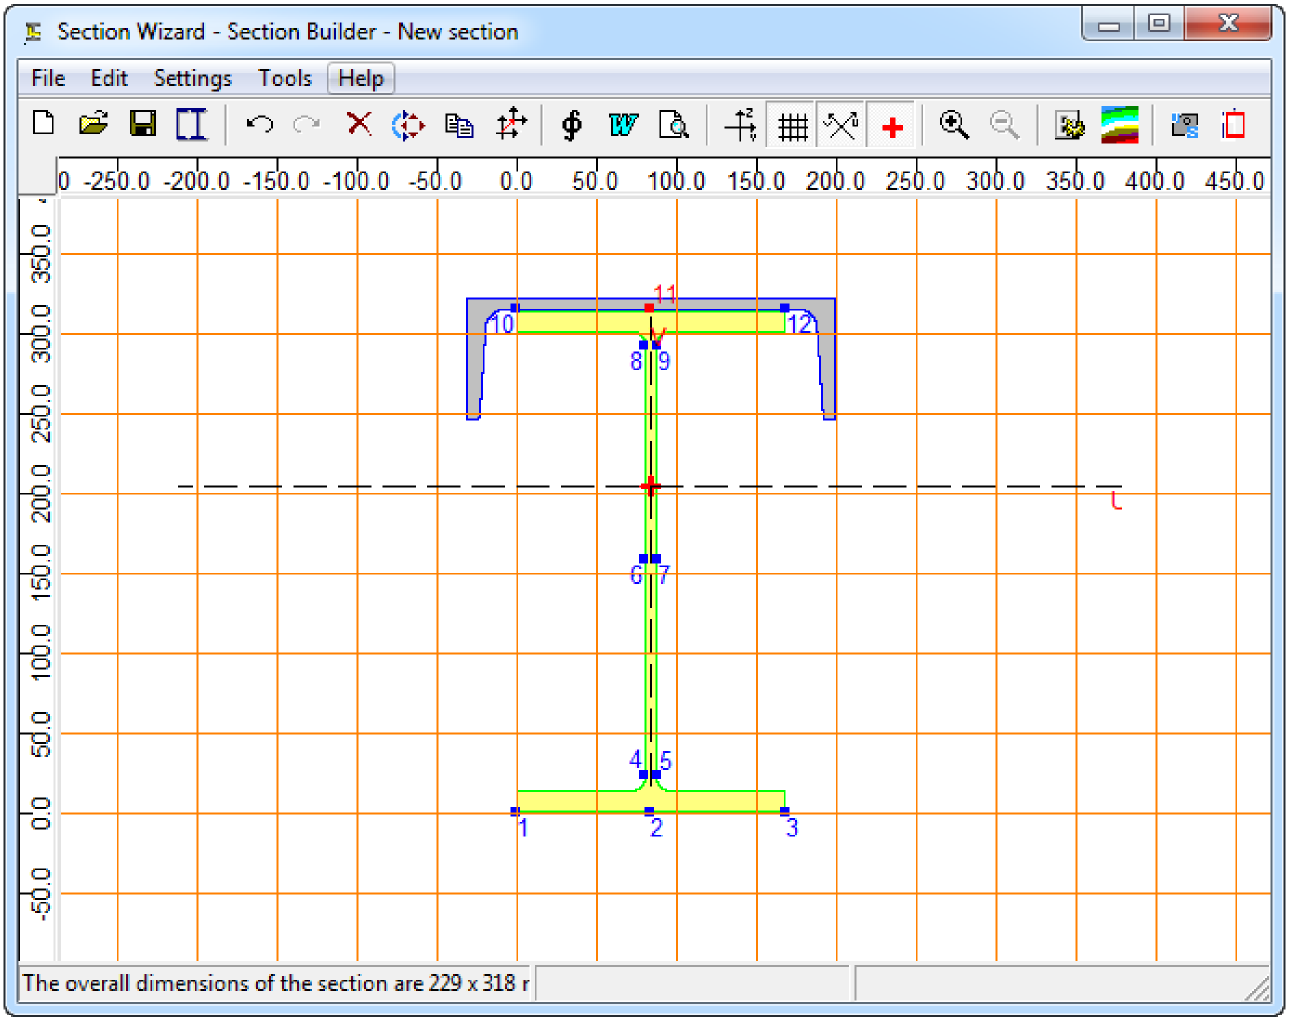


Figure 112: Section Builder module window

Window controls

Menu	
Toolbar	A series of commonly used tools are arranged at the top of the module window.

M. Toolbar
Contains several of the most commonly used tools found in the Section Builder module.

Tool	Description	Shortcut
New		

Tool	Description	Shortcut
Open	Opens the Open Data File dialog, which is used to select either Section Builder (file extension `.SEC`) files or Free Sketch (file extension `.CNS`) files. Controls in this dialog are analogous to a common Windows open dialog, except as noted in the following. If the **Preview** option is selected, then a graphical preview of the section in a selected file is displayed prior to opening the file.	
Save	Opens the Save dialog box if the file has not previously been saved and allows the Equivalent Section, section to be saved. If the file has previously been saved, then that file is updated with the new data. Files are saved in the Section Builder *.SEC format.	
Create Standard Section	Opens the M. Section dialog (on page 768) which is used to quickly generate a composite section based on one of seven options. This is the same option that is available in the Section Builder module.	
Undo	Negates the last drawing operation.	
Redo	Negates the last undo operation.	
Delete		
Shift/Rotate		
Copy		
Shift Coordinate Center		
Calculate Basic Geometry		

Tool	Description	Shortcut
Report	Once an equivalent section has been 'found', the data displayed in the table and a dimensioned drawing will be sent to a report formatted to the Report Type option defined in the Misc sheet of the Program Preferences dialog. See Preferences below.	
Preview		
Show Coordinate Axis	Toggles the display of the coordinate axis in the Section Builder view.	
Show Grid		
Show Principle Axis		
Show Current Center of Gravity		
Zoom In		
Zoom Out		
Preferences	Opens the Preferences dialog.	
Display Normal Stress Field		
Launch Free Sketch module	Launches the M. Free Sketch (on page 769) of Section Wizard and creates section based on the section that was 'found'.	
Launch Equivalent Section module		

M. Menus
Menus in the Section Builder module window.
M. File menu
Contains items for creating, opening, and closing section data files, printing, and exiting the program.

Table 25: File menu items

Menu item	Description	Same effect as selecting…
New	Opens an empty section design file. If the currently loaded section has been modified, then the option is given to save it prior to comencing with the new design.	CTRL+N
Open	Opens the Open Data file dialog, which is used to select an existing Section Data file (file extenstion `.SEC`). If the **Show Drawing** option is checked, then a preview of the section can be displayed prior to opening the file.	CTRL+O
Create Standard Section	Opens the M. Section dialog (on page 768) which is used to quickly generate a composite section based on one of seven options.	
Save	Saves any changes made to the current data file. **Note:** If the current file has not been previously saved, this has the same effect as selecting **Save As...**	CTRL+S
Save As...	Opens the Save data file dialog which is used to specify a file name and location for the section data file.	
Report	Formats and sends the data to the Report Type option defined in the Misc sheet of the Program Options dialog. See Options below.	
Preview	Displays the section as will be drawn in the report. Toggles the display of the Section Element dialog.	
Send...	Opens an e-mail (using your default e-mail client) and attaches the current data file.	

Menu item	Description	Same effect as selecting…
Export to STAAD.Pro >	Select either to export the section as a General or Prismatic section. A Save If an existing User Provide Table file is selected, the current section will be appended to the end of this table. Refer to the STAAD.Pro Technical Reference for additional information on using section types.	
Sections > <list>	A list of the most recent four section data files. Select one to open that data file.	
Exit	Closes the program. If any changes were made since the last time the data file was saved, a message dialog opens confirming you wish to save those changes.	ALT+F4

M. Edit menu

Menu item	Description	Same effect as selecting…
Undo	Negates the last modification performed in the window (for example, shift/rotate a section). You can undo a series of modifications by repeatedly selecting Undo.	
Redo	Negates the last undo modification. You can redo a series of negated modifications by repeatedly selecting Redo.	
Delete	Removes the selected section element from the composite section.	Delete key

Menu item	Description	Same effect as selecting…
Shift, Rotate Element	Opens the Element Shift/Rotation dialog which is used to displace the currently selected section by a relative dimension or rotation about it's basic node. See section Orientation of Elements for the basic node of each section type used by Section Builder.	
Shift Coordinate Center	Opens the M. Shift coordinate center dialog (on page 756) which is used to relocate the origin of the geometric axes relative to the composite section.	
Copy Element	Opens the Copy element dialog which is used to create one or more copies by specified offset dimensions in the Y and Z axes.	

M. Shift coordinate center dialog
Used to relocate the origin of the geometric axes relative to the composite section.

Dialog controls

1. Set it to the current center of gravity
2. Set it to a given node on the current section.
3. Set it to a given node on the current section.

M. Settings menu

Table 26: Settings menu items

Menu item	Description	Same effect as selecting…
Undo		
Redo		
Delete		
Shift, Rotate Element		
Shift Coordinate Center		
Copy Element		

M. Tools menu

Table 27: Tools menu items

Menu item	Description	Same effect as selecting…
Calculate	Calculates the cross-sectional properties of the composite section and the opens the Basic Geometry dialog to display the values.	
Stress Contour	Opens the Section forces dialog, which is used to specify major axis moments and axial force on the section. Click OK to close the dialog and display the stress distribution on the composite section.	
Free Sketch	Opens the M. Free Sketch (on page 769).	
Equivalent Section	Opens the M. Equivalent Section module (on page 763).	
Windows Calculator	Opens the Windows system Calculator window.	
Formula Calculator	Opens the M. Formula Calculation window (on page 790) which is used to evaluate a formula, from the numerical result can then be copied back into the Section Builder program.	
Unit Converter	Opens the Unit Converter Window which is used to as a value converter between different preset units of measurement. Select the tab pertaining to the type of measurement and then enter the known value in the appropriate field. Upon pressing **<Enter>**, all the other fields are updated to equivalent values.	

M. Help menu
The Help menu contains items for using online help.

Table 28: Help menu items

Menu item	Description	Same effect as selecting…
Help Topics	Opens the Section Builder help window.	F1
About	Opens the About Section Builder window, which displays version and copyright information.	

M. Orientation of Elements

Table 29: Standard element shapes and their default orientation and base nodes

Profile Type	Section	Base Node #	Nodes
Angles	Equal Leg Angle	1	
Profile Type	Section	Base Node #	Nodes
	Unequal Leg Angle	1	I Sections	I Sections with Tapered Flanges	10	
Profile Type	Section	Base Node #	Nodes
	I Sections with Parallel Flanges	10	Channels	Parallel Flanged Channels	1	
Profile Type	Section	Base Node #	Nodes
	Tapered Flange Channels	1		Cold Rolled Channels	1	
Profile Type	Section	Base Node #	Nodes
CHS	Circular Hollow Sections	1	Plate	Plate Sections	1	Tee Section	T Sections with Parallel Flanges		
Profile Type	Section	Base Node #	Nodes
	T Sections with Tapered Flanges	1	RHS	Rectangular Hollow Section	1	
M. Equivalent Section module

This module is used to find a best fit solution from the table of values of area, inertia, and elastic moduli. The data can either be entered directly into the table, or generated from the Section Builder or Free Sketch modules, or from the Standard Section toolbar command.

Section Types

The Equivalent Section module then finds the best fit on one of the following section types:

1. I Section, with independent dimensions for the top and bottom flanges
2. Rectangular Hollow Section, with separate dimensions for the side walls and the top and bottom flanges
3. I Section, with the same sizes for the top and bottom flanges
4. Rectangular Hollow Section, with the same thickness for the flanges and the side walls

5. Channel Section

Each of the values can be weighted for importance by setting a bias for that value. The larger the bias, the more the program will attempt to match that value rather than any of the others.

M. Application Window Layout

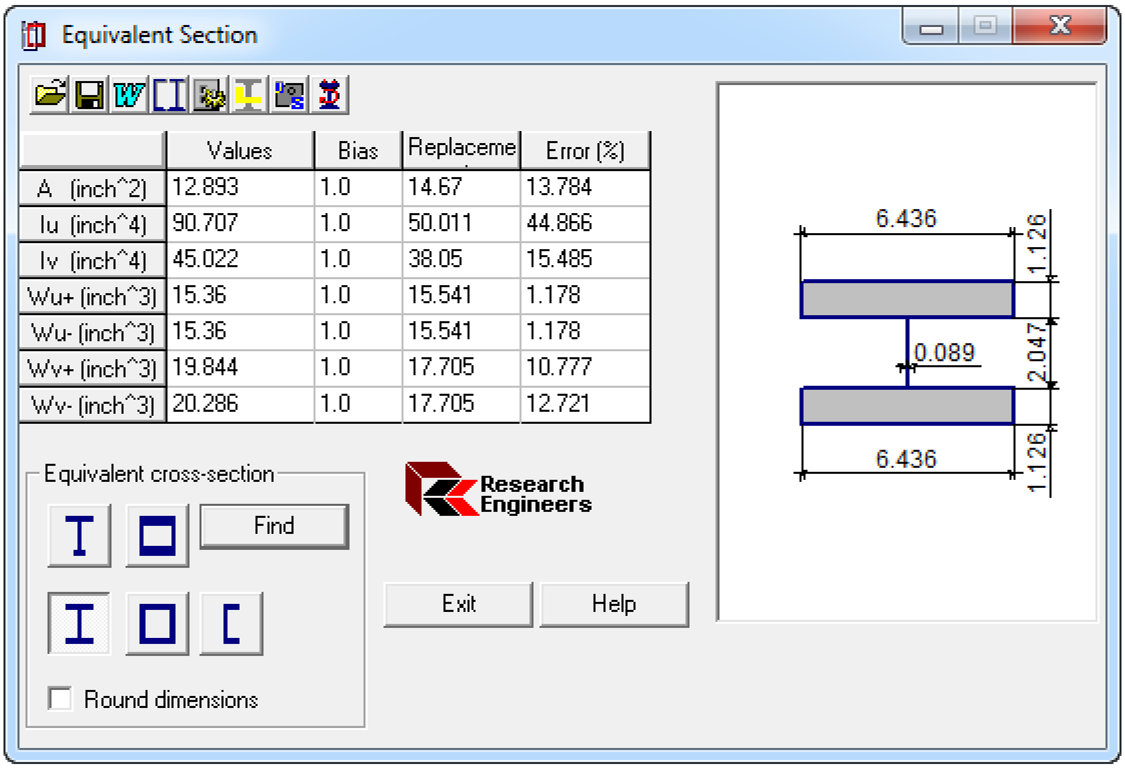

Figure 113: Equivalent Section module window

Window controls

Toolbar	A series of commonly used tools are arranged at the top of the module window.
Properties table	A list of the reference property values and bias values are entered here to provide data for the cross-section search. Once the Find button is clicked, a set of associate Replacement values and the percent Error will also be displayed, along with a graphical representation of the found equivalent section dimensions.
Equivalent cross-setion	A group of controls are arranged here depicting general cross-section types. The currently selected type is shown as depressed.
Find	Click to perform a search for an equivalent cross-section based on the specified section Values, weighted per the specified Bias values.
Round dimensions	Select this option to have the search use rounded dimensional values. If a search has already been performed, then the current dimension results are rounded.
Exit	Closes the module. Any unsaved data will be lost.
Help	Opens the Section Wizard help window to display the relevant help topic.

Views panels A graphical representation of a section as well as dimensions of the recommended section from a Find action are displayed in the right-hand side of the window.

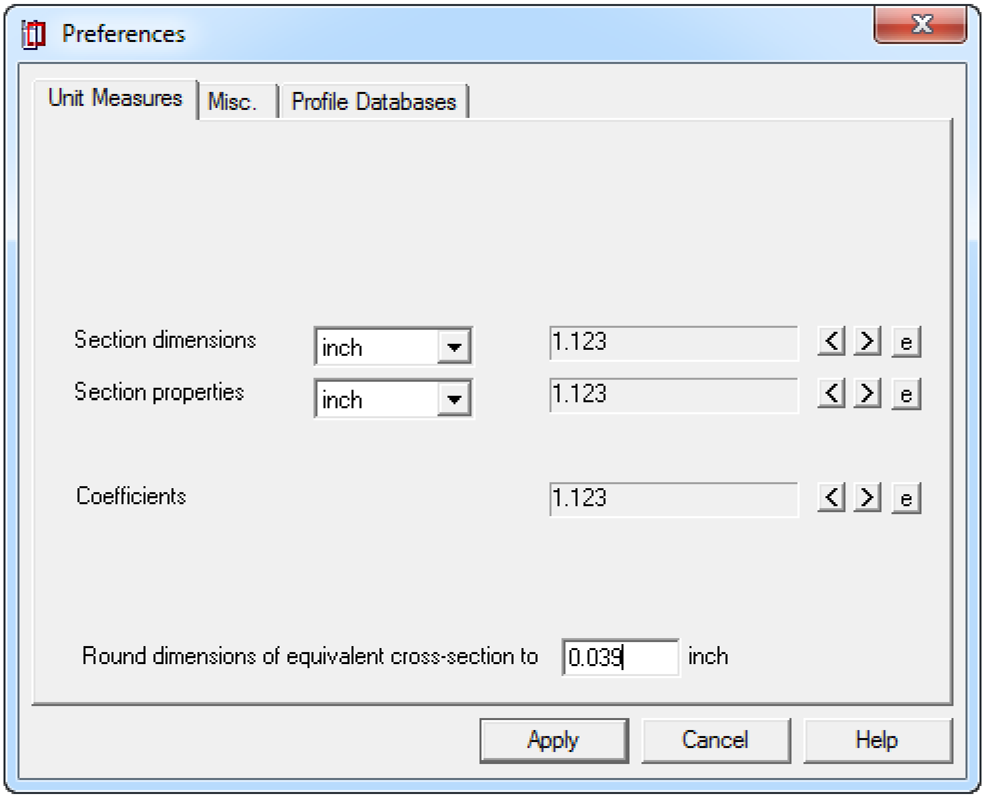
M. Toolbar
A list of tools found in Equivalent Section.

Tool	Description	Shortcut
Open	Opens the Open Data File dialog, which is used to select either Section Builder (file extension `.SEC`) files or Free Sketch (file extension `.CNS`) files. Controls in this dialog are analogous to a common Windows open dialog, except as noted in the following. If the **Preview** option is selected, then a graphical preview of the section in a selected file is displayed prior to opening the file.	
Save	Opens the Save dialog box if the file has not previously been saved and allows the Equivalent Section, section to be saved. If the file has previously been saved, then that file is updated with the new data. Files are saved in the Section Builder *.SEC format.	
Report	Once an equivalent section has been 'found', the data displayed in the table and a dimensioned drawing will be sent to a report formatted to the Report Type option defined in the Misc sheet of the Program Preferences dialog. See Preferences below.	
Create Standard Section	Opens the M. Section dialog (on page 768) which is used to quickly generate a composite section based on one of seven options. This is the same option that is available in the Section Builder module.	
Preferences	Opens the Preferences dialog.	

Tool	Description	Shortcut
Launch Section Builder module	Launches the Section Builder module of Section Wizard and creates section based on the section that was 'found'	
Launch Free Sketch module	Launches the M. Free Sketch (on page 769) of Section Wizard and creates section based on the section that was 'found'.	
Export STAAD User Database	This allows the current section data to be used to create STAAD External User tables. There are two types of database that can be created , either a Prismatic Section or a General Section. Selecting either command will ask for a name of file to be used. If the filename chosen exists already, then the current section will be added to the bottom of the file.	

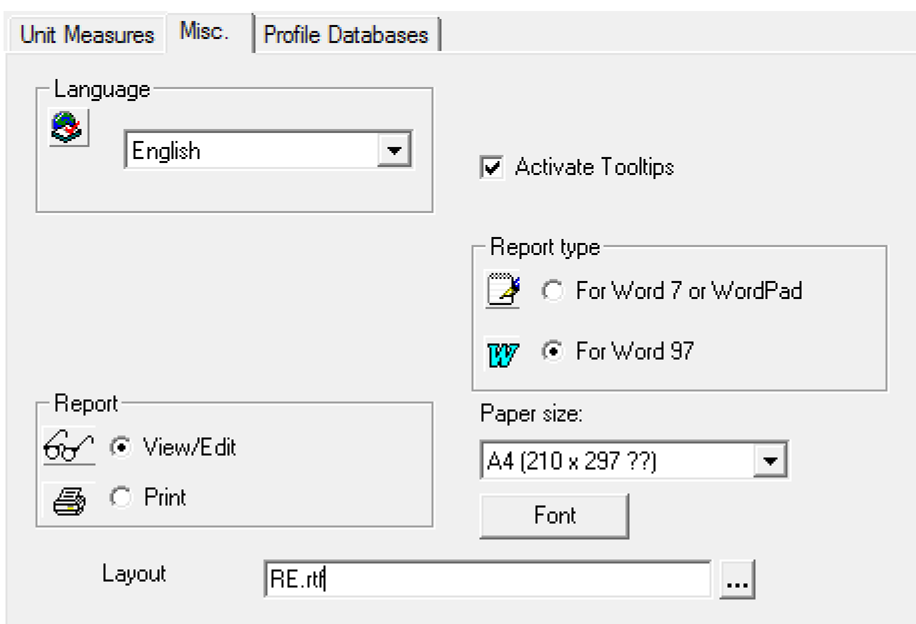
M. Preferences dialog
Used to set preferences for the Equivalent Section module.

Units Measures tab



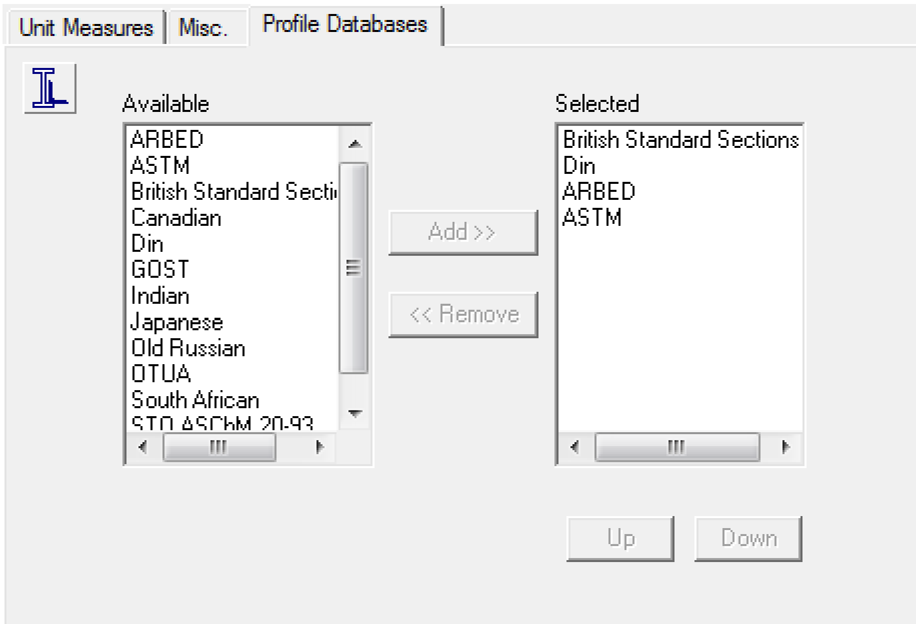
Select the units for angles, section dimensions, section properties, axial forces and moments, as well as the number of decimal places and whether or not to use an exponential form.

Misc. tab



Select the language, Report settings such as the template document, whether the documents should use Word 7 or Word 97 file formats, the paper size and font. Set whether documents should be sent direct to the printer or into Word for editing. Additional options determine the number of vertices to created by a circle, option to snap to grid and whether the ends of vertices are indicated by a circle or not.

Profile Databases tab



Select the range of databases that are referred to by the program. See Appendix 2: Section Databases for a current list of available database sections.

Other Controls

These controls are displayed at the bottom of the dialog for all tabs.

Apply	Saves any changes made in the dialog.
Cancel	Closes the dialog without saving any changes.
Help	Opens the Section Wizard help window to the relevant topic.

M. Section dialog

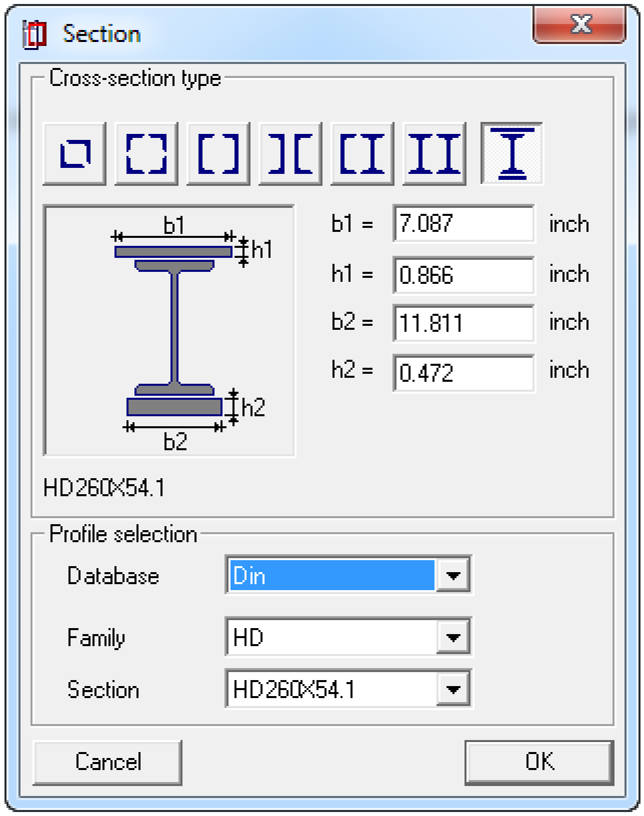


Figure 114: the Section dialog

Dialog controls

Section type selectors

Cover Plate dimensions (For I-sections with cover plates only) These fields become active when the I-section with cover plate type is selected. Specify values for **b1** and **h1** (width and thickness of top cover plate, respectively) as well as **b2** and **h2** (width and thickness of bottom cover plate, respectively).

Database

Family

Section

Cancel

OK

M. Free Sketch

Used to create sections with an outer boundary of any shape with a number of internal openings if required.

Free Sketch data files can saved in either one of two formats. `<filename>.CNS` is a binary file format which is the most compact and preferred way to store files. Alternatively, files can be stored as `<filename>.CON`, stores the file in an ASCII format which can be opened and edited by any text editor, such as Windows Notepad.

M. To set up the drawing environment

The scope of the section is determined by first setting the overall dimensions of the workspace to extend to (at least) the maximum dimensions of the section that is to be considered. A grid is then placed within this workspace, which if selected in the options, can be snapped to in order to accurately locate the coordinates of the boundary nodes.

1. Select either:

   Edit > **Overall dimensions**

   or

   the **Overall dimensions** tool 

   The **Overall dimensions** dialog opens
2. Type the maximum width and height of your section.

   Tip: This can be edited later by repeating this procedure.
3. Click **OK**.
   The section axis is displayed.
4. To set up a grid, do the following:
   a. Select either:

      Settings > **Grid options**

      or

      the **Grid step** tool 
      The **Grid parameters** dialog opens.
   b. Type the **Y** and **Z** direction grid increments.
   c. (Optional) Type an **Angle** used to orient the grid.

      The angle is measured positive counter-clockwise from the Y axis.
   d. Click **OK**.
5. To display the grid, select either:

   Settings > **Grid**

   or

   the **Grid** tool 
   The grid is displayed and the tool is depressed on the toolbar and in the menu.
6. To snap points to the grid, select **Settings** > **Snap to grid**.

   Note: This tool is on by default when the grid is displayed.

M. To draw an external contour

Used to define the outside of the section shape.

Only one closed shape may be used to define a cross section.

1. Select either

   Edit > **Draw External Contour**

   or

   the **External Contour** tool 
2. Click any point in the View window as the first vertex of the exterior of the shape.
   A line is rubber-banded between this point and the mouse pointer.
3. Click subsequent points to form additional vertices.

   Tip: You may right-click to undo a previous vertex.
4. Double click the final point once you have formed a closed geometric shape.

   The final point does not need to be a previously entered data point. The rubber band to the first point will give you a preview of what the shape will look like for any point in the View window.

   The shape is shaded solid.
5. Exit the external contour drawing mode by either

   repeating step one

   or

   select some other drawing mode

M. To draw an internal contour

Used to define the openings or negative spaces within the cross section shape.

Inner contours must be closed shapes. Inner contour areas or vertices may not overlap.

1. Select either

   Edit > **Draw Internal Contour**

   or

   the **Internal Contour** tool 
2. Click any point in the View window as the first vertex of the inner contour.
   A line is rubber-banded between this point and the mouse pointer.
3. Click subsequent points to form additional vertices.

   Tip: You may right-click to undo a previous vertex.
4. Double click the final point once you have formed a closed geometric shape.

   The final point does not need to be a previously entered data point. The rubber band to the first point will give you a preview of what the shape will look like for any point in the View window.

   The shading inside of the shape is removed.
5. Exit the internal contour drawing mode by either

   repeating step one

   or

   select some other drawing mode

M. To round a corner

Uses this procedure to round –also referred to as fillet– interior or exterior contour corners.

1. Select either

   Edit > **Radius Corner…**

   or

   the **Smooth** tool 
2. Select any interior or exterior contour vertex.

   Tip: When hovering over a vertex, the mouse pointer changes to a double-line cross-hair ().

   The Smooth Radius dialog opens.
3. Type a radius value, **R**, and click **OK**.
   The previously specified radius is the default value.
   The corner is redrawn as a series of points forming an arc with the specified radius.
4. Exit the radius drawing mode by either

   repeating step one

   or

   selecting some other drawing mode

M. To insert a round opening

Use the following procedure to insert a round hole by one of two means.

A hole is an interior contour which is parametrically defined with a center and radius. You may specify a radius by an exact value or by drawing in the View window, depending on your tool selection.

1. Select either

   the **Circle hole** tool 

   or

   the **Circle hole with specified radius** tool 
   If you selected to specify a radius, the Radius of the circle hole dialog opens.
2. If you selected to specify a radius, enter the value and click OK in the Radius of the circle hole dialog.
3. Click a point to define the center of the circular hole.
   If you are defining the radius graphically, a circle is rubber-banded to the mouse pointer. Otherwise, the hole is drawn with the previously specified radius.
4. Double click a point to define a radius.
   The hole is drawn.
5. Exit the hole drawing mode by either

   repeating your selection in step one

   or

selecting some other drawing mode

M. To copy an internal contour

Use this procedure to make a copy of any internal contour or hole.

Inner contours must be previously specified for the tools used to be active.

Inner contours can be placed anywhere within the external contour.

1. Select either

   Edit > **Copy inner contour**

   or

   the **Copy inner contour(s)** tool 2. From there, select either to use a **Rectangle** or **Polygon** window method for performing a selection.
   Depending on the window method selected, the mouse pointer either changes to a rectangular selection icon () or a polygonal selection icon ().
3. Click an initial point outside of the inner contour(s) you wish to copy.
   Depending on the window method selected, either a rectangle (rectangular) or a single line (polygon) is rubber banded to your mouse pointer.
4. Select the next point based on the following:

   For a rectangle, select the opposite corner of the rectangular window enclosing all of the inner contours you wish to copy.

   or

   For a polygon, click the next vertex along the polygon defining the outer edge of the window are. Repeat this step until the contours you wish to copy are enclosed, double-clicking the last point to close the polygon.
5. Specify a location of the copy by either

   Clicking anywhere within the windowed area and dragging the copy to where you wish to place it. Your mouse pointer becomes a multi-arrow icon () to indicate this option.

   or

   Right-click to open the **Copy of contour(s)** dialog which is used to specify **Y** and **Z** offsets. Click **OK** to place the copy at this location.
   Copies inner contours or their vertices may not overlap with other inner contours.

M. To delete vertices

Use this procedure to remove the vertices of external or internal contours.

1. Select either

   Edit > **Delete vertices**

   or

   the **Delete vertices** tool 

2. From there, select one of the following methods for vertex selection:

   Single

   or

   Rectangle

   or

   Polygon

   The mouse pointer updates to reflect the selection method.
3. Select either:

   a single vertex to delete; the mouse pointer changes to a double-line cross-hair ()

   or

   one corner of a rectangle window; the mouse pointer changes to a rectangular selection icon ()

   or

   the first vertex of a polygon window; the mouse pointer changes to a polygonal selection icon ()

   A single point selection is deleted and the shape is redrawn connecting the adjacent points. Once one or more vertices are enclosed in a completed rectangle or polygon window area, then those vertices are deleted and the adjacent vertices to those are connected.

M. To delete an opening

Use this procedure to delete an interior contour or hole from the shape.

Inner contours must be previously specified for the tools used to be active.

1. Select either

   Edit > **Delete internal contour**

   or

   the **Delete** tool 
2. Click anywhere inside the contour or hole you want to remove.
   The internal contour is removed from the shape.
3. Exit the delete contour mode by either:

   repeating step one

   or

   selecting some other drawing mode

M. To shift the coordinate center

Use this procedure to shift the coordinate center to any arbitrary point or to the center of gravity.

1. Select **Edit** > **Coordinate Center**
   The **Coordinate Center** dialog opens.

2. Specify a new coordinate center by either

   specifying both **Y** and **Z** shift values and click **Apply**

   or

   click **Shift** to specify the current shape center of gravity.

   Note: The origin must remain within the overall dimensions of the workspace.

   The coordinate origin shifts to the specified location.

M. To import a CAD drawing

This procedure is used to import a 2D CAD, closed area as a section profile. This allows you to use the CAD program of your choice to generate complex cross sections.

The following AutoCAD® entity types are supported in the import facility:

3DFACE
SOLID
TRACE
LINE
POLYLINE
LWPOLYLINE
ELLIPSE
CIRCLE
ARC

1. Select **File** > **Import DXF**
   The Import dialog opens.
2. Navigate to and select the `.dxf` file which you want to import.

   Note: The files that are to be imported are such that all the vertices are in a single plane and form closed areas.

3. Click **Open**.

To export shape for use in STAAD.Pro

To export the shape profile for use in STAAD.Pro as a user-provided table, do the following.

Note: This profile shape should consist of only an outer contour. Any internal voids such as internal contours or openings will be ignored, though section properties calculated by Section Wizard based on sections with voids will be used.

1. Select **File** > **Export to STAAD.Pro** > **General Section**.
   A **Save As** dialog opens.
2. Navigate to where you want to save the file, type a file name, and then click **Save**.
   The **User Table Units** dialog opens.
3. Select the unit of length for use with this shape and then click **OK**.
   The **General** shape dialog opens.
4. Type the **Section Name** for use in the STAAD.Pro user provided table.

5. (Optional) Type in any override values for section properties you want to use instead of those calculated by Section Wizard.

The shape vertices and calculated section properties are saved to the `.upt` file.

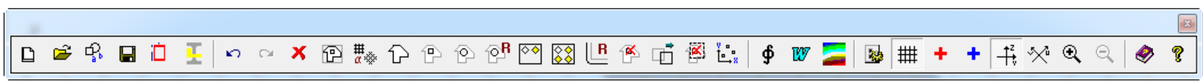
You can use this file as an external file for a user-provided section. Refer to M. To use a general shape created in Section Wizard (on page 746).

M. Application Window Layout

Drawing Window

Left click selects a data point. Double click to accept. Right click to void last data point or current action (same as selecting the **Cancel operation** tool).

M. Toolbar
Contains several of the most commonly used tools found in the Free Sketch module.



Tool	Description	Same effect as selecting ...
 **New**	Opens an empty section design file. If the currently loaded section has been modified, then the option is given to save it prior to commencing with the new design.	**File** > **New**
 **Open**	Opens the Open Data file dialog, which is used to select an existing Section Sketch Data file (file extension `.cns`). Controls in this dialog are analogous to a common Windows open dialog, except as noted in the following. If the **Preview** option is checked, then a preview of the section can be displayed prior to opening the file.	**File** > **Open ...**
 **Parametric Section**	Opens the Parametric Section dialog which is used to quickly create sections based on a section type and a number of key dimensions and insert that section as an external contour.	**File** > **Parametric Sections ...**

Tool	Description	Same effect as selecting ...
Save	Saves any changes made to the current data file. **Note:** If the current file has not been previously saved, this has the same effect as selecting **Save As...**	**File** > **Save**
Find Equivalent Section	Opens the M. Equivalent Section module (on page 763) with the current section properties as input values, which can be used to search for an Equivalent section to the current drawing.	**File** > **Equivalent Section ...**
Section Builder	Launches the M. Section Builder (on page 750).	
Undo	Negates the last drawing operation. You can undo a series of modifications by repeatedly selecting Undo.	**Edit** > **Undo**
Redo	Negates the last undo modification. You can redo a series of negated modifications by repeatedly selecting Redo.	**Edit** > **Redo**
Cancel Operation	Cancels the current drawing operation.	ESC
Overall Dimensions	Opens the Overall Dimensions dialog, which is used to specify the size of the workspace that will be required to create the section. The minimum it should be set to is the overall dimensions of the section but can be set larger.	**Edit** > **Overall Dimensions ...**
Grid Setup	Opens the Grid Parameters dialog, which is used to specify the grid spacing along the **Y** and **Z** directions and the Angle of rotation of the grid axes.	**Settings** > **Grid Options ...**

Tool	Description	Same effect as selecting ...
 **External Contour**	Used to set or clear the external contour drawing mode, which defines the outside of the section.	**Edit** > **Draw External Contour**
 **Internal Contour**	Used to set or clear the internal contour mode, which is used for creating internal openings within an external boundary.	**Edit** > **Draw Internal Contour**
 **Circle hole**	Used to set or clear the circular hole drawing mode, which is used to define the center of a hole (e.g., a parametrically defined, circular inner contour) and radius graphically.	**Edit** > **Insert circular hole, center and radius**
 **Circle hole with specified radius**	Insert circular hole with defined radius	**Edit** > **Insert circular hole with defined radius**
 **Copy inner contour(s)**	Used to window either a rectangle or polygonal area to select one or more internal contours for copying. Copies can be placed manually or by specifying offset distances.	**Edit** > **Copy inner contour**
 **Multiple copies of inner contour(s)**	Used to window either a rectangle or polygon area to select one or more internal contours making multiple copying. Copies can be placed manually or by specifying offset distances and a number of copies.	**Edit** > **Multiple copy of inner contour**
 **Smooth**	Used to set or clear the smooth corner drawing mode, which is used to select a corner to fillet and then opens the Smooth radius dialog to specify a radius value for the rounded corner.	**Edit** > **Radius Corner...**
 **Delete**	Used to set or clear the delete internal contour drawing mode, which is used to remove internal contours by clicking anywhere in their boundary.	**Edit** > **Delete internal contour**

Tool	Description	Same effect as selecting ...
Move Vertices	Used to window either a rectangular or polygonal area to select one or more vertices to move. Vertices can be moved either manually or by specifying offset distances.	**Edit** > **Move vertices**
Delete Vertices	Used to select a single vertex or window either a rectangular or polygonal area to select one or more vertices for deletion.	**Edit** > **Delete vertices**
Edit coordinates of Vertices	Displays all vertex numbers in the View window and opens the Coordinates dialog which is used to specify precise coordinates of each vertex for a selected contour.	**Edit** > **Edit vertices**
Calculation	First opens the Poisson's Ratio dialog which is used to specify a value for **Nu**. Calculates the cross-sectional properties of the composite section and the opens the Basic Geometry dialog to display the values.	**File** > **Calculation**
Report	Formats and sends the data to the Report Type option defined in the Misc sheet of the Program Options dialog. See Options below.	**File** > **Report**
Stress Field	Opens the Section forces dialog, which is used to specify major axis moments and axial force on the section. Click OK to close the dialog and display the stress distribution on the section drawing.	**File** > **Stress field**
Options	Opens the Preferences dialog, which is used to set the units, colors, output types, and databases for standard sections.	**Settings** > **Preferences ...**
Grid	Used to set or clear the display of the drawing grid in the View window.	**Settings** > **Grid**

Tool	Description	Same effect as selecting …
Center of Gravity	Used to set or clear the icon that shows the location of the center of gravity.	**Settings** > **Center of Gravity**
Shear Center	Used to set or clear the icon that shows the location of the shear center.	**Settings** > **Shear Center**
Show Coordinate Axis	Used to set or clear the display of the coordinate axis.	**Settings** > **Coordinate Axis**
Principle Axes	Used to set or clear the display of the principle axis of the current cross section.	**Settings** > **Principle Axis**
Zoom In	Used to increase the magnification in the View window.	**Settings** > **Zoom In**
Zoom Out	Used to decrease the magnification in the View window.	**Settings** > **Zoom Out**
Help	Opens the Section Builder help window.	**Help** > **Help Topics**
About	Opens the About Section Builder window, which displays version and copyright information.	**Help** > **About ...**

M. Menus
Menus in the Section Builder module window.
M. File menu
Contains items for creating, opening, and closing section data files, printing, and exiting the program.

Table 30: File menu items

Menu item	Description	Same effect as selecting…
New	Opens an empty section design file. If the currently loaded section has been modified, then the option is given to save it prior to commencing with the new design.	CTRL+N
Open	Opens the Open Data file dialog, which is used to select an existing Section Sketch Data file (file extension `.cns`). Controls in this dialog are analogous to a common Windows open dialog, except as noted in the following. If the **Preview** option is checked, then a preview of the section can be displayed prior to opening the file.	**<CTRL+O>**
Save	Saves any changes made to the current data file. **Note:** If the current file has not been previously saved, this has the same effect as selecting **Save As...**	**<CTRL+S>**
Save As…	Opens the Save data file dialog which is used to specify a file name and location for the section data file. Files are saved in the Free Sketch (`.CNS`) format.	
Close	This closes the current section and leaves Free Sketch ready to start a new file or open an existing file.	
Report	Formats and sends the data to the Report Type option defined in the Misc sheet of the Program Options dialog. See Options below.	

Menu item	Description	Same effect as selecting…
Calculation	First opens the Poisson's Ratio dialog which is used to specify a value for **Nu**. Calculates the cross-sectional properties of the composite section and the opens the Basic Geometry dialog to display the values.	
Stress Field	Opens the Section forces dialog, which is used to specify major axis moments and axial force on the section. Click OK to close the dialog and display the stress distribution on the section drawing.	
Parametric Sections…	Opens the Parametric Section dialog which is used to quickly create sections based on a section type and a number of key dimensions and insert that section as an external contour.	
Rolled Section…	Opens the Rolled Section dialog, which is used to select a catalog section to insert into an new drawing file. The section can then be modified, just as you would with any other sketch.	
Equivalent Section…	Opens the M. Equivalent Section module (on page 763) with the current section properties as input values, which can be used to search for an Equivalent section to the current drawing.	
Export to STAAD.Pro >	Select either to export the section as a General or Prismatic section. A Save If an existing User Provide Table file is selected, the current section will be appended to the end of this table. Refer to the STAAD.Pro Technical Reference for additional information on using section types.	

Menu item	Description	Same effect as selecting…
Import DXF	Opens a File Open dialog which is used to select CAD files to import in the *.DXF file format	
Send…	Opens an e-mail (using your default e-mail client) and attaches the current data file.	
Recent File list	A list of the most recent four section data files. Select one to open that data file.	
Exit	Closes the program. If any changes were made since the last time the data file was saved, a message dialog opens confirming you wish to save those changes.	**<ALT+F4>**

M. Parametric Sections dialog
Used to to quickly create sections based on a section type and a number of key dimensions and insert that section as an external contour.

Opens when **File** > **Parametric Sections ...** is selected.

Dialog controls

section type selector Select the general section type that you wish to use from the graphical list. The list contains 22 different generic section types. The parameters and diagram update according to the selection.

	Symbol	Section Type
1		Angle
2		Rectangle
3		Rounded Rectangle
4		Triangle
5		Six Side Polygon (Hexagon)
6		Eight Side Polygon (Octagon)

	Symbol	Section Type
7		Rectangular Hollow Section
8		Rounded Rectangular Hollow Section
9		Channel
10		Rounded Channel
11		Flanged Rectangular Hollow Section
12		Unsymmetric I Section
13		Rounded Symmetric I Section
14		Rounded Tee Section
15		Double Tee Section
16		Wedge
17		Z Section
18		Cruciform
19		Circle
20		Hollow Pipe
21		Half Pipe
22		Ellipse

section parameters	Fields for each of the section dimenions for the selected section type are displayed. Enter a dimension into each field (each section has at least one required dimension). Refer to the diagram for the selected section type for an explination of each field.
OK	Closes the dialog and adds an external contour with defined parametric section.
Cancel	Closes the dialog and returns to the previous sketch file.

M. Rolled Section dialog
Used to select a catalog section to insert into an new drawing file. The section can then be modified, just as you would with any other sketch.

Opens when **File** > **Rolled Sections ...** is selected.

Dialog controls

catalog lists	Catalog sections are listed in a tree format by Country/Standard, shape type, and section size. Expand the tree to locate the section you wish to add and select its entry.
OK	Closes the dialog and adds an external contour with selected catalog section.
Cancel	Closes the dialog and returns to the previous sketch file.

M. Edit menu
Contains items for

Table 31: Edit menu items

Menu item	Description	Same effect as selecting…
Undo	Negates the last drawing operation. You can undo a series of modifications by repeatedly selecting Undo.	CTRL+Z
Redo	Negates the last undo modification. You can redo a series of negated modifications by repeatedly selecting Redo.	CTRL+Y
Overall Dimensions ...	Opens the Overall Dimensions dialog, which is used to specify the size of the workspace that will be required to create the section. The minimum it should be set to is the overall dimensions of the section but can be set larger.	
Draw external contour	Used to set or clear the external contour drawing mode, which defines the outside of the section.	

Menu item	Description	Same effect as selecting…
Locate circular external contour	Opens the Radius of the external contour dialog, which is used to specify a radius value for a parametrically defined, circular external contour. **Note:** This menu item is only active if no other external contour has been defined.	
Draw internal contour	Used to set or clear the internal contour mode, which is used for creating internal openings within an external boundary.	
Copy inner contour > <list>	Used to window either a rectangle or polygonal area to select one or more internal contours for copying. Copies can be placed manually or by specifying offset distances.	
Multiple copy of inner contour > <list>	Used to window either a rectangle or polygon area to select one or more internal contours making multiple copying. Copies can be placed manually or by specifying offset distances and a number of copies.	
Delete internal contour	Used to set or clear the delete internal contour drawing mode, which is used to remove internal contours by clicking anywhere in their boundary.	
Insert circular hole, center, and radius	Used to set or clear the circular hole drawing mode, which is used to define the center of a hole (e.g., a parametrically defined, circular inner contour) and radius graphically.	
Insert circular hole with defined radius	Used to set or clear the circular hole with defined radius drawing mode, which is used to define the center of a hole graphically and then specify an exact radius.	

Menu item	Description	Same effect as selecting…
Parametric hole …	Opens the Parametric holes dialog, which is used to define the location and dimensions of either a circular or rectangular inner contour.	
Radius corner …	Used to set or clear the smooth corner drawing mode, which is used to select a corner to fillet and then opens the Smooth radius dialog to specify a radius value for the rounded corner.	
Move vertices	Used to window either a rectangular or polygonal area to select one or more vertices to move. Vertices can be moved either manually or by specifying offset distances.	
Edit vertices	Displays all vertex numbers in the View window and opens the Coordinates dialog which is used to specify precise coordinates of each vertex for a selected contour.	
Delete vertices	Used to select a single vertex or window either a rectangular or polygonal area to select one or more vertices for deletion.	
Coordinate center …	Opens the Coordinate Center dialog, which is used to specify shift the global coordinates to either an arbitrary location or to the center of gravity of the shape.	

M. Settings menu
Contains items for controlling non-element specific settings as well as the behavior and display of the drawing environment.

Table 32: Settings menu items

Menu item	Description	Shortcut
Preferences …	Opens the Preferences dialog, which is used to set the units, colors, output types, and databases for standard sections.	

Menu item	Description	Shortcut
Grid Options ...	Opens the Grid Parameters dialog, which is used to specify the grid spacing along the **Y** and **Z** directions and the Angle of rotation of the grid axes.	
Grid	Used to set or clear the display of the drawing grid in the View window.	
Snap to grid	Used to set or clear the snap to grid behavior, which provides drawing assistance by selecting the nearest grid point to a selected point in the View window.	
Snap to vertices	Used to set or clear the snap to vertices behavior, which provides drawing assistance by selecting the nearest vertex point to selected in the View window.	
Center of Gravity	Used to set or clear the icon that shows the location of the center of gravity.	
Shear Center	Used to set or clear the icon that shows the location of the shear center.	
Coordinate Axis	Used to set or clear the display of the coordinate axis.	
Principle Axis	Used to set or clear the display of the principle axis of the current cross section.	
Zoom In	Used to increase the magnification in the View window.	
Zoom Out	Used to decrease the magnification in the View window.	

M. Preferences dialog
Used to set the units, colors, output types, and databases for standard sections.

Opens when **Settings** > **Preferences ...** is selected.

Units of measurement tab

Select the units for angles, section dimensions, section properties, axial forces and moments, as well as the number of decimal places and whether or not to use an exponential form.

Misc. tab

Select the language, Report settings such as the template document, whether the documents should use Word 7 or Word 97 file formats, the paper size and font. Set whether documents should be sent direct to the printer or into Word for editing. Additional options determine the number of vertices to created by a circle, option to snap to grid and whether the ends of vertices are indicated by a circle or not.

Stress scale tab

Used to set the colors of the maximum compression and tension stresses and the colour these grade to for zero stress, along with the number of bands to be displayed

Profile databases tab

M. Grid Parameters dialog
Used to specify the grid spacing along the **Y** and **Z** directions and the Angle of rotation of the grid axes.

Opens when **Settings** > **Grid Options ...** is selected.

Dialog controls

Y	Grid spacing along the section local y axis (horizontal on screen).
Z	Grid spacing along the section local z axis (vertical on screen).
Angle	Angle from the coordinate axis to the grid lines, taken counterclockwise. Accepted values range between zero (inclusive) and 90 degrees. Negative values are not accepted. Only the drawing grid is rotated; no section data is changed.
OK	Saves changes and closes the dialog.
Cancel	Closes the dialog without saving any changes.

M. Service menu
Contains items for opening tools and utilities related to the Free Sketch module.

Table 33: Service menu items

Menu item	Description
Windows Calculator ...	Opens the Windows system Calculator window.
Formula Calculator ...	Opens the M. Formula Calculation window (on page 790) which is used to evaluate a formula, from the numerical result can then be copied back into the Free Sketch module.
Unit Converter ...	Opens the **Unit Converter** Window which is used to as a value converter between different preset units of measurement. Select the tab pertaining to the type of measurement and then enter the known value in the appropriate field. Upon pressing **<Enter>**, all the other fields are updated to equivalent values.

Menu item	Description
Section Builder ...	Launches the M. Section Builder (on page 750).

M. Help menu
The Help menu contains items for using online help.

Table 34: Help menu items

Menu item	Description	Shortcut
Help Topics	Opens the Section Builder help window.	F1
About	Opens the About Section Builder window, which displays version and copyright information.	

M. Formula Calculation window

Used for holding evaluations under the formulas, which are set by the user in the window of lead

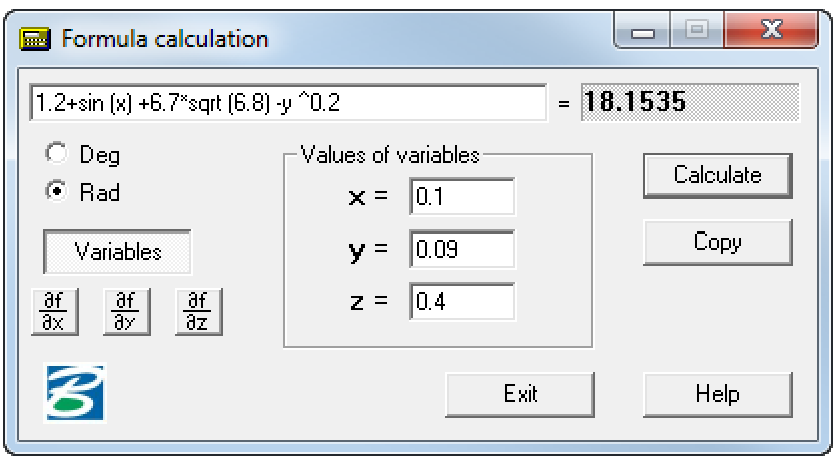


Figure 115: Formula calculation window

Formula Syntax

At lead of the formulas it is necessary to observe the following rules:

- the names of functions are entered by lower case letters of the Latin alphabet;
- a separator of fractional and whole parts of number is the point;
- the arithmetical operations are set by characters +, -, *, /, exponentiation ^ (for example, `2.5*2.5*2.5` is typed as `2.5 ^ 3`).

Supported Functions

At record of the formulas it is possible to use the following functions:

floor - the greatest integer not exceeding preset
tan - a tangent
sin - sine
cos - cosine
asin - an arcsine
acos - an arccosine
atan - an arctangent
exp - an exponential curve
ceil - the least integer exceeding preset
tanh - a tangent hyperbolic
sinh - sine hyperbolic
cosh - cosine hyperbolic
log - a Napierian logarithm
log10 - a Brigg's logarithm
abs - an absolute value
sqrt - the radical square

Depending on a state of the switch Degrees / radians, arguments trigonometrically functions (sin, cos, tan) and the outcomes return trigonometrically functions (asin, acos, atan) are reduced in degrees or radians accordingly.

Usage only of parenthesizes is admitted at arbitrary depth of an enclosure.

Examples

The formula:

$$1.2 + \sin(0.43) + 6.7\sqrt{6.8} - \sqrt[5]{0.003}$$

is typed as follows:

```
1.2+sin (0.43) +6.7*sqrt (6.8) -0.003 ^ 0.2
```

Click **Variable** and then the **x**, **y**, and **z** fields become active. Thus values of variables are set in appropriate windows of lead. It allows to carry out a series of one-type evaluations at different values of parameters. For example, in this condition the following formula

$$1.2 + \sin(x) + 6.7\sqrt{6.8} - \sqrt[5]{y}$$

is typed as follows:

```
1.2+sin (x) +6.7*sqrt (6.8) -y ^ 0.2
```

Then click **Calculate** to have the program resolve the variables into the formula.

Click **Copy** to copy the result to the Windows clipboard.

Moreover, the program allows to input some symbolic expression (depending on the variables x,y,z); click $\frac{\partial \mathbf{f}}{\partial \mathbf{x}}$, $\frac{\partial \mathbf{f}}{\partial \mathbf{y}}$, or $\frac{\partial \mathbf{f}}{\partial \mathbf{z}}$ and retrieve symbolic expression for the corresponding partial derivative.

M. Unit Converter

This is a utility program used to convert measurements from a known units of measurement into several different units.

The dialog includes several tabs, each corresponding to a type of measurement.

Length
Area
Volume
Force
Angle
Pressure
Moment of Couple

To convert units

1. Select the tab with the type of measurement you want to convert.
2. Type the known value in the field with the known units.
3. Press **<Enter>**. The value is converted in each field with different units on this tab.

Tip: You can double-click in a field to quickly select the contents. Right-click and then select **Copy** from the pop-up menu to save this value to the Windows clipboard.

Click **Exit** when you are finished converting values.

M. Materials and Constants

You can use material definitions or assign individual material constant values to beams, plates, and solids.

Note: Material definitions are recommended for most models.

M. To create a material definition

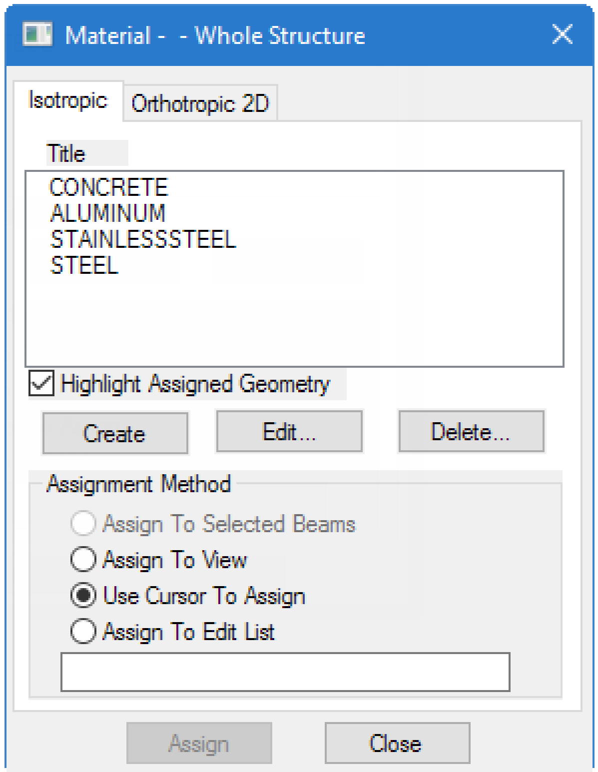
To create a new isotropic material definition for use with your model, use the following procedure.

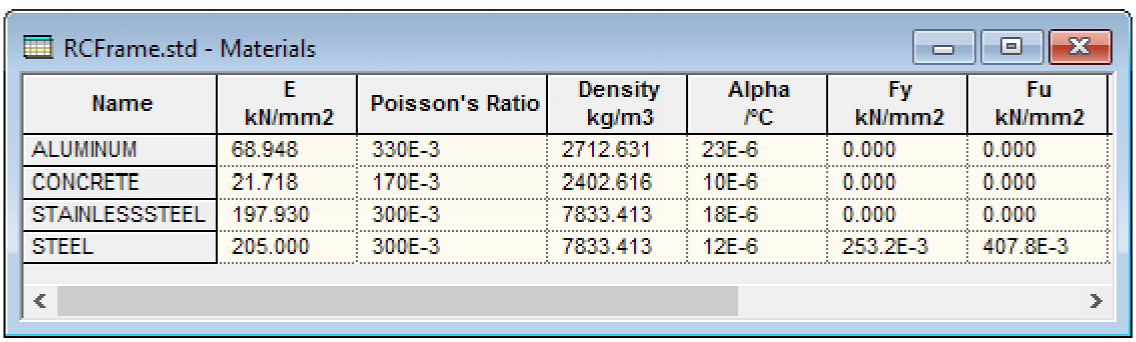
You may want to set the input units to a familiar set of units for defining materials before creating a new material definition.

STAAD.Pro includes a set of predefined materials for concrete, aluminum, steel, and stainless steel.

1. Select the **Materials** page in the **Analytical Modeling** page control bar.

   The **Material - Whole Structure** dialog and the **Materials** table open.



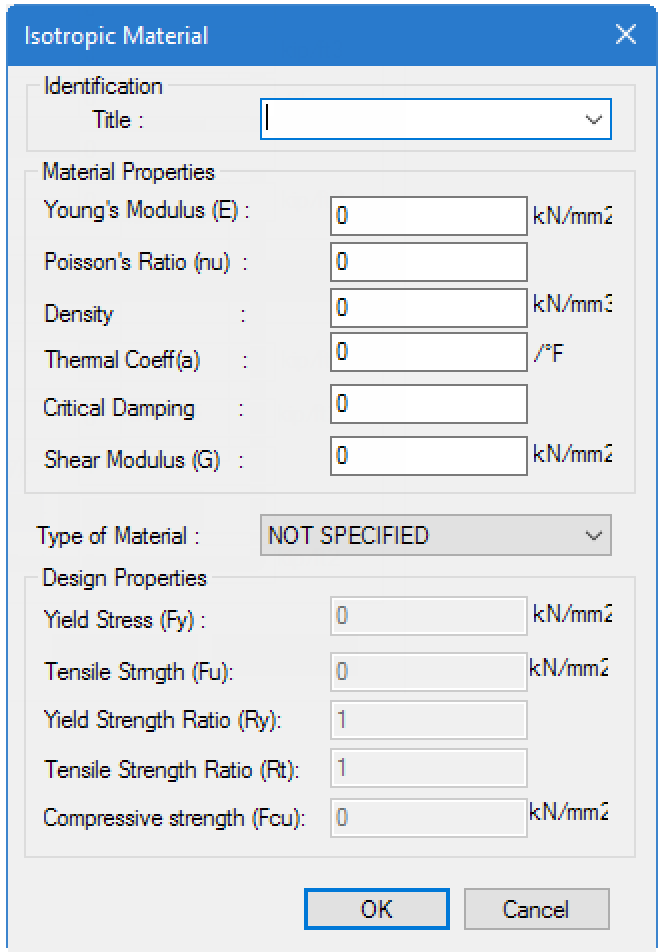


RCFrame.std - Materials

Name	E kN/mm2	Poisson's Ratio	Density kg/m3	Alpha /°C	Fy kN/mm2	Fu kN/mm2
ALUMINUM	68.948	330E-3	2712.631	23E-6	0.000	0.000
CONCRETE	21.718	170E-3	2402.616	10E-6	0.000	0.000
STAINLESSSTEEL	197.930	300E-3	7833.413	18E-6	0.000	0.000
STEEL	205.000	300E-3	7833.413	12E-6	253.2E-3	407.8E-3

2. In the **Material - Whole Structure** dialog **Isotropic** tab, click **Create**.

   The **Isotropic Material** dialog opens.



3. Type a **Title** to identify the material.

   This title must be different than the predefined material names or any other existing user-defined material name.
4. Type the values of the Material Properties used for analysis:

   Young's Modulus, E
   Poisson's Ratio, ν
   Density, γ
   Thermal Coefficient, α
   Critical Damping
   Shear Modulus, G
5. Select the **Type of Material** from the drop-down list.
6. Type the strength values in the **Design Properties** section.

   The fields corresponding to the selected material type are active.
7. Click **OK**.

The material definition is now added to the **Materials** table and is available for selecting when assigning shapes and in **Material - Whole Structure** dialog.

Related Links

- *TR.26.1 Define Material* (on page 2303)

- *Isotropic Material dialog* (on page 2821)

M. To add a predefined material

To add a predefined material definition, use the following procedure.

The program ships with a macro which reads predefined material data from a spreadsheet file and can be used to quickly add standard AISC and CSA steel material grades to your model.

Note: You can edit the data file `MaterialSpreadsheet.csv` (typically installed in `C:\Program Files\Bentley\Engineering\STAAD.Pro CONNECT Edition\STAAD\PlugIns\VBS\`) listed in the dialog to add more material values.

1. On the **Utilities** ribbon tab, select the **User Tools** > **Add Material** tool in the **Developer** group.

   The **Add Materials** dialog opens.
2. Select a material name and grade combination in the list.
3. Click **Add Material**.
   The material name is added to the **Material - Whole Structure** dialog.
4. (Optional) Repeat steps 2 and 3 to add additional materials.
5. Click **Cancel** to close the dialog.

M. To create an orthotropic material

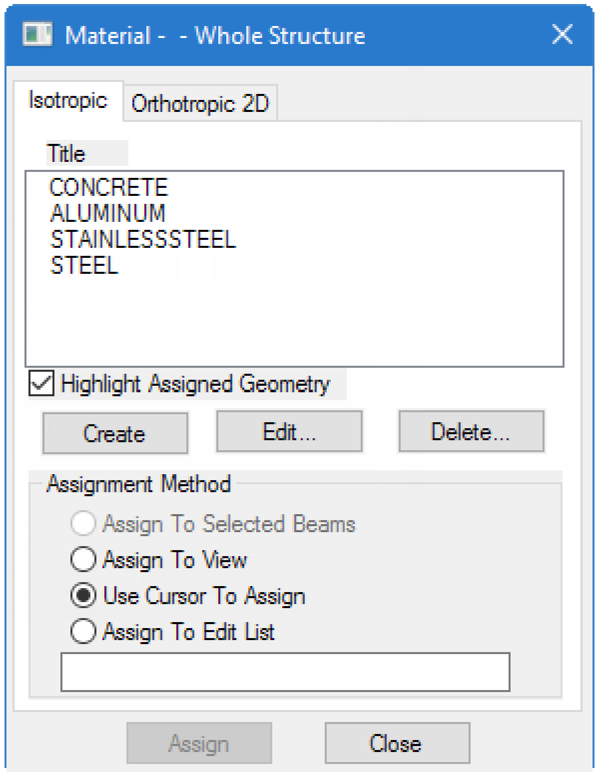
To create a 2D orthotropic material definition for use with orthotropic plate elements, use the following procedure.

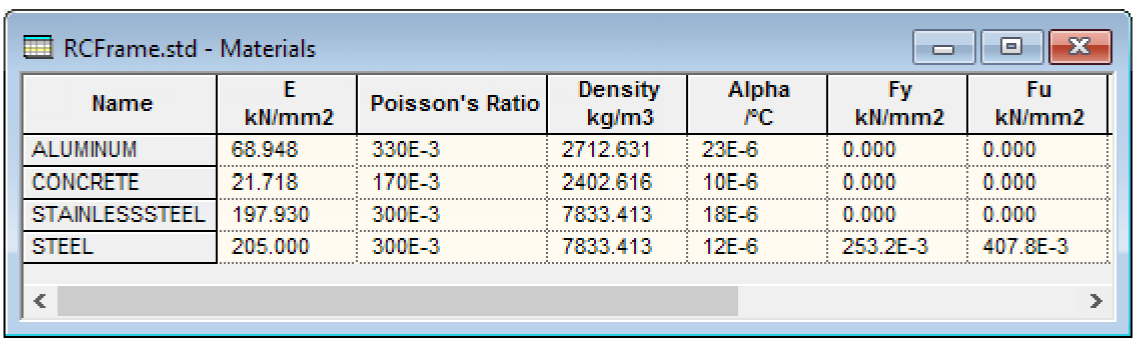
You may want to set the input units to a familiar set of units for defining materials before creating a new material definition.

Note: 2D othrotropic material definitions are for use with plate elements only.

1. Select the **Materials** page in the **Analytical Modeling** page control bar.

   The **Material - Whole Structure** dialog and the **Materials** table open.

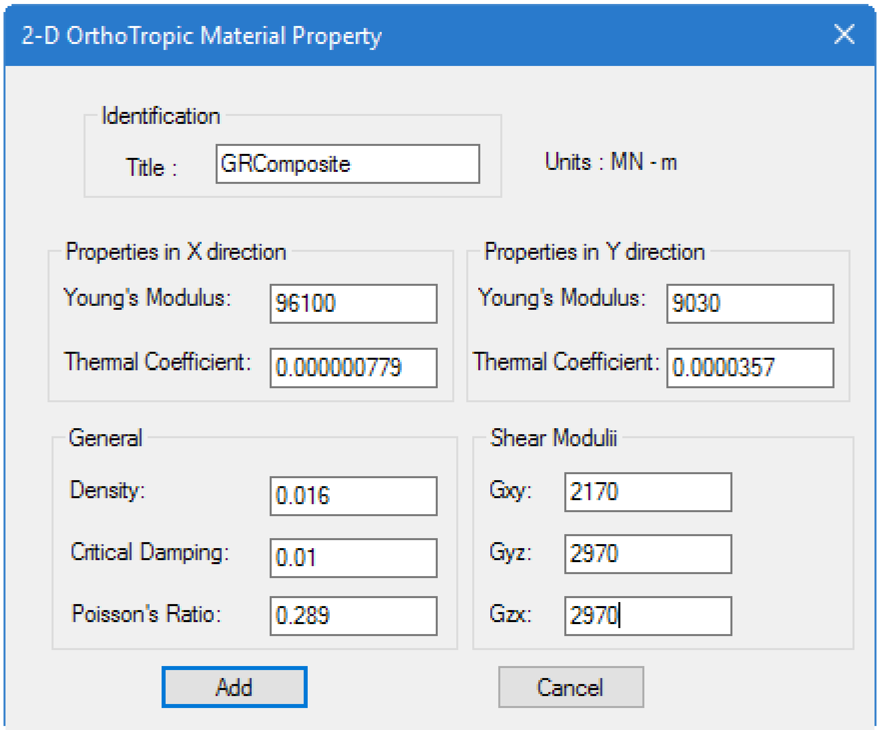




RCFrame.std - Materials

Name	E kN/mm2	Poisson's Ratio	Density kg/m3	Alpha /°C	Fy kN/mm2	Fu kN/mm2
ALUMINUM	68.948	330E-3	2712.631	23E-6	0.000	0.000
CONCRETE	21.718	170E-3	2402.616	10E-6	0.000	0.000
STAINLESSSTEEL	197.930	300E-3	7833.413	18E-6	0.000	0.000
STEEL	205.000	300E-3	7833.413	12E-6	253.2E-3	407.8E-3

2. In the **Material - Whole Structure** dialog, select the **Orthotropic 2D** tab.
3. Click **Create**.
   The **2-D OrthoTropic Material Property** dialog opens.



4. Type a **Title** for the material.
5. Type the material values:
   a. Type the **Young's Modulus** and **Thermal Coefficients** in the X direction.
   b. Type the **Young's Modulus** and **Thermal Coefficients** in the Y direction.
   c. Type the **Density**, **Critical Damping**, and **Poisson's Ratio** values.

      The same values are used in both X and Y directions.
   d. Type the Shear Modulus values for in-plane shear (**Gxy**), shear transverse to the local Y-Z direction (**Gyz**), and shear transverse to the local Z-X direction (**Gzx**).
6. Click **Add**.

The material definition is now added to the **Materials** table and is available for selecting when assigning shapes and in **Material - Whole Structure** dialog.

Related Links

- *TR.26.1 Define Material* (on page 2303)
- *2D Orthotropic Material Property dialog* (on page 2822)

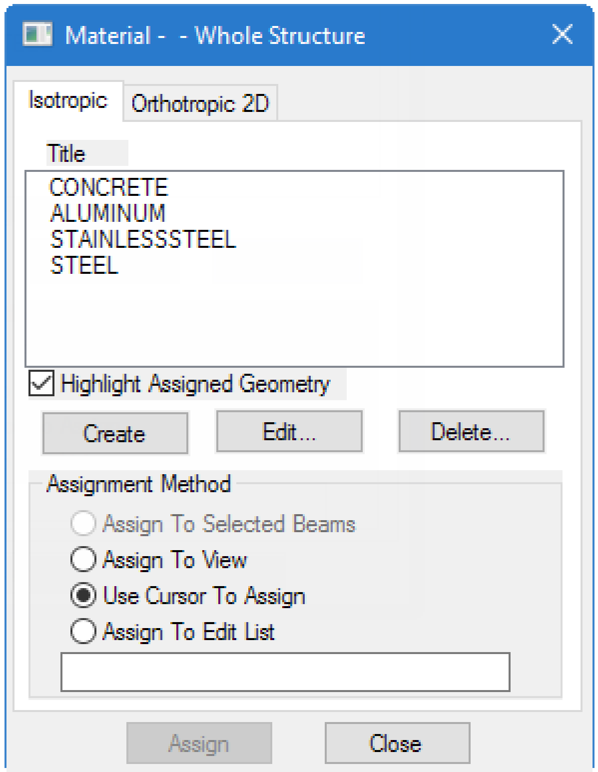
M. To assign material definitions

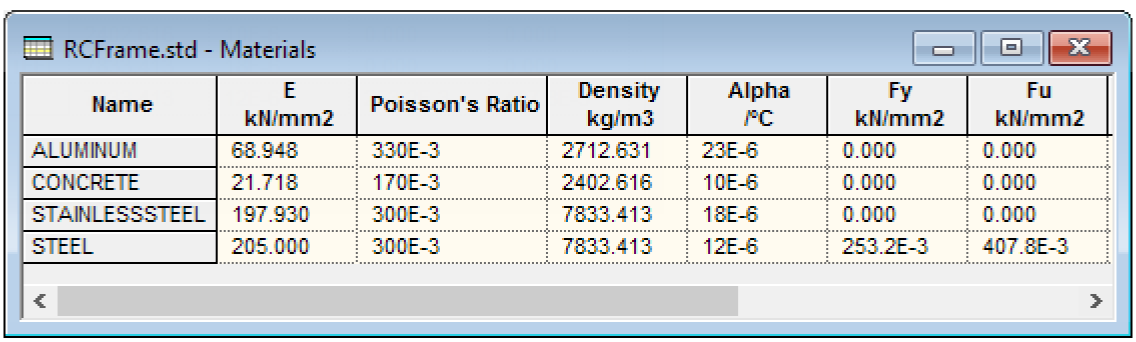
To assign material definitions to model objects (beams, plates, or solids), use the following procedure.

Often, you will assign a material definition to a beam along with the section assignment or to a plate with the thickness definition, as the material and profile or thickness are typically intrinsically associated. However, if you need to change materials or make assignments separately, this is done using the **Material - Whole Structures** dialog.

1. Select the **Materials** page in the **Analytical Modeling** page control bar.

   The **Material - Whole Structure** dialog and the **Materials** table open.





RCFrame.std - Materials

Name	E kN/mm2	Poisson's Ratio	Density kg/m3	Alpha /°C	Fy kN/mm2	Fu kN/mm2
ALUMINUM	68.948	330E-3	2712.631	23E-6	0.000	0.000
CONCRETE	21.718	170E-3	2402.616	10E-6	0.000	0.000
STAINLESSSTEEL	197.930	300E-3	7833.413	18E-6	0.000	0.000
STEEL	205.000	300E-3	7833.413	12E-6	253.2E-3	407.8E-3

2. Select the **Materials** page on the **Analytical Modeling** workflow page control bar.
   The
3. Assign the materials using one of the standard assign methods in the **Material - Whole Structures** dialog.

M. To assign material constants

To assign material constants to model objects (beams, plates, or solids), use the following procedure.

You may want to set the input units to a familiar set of units for a particular material value before assigning a material constant.

Tip: It is recommended to use material definitions in place of material constants. Material definitions also allow you to assign design strength properties.

1. Select the model object which have the same material constant.
2. On the **Specifications** ribbon tab, select the **Constants** tool in the **Materials** group.

A drop-down list of material constants opens.

3. Select the constant you want to assign:

    Young's Modulus
    Poisson's Ratio
    Shear Modulus
    Density
    Thermal Coefficient
    Damping Ratio

    The corresponding dialog for the material constant opens.

4. Either:

    select a predefined material constant value for a built-in material name: Aluminum, Concrete, or Steel

    or

    select the Enter Value option and type a value for the material constant
5. Select the **To Selection** option to limit the assignment to the selection set.
6. Click **OK**.

Related Links
- *Material Constant dialog* (on page 2809)
- *TR.26.2 Specifying Constants for Members and Elements* (on page 2305)

M. Member Orientation

Related Links
- *M. To change a beam incidence* (on page 917)

M. To assign a member rotation angle

To assign an arbitrary member rotation angle about its longitudinal axis, use the following procedure.

The rotation of a member about it's longitudinal axis is referred to as the “beta angle” in STAAD.Pro.

1. Select one or more members in the view window.
2. On the **Specification** ribbon tab, select the **Beam** > **Beta Angle** tool in the **Specifications** group.

    The **Beta Angle** dialog opens.
3. Select the **Angle in Degrees** option and then type the angle of rotation.
4. Select the **To Selection** option.

> **Tip:** The **To View** option assigns the specification to all members in the view window.

5. Click **OK**.
   The rotation angle is assigned. A new beta angle specification is added to the Beta Angle tab on the **Properties - Whole Structure** dialog. This angle can be assigned to additional beams from this dialog.

Related Links

- *G.4.3 Relationship Between Global and Local Coordinates* (on page 2092)
- *TR.26.2 Specifying Constants for Members and Elements* (on page 2305)
- *Beta Angle dialog* (on page 2811)

M. To align a single angle to its flanges

To orient a single angle member aligned to its flanges, use the following procedure.

1. Select one or more members with single angle profiles in the view window.
2. On the **Specification** ribbon tab, select the **Beam** > **Beta Angle** tool in the **Specifications** group.

   The **Beta Angle** dialog opens.
3. Select the option to align the flanges (i.e., geometric axis):

To align…	Description
the long leg with the local y axis (ST angles)	select the **Angle** option This will rotate the angle section by *90°-a*.
the short leg with the local y axis (ST angles)	select the **RAngle** option This will rotate the angle section by *180°-a*.

where

a = the angle between the principle axis system and the geometric axis (i.e., parallel to the flange faces) system of the single-angle profile

> **Note:** The orientation with the local y axis is for ST angles. RA angles are defined as being rotated 90° and thus the Angle and RAngle options similarly rotate from that initial orientation.

4. Select the **To Selection** option.

> **Tip:** The **To View** option assigns the specification to all members in the view window.

5. Click **OK**.

Table 35: Effect of BETA ANGLE and BETA RANGLE commands

BETA value =	Zero (0)	ANGLE	RANGLE
ST Angle			RA Angle

M. To align a member to a reference point

To orient a member to an existing node or arbitrary point, use the following procedure.

1. Select one or more members in the view window.
2. On the **Specification** ribbon tab, select the **Beam** > **Beam Reference Point** tool in the **Specifications** group.

   

   The **Referene Point** dialog opens.
3. Select the type of point to use as a reference for orientation:

To orient by...	Select the following...
an arbitrary point in space	select the **Point** option and define the coordinates with respect to the model origin

To orient by...	Select the following...
a vector from the member start node	select the **Vector** option and then define the second point of the vector coordinates with respect to the member start node
a node in the model	select the **Node** option and then select the node number from the drop-down list

4. Select the **To Selection** option.

   Tip: The **To View** option assigns the specification to all members in the view window.
5. Click **OK**.

- *TR.26.2 Specifying Constants for Members and Elements* (on page 2305)

M. Member Specifications

M. To add a member specification

To add a specification for beam members in your model, use the following procedure.

Tip: As with most assignment options, you can select a set of objects prior to starting this procedure and make the assignments to this selection set by using the dialog's **Assign** button.

Member specifications are used to assign beam members as cables, truss, tension- or compression-only. Similarly, additional specifications for member end offsets, fireproofing, and inactive members can be assigned.

1. Select the **Specifications** page in the Analytical Modeling page control bar.

   The **Specifications - Whole Structure** dialog opens.
2. In the **Specifications - Whole Structure** dialog, click **Beam**.
   The **Member Specification** dialog opens.
3. Select the dialog tab corresponding to the member specification you want to add:

   Release
   Offset
   Property Reduction Factor
   Cable
   Truss
   Compression
   Tension
   Inactive
   Fire Proofing
   Imperfection

> **Note:** Truss, Compression, Tension, and Inactive specifications have no additional parameters required. All other specifications require some additional input on the respective tab.

4. Either:

To...	Do the following...
add the specification to the model for later assignment	click **Add.**
add the specification to the model and assign to the current member selection	click **Assign.**

   The dialog closes.

The member specification is added to the **Specifications - Whole Structure** dialog and the **Specification Values** table.

You can repeat this procedure as many times as necessary to add additional member specifications to your model.

If you did not assign the specification to a selection set, you must select the specification in the **Specifications - Whole Structure** dialog and assign it using one of the assignment methods.

Related Links

- *Specifications - Whole Structure dialog* (on page 2783)
- *Member Specification dialog* (on page 2786)

M. To assign axial action members

To assign a member as compression-only, tension-only, or a truss (axial-only) member, use the following procedure.

STAAD.Pro allows you to specify the axial actions of members.

> **Note:** This assigns the analytical specification for truss members. For the purpose of Connection Design, you must additionally D. To assign member type attributes (on page 1031).

1. (Optional) Select the members which will all have the same member specification assigned.
2. On the **Specification** ribbon tab, select the **Beam** tool in the **Specification** group.

   

   A list of member specification types opens.
3. Select the specification type you want to assign:

   Compression Only – members are capable of carrying compression forces only

   or

   Tension Only – members are capable of carrying tensile forces only

   or

   Truss – members are capable of carrying axial forces only

   > **Note:** These member specifications have no additional parameters.

The **Member Specification** dialog opens to the corresponding tab.

4. Either:

To...	Do the following...
add the specification to the model and assign to the current member selection	click **Assign**.
add the specification to the model for later assignment	click **Add**.

The dialog closes.

The member specification is added to the **Specifications - Whole Structure** dialog and the **Specification Values** table.

Related Links

- *G.8.1 Truss and Tension- or Compression-Only Members* (on page 2121)
- *TR.23.1 Member Truss Specification* (on page 2289)
- *TR.23.3 Member Tension/Compression Specification* (on page 2292)
- *Member Specification dialog* (on page 2786)

M. To assign member end release

To assign a member end release or partial member end release, use the following procedure.

Release specifications are created for each of a member separately. To release both ends, you must create two specifications.

1. (Optional) Select the members which will all have the same member specification assigned.
2. On the **Specifications** ribbon tab, select the **Beam** > **Release** tool in the **Specifications** group.

The **Member Specification** dialog opens to the **Release** tab.

3. Select which location on the member to which the release applies: **Start** or **End**.
4. Select the **Release Type**:

Partial Moment Release

or

Release

5. For **Partial Moment Release**, select the directions which are partially released and the release ratio:
   a. Check the boxes corresponding to the directions of release.

      Check MP to assign the same partial moment release in all three local directions. Check a combination of MPX, MPY, and MPZ to apply different partial moment releases in each direction.
   b. For each direction checked, type a release ratio.

      This is a ratio between 0 and 1, where 0 indicated full moment restraint and 1 indicates full release.
6. For full **Release**, check the release directions which apply.

   These are FX, FY, FZ, MX, MY, and MZ. Any directions not checked will be fully restrained in that degree of freedom.
7. (Optional) To specify a spring in any degree of freedom, check the corresponding Release spring direction and type a spring constant in the adjacent field (in the indicated units).

Springs can be applied to partial moment release or release types.

8. Either:

To...	Do the following...
add the specification to the model and assign to the current member selection	click **Assign**.
add the specification to the model for later assignment	click **Add**.

The dialog closes.

Related Links
- *G.7 Member and Element Release* (on page 2120)
- *TR.22.1 Member Release Specification* (on page 2286)
- *Member Specification dialog* (on page 2786)

M. To assign member end offsets

To assign a rigid end offset to one end of a member, use the following procedure.

Member end offsets can be used to model any situation where the end of the actual member does not coincide with the analytical node used for the member end incidence. For example,

working points that do not align (e.g., a gusset plate connection)
rigid end zones (e.g., a beam that connects to the flange of a stiff column)
modeling top of steel (e.g., the center line of a beam that supports a slab)

1. (Optional) Select the members which will all have the same member specification assigned.
2. On the **Specification** ribbon tab, select the **Beam** > **Offset** tool in the **Specification** group.

The **Member Specification** dialog opens to the **Offset** tab.
3. Select which **Location** on the member to which the offset applies: **Start** or **End**.
4. Select which **Direction** reference to use for the offset values: **Global** or **Local**.
5. Type the **Offsets** to use along each of the **X**, **Y**, and **Z** axes.
6. Either:

To...	Do the following...
add the specification to the model and assign to the current member selection	click **Assign**.
add the specification to the model for later assignment	click **Add**.

The dialog closes.

Related Links
- *G.11 Member and Plate Offsets* (on page 2125)
- *TR.25.1 Member Offset Specification* (on page 2296)
- *Member Specification dialog* (on page 2786)

M. To assign member imperfection for members

To assign member drift or camber for use with an imperfection analysis, use the following procedure.

1. (Optional) Select the members which will all have the same member specification assigned.
2. On the **Specification** ribbon tab, select the **Beam** > **Imperfection** tool in the **Specification** group.

   

   The **Member Specification** dialog opens to the **Imperfection** tab.
3. Do either of the following:

   select **Camber** to define the maximum offset along a beam from a line connecting the end points (typically for beams)

   or

   select **Drift** to define the offset at the end of a member (typically for columns)
4. Select the **Local Direction** of the imperfection and then type the **Value**, which is taken as a ratio of the member length to offset (i.e., L/d).
5. (Optional) For Camber, type a **Respect** value which is used to determine when to skip camber imperfection calculations.

   This ratio results in the camber imperfection calculations being skipped when:

   - the compressive load is small,
   - the member stiffness (EI) is large, or
   - the member is short
6. Either:

To...	Do the following...
add the specification to the model and assign to the current member selection	click **Assign**.
add the specification to the model for later assignment	click **Add**.

   The dialog closes.

You must assign the member imperfection specification to one or more members. An imperfection analysis is required in order to perform these calculations.

Related Links

- *TR.26.6 Member Imperfection Information* (on page 2313)
- *Member Specification dialog* (on page 2786)
- *Perform Imperfection Analysis tab* (on page 2924)
- *TR.26.6 Member Imperfection Information* (on page 2313)

M. To assign nonlinear cable members

1. (Optional) Select the members which will all have the same member specification assigned.
2. On the **Specification** ribbon tab, select the **Beam** > **Cable** tool in the **Specification** group.

The **Member Specification** dialog opens to the **Cable** tab.

3. (Optional) Do either of the following:

   select the **Initial TENSION** option and then type a value for the tension force in the cable

   or

   select the **Unstressed TENSION** option and then type a value for the initial length of the cable

   If no value is given for either option, then a minimal cable tension is assumed.
4. Type a ratio value for one or more of the **Factor in global X : Fwx**, **Factor in global Y : Fwy**, or **Factor in global Z : Fwz**.

   Note: These loads are used for Advanced Cable Analysis only.

   The values are a multiplier of the self weight of the cable, applied in the selected global direction.
5. Either:

To...	Do the following...
add the specification to the model and assign to the current member selection	click **Assign**.
add the specification to the model for later assignment	click **Add**.

The dialog closes.

Related Links

- *TR.23.2 Member Cable Specification* (on page 2290)

M. To assign cracked section properties to a member

To assign reduced section property factors to a member, use the following procedure.

Global reduction factors will be applied to any member, regardless of material. Code-specific reduction factors are only applied to concrete members (non-concrete members included in the assignment are ignored).

Note: Automated stiffness reduction requires a STAAD.Pro Advanced license.

Note: For reducing the stiffness of a steel member for direct analysis per AISC 360, it is recommended use the `REDUCEDEI` parameter in the steel design parameters instead.

Notes:

a. Reduction factors are considered for analysis only but not for design.
b. Results using the reduced section properties are not available when using the member query feature.

1. (Optional) Select the members which will all have the same member specification assigned.
2. On the **Specification** ribbon tab, select the **Beam** > **Cracked Property** tool in the **Specification** group.

The **Member Specification** dialog opens to the **Property Reduction Factors** tab.

3. Select either:

   Global – specify the **Reduction Factors** to be used below, which will apply to any member regardless of material.

   or

   Code Specific – select the building code to use reduction factors specific to load cases per that code which are only applied to concrete members:

   IS1893 2016
4. Type the reduction factor values to assign to the current member selection:
   - Reduction Factor for Cross sectional Area (RAX)

     Note: For IS1893 2016 reduction factors, the **RAX** input field is inactive as this property reduction is not mandated by that code for concrete members.
   - Reduction Factor for Torsion Constant (RIX)
   - Reduction Factor for Moment of Inertia, major axis (RIY)
   - Reduction Factor for Moment of Inertia, minor axis (RIZ)

   Note: Reduction factor values should be between 0 and 1 (inclusive).
5. Either:

To…	Do the following…
add the specification to the model and assign to the current member selection	click **Assign.**
add the specification to the model for later assignment	click **Add.**

The dialog closes.

Notes:

a. Reduction factors are considered for analysis only but not for design.
b. Results using the reduced section properties are not available when using the member query feature.

M. To assign member fire proofing

To assign fire proofing to a member, use the following procedure.

Tip: Fire proofing thickness is specified in the current units of distance. You may want to change the units to a convenient value before beginning.

The fire proofing specification allows the program to automatically calculate the weight of the fire proofing material applied to members.

1. (Optional) Select the members which will all have the same member specification assigned.
2. On the **Specification** ribbon tab, select the **Beam** > **Fire Proofing** tool in the **Specification** group.

   

   The **Member Specification** dialog opens to the **Fire Proofing** tab.
3. Select the **Fire Proofing Type**:
   - **BFP (Block Fireproofing):**

     The fire-protection material forms a rectangular block around the steel section. The thickness specified is the minimum thickness which defines the outer block dimensions.

     
     Figure 116: BFP: Block Fireproofing
   - **CFP (Contour Fireproofing):**

     The fire-protection material forms a coating around the steel section. The thickness specified is a constant thickness around the section profile.

     
     Figure 117: CFP Contour Fireproofing
4. Type the **Thickness** of the fire proofing in the units indicated.
5. Type the **Density** of the fire proofing material.
6. Either:

To...	Do the following...
add the specification to the model and assign to the current member selection	click **Assign.**
add the specification to the model for later assignment	click **Add.**

The dialog closes.

Related Links

- *TR.20.9 Applying Fireproofing on members* (on page 2279)
- *Member Specification dialog* (on page 2786)

M. To assign specifications to physical members

To assign member end or axial specifications to physical members, use the following procedure.

Physical members can have member end releases, member end offsets, and truss specifications. Other analytical member specifications do not apply to physical members.

Note: For a physical member whose physical member specification is already assigned, the individual analytical members in that Physical member will adopt the same member specification that of the physical member. However, in case, where the analytical member specification is assigned to any member in that physical member, then this analytical member specification will supersede physical member specification.

1. Select the **Specifications** page in the Analytical Modeling page control bar.
   The **Specifications - Whole Structure** dialog opens.
2. On the **Geometry** ribbon tab, select the **Toggle Physical Member Mode** tool in the **Physical Members** group.

   

   The tool is highlighted to indicate the mode is active.
3. Click **Beam** in the **Specifications - Whole Structure** dialog.
   The **Member Specification** dialog opens.

   Note: The dialog only shows three tabs in the physical modeling mode.
4. Select the specification type you want to assign:

   Release – one or more degrees of freedom are free or partially restrained at one end of the member

   or

   Offset – a rigid offset is present between one end of the member and the joint

   or

   Truss – members are capable of carrying axial forces only
5. Add Release or Offset attributes as you would for analytical members.
   a. Select the **Location** on the member: **Start** or **End**.
   b. For a **Release**, select if either partial or full release and the degrees of freedom of the release.
   c. For an **Offset**, select the directions of the offset.
6. Click **Add**.

M. Plate Specifications

M. To align a plate to a reference point

To orient the local axis of a plate element towards or away from an arbitrary point, use the following procedure.

The local z axis of the plates will remain perpendicular to the plane of the elements. This tool will simply orient the local axis such that this z axis points generally toward or away from the specified reference point. Refer to G. 5.1 Plate and Shell Elements (on page 2099) for additional details.

1. Select one or more plates in the view window.
2. On the **Specification** ribbon tab, select the **Plate** > **Plate Reference Point** tool in the **Specifications** group.

   

   The **Plate Reference Point** dialog opens.
3. Specify the **X**, **Y**, and **Z** coordinates of an arbitrary reference point.
4. Select if the **Local Z Axis** of the elements should point towards or away from the reference point.

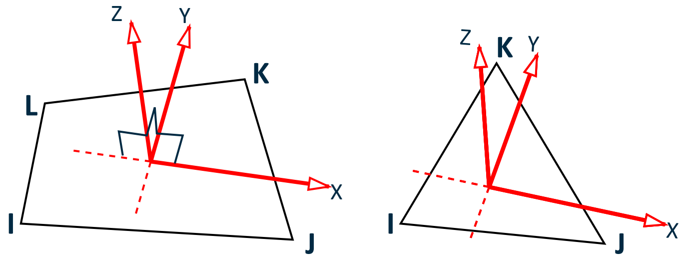

Figure 118: The local z axis of the plate is perpendicular to the plane of the element

5. Select the **To Selection** option.

   Note: The **To View** option assigns the specification to all plates in the view window.
6. Click **OK**.

Related Links

- *G.5.1 Plate and Shell Elements* (on page 2099)
- *Plate Reference Point dialog* (on page 2813)

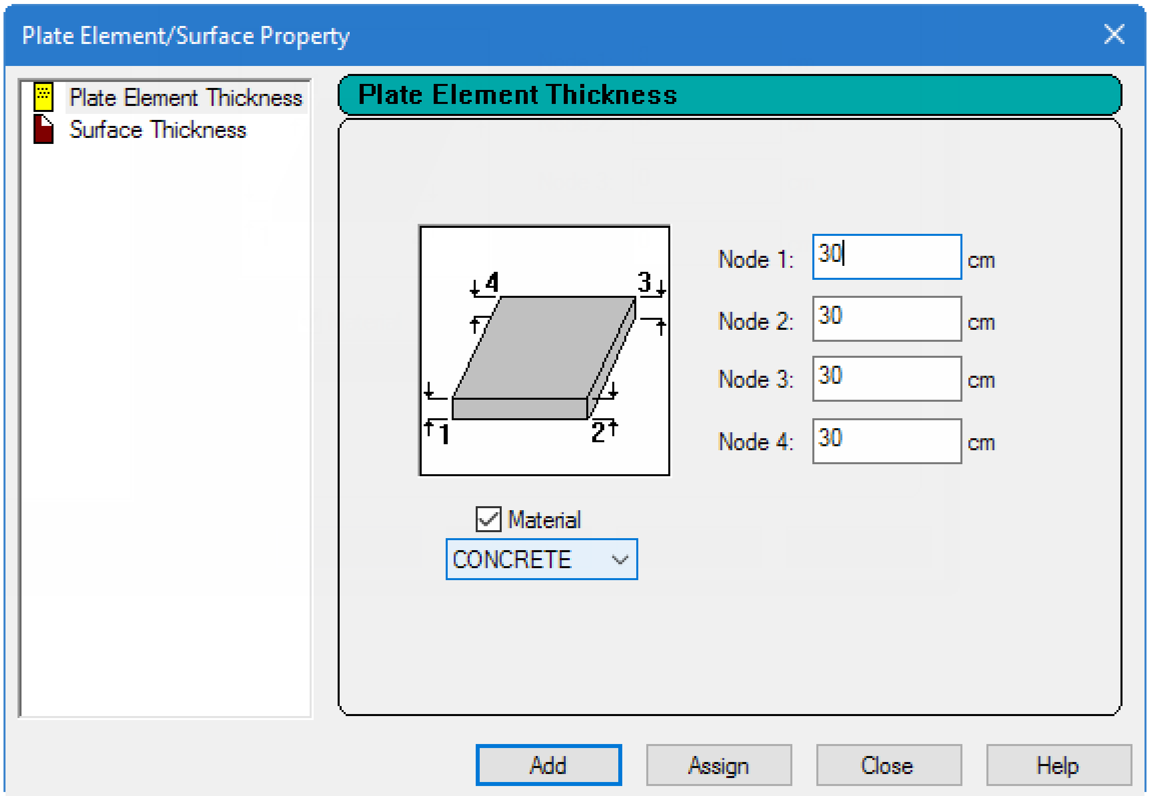
M. To specify plate thickness

To specify the thickness of a plate element, use the following procedure.

1. Select the plates which will have a similar thickness.
2. On the **Specification** ribbon tab, select the **Plate Thickness** tool in the **Plate Profiles** group.

The **Properties - Whole Structure** and the **Plate Element/ Surface Property** dialogs open.



3. Select the Plate Element Thickness tab.
4. Type the thickness values for the plate:

For a...	Do this...
uniform plate thickness	type the thickness in the Node 1 field. The other node fields will use this value by default
linearly varying thickness	type the thickness of the plate at each corner node in the corresponding field

5. (Optional) Check the **Material** option and select the material definition from the drop-down list.
6. Either:

   click **Assign** to assign the thickness (and optional material) to the selection set

   or

   click **Add** to add the thickness property to the model for assignment later

Related Links

- *G.5.1 Plate and Shell Elements* (on page 2099)
- *TR.21.1 Element Property Specification* (on page 2284)
- *Plate ElementProperty dialog* (on page 2813)

To assign plate offsets

To add rigid link offsets to one or more corners of a plate, use the following procedure.

Plate corner offsets can be used to model any situation where the corners of a plate element do not coincide with the analytical node used for the plate incidences. For example,

walls that meet at a corner (e.g., so that walls do not overlap)
wall and slab intersections (e.g., a wall that bears on top of a slab)

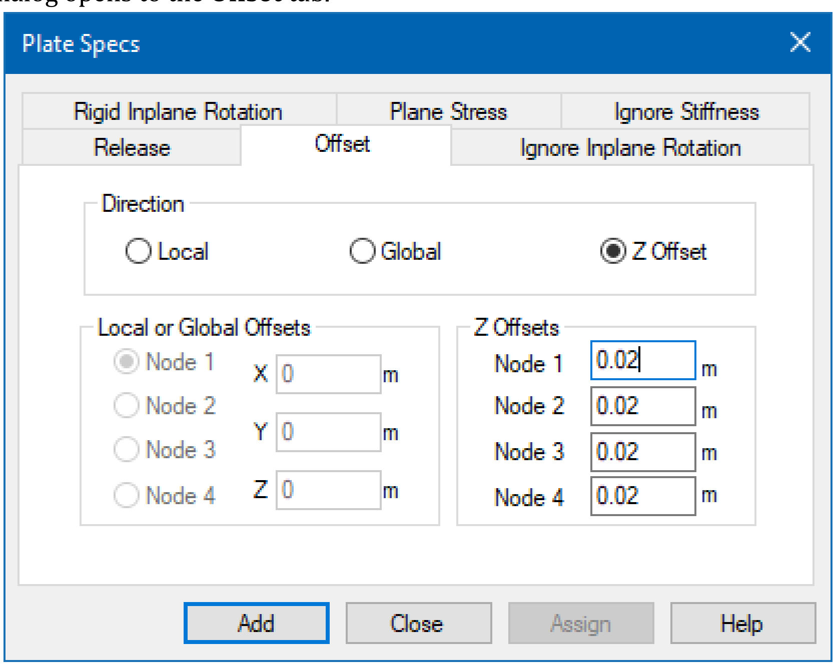
1. (Optional) Select the plates which will have the same plate offset specifications assigned.
2. Either:

   on the **Specification** ribbon tab, select the **Plate** > **Offsets** tool in the **Specification** group

   or

   on the **Specifications - Whole Structure** dialog, click **Plate**
   The **Plate Specs** dialog opens to the **Offset** tab.



3. Select the **Direction** in which you want to specify offsets:
   - **Local -** the nodal offsets at a specified joint are given in the element local axes.
   - **Global -** the nodal offsets at a specified joint are given in the global axes.
   - **Z Offset -** the offset is specified along the local z axis of the element (i.e., parallel offset to the plane of the element)
4. Specify the offset values:

For...	Do...
Local or global offsets	Select the local incidence node number and then specify the offsets in the local or global directions.
Z offsets	Type the offset value to use. By default, the same value will populate in all the node fields (i.e., a parallel offset to the plane of the plate). You can override these values by typing different values at different nodes.

Tip: To quickly identify the order of element corners, use the **Plate Cursor** tool and double click a plate. The Plate query dialog displays the nodes in order on the Geometry tab.

Note: The joint offsets must result in offset corners which are co-planar to prevent a warped surface.

5. Either:

To...	Do the following...
add the specification to the model and assign to the current plate selection	click **Assign**.
add the specification to the model for later assignment	click **Add**.

The dialog closes.

Related Links

- *G.11 Member and Plate Offsets* (on page 2125)
- *TR.25.2 Element Offset Specification* (on page 2298)

M. To assign plate corner release

To release degrees of freedom of a plate element corner node, use the following procedure.

Releases are created for each node (by reference order) separately. To release multiple corners, you must create multiple specifications.

1. (Optional) Select the plates which will have the same plate release specifications assigned.
2. On the **Specification** ribbon tab, select the **Plate** > **Release** tool in the **Specifications** group.

The **Plate Specs** dialog opens to the **Release** tab.
3. Select which **Node** to which the release applies.

These are based on the local coordinate system for the element.

Tip: To quickly identify the order of element corners, use the **Plate Cursor** tool and double click a plate. The Plate query dialog displays the nodes in order on the Geometry tab.

4. Check the **Release** directions.

These are FX, FY, FZ, MX, MY, and MZ. Any directions not checked will be fully restrained in that degree of freedom.
5. Either:

To...	Do the following...
add the specification to the model and assign to the current plate selection	click **Assign**.
add the specification to the model for later assignment	click **Add**.

The dialog closes.

Related Links

- *G.7 Member and Element Release* (on page 2120)
- *Plate Specs dialog* (on page 2791)
- *TR.22.2 Element Release Specification* (on page 2287)

M. To assign plates as plane stress

To assign plate elements as plane stress elements, use the following procedure.

This specification results in plates that only resist stress within the plane of the plate, but resist no out-of plane bending. These plate elements are analogous to truss members.

Tip: You can also assign this plate specification from the **Plate Specs** dialog, which opens when you click **Plate** on the **Specifications - Whole Structure** dialog.

1. Select the plates which will be plane stress elements.
2. On the **Specification** ribbon tab, select the **Plate** > **Plane Stress** tool in the **Specifications** group.

   The **Plate Specs** dialog opens to the **Plane Stress** tab.

   Note: There are no parameters to provide for this plate specification.
3. Either:

To...	Do the following...
add the specification to the model and assign to the current plate selection	click **Assign**.
add the specification to the model for later assignment	click **Add**.

The dialog closes.

Related Links

- *G.5.1 Plate and Shell Elements* (on page 2099)
- *Plate Specs dialog* (on page 2791)
- *TR.24 Element Plane Stress and Ignore Inplane Rotation Specification* (on page 2295)

M. To assign inplane rotation behavior to plates

To specify either no inplane rotational stiffness or completely rigid inplane rotational stiffness, use the following procedure.

Typically, the plate element used in STAAD.Pro has a very "soft" in-plane rotational, Mz, stiffness. There may be circumstances where this rotation should be ignored entirely (that is, with zero in-plane rotational stiffness). Alternatively, there may be circumstances where a rigid body rotation is required in plate elements.

1. Select the plates which will have the same inplane rigidity.
2. On the **Specification** ribbon tab, in the **Specifications** group, select either:

To...	Select this tool...
ignore the in-plane rotation actions of the plates	**Plate** > **Ignore Inplane Rotatoin**
treat the plates as rigid bodies for in-plane rotation	**Plate** > **Rigid Inplane Rotatoin**

   The **Plate Specs** dialog opens to the corresponding tab.

   Note: There are no parameters to provide for this plate specification.
3. Either:

To...	Do the following...
add the specification to the model and assign to the current plate selection	click **Assign**.
add the specification to the model for later assignment	click **Add**.

   The dialog closes.

Related Links
- *G.5.1 Plate and Shell Elements* (on page 2099)
- *Plate Specs dialog* (on page 2791)
- *TR.24 Element Plane Stress and Ignore Inplane Rotation Specification* (on page 2295)

M. To ignore plate stiffness

To ignore the stiffness of a selection of plates, use the following procedure.

A plate element whose stiffness is ignored by the program acts will distribute any element loads but the stiffness of the plate does not contribute to the stiffness of the structure. In this way, plate elements can be used to model non-structural components, such as glass cladding.

Tip: You can also assign this plate specification from the **Plate Specs** dialog, which opens when you click **Plate** on the **Specifications - Whole Structure** dialog.

1. Select the plates which will have their stiffness ignored by the program.
2. On the **Specification** ribbon tab, select the **Plate** > **Ignore Stiffness** tool in the **Specifications** group.

   The **Plate Specs** dialog opens to the **Ignore Stiffness** tab.

Note: There are no parameters to provide for this plate specification.

3. Either:

To...	Do the following...
add the specification to the model and assign to the current plate selection	click **Assign**.
add the specification to the model for later assignment	click **Add**.

The dialog closes.

Related Links
- *G.5.1 Plate and Shell Elements* (on page 2099)
- *Plate Specs dialog* (on page 2791)
- *TR.22.3 Element Ignore Stiffness* (on page 2288)

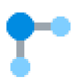
M. Node Specifications

M. To assign a rigid link between nodes

To create a rigid link between a control node any number of dependent nodes, use the following procedure.

A control/dependent specification establishes a primary node and a set of one or more subordinate nodes. Any displacements or rotations along the specified direction at the control node will be directly translated to the dependent nodes.

1. Select the nodes that will be the dependent nodes.
2. On the **Specifications** ribbon tab, select the **Nodes** > **Add Control/Dependent Specification** tool in the **Specifications** group.



The **Node Specification** dialog opens to the **Control/Dependent** tab.
3. Select the **Control Node** number from the drop-down list of nodes.
4. Select a rigid link specification in the **Dependent Directions**:

Rigid link type	Select...
in all directions	the **Rigid** option
within a plane	either the **XY**, **YZ**, or **XZ** option, corresponding to the plane
in specified degrees of freedom	the specific degrees of freedom which are linked between the primary and subordinate nodes: **FX**, **FY**, **FZ**, **MX**, **MY**, and **MZ**

5. Either:

To...	Do the following...
add the specification to the model and assign to the current node selection	click **Assign**.
add the specification to the model for later assignment	click **Add**.

The dialog closes.

Related Links

- *G.14 Rigid Diaphragms* (on page 2128)
- *TR.28.1 Control/Dependent Specification* (on page 2327)
- *Node Specification dialog* (on page 2784)

M. To assign nodes to a floor diaphragm

To define nodes that make up a floor diaphragm, use the following procedure.

Tip: Diaphragm heights and optional ranges are given in the current units of length. You may want to change the units of length to a convenient value before defining the diaphragm.

In order to generate the center of gravity for a diaphragm, you must create a mass load case which includes the weights to be considered for the diaphragm.

Note: A single diaphragm may be defined at a given level in STAAD.Pro.

1. (Optional) Select a set of nodes which will be used to define the diaphragm.
2. Select the **Specifications** page in the **Analytical Modeling** page control bar.
   The **Specifications - Whole Structure** dialog opens.
3. On the **Specifications - Whole Structure** dialog, click **Node**.
   The **Node Specification** dialog opens.
4. Select the **Floor Diaphragm** tab.
5. Specify the floor level of the diaphragm by either:

   selecting **Height** and then typing the height of the floor (Y coordinate value)

   or

   selecting **YRange** and then typing the **Minimum** and **Maximum** values of the diaphragm (Y coordinates)
6. (Optional) Select the **Define Floor Range** option to specify a boundary in the XZ plane of the diaphragm to define its edges:

   select the **Select Nodes** option to either assign the diaphragm to the current node selection or to assign it later

   or

   select the **Floor Range** option to type maximum and minimum values in the global X and Z directions to bound the diaphragm

   Nodes lying outside of this selection or range will not be considered to be part of the diaphragm even if they are at the diaphragm height.
7. (Optional) You can specify a control node to use as the center of gravity by selecting the **Select Control Node** option and then selecting the node number to use as the center of gravity.

   Otherwise, the program will calculate the center of gravity location for the diaphragm and add an analytical node at this location.

   Tip: To report calculated CGs, add the Cg (Center of Gravity) option in the Post-Analysis Print Commands.
8. Either:

To...	Do the following...
add the specification to the model and assign to the diaphragm to the current nodes	click **Assign**.
add the specification to the model for later assignment or to use all nodes at the specified Height	click **Add**.

The dialog closes.

Note: Soft story checks can be made for structures with rigid floor diaphragms per the IS 1893 2002, IS 1893 2016, and ASCE 7 specifications.

- *Node Specification dialog* (on page 2784)

M. Supports

This section describes how to create boundary conditions for your model.

Select the **Supports** page in the in the **Analytical Modeling** workflow to open the **Supports - Whole Structure** dialog.

In STAAD.Pro, you will create support types that can be assigned to multiple nodes.

M. To assign a fixed or pinned support

To specify a node as either a fixed or pinned support, use the following procedure.

A fixed support is restrained against movement (translation and rotation) in all degrees of freedom. A pinned support is restrained against translation only, but is otherwise free to rotate. Refer to Description of Pinned and Fixed (on page 2316) for additional details.

1. Select the nodes that will have the same support condition.
2. On the **Specifications** ribbon tab, select one of the following tools in the **Supports** group:

   Fixed 
   or

   Pinned 3. The **Create Support** dialog opens to the corresponding tab.
4. Either:

To...	Do the following...
add the support type to the model and assign to the current node selection	click **Assign**.
add the support to the model for later assignment	click **Add**.

The dialog closes.

Related Links

- *G.13 Supports* (on page 2127)
- *Create Support dialog* (on page 2815)
- *Supports - Whole Structure dialog* (on page 2814)
- *TR.27.1 Global Support Specification* (on page 2316)

M. To assign an enforced support

To assign a support which can have a support displacement imposed as a load, use the following procedure.

In STAAD.Pro, a special support type is used for supports that will have an imposed displacement as part of a load case. These are called "enforced" supports.

Note: If no support displacements are defined for an enforced support, then this support behaves as a fixed support (i.e., no translation or rotation). Similarly, an enforced but support behaves like a corresponding fixed but support if no support displacements are defined.

1. Select the nodes that will have the same support condition.
2. On the **Specifications** ribbon tab, select the **Other Supports** tool in the **Supports** group.
3. Select one of the drop-down support types as follows:

Support condition...	Select the following other support...
fixed in all degrees of freedom	**Enforced**
released in one or more degrees of freedom	**Custom Enforced**

   To impose a displacement on a joint with releases (e.g., a "pinned" support), you must use a custom enforced (i.e., `ENFORCED BUT`) support type and define the released degrees of freedom.

   The **Create Supports** dialog opens to the corresponding tab.
4. (Optional) For an enforced but support type, check the **Releases** for this support type.

   For example, to create a "pinned" type support, you would check the **MX**, **MY**, and **MZ** release options.
5. Either:

To...	Do the following...
add the support type to the model and assign to the current node selection	click **Assign**.
add the support to the model for later assignment	click **Add**.

   The dialog closes.

You must create a load case with support displacements defined at nodes with enforced or enforced but support types assigned in order for this support type to have an effect on your model beyond behaving as a corresponding fixed or fixed but support.

- *EX. US-24 Analysis of a Concrete Block Using Solid Elements* (on page 6495)
- *EX. UK-24 Analysis of a Concrete Block Using Solid Elements* (on page 6782)
- *TR.27.1 Global Support Specification* (on page 2316)

- *Create Support dialog* (on page 2815)

M. To assign custom release supports

To assign a set of custom releases to a supported node, use the following procedure.

1. Select the nodes that will have the same support condition.
2. On the **Specifications** ribbon tab, select the **Custom** tool in the **Supports** group.

   

   The **Create Supports** dialog opens to the **Fixed But** tab.
3. In the **Releases** group, check the degrees of freedom to be released for this support type.

   Note: If a spring constant is specified in a direction, then the corresponding degree of freedom cannot be released. A given support type can have a mix of releases and springs, but only in different degrees of freedom.
4. Either:

To...	Do the following...
add the support type to the model and assign to the current node selection	click **Assign**.
add the support to the model for later assignment	click **Add**.

   The dialog closes.

M. To assign a spring support

To assign a linear spring in one or more degrees of freedom to a support, use the following procedure.

You may want to change the system of input units to convenient values for your spring constants before creating a spring support type.

In STAAD.Pro, linear spring constants are specified as part of “fixed but” support types.

1. Select the nodes that will have the same support condition.
2. On the **Specifications** ribbon tab, select the **Custom** tool in the **Supports** group.

   

   The **Create Supports** dialog opens to the **Fixed But** tab.
3. In the **Define Springs** group, type the linear spring constant to use for each translational and rotational spring direction.

   KFX - translation in the global x direction
   KFY - translation in the global y direction
   KFZ - translation in the global z direction
   KMX - rotation about the global x axis

KMY - rotation about the global y axis
KMZ - rotation about the global z axis

Note: If a spring constant is specified in a direction, then the corresponding degree of freedom cannot be released. A given support type can have a mix of releases and springs, but only in different degrees of freedom.

For example, a fixed but support could have MX, MY, and MZ released as in a pinned support and also have spring constants defined in FX, FY, and FZ.

4. Either:

To…	Do the following…
add the support type to the model and assign to the current node selection	click **Assign**.
add the support to the model for later assignment	click **Add**.

The dialog closes.

You can now assign tension-only, compression-only, or multi-linear springs to these same supported nodes if necessary.

Related Links

- *G.13 Supports* (on page 2127)
- *EX. US-3 Soil Springs for Portal Frame* (on page 6327)
- *EX. UK-3 Soil Springs for Portal Frame* (on page 6611)
- *TR.27.1 Global Support Specification* (on page 2316)
- *Create Support dialog* (on page 2815)

M. To assign multilinear springs to spring supports

To model varying resistance to external loads at a spring support, use the following procedure.

You must assign spring supports to nodes before assigning multilinear spring definitions. You may not use multilinear springs in a model that contains tension-only or compression-only springs.

You may want to change the system of input units to convenient values for your spring constants before creating a spring support type.

Note: Multilinear springs can only be used with a select set of analysis types. Each load case should be separated by a Change command as well. See TR.27.4 Multilinear Spring Support Specification (on page 2322) for details.

1. Select one or more nodes assigned with spring support types.
2. On the **Specifications** ribbon tab, select the **Other Supports** > **Multi-Linear Spring** tool in the **Supports** group.
   The **Create Support** dialog opens to the **Multilinear Spring** tab.
3. In the table, type the Spring Stiffness constant which corresponds to a Displacement.
   These should be in order starting with the minimum displacement (e.g., this may also be the largest negative displacement) to the maximum positive displacement. All spring constants should be zero or positive values.
4. Click **Assign**.

M. To assign support springs as a one-way

To specify sprint supported nodes as capable of carrying only tension or compression, use the following procedure.

You must assign spring supports to nodes before assigning tension-only or compression-only spring definitions. You may not use tension-only or compression-only springs in a model that contains multilinear springs.

STAAD.Pro assumes that negative displacement is compression and positive displacement is tension.

1. Select one or more nodes assigned with spring support types.
2. On the **Specifications** ribbon tab, select the **One-way Spring** tool in the **Supports** group.

   

   The **Create Support** dialog opens to the **Tension/Compression Only Springs** tab.
3. Select the load direction the support is capable of resisting:

   Tension Only

   or

   Compression Only
4. Select the Spring Direction options for this support type:

   KFX
   KFY
   KFZ

   Note: One-way action is for translational springs only.
5. Click **Assign**.

Related Links

- *TR.27.5 Spring Tension/Compression Specification* (on page 2324)
- *Create Support dialog* (on page 2815)

M. To assign an inclined support

To assign a support that acts inclined with respect to the global axis, use the following procedure.

You may want to change the length unit to a more convenient value if you are going to define an incline direction by coordinate or vector.

See Inclined Support Axis System (on page 2318) for details on how the reaction directions are determined from the reference coordinate.

1. Select the nodes that will have the same support condition.
2. On the **Specification** ribbon tab, select the **Other Supports** > **Inclined** tool in the **Supports** group.
   The **Create Support** dialog opens to the **Inclined** tab.
3. Select the method for specifying the **Incline Reference Point**:

To use this reference...	Do...
an arbitrary point with respect to the supported node	select the **Coordinate** option and then type the relative global X, Y, and Z distances to the reference point
an arbitrary point with respect to the model origin	select the **Ref** option and then type the global X, Y, and Z coordinates
an existing node in the model	select the **RefJt** option and then select the node number from the drop-down list

Note: If you select the **Ref** or **RefJt** options, then the orientation of the inclined support axis system may vary from node to node.

4. Select the **Support Type** to use.

   Pinned - restrained against translation but free to rotate
   Fixed - restrained in all degrees of freedom
   Fixed But - released in specified degrees of freedom and can have spring constants assigned in restrained degrees of freedom
   Enforced - restrained in all degrees of freedom and can have imposed support displacements assigned as loads
   Enforced But - released in specified degrees of freedom and can have imposed support displacements assigned as loads
5. (Optional) For **Fixed But** support type, type linear spring constants to use as necessary.
6. For **Fixed But** or **Enforced But** support types, select the released degrees of freedom.
7. Either:

To...	Do the following...
add the support type to the model and assign to the current node selection	click **Assign**.
add the support to the model for later assignment	click **Add**.

The dialog closes.

Related Links

- *Create Support dialog* (on page 2815)

M. To assign a foundation support

To automatically model a support using foundation parameters, use the following procedure.

Isolated footing dimensions and subgrade modulus values are specified in the current input units. You may want to change those to a convenient value before specifying a foundation support.

STAAD.Pro can take foundation parameters for footings or mat foundations and automatically model spring supports.

1. Select the nodes that will have the same support condition.

2. On the **Specification** ribbon tab, select the **Foundation** tool in the **Supports** group.

   
   The **Create Support** dialog opens to the **Foundation** tab.
3. Select the **Foundation** type to model:

   Footing - a rectangular, isolated footing (i.e., spread footing) area is used to model spring stiffness using the subgrade modulus

   or

   Elastic Mat - the program calculates the influence area of the load and then calculates a spring stiffness based on this area using the subgrade modulus

   or

   Plate Mat - the program calculates the influence area of the load within a specified plate and then calculates a spring stiffness based on this area using the subgrade modulus

   For additional details on the foundation types and their applicability, refer to TR.27.3 Automatic Spring Support Generator for Foundations (on page 2319).
4. Select the **Direction** of the resistance of the spring supports.

   The directions X, Y, or Z generate a spring in that global direction. The other two global directions are fixed against translation and moment about the selected direction is also fixed. The directions X Only, Y Only, or Z Only generate a spring in that global direction only.
5. Type the **Subgrade Modulus** of the soil.
6. (Optional) For **Elastic Mat** or **Plate Mat** foundation types, check the option **Print influence area of each joint** to include this information in the output.
7. (Optional) For **Elastic Mat** or **Plate Mat** foundation types, select a nonlinear spring option if necessary:

Option	Description
None	linear springs are generated
Compression Only	generated springs are compression only (made inactive if in tension)
Multi-Linear	generated springs can have a multilinear displacement-spring constant curve associated with the mat foundation

Tip: Multilinear springs must be specified using the STAAD Editor. The dialog box cannot accept displacement-spring constant curve data.

8. Either:

To...	Do the following...
add the support type to the model and assign to the current node selection	click **Assign**.
add the support to the model for later assignment	click **Add**.

   The dialog closes.

M. Loading Your Model

Load items in STAAD.Pro follow the general assigning workflow: you will define the load items within a primary load case. Then you will assign these load items to structural objects.

M. Available Structural Load Specifications in STAAD.Pro

The program contains the following load specifications:

Response Spectrum

Table 36: Codes available in STAAD.Pro with Response Spectrum loads

Country	Code	Title
Canada	TR.32.10.1.2 Response Spectrum Specification per NRC 2005 (on page 2506)	National Building Code(NRC/CNRC) of Canada
	TR.32.10.1.3 Response Spectrum Specification per NRC 2010 (on page 2512)	National Building Code(NRC/CNRC) of Canada
China	TR.32.10.1.6 Response Spectrum Specification per GB 50011 2010 (on page 2531)	*Code for seismic design of buildings* GB50011-2010 (2016 Edition)
India	TR.32.10.1.7 Response Spectrum Specification per IS: 1893 (Part 1)-2002 (on page 2534)	Criteria for Earthquake Resistant Design of Structures - Part 1: General Provisions and Buildings and Part 4: Industrial structures including Stack-like structures
	TR.32.10.1.8 Response Spectrum Specification per IS: 1893 (Part 1)-2016 (on page 2544)	Criteria for Earthquake Resistant Design of Structures - Part 1: General Provisions
	TR.32.10.1.9 Response Spectrum Specification per IS: 1893 (Part 4)-2015 (on page 2555)	Criteria for Earthquake Resistant Design of Structures Part 4 Industrial Structures Including Stack-Like Structures

Country	Code	Title
Europe	TR.32.10.1.4 Response Spectrum Specification per Eurocode 8 1994 (on page 2520)	Eurocode 8: Design of structures for earthquake resistance – Part 1: General rules, seismic actions and rules for buildings (published 1996)

M. To create a new primary load case

This procedure applies to the **Loading** page in the **Analytical Modeling** workflow.

1. Either:

   select the **Primary Load Cases** tool in the **Loading** group on the **Loading** ribbon tab

   
   or

   select the **Load Cases Details** section on the **Load & Definitions** dialog and then click **Add**

   The Add New Load Cases dialog opens.
2. Select the **Primary** tab.
3. (Optional) Type a Number for the load case.

   The program will increment the load case number based on existing load case numbers.
4. (Optional) Select the **Loading Type**.

   This selection is used when automatically generating load combinations. If you select a live load type, you may also indicated if the load is **Reducible per UBC/IBC**.

Dead	Soil	Ice

Live	Rain Water/ Ice	Wind on Ice
Roof Live	Ponding	Crane Hook
Wind	Dust	Mass (Notes (on page 2461))
Seismic-H (horizontal, Notes (on page 2461))	Traffic	Gravity
Seismic-V (vertical, Notes (on page 2461))	Temperature	Push
Snow	Accidental	None
Fluids	Flood	

5. Type a **Title** used to easily identify this load case.
6. Click **Add**.
   The empty load case is added to the **Load Cases Details** list.

You must now add load items to this load case and assign them to objects in the structure.

You can edit the load case title and loading type by selecting the entry in the **Load Cases Details** list and then clicking **Edit** in the **Load & Definitions** dialog.

You can remove the load case (along with any associated load items) by selecting the entry in the **Load Cases Details** list and then clicking **Delete** in the **Load & Definitions** dialog.

Related Links

M. Load Items

Individual load items are added to primary load cases.

M. To add selfweight load

To add the calculated weight of the structure objects as a load item, use the following procedure.

You must create a primary load case first.

Note: The material definition or density constant is used for each member, element, or solid to determine the self weight load.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group 

Tip: This will add the load item to the currently selected load group selected in the program status bar.

or

In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

The **Add New Load Items** dialog opens.

2. Select the **Selfweight** > **Selfweight Load** tab.
3. Select a global **Direction** for the selfweight.

   This is typically the "vertical" direction but can be any global direction.
4. Type a **Factor**.

   This is multiplier on the calculated weight of the structure objects. You do not need to use a load factor for ultimate strength design here, as that is typically applied to load combinations.

   Note: A positive value will act in the positive global direction, so you will typically use a negative value here for gravity loads (`-1` being the most commonly used value).
5. Click **Add**.
   The load item is added to the selected load case.

You must assign the load items to structure objects.

Tip: As selfweight typically will act on all members, plates, etc., you can use the **Assign to View** option and click **Assign** to quickly assign this load item to all objects in the structure (assuming that you have all objects currently displayed in the view window).

Related Links
- *TR.32.9.1 Selfweight Loads* (on page 2496)
- *Selfweight tab* (on page 2841)

M. To add a nodal load

To add forces or moments that act a nodes, use the following procedure.

Tip: Nodal loads are also referred to as "Joint Loads" in the STAAD command reference.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group 

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the **Nodal Load** > **Node** tab.
3. Type the force and moment magnitudes acting in the global directions (with sign) applied at the same nodes.

   You can use any combination of forces and moments.
4. (Optional) To apply the load along an inclined coordinate system:
   a. Select the **Inclined Load?** option.

The force and moment labels are updated with (') to indicate that the loads and moments will act in the inclined axes.

b. Select the method of defining the reference point.

- **Reference Node -** select an existing node number from the model. The global coordinates of that node are displayed as read-only.
- **Absolute -** type the global coordinates of an arbitrary point to use as the reference.
- **Relative -** type relative distances from the loaded joint to the reference point. These distances are measured along the global axes.

Tip: To easily select a reference node with respect to an existing node, first use the **Reference Node** option to populate the fields with that node's coordinates. Then select the **Absolute** option to modify the values. For example, you can update the Y coordinate of an existing node to select a point directly above or below that node.

c. Type the global coordinates (Absolute) or distances (Relative) to the reference point.

5. Click **Add**.
The load item is added to the selected load case.

Related Links

- *G.15.1 Joint Loads* (on page 2128)
- *TR.32.1 Joint Load Specification* (on page 2462)
- *Nodal Load tab* (on page 2841)

M. To add a support displacement

To add a support displacement to a supported node, use the following procedure.

1. Either:

On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group 

Tip: This will add the load item to the currently selected load group selected in the program status bar.

or

In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

The **Add New Load Items** dialog opens.

2. Select the **Nodal Load** > **Support Displacement** tab.

3. Select the displacement **Direction**.

4. Either

type the **Displacement** distance for translations (i.e., Fx, Fy, or Fz directions).

or

type the **Rotation** angle for rotations (i.e., Mx, My, or Mz directions).

5. Click **Add**.
The load item is added to the selected load case.

Related Links

- *G.15.7 Support Displacement Loads* (on page 2133)
- *TR.32.8 Support Joint Displacement Specification* (on page 2494)
- *Nodal Load tab* (on page 2841)

M. Member Load Items

M. To add a concentrated force or moment on members

To add either concentrated forces or members at a point along the length of a member, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group 

   > **Tip:** This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select either:

   the **Member Load** > **Concentrated Force** tab

   or

   the **Member Load** > **Concentrated Moment** tab
3. Type the location along the length of the member to the concentrated load, **d1**.

   This distance is measured from the start node of the member.
4. Type the lateral offset from the geometric centerline to the load, **d2**.
5. Select the **Direction** option in which the load acts.
   Concentrated loads can be applied in the global or local coordinates.
6. Click **Add**.
   The load item is added to the selected load case.

Related Links

- *G.15.2 Member Load* (on page 2129)
- *TR.32.2 Member Load Specification* (on page 2464)
- *Member Load tab* (on page 2842)

M. To add a uniform load to members

To add a uniform force or moment along the full or partial member length, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group 

> **Tip:** This will add the load item to the currently selected load group selected in the program status bar.

or

In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**. The **Add New Load Items** dialog opens.

2. Select either:

   the **Member Loads** > **Uniform Force** tab

   or

   the **Member Loads** > **Uniform Moment** tab
3. Type the magnitude of the distributed load (with sign), **W1**.
4. Type the location along the length of the member to the start of the uniform load, **d1** and to the end of the uniform load, **d2**.

   Both distances are measured from the start node of the member. If **d2** is zero, then the load will act to the end node of the member.
5. Type the lateral offset from the geometric centerline to the load, **d3**.
6. Select the Direction option in which the load acts.

   Uniform loads can be applied in the global, local, or projected coordinates.
7. Click **Add**.
   The load item is added to the selected load case.

Related Links

- *G.15.2 Member Load* (on page 2129)
- *TR.32.2 Member Load Specification* (on page 2464)
- *Member Load tab* (on page 2842)

M. To add a linear varying load to members

To add linear varying force along the length of a member, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   > **Tip:** This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**. The **Add New Load Items** dialog opens.
2. Select .

   the **Member Loads** > **Linear Varying** tab

   or

   the **Member Loads** > **Trapezoidal** tab
3. Select the load shape to apply:

Load increases...	**Select...**
linearly along entire length of beam	the **W1**, **W2** option on the **Linear Varying** tab
load increases from zero to peak at midspan and back to zero	the **W3** option on the **Linear Varying** tab
linearly along a partial section of the beam	the **Trapezoidal** tab

4. Type the load values at the ends (**W1**, **W2** option) or at midspan (**W3** option) (with sign).
5. Select the **Direction**.
6. Click **Add**.
   The load item is added to the selected load case.

Related Links

- *G.15.2 Member Load* (on page 2129)
- *TR.32.2 Member Load Specification* (on page 2464)
- *Member Load tab* (on page 2842)

M. To add a prestress or post-tension load to members

To add a load due to prestressing or post-tensioning to members, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the loading **Type**:

   Prestress – prestress force is considered at the time of stressing and thus the force is transferred to the adjacent members or supports

   or

   Poststress - the prestress force is considered after the time of stress and thus the force is applied to the member itself (not transferred to the adjacent members or supports)
3. Type the prestress **Force** (in current units).
4. Type the **Eccentricity Distances** used to control the tendon profile at the **Start**, **Middle**, and **End** of the member.

   Eccentricities are measured in the local y axis (i.e., positive is "up" with respect to the local y axis). The cable profile is assumed to be parabolic (i.e, a "draped" tendon profile). Refer to G.15.5 Prestress and Poststress Member Load (on page 2131) for further details on how the tendon profile shape is calculated.
5. Click **Add**.
   The load item is added to the selected load case.

Related Links

- *G.15.5 Prestress and Poststress Member Load* (on page 2131)

- *EX. US-6 Prestress and Poststress Loading* (on page 6351)

- *TR.32.5 Prestress Load Specification* (on page 2489)
- *Member Load tab* (on page 2842)

M. To add fixed end member loads

To apply fixed end loads to ends of a beam, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the **Member Loads** > **Fixed End** tab.
3. Type the load values to apply at the **Start Node** and **End Node**.

   These reference the ends of the member but the loads are applied directly to the member ends, not the joints. These loads are given in terms of the member coordinate system and the directions are opposite to the actual load on the member.
4. Click **Add**.
   The load item is added to the selected load case.

Related Links

- *G.15.4 Fixed End Member Load* (on page 2131)
- *TR.32.7 Fixed-End Load Specification* (on page 2494)

M. Plate, Surface, Area, and Solid Load Items

M. To add pressure load on a plate

To add a uniform pressure load over an entire plate or a rectangular portion of a plate, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

The **Add New Load Items** dialog opens.

2. Select either:

   the **Plate Loads** > **Pressure on Full Plate** tab

   or

   the **Plate Loads** > **Partial Plate Pressure** tab
3. Type the magnitude of the uniform pressure (with sign), **W1**.
4. For partial plate pressure loads, type the coordinates (with respect to the center of the element) to the first and second corners of the loaded rectangular area: **X1**, **Y1**, **X2**, and **Y2**

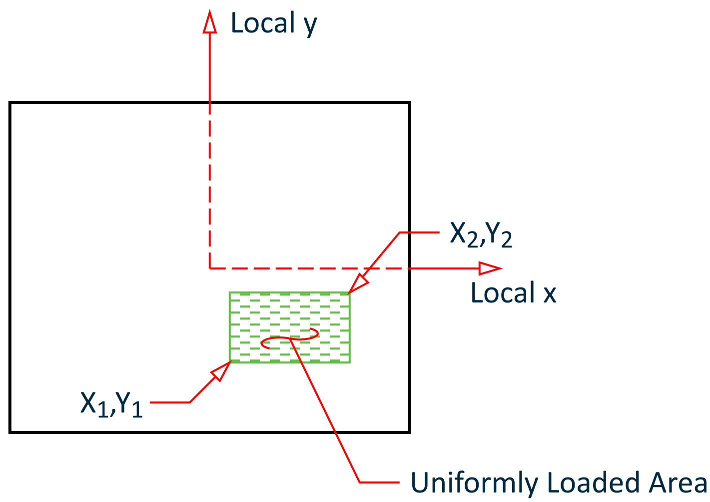

Figure 119: Coordinate values, x1,y1 & x2,y2, in the local coordinate system

5. Select the **Direction** option in which the load acts.

   Pressure loads can act in any of the global directions: **GX**, **GY**, or **GZ** as well as in the **Local Z** direction of the plate.

   Additionally, full pressure loads can act in the **Local Y** or **Local X** directions of the plate as well along projected directions, **PX**, **PY**, or **PZ.**
6. Click **Add**.
   The load item is added to the selected load case.

Related Links

- *Plate Loads tab* (on page 2847)
- *TR.32.3.1 Element Load Specification - Plates* (on page 2469)

M. To add a concentrated load on a plate

To add a point load anywhere on the face of a plate, use the following procedure.

Note: If a load acts at a node point of an element, it is advisable to apply it using the Nodal Load option instead.

1. Either:

On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

Tip: This will add the load item to the currently selected load group selected in the program status bar.

or

In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

The **Add New Load Items** dialog opens.

2. Select the **Plate Loads** > **Concentrated Load** tab.
3. Type the magnitude of the concentrated **Force** (with sign).
4. Type the local **X** and **Y** coordinates of the force on the plate face.

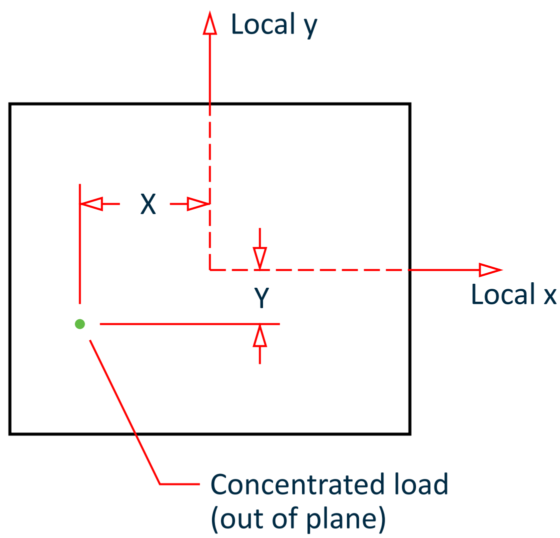

Figure 120: Coordinate values, X & Y, in the local element coordinate system

5. Select the **Direction** option in which the load acts.

   Concentrated loads can act in any of the global directions: **GX**, **GY**, or **GZ** as well as in the **Local Z** direction of the plate.
6. Click **Add**.
   The load item is added to the selected load case.

Related Links

- *G.15.8 Loading on Elements* (on page 2133)
- *Plate Loads tab* (on page 2847)
- *TR.32.3.1 Element Load Specification - Plates* (on page 2469)

M. To add an area load

To add an loaded area which distributes pressure to beams forming a closed loop, use the following procedure.

Note: The `AREA LOAD` command has been deprecated in favor of the `ONEWAY LOAD` or `FLOOR LOAD` commands.

1. Either:

On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

Tip: This will add the load item to the currently selected load group selected in the program status bar.

or

In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

The **Add New Load Items** dialog opens.

2. Type the magnitude of the **Pressure** in the current units.
3. Select the **Direction** in which the pressure acts.
   - **Local Z -** parallel to the member local Z axis
   - **GX** – parallel to the global X axis
   - **GY** – parallel to the global Y axis
   - **GZ** – parallel to the global Z axis
4. Click **Add**.
   The load item is added to the selected load case.

- *Area Load tab* (on page 2845)

M. To add a floor load or one-way load

To generate a pressure load over a floor area using either two-way or one-way load distribution, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the **Floor Load** tab.
3. Either:

   select a range option –XRANGE, YRANGE, or ZRANGE– and then type the upper and lower bound distances (i.e., range) to define the members which define this loaded floor

   or

   select the **Group** option to apply the load to a named group and then select the Member Group name from the list

   Tip: This can be used to select a Composite Deck to assign a floor load to an entire deck. When decks are formed, this automatically creates a new group with the same name.

4. Type the **Pressure** in the current units.
5. Select the **Direction** in which the load acts.
6. (Optional) Select the **One Way Distribution** option to distribute the load towards the longer supporting members (i.e., along the shorter load path).
7. (Optional) When applying the load to a Group, you can check the **Inclined Floor** option to instruct the program that the load is applied to a set of members that form panels inclined to one of the global planes.
8. (Optional) You can report the panel and load data the program calculates:
   a. Check the **Print to output file** to have data included in the STAAD Output and then select the data to include there.
   b. Check the **Print to external text file** to have the data included in an external file and then select the data to include there.
9. Click **Add**.
   The load item is added to the selected load case.

M. To add a surface selfweight load

To add a selfweight load for surface elements so the weight of the surface elements is included in the analysis of the structure, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group 

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the **Surface Loads** > **Selfweight Load** tab.
3. Select a global **Direction** for the selfweight.

   This is typically the “vertical” direction but can be any global direction.
4. Type a **Factor**.

   This is multiplier on the calculated weight of the structure objects. You do not need to use a load factor for ultimate strength design here, as that is typically applied to load combinations.

   Note: A positive value will act in the positive global direction, so you will typically use a negative value here for gravity loads (`-1` being the most commonly used value).

5. Click **Add**.
   The load item is added to the selected load case.

The `SSELFWT` command, along with direction and factor, are added to the load case.

You must assign the load items to structure objects.
Related Links

- *TR.32.9.2 Surface Selfweight Load* (on page 2497)

M. To add a hydrostatic load to objects

To assign a hydrostatic load to members or plate elements, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group 

   > **Tip:** This will add the load item to the currently selected load group selected in the program status bar.

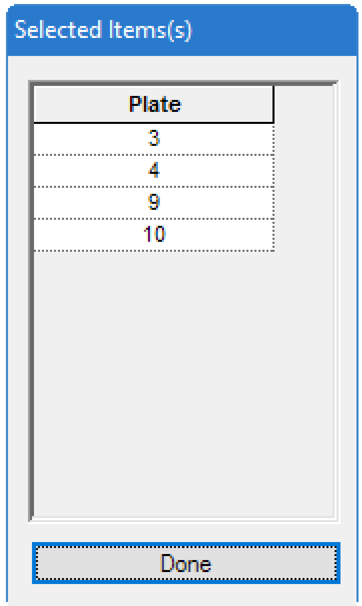
   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the appropriate tab:

Object type	Select this tab
Members	**Member Load** > **Hydrostatic**
Plates	**Plate Loads** > **Hydrostatic**

   > **Note:** A message on the dialog indicates this option is disabled because no objects are selected.
3. Click **Select *`objects`*** .
   The **Selected Item(s)** dialog opens and the **Add New Load Items** dialog closes temporarily.



4. Use the appropriate selection tool to select all the objects to which you want to apply the hydrostatic load in the view window.

   All objects must be of the correct type to populate the list (e.g., only members can be added to the Member list, only plates can be added to the Plate list).

   Note: Hold the **<Ctrl>** to select multiple objects individually.

   As objects are selected, their corresponding object id number is added to the object list.
5. Click **Done**.
   The **Selected Item(s)** dialog closes and the **Add New Load Items** dialog re-opens. The selected objects are now displayed in the objects list.
6. Type values for the minimum and maximum global forces.
7. Select the direction in which the force acts and the global axis along which the program should interpolate loads.
8. Click **Add**.
   The dialog closes and the hydrostatic load items are added to the selected load case.

Unlike most other loads, you do not need to assign these load items. The selection of the objects is used for assigning the load. The program will calculate the exact trapezoidal load pattern based on the other parameters.

M. To calculate the structure frequency

To calculate the frequency of the structure for a load case, use the following procedure.

Frequency calculation is made for a specific load case, so you must have at least one primary load case added to the input file.

This can be done by either the Rayleigh method or the eigenvalue extraction method. The latter can consider missing mass mode.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select either:

   the **Frequency** > **Rayleigh Frequency** tab to use the approximation method

   or

   the **Frequency** > **Modal Calculation** tab to use the more exact eigenvalue extraction method
3. (Optional) For Modal Calculation, check the **Consider Missing Mass** option to include the missing mass procedure for steady state or harmonic analysis.
4. Click **Add**.
   The frequency calculation is added to the load case.

M. Wind Loads

This section describes how to add wind loads to your STAAD.Pro model.

M. To add a wind load definition

To add a custom wind profile definition to your model, use the following procedure

Wind load definitions describe the vertical wind profile that acts in a specific direction.

1. In the **Load & Definition** dialog, select the **Definitions** > **Wind Load** entry and then click **Add**.
   The **Add new: Wind Definition** dialog opens.
2. Select **Custom** from the **Code** drop-down list.

   Tip: You can also type optional **Comments** to further describe the wind definition (e.g., “Wind in X direction”).
3. Click **Add**.

The definition type is added to the **Definitions** > **Wind Load** entry in the **Load & Definition** dialog.

4. Either:

   Repeat steps 2-3 to add more wind definitions

   or

   click **Close**
5. In the **Load & Definition** dialog, select the new wind definition type and click the **Add**.
   The **Add New: Wind Definitions** dialog opens. The dialog now displays the **Intensity** and **Exposures** tabs.

   Note: The previously selected **Code** displays as a read-only selection.
6. Enter the wind profile data in a specific direction in pressure and height above ground pairs.

   Tip: You can paste data copied from a spreadsheet.
7. On the **Exposure** tab, type the **Factor** value.

   A value of 1.0 means that the wind force may be applied on the full influence area associated with the joint(s) if they are also exposed to the wind load direction.
8. Click **Add**.
9. (Optional) Repeat Steps 5, 7, and 8 to add additional exposure factors to this wind definition.

   You may add up to 99 exposure factors to a wind definition.

You must now apply this wind profile in a load case and specify the direction of the wind.

M. To add an ASCE 7 wind load definition

To populate the wind intensity table with values calculated per ASCE 7, use the following procedure.

These steps are performed when M. To add a wind load definition (on page 844) in the **Add New: Wind Definitions** dialog.

1. In the **Load & Definition** dialog, select the **Definitions** > **Wind Load** entry and then click **Add**.
   The **Add new: Wind Definition** dialog opens.
2. Select one of the following options from the **Code** drop-down list:

   - ASCE 7: 1995
   - ASCE 7: 2002
   - ASCE 7: 2010
   - ASCE 7: 2016

   Tip: You can also type optional **Comments** to further describe the wind definition (e.g., “Wind in X direction”).
3. Click **Add**.
   The definition type is added to the **Definitions** > **Wind Load** entry in the **Load & Definition** dialog.

4. In the **Load & Definition** dialog, select the new wind definition type and click the **Add**.
   The **Add New: Wind Definitions** dialog opens. The dialog now displays the **Intensity** and **Exposures** tabs.

   Note: The previously selected **Code** displays as a read-only selection.

5. Click **Generate**.
   The **ASCE-7: Wind Load** dialog opens.
6. On the Common tab, enter the general code and site information:
   a. Select the year (edition) of ASCE-7 code.
   b. Select the **Building Classification Category**.
   c. Type the **Basic Wind Speed** in the selected units.
   d. Select the **Exposure Category**.
   e. Select the **Structure Type** that best describes your structure.
   f. For ASCE 7-16, type the **Height Above Sea Level** of the base of the structure and select the appropriate units of length for this input.
   g. (Optional) If you need to **Consider wind speed-up over Hills or Enscarpment**, select the **Yes** option and then provide the rise type and dimensions
7. Click **Apply**.

   Note: The second tab of the dialog updates to reflect the **Structure Type** selection.

8. Select the second tab and enter the structure data:
   a. Type the structure dimensions.
   b. Select the structure cross-section type (where applicable).
   c. Select the orientation of members exposed to wind (where applicable).
   d. Select the shape of exposed structural members (where applicable).
   e. Type the **Structure Natural Frequency**.

      When the natural frequency is less than 1 Hz, the structure is considered “flexible” when calculating the gust effect factor, G. When the natural frequency is greater than or equal to 1 Hz, then the structure is considered “rigid” when calculating the gust effect factor.
   f. Type the **Structure Damping Ratio**.
   g. Select the Enclosure Classification (where applicable).
   h. (Optional) Select any combination of the **Use Kzt**, **Use Kd**, **Use Kz**, or **Use Ke** options to manually type values for these coefficients.

      The calculated coefficients are otherwise used.
9. Select the **Design Pressure** tab.
   The height vs. intensity data calculated for the current input is displayed here.
10. (Optional) You can check the options for Use G and Use Cf to manually type values for these coefficients.

    The calculated coefficients are otherwise used.
11. Click **OK**.
    The dialog closes and the wind intensity at height data is added to the table on the Intensity tab.

Note: The input fill will contain a section on ASCE 7 wind load generation data. Though this is not read directly by the STAAD analysis engine, these values are stored to allow you to make changes to the wind load parameters.

You can now proceed with the wind load definitions using the calculated values per ASCE-7.

M. To add a SNiP wind load definition

To add a parametric wind load definition per the SP 2.07.7 or SP 20.13330.2016 Loads and Actions building codes, use the following procedure.

Tip: Change units for convenience.

1. In the **Load & Definition** dialog, select the **Definitions** > **Wind Load** entry and then click **Add**.
   The **Add new: Wind Definition** dialog opens.
2. Select one of the following options from the **Code** drop-down list:
   - SNiP 2.07.7-85
   - SNiP 20.13330.2016

   Tip: You can also type optional **Comments** to further describe the wind definition (e.g., “Wind in X direction”).
3. Click **Add**.
   The definition type is added to the **Definitions** > **Wind Load** entry in the **Load & Definition** dialog.
4. In the **Load & Definition** dialog, select the new wind definition type and click the **Add**.
   The **Add New: Wind Definitions** dialog opens. The dialog now displays the **Intensity** and **Exposures** tabs.

   Note: The previously selected **Code** displays as a read-only selection.
5. Type the **Wind Pressure**.
6. Select the **Terrain** type from the drop-down list.
7. Select the **Region** from the drop-down list.
8. Type the **Delta** value.
9. Click **Add**.

M. To add a GB50009 wind load definition

To add a wind load definition and load cases for the Chinese GB50009-2012 code, use the following procedure.

These steps are performed when M. To add a wind load definition (on page 844) in the **Add New: Wind Definitions** dialog.

This procedure is used to generate a series of wind intensity vs. height values based on the procedure of the GB 50009-2012 code.

1. In the **Load & Definition** dialog, select the **Definitions** > **Wind Load** entry and then click **Add**.
   The **Add new: Wind Definition** dialog opens.
2. Select **GB 50009-2012** from the **Code** drop-down list.
3. Click **Add**.
   The definition type is added to the **Definitions** > **Wind Load** entry in the **Load & Definition** dialog.
4. In the **Load & Definition** dialog, select the new wind definition type and click the **Add**.
   The **Add New: Wind Definitions** dialog opens. The dialog now displays the **Intensity** and **Exposures** tabs.

   Note: The previously selected **Code** displays as a read-only selection.
5. Click **Generate**.
   The **Generate Wind Definition and Wind Load Case for Chinese GB 50009** dialog opens.
6. Enter the parameters to calculate the height variation factor for the wind pressure, μ_z:
   a. Type the **Building Height** and **Bottom Elevation**.

      Note: STAAD.Pro supports negative values for the Y coordinate used for wind load generation for the GB 50009-2012 code only.
   b. Select the method to sub-divide the height above ground into discreet points of the wind intensity curve.
      - **Segment Count to Divide Height (H) Equally -** This is the segment count to divide equally the total height (H) of the current building. This is used to calculate the individual height (z) where the wind pressure needs to be calculated.
      - **Equal Segment Length Along Height (H) -** This is the segment length, and the length is equal. The length is along the total height (H) of the current building. This is used to calculate the individual height (z) where the wind pressure needs to be calculated.
      - **Provide Special Height (z) -** This is the special height (z) list. This is the individual height (z) where the wind pressure needs to be calculated. The delimiter for the individual height (z) can be comma (,) or space, such as `3,6,9`.
   c. Select the **Roughness Type**.
   d. (Optional) Type a **Modification Factor**.
7. Select the options used to calculate the wind shape factor, μ_s:
   a. Select the **Shape Item ID** from the drop-down list:
      - 30 : Closed Polygon Building
      - 37 : Circular Section Structure (Chimney)
   b. For closed polygon buildings, select the **Secondary Shape Type** from the drop-down list.
   c. Click **Set Shape Factor** to specify shape factor parameters in the **Set Shape Factor** dialog.

      For closed polygon buildings, refer to the dialog diagrams for definitions of the faces. For circular structures, select the change in diameter and specify the diameter values accordingly.
   d. Type shape factor values for each structure face and wind direction.

   e. Click **OK**.
   f. (Optional) Type the **Interference Factor from Other Building** value if appropriate.
8. Specify the values for the reference wind pressure, $w0$:
   a. Type the **Reference Wind Pressure** value.
   b. (Optional) Type a **Modification Factor** value to use if appropriate.
9. (Optional) If the wind-induced vibration factor, β_z, along-wind is to be considered, do the following:
   a. Check the **Consider Along-wind Vibration Factor** option.
   b. Type the **Damping Ratio** to use.

      This should be greater than zero.
   c. Type the **Basic Natural Vibration Period (T1)** of the building.
   d. Select the appropriate **Structure Type**:
      - **High-rise Building -** The structure type of the current building is high-rise building. The high-rise building is the modern building which is very tall and has many levels or floors. The width of the windward face of the high-rise building is larger than that of the high-tower structure.
      - **High-tower Structure -** The structure type of the current structure is high-tower structure. The width of the windward face of the high-tower structure is far less than its height, and is also less than that of the high-rise building.
   e. Click **Provide Width of Windward Face** to specify the windward face dimensions based on the Structure Type selected.
10. Generate wind load cases for the load definition automatically:
    a. Select the **Wind Load Case** tab.
    b. Check the **Generate Wind Load Case** option.
    c. Enter the range values in each of the global axis directions to specify the range of the wind load.
    d. If the structure is open, then check the **Open** option.
11. Click **OK**.

    The Intensity vs. Height table is populated with the calculated values. If a negative value is used for the ground elevation, then the first row indicates this elevation only (i.e., the intensity value in this case is given as “0.000”).
12. Click **Add**.

    The wind definition and generated load cases are added to the model.

A series of four load cases are generated (one for each structure face), each with four load items for each of the four wind directions. The wind load generation data is stored within the STAAD input file.

M. To add an IS-875 (Part 3): 2015 wind load

To add a wind load definition and load cases for the Indian IS-875 (Part 3): 2015 code, use the following procedure.

This procedure is used to generate a series of wind intensity vs. height values based on the procedure of the IS-875 (Part 3): 2015 code. The wind intensity will either be the net pressure coefficient or the force coefficient multiplied by the design wind pressure, based on the user selection.

Note: This procedure may be used for Rectangular Clad Buildings and Unclad Frame Buildings. The Load & Definition dialog can be used to also create definitions for Signs or Lattice Tower structures.

Notes: The following limitations pertain to generation of IS 875 (Part 3) : 2015 wind loads:

- The wind profile for the loading is calculated based on Y ordinate set to 0 rather than lowest point of the building. Thus, the topographical factor (k3) may not be relevant and should be applied with caution.
- Only Y-up models may be used (that is, the `SET Z UP` command may not be used).
- The resulting wind load intensity vs. height values generated for IS 875 (Part 3) : 2015 are in metric, regardless of the current input units.
- The dynamic effect of wind load is not considered.
- Cl. 6.3.2.4 and Annex B for changes in terrain categories (Table 3 Fetch and Developed Height Relationships) are not considered.
- For rectangular buildings, the frictional drag per Cl. 7.4.1 is not considered.
- For free standing walls and hoarding type structures, the check for oblique wind loads per Cl. 7.4.2.3 is not considered.
- For lattice tower structures, the corner wind effect on square lattice towers with flat-sided members per Cl. 7.4.3.5(b) is not considered.

1. On the **Loading** ribbon tab, select **Wind Load Generator** > **IS 875 (Part 3) : 2015** in the **Load Generation** group.

   

   The **Wind Load Generation - IS 875 (Part 3) : 2015** dialog opens.
2. Specify the **General Information** for the wind load:
   a. Select the **Type of Structure** from the drop-down list.
      - Rectangular Clad Building
      - Unclad Frame Building

      The parameters on the **Wind Load Data** tab update based on this selection.
   b. (Optional) Type the **Structure Height** and **Ground Level Elevation** values.
      The default values are taken as the maximum Y coordinate of the structure and zero, respectively.
   c. Type the **Height Interval for Intensity** to use for developing the height vs. intensity values for the wind load definition.
      The default value is 5 m.
   d. (Optional) Check the **Custom** option for the **Starting Loadcase No** and then type a load case number for the first generated wind load case.
      The default is the next load cases number after the highest load cased in the model.
3. Specify the **Wind Parameters** for the wind load:
   a. Specify the **Basic Wind Speed (Vb)** by either:

      selecting a city from the drop-down list

or

checking the **Custom** option and typing the basic wind speed in m/s

b. Specify the **Risk Factor Coefficient (k1)** by either:

   selecting the class of structure the drop-down list

   or

   selecting **Custom** from the drop-down list and typing the value for k1

c. Type the **Topography Factor (k3)** to use.

d. Specify the **Importance Factor (k4)** by either:

   selecting the importance category from the drop-down list

   or

   selecting **Custom** from the drop-down list and typing the value for k4

e. Specify the **Aerodynamic Roughness Height (z0i)** by either:

   selecting the **Terrain Category** from the drop-down list

   or

   selecting **Custom** from the drop-down list and typing the value for z0i. The values of the Height Factor (k2) may also be entered for each height interval in the wind intensity data table for the custom option.

f. Type the **Wind Directionality Factor (Kd)**.

g. Type the **Area Averaging Factor (Ka)**.

h. Type the **Combination Facotr (Kc)**.

The wind intensity table and graph update with the resulting values.

4. Select the **Wind Load Data** tab.
5. Enter the wind load data based on the selected structure type

   Rectangular Clad Buildings

Wind Direction	Select one of the global directions for the wind: +X, -X, +Z, or -Z.
Building Dimensions	By default, the dimensions are calculated based on the minimum and maximum global coordinates of the structure along the X, Z, and Y global axes, respectively. You may also type the **Length Along X (Lx)**, **Length Along Z (Lz)**, and **Height (H)** dimension values.
Use Coefficient Factor	Select the option for evaluating the coefficient factor: • **None -** no coefficient factor is multiplied with wind intensity value. • **Pressure Coefficient -** select this option to specify parameters to calculate the pressure coefficients on building face per Cl. 7.3.2 and 7.3.3. • **Force Coefficient -** select this option to directly specify the **Force Coefficient Factor (Cf)** on the building per Cl. 7.4.2.
Pressure Coefficient on Face	Use these options when the **Use Coefficient Factor** option selected is **Pressure Coefficient**: **Wind on Face**: Select the face of the structure (as labeled in the diagram in the dialog) to which this wind definition is applicable. **External Pressure Coefficient (Cpe)**: Select to use either the **Code Calculated** or **Custom** (manually typed) value of Cpe. If the maximum range of l/w from Tabe 5 of

	IS 875 (Part 3): 2015 is exceeded, then the upper values of Cpe for $3/2 < l/w < 4$ are still used. You may also enter custom Cpe values.
Internal Pressure Coefficient (Cpi)	Check this option to include the Internal Pressure Coefficient (Cpi).
Building Permeability	Select the range of openings to overall building exterior from the drop-down list. This is used to select the Cpi and Cpnet values per Clause 7.3.2.1 of IS-875. Alternatively, select **Custom** from the drop-down list to type a value to use for Cpi
Use (-) Cpi	Check this option to use negative Internal Pressure Coefficient (Cpi) value to calculate Net Pressure Coefficient (Cpnet)

Force Coefficient on Building	Type the Force Coefficient (Cf) value as per clause 7.4.2 of IS-875 when the **Use Coefficient Factor** option selected is **Force Coefficient**.

Unclad Frame Building

Frame Type	Select if the structure contains a **Single** frame or **Multiple** frames spaced along the wind direction. For either frame type, you must specify the **Solidity Ratio** (Φ) at each height interval of the structure in the frame information table. For multiple frames, you must also specify the **Effective Solidity Ratio** (Φ_e) at each height interval. Providing the **Solidity Ratio** (Φ) for a single frame at the given height interval, the force coefficient (Cf) will be selected according to the user provided solidity ratio values from Table 31 of IS 875 (Part 3) : 2015 by interpolation. Providing the **Effective Solidity Ratio** (Φ_e) for multiple frames at the given height interval, the shielding factor (H) will selected according to the user provided effective solidity ratio values from Table 32 of IS 875 (Part 3) : 2015 by interpolation.
Member Profile Cross Section	Select if the cross section profile of the frame(s) is **Flat Sided** or **Rounded**. For rounded members, you must also specify the **Diameter** of the members used at each height interval in the frame information table.
Frame Spacing Ratio	For **Multiple** frames, type the frame spacing ratio as indicated in Table 32 (Clause 7.4.3.4) of IS-875.
Force Coefficient	The intermediate values along with the calculated values are displayed in the table. If the **Custom** option is selected, then you must specify the Force Coefficient (**Cf**) values at each height interval. For multiple frames in the Custom option, you must also specify the **Shielding Factor** at each height interval in the table.

6. Select the method of assigning the wind loads to the model:

Type of Structure	Assignment method options
Rectangular Clad Building	There are four method of assignments for the generated load cases: • **Automatic -** The program will select faces A, B, C, and D. The list of members in this selection are displayed in the read-only **Member List** cell. • **Group -** An existing group name is used to define the members which make up the building wind faces. • **Member List -** Each face is defined by typing a list of members. • **Range -** Type the minimum and maximum values for the global coordinates (in the units shown) for each face. Check the **Exclude** option for an row to exclude assigning wind loads to this building face.
Unclad Frame Building	There are three method of assignments for the generated load cases: • **Group -** An existing group name is used to define the members which make up the frames. • **Member List -** Each frame is defined by typing a list of members. • **Range -** Type the minimum and maximum values for the global coordinates (in the units shown) for each frame. Check the **Exclude** option for an row to exclude assigning wind loads to this frame.

7. Click **Generate**.

For a rectangular clad building type, a series of four load definitions and eight load cases are generated, each with four load items for each of the four wind directions. The definitions contain the load vs design wind pressure values.

For an unclad frame type, the definitions include height vs intensity. For this case, the intensity generated is the force coefficient (Cf or Cf') multiplied by the design wind pressure (Pd).

The wind load generation data is stored within the STAAD input file.

You may edit the height vs design wind pressure values generated by clicking **Edit** in the **Load & Definition** dialog when one of the wind definition intensities is selected. After editing and regenerating the wind loads, all previous wind definitions and associated loads are deleted.

M. To assign exposure for joints

To assign wind load definition exposure to joints, use the following procedure.

If your wind load definition has multiple exposure factors, you can specify the exact nodes for each factor this way.

This method assumes that you select the nodes first and then assign the exposure value to them. However, you can select the exposure method and then assign that to nodes using a different assignment method if more convenient.

Note: You can alternatively use a coordinate value range to assign exposure. These are applied in the load case.

1. Select the nodes which will all use a specific exposure ratio.
2. In the **Load & Definition** dialog, select that **Exposure** entry within a wind load definition.
3. Select the **Assign to Selected Nodes** method for assignment.
4. Click **Assign**.
   A message prompts you to confirm this assignment.
5. Click **Yes**.

The exposure ratio is assigned to these joints. When an exposure is selected, the assigned nodes are highlighted red in the view window.

You must now apply the wind load to the structure within a load case.

M. To apply a wind load

To apply a defined wind load to your structure, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group 

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the **Wind Load** > **Wind Load** tab.

   Note: If you have not previously added a wind load definition to the model, this tab is inactive. Refer to M. To add a wind load definition (on page 844) for details.
3. In the **Select Type** drop-down list, select the wind load definition for this load case.
4. Select the **Exposed Surface and Direction** of the load and then type the load **Factor** value.
5. (Optional) If the wind load definition is for a SNiP code, specify the additional SNiP Parameters:
   a. Select the configuration from the drop-down list.
   b. Type the wind pressure coefficient.
6. Specify the range of values over which the load applies. Type the along the global axis of how the wind load acts.

   Depending on the arrangement of walls, you may need to sub-divide the wind load application into multiple entries with overlapping ranges. The program may not automatically recognize all open-ended wind panels. Refer to Controlling Open-Ended Panel Identification (on page 2606) for additional details.

   Tip: Alternately, you may specify member lists or group definitions using the command input.
7. (Optional) Check the **Open Structure** option for truss, lattice, or other open structure types.

   This will apply the load only to the projected area of the members and joints, not to the bounded area of members or surfaces.
8. Click **Add**.

The program will automatically calculate the joint loads for structure that lies within the specified range. Selecting the wind load item in the **Load & Definition** dialog will highlight the loading members. The calculated surface exposure and the tributary areas will also be displayed for closed structures.

Review the wind panels for each wind load case to ensure that the intended areas are loaded. The panels are color coded to identify unique tributary areas.

M. To apply a dynamic wind load per SP 20.13330.2016

To apply a SP 20.13330.2016 wind definition as a dynamic load to your structure, use the following procedure.

A modal analysis and at least one static load cases are required in order to use a dynamic wind load case.

In order to perform dynamic wind load generation in STAAD.Pro you must previously define a static load case. The static load case could be any primary static load case which is defined before the Russian dynamic load case, including a static wind loading per the same code. This static load case will provide static load vector to the dynamic wind load module.

As the Russian dynamic wind load component requires modal masses and eigen vectors to calculate the dynamic wind load component at nodes, modal analysis must be performed before the dynamic wind load definition. Therefore, you must also include a separate load case for modal analysis with reference mass defined before the load case. See G.17.3.2 Mass Modeling (on page 2157) for details. Alternatively, if the mass loads are not needed for use with other load cases (that is, a reference load case is not needed for other loads), then you may define the mass loads within the dynamic load case prior to the `WIND LOAD` command.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the **Wind Load** > **Wind Load - Dyanmic** tab.

   Note: If you have not previously added a SP 20.13330.2016 wind load definition to the model, this tab is inactive. Refer to M. To add a SNiP wind load definition (on page 847) for details.
3. In the **Select Type** drop-down list, select the wind load definition for this load case.

   Only SP 20.13330.2016 wind definitions are present in this list.
4. Type the **Width of building along wind dir.** and **Width of building across wind dir.** values.

   These are the width parallel and perpendicular to the wind direction, respectively.
5. Type the load **Factor** value.
6. (Optional) Check the **Allow All Mode Shapes** to include all mode shapes from the modal analysis.

   Otherwise, only the first mode shape will be used.
7. Select the **Static Wind Case** from the drop-down list of primary load cases that precede this load case in the model.
8. Select the direction in which the wind is applied from the graphical plan view.
9. Click **Add**.

M. Seismic Loads

This section describes how to add seismic loads to your STAAD.Pro model.

M. To add a seismic load definition

To add seismic load parameters per a building code, use the following procedure.

Static equivalent seismic loads are applied based on a set of parameters used to define the load. The parameters vary for each building code.

1. On the **Load & Definition** dialog, select **Definitions** > **Seismic Definitions** and the click **Add**.
   The **Add New: Seismic Definitions** dialog opens.
2. On the **Seismic Parameters** tab, select the building code from the **Type** drop-down list.
3. (Optional) Check the **Include Accidental Load** option to consider accidental torsion.

   Note: Not applicable for the Canadian NRC 1995 code.
4. (Optional) For the Indian IS 1893 - 2002/2005/2016 codes:
   a. (Optional) For the IS 1893 - 2002/2005 codes, check the **Include IS 1893 Part 4** option for industrial or stack-like structures.
   b. Click **Generate** to open the IS 1893 Seismic Parameters dialog, which provides a simpler method for entering the parameters with additional context for IS 1893 Part 1.
   c. Click **Generate**.
5. Type the seismic parameters in the table as required for the selected building code.
   A contextual note is displayed below the table for each parameter. Refer to TR.31.2 Definitions for Static Force Procedures for Seismic Analysis (on page 2349) for detailed descriptions of the parameters for each code.
6. Click **Add**.
   If you have not provided all the required parameters, a message opens to alert you of missing items. Once the minimum required parameters have been provided, the seismic definition is added to the **Definitions** > **Seismic Definitions** entry in the **Load & Definition** dialog. The **Seismic Parameters** tab is removed from the **Add New: Seismic Parameters** dialog.
7. Click **Close**.

You will need to add weight items to the load definition. You can do this through a series of loads, a reference load case, or a combination of both.

For IS 1893 2016 seismic loads on buildings with either RC structural walls, you will also need to specify the first story wall area data required to calcualte the natural period of the structure.

Related Links

- *TR.31.2 Definitions for Static Force Procedures for Seismic Analysis* (on page 2349)
- *TR.31.2.5 Chinese Static Seismic per GB50011-2001* (on page 2369)
- *Add New Seismic Definitions dialog* (on page 2895)

M. To add wall data area to an IS1893 2016 seismic definition

To add the first story wall area data for an IS 1892 2016 seismic load definition, use the following procedure.

You must create a reference load case containing the load items to be used as weights in the seismic load. Refer to M. To create a reference load (on page 893) for details.

The wall data area is only required for an IS 1893 2016 seismic load applied to a buiding of structure type 4 (i.e., reinforced concrete structural walls). This data is ignored for any other code or building type.

1. In the **Loads & Defintions** dialog, select the seismic defintion to which you want to add weights and then click **Add**.
   The **Add New: Seismic Definitions** dialog opens.
2. Select the **Wall Area** tab in the **Add New: Seismic Definitions** dialog.
3. For each wall in the global X direction in the first story above ground, type the Width and Length of the wall in plan.
4. For each wall in the global Z direction in the first story above ground, type the Width and Length of the wall in plan.
5. Click **Add**.
6. Either:

   To close the dialog, click **Close**.

   or

   To proceed to manually add weight data, select one of the weight types. See M. To add weight items to a seismic load definition (on page 858) for details.

   or

   To proceed to use a reference load for weight data, select the Reference Load tab. See M. To add weight by a reference load to a seismic load definition (on page 859) for details.

Related Links

- *TR.31.2 Definitions for Static Force Procedures for Seismic Analysis* (on page 2349)
- *TR.31.2.11 IS:1893 (Part 1) 2016 Codes - Lateral Seismic Load* (on page 2393)
- *Add New Seismic Definitions dialog* (on page 2895)
- *IS:1893 Seismic Parameters dialog box* (on page 2898)

M. To add weight items to a seismic load definition

To create structural weights for a seismic load definition, use the following procedure.

If you want to assign floor weights to a floor group, you must have at least one group of the type **Floor** previously defined to use this option.

Tip: If you want to use the same loads for both seismic weights and another load (e.g., the dead load case), you can M. To add weight by a reference load to a seismic load definition (on page 859) instead of this procedure.

1. In the **Loads & Defintions** dialog, select the seismic defintion to which you want to add weights and then click **Add**.
   The **Add New: Seismic Definitions** dialog opens.
2. Select the tab in the **Add New: Seismic Definitions** dialog corresponding to the weight you want to add.

3. Specify the weight parameters:
   For the following weight types, enter the data as indicated:

Weight type	Data to enter
Self	Type a **Self Weight Factor**
Joint	Type a **Joint Weight**
Member	Select the **Loading Type.** Type the **Weight** to use, the **Starting Distance**, and for uniform weights, the **Ending Distance**.
Element	Type a uniform **Pressure**

   For Floor Weights, do the following:
   a. Type a uniform floor **Pressure.**
   b. Select if the load is applied over a **Range** or a floor **Group**.
   c. (Optional) Check the **One Way Distribution** option to use that load distribution to supporting members.
      You can select the default behavior or select a specific member towards which the load is directed.
   d. For the **Range** option, specify Y range limits and optionally X and Z range limits.
   e. For the **Group** option, select a named group of members.
   f. (Optional) For the **Group** option, select the **Inclined Floor** option if the group includes members forming a panel that is inclined from the global XZ plane.

   Refer to TR.32.4.3 Floor Load Specification (on page 2483) for additional details on specifying floor loads.
4. Click **Add.**
5. Repeat steps 1 through 3 to add additional weights to your seismic load definition.
6. Click **Close.**

You must assign the weight items to the appropriate objects.

M. To add weight by a reference load to a seismic load definition

To use a previously defined reference load case for the weights in your seismic load definition, use the following procedure.

You must create a reference load case containing the load items to be used as weights in the seismic load. Refer to M. To create a reference load (on page 893) for details.

This approach is preferable if you need to use the same weight tables for multiple loads or analysis.

1. In the **Loads & Defintions** dialog, select the seismic defintion to which you want to add weights and then click **Add.**
   The **Add New: Seismic Definitions** dialog opens.
2. Select the **Reference Load** tab in the **Add New: Seismic Definitions** dialog.
3. Either:

   select a reference load definition and then click **>** to add it to the Reference Load item

   or

   click **>>** to add all the available reference load definition to the Reference Load item.
4. (Optional) Type a Factor to apply to each reference load definition in the Reference Load item as needed.
5. Select the global direction along which the load is applied from the **Along** drop-down list.
6. Click **Add.**

7. Click **Close**.

Related Links

- *TR.31.6 Defining Reference Load Types* (on page 2453)

M. To add a seismic load

To add a seismic load to a primary load case, use the following procedure.

Note: You must have at least one M. To add a seismic load definition (on page 857) in your model before you can add seismic loads.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group 

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the **Seismic Loads** tab.

   Note: If you do not have a seismic load definition created, this tab is disabled.
3. Select the global **Direction** in which this seismic load acts.
4. (Optional) Type the scale **Factor** to apply to the load.
5. (Optional) Check the option to use **Multiplying factor for Accidental Torsion Moment** and type a **Factor**.

   This value is the ratio of the total building width and is taken from the center of mass for each level.
6. (Optional) Check the option to use **Multiplying factor for Natural Torsion Moment** and type a **Factor**.

   Note: This is only applicable for structures modeled with a rigid diaphragm.

   This torsion -referred to as the natural torsion- accounts for the static eccentricity which is the difference between center of mass and center of rigidity of a rigid floor diaphragm
7. Click **Add**.

- *TR.32.12.2 Generation of Seismic Loads* (on page 2598)

M. Response Spectra

This section describes how to add response spectra to your STAAD.Pro model.

Tip: In STAAD.Pro, a response spectrum analysis is performed on the model when it contains response spectra load case. It is possible to use a linear, elastic analysis with a response spectrum load.

M. To add a generic response spectrum

To add a custom response spectrum (referred to as the “generic” method) to your model, use the following procedure.

Note: You must enter in spectra values using the dialog. To reference an external file containing spectra data, you must use the STAAD.Pro Editor.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the **Response Spectrum** tab.
3. Select **Custom** from the **Code** drop-down list.
4. Select the **Combination Method** to use to combine the responses from each mode into a total response.

   Note: For the **ASCE** method, there are two optional parameters, **FF1** and **FF2**, which can be checked and specified.
5. (Optional) Check the **Save** option to create a file contain the joint accelerations in ratios of gravity and in radians/sec^2.

   The file name is saved in the same location as the STAAD input file, will have the same root filename as the STAAD input file but with an `.acc` file extension.
6. Specify the spectrum data:
   a. Select if the **Spectrum Type** uses **Acceleration** or **Displacement** values.
      The spectrum data table updates accordingly.
   b. Type in the period and spectra data pairs in the table.
      As you add pairs of data, the response spectrum plot is generated to help review the input.
7. Select if the **Interpolation Type** is **Linear** or **Logarithmic**.

   The logarithmic option is recommended when only a few spectra data points are entered, as spectra vs period curves are typically only linear on a log-log scale.
8. Select the **Damping Type** to use and, if explicit **Damping** is selected, type the damping ratio to be used for all modes.
9. Select the directions which spectrum is applied and for each, type a factor (0-1.0).
10. (Optional) You can apply each of the following optional steps as needed:
    a. Select one of the **Signed Response Spectrum Results Options** if needed:

       check **Dominant** and type a **Mode No** to use for determine the signs of all modes. You can alternatively type 0 for the Mode No to have the program select the mode with the greatest percent participation in the excitation direction for the dominant mode.

       or

check **Sign** to create signed values for all results by comparing the sum of the squares of positive versus negative results.

b. To generate individual modal response load cases, check the **Generate load case(s) for first** option and then type the number of load cases to generate. You can also type the Load Case number to use for the first of the generated load cases.

   If the number of load cases requested is larger than the number of modes extracted, then only the number of modes extracted is used.

c. Type a **Scale** factor to apply to the spectra data.

d. Check the **Missing Mass** option to include the static effect of masses not represented in the modes. Type an optional spectral acceleration for this missing mass mode.

e. If the Missing Mass option is used and you want to specify an acceleration corresponding to a frequency instead, check the **ZPA** option and type a frequency.

   If neither the missing mass acceleration value or ZPA frequency is specified, then the spectral acceleration at 33Hz is used to calculate the missing mass mode.

11. Click **Add**.

Related Links

- *TR.32.10.1.1 Response Spectrum Specification - Custom* (on page 2499)
- *Response Spectra tab* (on page 2854)

M. To add an IBC 2000 response spectrum

To specify a response spectrum for seismic loading per the IBC 20005 code, use the following procedure.

The period and acceleration or displacement values for an IBC 2000 response spectrum can be generated by the program to use with a “custom” response spectrum load.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the **Response Spectrum** tab.
3. Select **Custom** in the **Code** list.
4. Generate the IBC 2000 values for the table:

   Note: In order to use the generated spectrum values, you must leave the **Spectrum Type** selection as **Acceleration.**

   a. Click **Generate IBC Spectrum - 2000**.
      The **Spectrum Parameters** dialog opens.
   b. Specify the mapped acceleration values by either:

      select the **Zip** code from the drop-down list, click **Find Lat / Long**, and then click **Calculate S1 / SS**

      or

enter the **Latitude** and **Longitude** and then click **Calculate S1 / SS**

or

enter the **S1** and **SS** values directly

c. Select a **Site Class** for the location.
   The Fa and Fv values for the site location are displayed.
d. Type the **Start**, **End**, and **Interval** values for the period.
e. Click **Generate Spectrum**.
   The Generated Spectrum: IBC 2000 dialog opens. The values are tabulated and the spectrum is plotted. You can use the settings on this dialog to review the data.
f. Click **Close**.

The response spectrum values and plot is generated.

> **Note:** If you select

5. Select the **Combination Method** to use to combine the responses from each mode into a total response.

> **Note:** For the **ASCE** method, there are two optional parameters, **FF1** and **FF2**, which can be checked and specified.

6. (Optional) Check the **Save** option to create a file contain the joint accelerations in ratios of gravity and in radians/sec^2.

   The file name is saved in the same location as the STAAD input file, will have the same root filename as the STAAD input file but with an `.acc` file extension.
7. Select if the **Interpolation Type** is **Linear** or **Logarithmic**.

   The logarithmic option is recommended when only a few spectra data points are entered, as spectra vs period curves are typically only linear on a log-log scale.
8. Select the **Damping Type** to use and, if explicit **Damping** is selected, type the damping ratio to be used for all modes.
9. Select the directions which spectrum is applied and for each, type a factor (0-1.0).
10. (Optional) You can apply each of the following optional steps as needed:
   a. Select one of the **Signed Response Spectrum Results Options** if needed:

      check **Dominant** and type a **Mode No** to use for determine the signs of all modes. You can alternatively type 0 for the Mode No to have the program select the mode with the greatest percent participation in the excitation direction for the dominant mode.

      or

      check **Sign** to create signed values for all results by comparing the sum of the squares of positive versus negative results.
   b. To generate individual modal response load cases, check the **Generate load case(s) for first** option and then type the number of load cases to generate. You can also type the Load Case number to use for the first of the generated load cases.

      If the number of load cases requested is larger than the number of modes extracted, then only the number of modes extracted is used.
   c. Type a **Scale** factor to apply to the spectra data.
   d. Check the **Missing Mass** option to include the static effect of masses not represented in the modes. Type an optional spectral acceleration for this missing mass mode.
   e. If the Missing Mass option is used and you want to specify an acceleration corresponding to a frequency instead, check the **ZPA** option and type a frequency.

If neither the missing mass acceleration value or ZPA frequency is specified, then the spectral acceleration at 33Hz is used to calculate the missing mass mode.

11. Click **Add**.
The new response spectrum is added to the currently selected load case.

M. To add an IS 1893 response spectrum

To specify a response spectrum for seismic loading per the IS 1893 code, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the **Response Spectrum** tab.
3. Select **IS-1893** in the **Code** list.
4. Specify the IS 1893 specific parameters:
   a. Select a **Subsoil class** for the location.

Subsoil option	Description
Custom	You must enter Period and Acceleration or Displacement value pairs in the table, based on the **Interpolation Type** selected. You can also select the **Interpolation Type** for values between data points.
Hard, Medium, or Soft Soil	Average response acceleration coefficient is calculated. You will not need to select **Spectrum Type** or **Interpolation Type** for these options.

   b. (Optional) Select the **Ignore mode(s) with mass participation (IGN)** option and then enter a percentage value.

   Local and torsional modes whose mass participation is less than this percent value are then considered negligible and there fore will be excluded.

   The response spectrum plot is generated as these parameters are specified.
5. (Optional) Select the **Use Torsion** option and then enter the **Dynamic Eccentricity (DEC)** and **Accidental Eccentricity** (ECC) factors.

   The dynamic eccentricity factor is multiplied by the static eccentricity (i.e., the distance between the center of mass and center of rigidity) to get the dynamic eccentricity. This value should typically be 1.0 or higher.

The accidental eccentricity is used to calculate the value of accidental eccentricity. This value is typically 0.05 but may be increased to 0.10 for highly irregular buildings. This value can be positive or negative to accommodate clockwise or counter-clockwise rotation.

6. Select the **Combination Method** to use to combine the responses from each mode into a total response.

   Note: For the **ASCE** method, there are two optional parameters, **FF1** and **FF2**, which can be checked and specified.

7. (Optional) Check the **Save** option to create a file contain the joint accelerations in ratios of gravity and in radians/sec^2.

   The file name is saved in the same location as the STAAD input file, will have the same root filename as the STAAD input file but with an `.acc` file extension.

8. Select if the **Interpolation Type** is **Linear** or **Logarithmic**.

   The logarithmic option is recommended when only a few spectra data points are entered, as spectra vs period curves are typically only linear on a log-log scale.

9. Select the **Damping Type** to use and, if explicit **Damping** is selected, type the damping ratio to be used for all modes.
10. Select the directions which spectrum is applied and for each, type a factor (0-1.0).
11. (Optional) You can apply each of the following optional steps as needed:
    a. Select one of the **Signed Response Spectrum Results Options** if needed:

       check **Dominant** and type a **Mode No** to use for determine the signs of all modes. You can alternatively type 0 for the Mode No to have the program select the mode with the greatest percent participation in the excitation direction for the dominant mode.

       or

       check **Sign** to create signed values for all results by comparing the sum of the squares of positive versus negative results.

    b. To generate individual modal response load cases, check the **Generate load case(s) for first** option and then type the number of load cases to generate. You can also type the Load Case number to use for the first of the generated load cases.

       If the number of load cases requested is larger than the number of modes extracted, then only the number of modes extracted is used.

    c. Type a **Scale** factor to apply to the spectra data.
    d. Check the **Missing Mass** option to include the static effect of masses not represented in the modes. Type an optional spectral acceleration for this missing mass mode.
    e. If the Missing Mass option is used and you want to specify an acceleration corresponding to a frequency instead, check the **ZPA** option and type a frequency.

       If neither the missing mass acceleration value or ZPA frequency is specified, then the spectral acceleration at 33Hz is used to calculate the missing mass mode.

12. Click **Add**.
    The new response spectrum is added to the currently selected load case.

- *TR.32.10.1.7 Response Spectrum Specification per IS: 1893 (Part 1)-2002* (on page 2534)

M. To add an IBC 2006 response spectrum

To specify a response spectrum for seismic loading per the IBC 2006 / ASCE 7-05 codes, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   > **Tip:** This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the **Response Spectrum** tab.
3. Select **IBC 2006/ASCE 7-05** in the **Code** list.
4. Specify the IBC 2006 / ASCE 7-05 specific parameters:
   a. Specify the mapped acceleration values by either:

      typing the **Zip** code (location and values are populated)

      or

      delete the Zip code value and type **Latitude** and **Longitude** (values are populated)

      or

      delete the Latitude value and type the **Ss** and **S1** values directly
   b. Type the **Long Period (TL)** value for the structure.
   c. Type the **Fa** and **Fv** values for the soil conditions at the location.
   d. Select a **Site class (SCL)** for the location.

   The response spectrum plot is generated as these parameters are specified.
5. Select the **Combination Method** to use to combine the responses from each mode into a total response.

   > **Note:** For the **ASCE** method, there are two optional parameters, **FF1** and **FF2**, which can be checked and specified.
6. (Optional) Check the **Save** option to create a file contain the joint accelerations in ratios of gravity and in radians/sec^2.

   The file name is saved in the same location as the STAAD input file, will have the same root filename as the STAAD input file but with an `.acc` file extension.
7. Select if the **Interpolation Type** is **Linear** or **Logarithmic**.

   The logarithmic option is recommended when only a few spectra data points are entered, as spectra vs period curves are typically only linear on a log-log scale.
8. Select the **Damping Type** to use and, if explicit **Damping** is selected, type the damping ratio to be used for all modes.
9. Select the directions which spectrum is applied and for each, type a factor (0-1.0).
10. (Optional) You can apply each of the following optional steps as needed:

a. Select one of the **Signed Response Spectrum Results Options** if needed:

   check **Dominant** and type a **Mode No** to use for determine the signs of all modes. You can alternatively type 0 for the Mode No to have the program select the mode with the greatest percent participation in the excitation direction for the dominant mode.

   or

   check **Sign** to create signed values for all results by comparing the sum of the squares of positive versus negative results.

b. To generate individual modal response load cases, check the **Generate load case(s) for first** option and then type the number of load cases to generate. You can also type the Load Case number to use for the first of the generated load cases.

   If the number of load cases requested is larger than the number of modes extracted, then only the number of modes extracted is used.

c. Type a **Scale** factor to apply to the spectra data.

d. Check the **Missing Mass** option to include the static effect of masses not represented in the modes. Type an optional spectral acceleration for this missing mass mode.

e. If the Missing Mass option is used and you want to specify an acceleration corresponding to a frequency instead, check the **ZPA** option and type a frequency.

   If neither the missing mass acceleration value or ZPA frequency is specified, then the spectral acceleration at 33Hz is used to calculate the missing mass mode.

11. Click **Add**.
    The new response spectrum is added to the currently selected load case.

Related Links

- *TR.32.10.1.10 Response Spectrum Specification per IBC 2006* (on page 2561)

M. To add an EC8 response spectrum

Floor height is determined by the program as a joint where one or more beams frame in a column.

Eurocode 8 requires the use of cracked section stiffness when considering concrete buildings, which however is lacking in the current analysis engine. This can be overcome by using a section reduction factor as suggested in the code. STAAD.Pro has a “section reduction factor” that can be used for this purpose (i.e., the `MEMBER CRACKED` command). Refer to TR.20.10 Member Property Reduction Factors (on page 2282) for details on this command.

Note: Refer to TR.32.10.1.5 Response Spectrum Specification per Eurocode 8 2004 (on page 2525) for additional information on using the response spectrum specifications per Eurocode 8.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group 

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the **Response Spectrum** tab.
3. Select **EURO (EC8) - 2004** in the **Code** list.

4. Specify the EC8-2004 specific parameters:
   a. In the Spectrum table group, type the **Design Ground Acc**(eleration) factor.
   b. Type the **Behaviour Factor**.
   c. Select the **Subsoil Class** from the drop-down list.
   d. In the **Load Type** group, select if the load is in the **Elastic** or **Design** range and then select if the load is **Type I** or **Type II**.

   The response spectrum plot is generated as these parameters are specified.
5. Select the **Combination Method** to use to combine the responses from each mode into a total response.

   Note: For the **ASCE** method, there are two optional parameters, **FF1** and **FF2**, which can be checked and specified.
6. (Optional) Check the **Save** option to create a file contain the joint accelerations in ratios of gravity and in radians/sec^2.

   The file name is saved in the same location as the STAAD input file, will have the same root filename as the STAAD input file but with an `.acc` file extension.
7. Select if the **Interpolation Type** is **Linear** or **Logarithmic**.

   The logarithmic option is recommended when only a few spectra data points are entered, as spectra vs period curves are typically only linear on a log-log scale.
8. Select the **Damping Type** to use and, if explicit **Damping** is selected, type the damping ratio to be used for all modes.
9. Select the directions which spectrum is applied and for each, type a factor (0-1.0).
10. (Optional) You can apply each of the following optional steps as needed:
    a. Select one of the **Signed Response Spectrum Results Options** if needed:

       check **Dominant** and type a **Mode No** to use for determine the signs of all modes. You can alternatively type 0 for the Mode No to have the program select the mode with the greatest percent participation in the excitation direction for the dominant mode.

       or

       check **Sign** to create signed values for all results by comparing the sum of the squares of positive versus negative results.
    b. To generate individual modal response load cases, check the **Generate load case(s) for first** option and then type the number of load cases to generate. You can also type the Load Case number to use for the first of the generated load cases.

       If the number of load cases requested is larger than the number of modes extracted, then only the number of modes extracted is used.
    c. Type a **Scale** factor to apply to the spectra data.
    d. Check the **Missing Mass** option to include the static effect of masses not represented in the modes. Type an optional spectral acceleration for this missing mass mode.
    e. If the Missing Mass option is used and you want to specify an acceleration corresponding to a frequency instead, check the **ZPA** option and type a frequency.

       If neither the missing mass acceleration value or ZPA frequency is specified, then the spectral acceleration at 33Hz is used to calculate the missing mass mode.
11. Click **Add**.

    The new response spectrum is added to the currently selected load case.

This response spectrum may be used with a linear, elastic analysis, geometric nonlinear analysis, or a pushover analysis for review of Eurocode 8 seismic requirements in P. Earthquake workflow (on page 2032).

M. To add a GB 50011-2010 response spectrum

To specify a response spectrum for seismic loading per the Chinese GB 50011 2010 (2016 edition) code, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the **Response Spectrum** tab.
3. Select **Chinese GB 50011 - 2010** in the **Code** list.
4. Select the **Combination Method** to use to combine the responses from each mode into a total response.

   The **CQC** and **SRSS** methods are available for the GB 50011-2010 response spectra.
5. (Optional) Check the **Save** option to create a file contain the joint accelerations in ratios of gravity and in radians/sec^2.

   The file name is saved in the same location as the STAAD input file, will have the same root filename as the STAAD input file but with an `.acc` file extension.
6. Specify the GB 50011-2010 specific parameters:
   a. Select a **Fortification Intensity**, **Seismic Frequency**, and **Site Class (SCL)** for the location.
   b. Select the **Seismic Group** appropriate for the structure.

   The resulting **Max. Horizontal Influence Factor** and building **Period (Tg)** are displayed for the selected spectrum table input.

   The response spectrum plot is generated as these parameters are specified.
7. Select if the **Interpolation Type** is **Linear** or **Logarithmic**.

   The logarithmic option is recommended when only a few spectra data points are entered, as spectra vs period curves are typically only linear on a log-log scale.
8. Select the **Damping Type** to use and, if explicit **Damping** is selected, type the damping ratio to be used for all modes.
9. Select the directions which spectrum is applied and for each, type a factor (0-1.0).
10. (Optional) Select the **Use Torsion** option and then enter the **Dynamic Eccentricity (DEC)** and **Accidental Eccentricity** (ECC) factors.

    The dynamic eccentricity factor is multiplied by the static eccentricity (i.e., the distance between the center of mass and center of rigidity) to get the dynamic eccentricity. This value should typically be 1.0 or higher.

The accidental eccentricity is used to calculate the value of accidental eccentricity. This value is typically 0.05 but may be increased to 0.10 for highly irregular buildings. This value can be positive or negative to accommodate clockwise or counter-clockwise rotation.

11. You can apply each of the following optional steps as needed:
    a. Select one of the **Signed Response Spectrum Results Options** if needed:

       check **Dominant** and type a **Mode No** to use for determine the signs of all modes. You can alternatively type 0 for the Mode No to have the program select the mode with the greatest percent participation in the excitation direction for the dominant mode.

       or

       check **Sign** to create signed values for all results by comparing the sum of the squares of positive versus negative results.
    b. To generate individual modal response load cases, check the **Generate load case(s) for first** option and then type the number of load cases to generate. You can also type the Load Case number to use for the first of the generated load cases.

       If the number of load cases requested is larger than the number of modes extracted, then only the number of modes extracted is used.
    c. Check the **Missing Mass** option to include the static effect of masses not represented in the modes. Type an optional spectral acceleration for this missing mass mode.
    d. If the Missing Mass option is used and you want to specify an acceleration corresponding to a frequency instead, check the **ZPA** option and type a frequency.

       If neither the missing mass acceleration value or ZPA frequency is specified, then the spectral acceleration at 33Hz is used to calculate the missing mass mode.
12. Click **Add**.
    The new response spectrum is added to the currently selected load case.

M. Snow Loads

This section describes how to add snow loads to your STAAD.Pro model.

M. To add an ASCE 7-02 snow load

Loads and definitions are added from the **Load & Definition** dialog in the **Loading** page.

Snow load definitions are applied to floor groups. You must have at least group of the type **Floor** previously defined.

Tip: You may want to change your input units to make entering snow loads convenient.

1. In the **Load & Definition** dialog, select the **Definitions** > **Snow Definition** entry and click then **Add**.
   The **Add New: Snow Definition** dialog opens.
2. Enter the general snow parameters and click the **Add** button.

   The newly created snow load definition will appear in the **Definitions** > **Snow Definition** section in the **Load & Definition** dialog.
3. Either:

   Repeat step 2 to add a second snow load definition.

   or

   Click **Close** to stop adding snow load definitions.
4. (Optional) Create a new primary load case for use with the snow load.
5. In the **Load & Definition** dialog, select the primary load case which will include the snow load.
6. Click **Add**.
   The **Add New: Load Items** dialog opens.
7. Select the **Snow Load** tab.

   Note: If no floor groups have been defined, this page will be inactive and a warning message is displayed in the dialog.
8. Select the **Floor Group** and select the Snow Load parameters.
9. Click **Add**.
   The snow load is added to the primary load case.

Related Links

- *TR.32.12.4 Generation of Snow Loads* (on page 2609)

M. Notional Loads

Notional loads are nominal lateral loads used in a direct analysis, such as specified in AISC 360.

M. To define direct analysis parameters

To define the member parameters used in an AISC 360 direct analysis, use the following procedure.

Note: The yield strength of the steel is taken from the TR.26.1 Define Material (on page 2303). If the material definition is not provided for a member, then a default value of F_y = *36 ksi* is used.

1. On the **Loading** ribbon tab, select the **Direct Analysis** tool in the **Define Load Systems** group.
   The **Create New Load Items** dialog open.
2. Specify the initial τ_b value:

Members whose flexural stiffness are considered to contribute to the lateral stiffness of the structure will have their flexural stiffness (EI) reduced by $0.8 \times \tau_b$.

a. Select the **FLEX Parameter** tab.
b. Type a **FLEX** value.
c. Click **Add**.

3. (Optional) Identify any axial members which contribute to the lateral stiffness of the structure:
   a. Select the **AXIAL Parameter** tab.
   b. Click **Add**.
4. Click **Close**.
5. In the **Load & Definition** dialog, expand the **Definitions** > **Direct Analysis Definition** group.
6. Assign each of the `FLEX` and `AXIAL` parameters listed to the corresponding members in the model.

You must add one or more load cases with notional loads to your model for a direct analysis.
Related Links

- *G.17.2.1.4 AISC 360 Direct Analysis* (on page 2144)
- *TR.31.7 Definition of Direct Analysis Members* (on page 2454)
- *Add New Direct Analysis Definition dialog* (on page 2899)

M. To add a notional load case

To add notional loads to a load case for use with direct analysis, use the following procedure.

Notional loads are lateral loads which are defined as a small percentage of gravity loads. Therefore, you must define your gravity loads in a separate reference load case (recommended) or primary load case before adding notional loads.

The notional loads are calculated as lateral loads applied to the joints in the selected global direct.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group 

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
2. Select the **Repeat Load** > **Notional Load** tab.

   Two load lists are displayed. The first is a list of primary load cases which occur *before* the current primary load case and the second is a list of reference load definitions.
3. Either:

   select a load case or reference load case on the right and click **>** to add it to the notional load

   or

   click either **>>** to add either all of the load cases or reference loads to the notional load
4. Type a **Factor** to use for the ratio of lateral to gravity loads for each load case added to the notional load.

   Typically, codes recommend 0.2 to 0.3 % (0.002 to 0.003). The default value will be the Notional Load Factor specified in the Direct Analysis Definition.

5. Select the global **Direction** for each load case added to the notional load.
6. Click **Add**.

M. Moving Loads

This section describes how to generate basic moving loads to your STAAD.Pro model.

Moving loads generated by the moving load generator in STAAD.Pro are only applied to beams. Plates and surfaces cannot be loaded using these loads.

For bridge decks which are skewed with respect to the global axes, the load generation may not yield the most satisfactory results. In such cases, the M. Bridge Deck workflow (on page 908) is recommended is recommended. The Bridge Deck workflow works on the influence line/influence surface method, and is considerably superior to the moving load generator. It also has the advantage of being able to calculate the critical load positions on decks modeled using plate elements.

- *TR.31.1 Definition of Moving Load System* (on page 2346)
- *V. Moving Load Generator* (on page 3597)

M. To define a vehicle for loading

In order to generate a set of static loads, due to the movement of the vehicle or load on the structure, there are multiple steps involved.

Note: This procedure is used to generate a set of static loads at intervals on a structure. The M. Bridge Deck workflow (on page 908) can also be used to automatically place loads at locations to achieve maximum or minimum actions on a bridge deck.

1. Either:

   on the **Loading** ribbon tab, select the **Moving Loads** tool in the **Loading** group

   

   or

   Select **Vehicle Definitions** under **Definitions** in the **Load & Definition** dialog and then click **Add**.

   The **Add New Vehicle Definition** dialog opens.
2. Specify a **Vehicle Type Ref** number.

   This identification number is used to refer to this vehicle load definition in the moving load generator.

3. Either:

   define a custom vehicle using the **Define load** tab

   or

   select a standard AASHTO vehicle definition using the **AASHTO Spec** tab

   or

   select an external file containing vehicle data using the **File Input** tab
4. Click **Add**.

Related Links

- *G.16.1 Moving Load Generator* (on page 2134)
- *Add New Vehicle Definitions dialog* (on page 2899)
- *TR.31.1 Definition of Moving Load System* (on page 2346)

M. To generate moving load cases

To create a generation of load cases, use the following procedure.

1. In the **Load & Definition** dialog, select the **Load Case Details** entry and then click **Add**.
   The **Add New: Load Cases** dialog opens.
2. Select the **Load Generation** tab.
3. Type the **No. of Loads** to be generated.

   This is the total number of load positions that will be generated. You will later define the starting location and the increment distance between each position.
4. (Optional) Select the **Predefined Loads to be Added** from the drop-down list.
5. Click **Add**.

The moving load generation case is added to the **Load Case Details** entry in the **Load & Definition** dialog. These cases are marked with a **[G]** to indicate that they are generations of load cases. The load case number range is given in the title.

- *Load Generation dialog* (on page 2866)
- *TR.32.12.1 Generation of Moving Loads* (on page 2596)

M. To add vehicles to the load generation

To add a vehicle definition to the moving load generation, use the following procedure.

1. Select a moving load generation case in the **Load Case Details** entry in the **Load & Definition** dialog and then click **Add**.
   The **Add New: Load Cases** dialog opens.
2. Select the vehicle definition in the **Type** drop-down list.
3. Type the coordinates for the **Initial Position of the Load**.

   This is where the reference load (i.e., the first specified concentrated load in the moving load system) is placed on the structure for the first load case in the generation.
4. Type the **Load Increment** values in the planar directions to move the load for each subsequent load case.

5. Click **Add**.
6. (Optional) Repeat steps 2 through 5 to add additional moving loads to the load generation case.
7. Click **Close**.

M. Time History Loads

This section describes how to add time history loads to your STAAD.Pro model.

M. To define a time history type from tabular data

To use a set of time value pairs to define a time history load, use the following procedure.

1. On the **Loading** ribbon tab, select the **Time History** > **Forcing Function** tool in the **Dynamic Specifications** group.

   

   The **Add New: Time History Definitions** dialog opens.
2. Type an **Integration Time Step** value in seconds.
3. (Optional) Select the **Consider Missing Mass Mode** option if necessary.
4. (Optional) Select the **Save** option to generate a file with time history data.
5. Select the **Loading Type** for your data:

   Acceleration

   or

   Force

   or

   Moment
6. Type the **Define Time vs** load data values in the table.
   As you add data pairs, the chart below is populated.
7. Click **Add**.

Note: You must define time history parameters to complete the time history load definition.

Related Links

- *G.17.3.5 Response Time History* (on page 2165)
- *TR.31.4 Definition of Time History Load* (on page 2441)

- *Add New Time History Definitions dialog* (on page 2907)

M. To define a time history type from a function

To use a parametric function to define a time history load, use the following procedure.

1. On the **Loading** ribbon tab, select the **Time History** > **Forcing Function** tool in the **Dynamic Specifications** group.

   

   The **Add New: Time History Definitions** dialog opens.
2. Type an **Integration Time Step** value in seconds.
3. (Optional) Select the **Consider Missing Mass Mode** option if necessary.
4. (Optional) Select the **Save** option to generate a file with time history data.
5. Select the **Loading Type** for your data:

   Acceleration

   or

   Force

   or

   Moment
6. Select the **Harmonic Function** option in the Function Options group.
7. Select the harmonic function to use: **SINE** or **COSINE.**
8. Select one of the options for specifying wave length:

   select **Frequency** and enter a cyclic frequency in cycles/sec.

   or

   select **RPM** and enter the revolutions per minute
9. Specify the harmonic wave parameters:
   a. Enter the **Amplitude** in the units indicated.
      These correspond to the current input units and the **Loading Type** selection.
   b. (Optional) Enter the **Phase** angle in degrees.
   c. Enter the number of **Cycles** of loading.
10. Specify the number of time steps per cycle by either:

    select the **Step** option and enter the time step of the loading.

    or

    select the **SubDiv** option and enter a number of subdivisions per quarter cycle (i.e., from zero to peak amplitude along the sine or cosine wave).
11. Click **Add.**

Note: You must define time history parameters to complete the time history load definition.

Related Links

- *G.17.3.5 Response Time History* (on page 2165)
- *TR.31.4 Definition of Time History Load* (on page 2441)
- *Add New Time History Definitions dialog* (on page 2907)

M. To define a time history type by spectrum

To define a time history type using spectral parameters, use the following procedure.

1. On the **Loading** ribbon tab, select the **Time History** > **Forcing Function** tool in the **Dynamic Specifications** group.

   

   The **Add New: Time History Definitions** dialog opens.
2. Type an **Integration Time Step** value in seconds.
3. (Optional) Select the **Consider Missing Mass Mode** option if necessary.
4. (Optional) Select the **Save** option to generate a file with time history data.
5. Select the **Loading Type** for your data:

   Acceleration

   or

   Force

   or

   Moment
6. Select the **Spectrum** option in the Function Options group.
7. Specify the time data:
   a. Enter the maximum time (in second) in the generated time history in the **Tmax** field.
   b. Enter the time step (in seconds) in the **DeltaT** field.
   c. Enter the time at the end of rising acceleration in the **T1** field.
   d. Enter the time at the end of the steady acceleration in the **T2** field.
   e. Enter the time at the end of the acceleration decay in the **T3** field.

   Note: The value of **T1** must be greater than zero. Further, **T3** > **T2** > **T1** and **Tmax** must be greater than **T3**.
8. Enter the damping ratio in the **Damp** field.
9. Specify the options:
   a. (Optional) Type a **Random Seed** value.

      Enter a positive integer (in the range of 1 to 2,147,483,647) to be used as a unique random number generation "seed." A unique time history will be produced for each seed value. Change this value when you want to produce a "different (from the time history generated with the prior seed value)" but statistically equivalent time history.
   b. Enter the **No of digitized Freq**.

      This is the number of equally spaced frequencies at which the input shock spectrum is re-digitized (by interpolation).
   c. Enter the **No. of Iteration** which will be used to perfect the computed time history.
10. Click **Add**.

For response spectra time history, there are some additional output parameters that must be input via the STAAD.Pro Editor if used.

Note: You must define time history parameters to complete the time history load definition.

Related Links

- *G.17.3.5 Response Time History* (on page 2165)
- *TR.31.4 Definition of Time History Load* (on page 2441)
- *Add New Time History Definitions dialog* (on page 2907)

M. To generate output for time history spectrum

To generate some additional output data for spectrum input for a time history definition, use the following procedure.

Create a structure with a time history definition using the Spectrum option.

These optional commands cannot be entered via the graphical user interface. They are required to be added using the STAAD.Pro Editor.

1. On the **Utilities** ribbon tab, select the **Command File Editor** tool in the **Utilities** group.

   

   The STAAD.Pro Editor window opens with the current STAAD input file.
2. (Optional) To output time history data: after the`DEFINE TIME HISTORY` command, in the`SPECTRUM` options, add the command `THPRINT` *`f18`* .

   Where *f18* directs the program to output either the beginning and last 54 data points (*f18* = 1) or the entire curve (*f18* = 2) or a select number of beginning and last data points (*f18* ≥ 10).

   The spectrum input parameters will be included in the STAAD Output (`.anl`) file along with the Time History Output (limited to the *f18* value specified).
3. (Optional) To generate spectrum output for a time history: after the`DEFINE TIME HISTORY` command, in the`SPECTRUM` options, add the command `SPRINT` *`f19`* .

   Where *f19* represents an integer value after the `SPRINT` command to instruct the program to only output the beginning and last number of values equal to this integer.

   A summary of the Spectrum input and the curve points will be included in the STAAD Output (`.anl`) file.
4. Save the command input file and then exit the STAAD.Pro Editor.

Related Links

- *TR.31.4 Definition of Time History Load* (on page 2441)

M. To use frequency-spectra pairs in a time history load

To instruct the program to use frequency-spectra pairs in lieu of period-spectra pairs for the time history spectrum input, use the following procedure.

Create a structure with a time history definition using the Spectrum option.

These optional commands cannot be entered via the graphical user interface. They are required to be added using the STAAD.Pro Editor.

1. On the **Utilities** ribbon tab, select the **Command File Editor** tool in the **Utilities** group.

   

   The STAAD.Pro Editor window opens with the current STAAD input file.
2. After the `DEFINE TIME HISOTRY` command, in the `SPECTRUM` options, add the command `FREQ`.
3. Save the command input file and then exit the STAAD.Pro Editor.

Related Links

- *TR.31.4 Definition of Time History Load* (on page 2441)

M. To define a time history type by external file

To define a time history type using data in an external text file, use the following procedure.

You must have a separate text file containing pairs of times and values (acceleration, force, or moment). The file extension is not important, but the values must be in plain text.

1. On the **Loading** ribbon tab, select the **Time History** > **Forcing Function** tool in the **Dynamic Specifications** group.

   

   The **Add New: Time History Definitions** dialog opens.
2. Type an **Integration Time Step** value in seconds.
3. (Optional) Select the **Consider Missing Mass Mode** option if necessary.
4. (Optional) Select the **Save** option to generate a file with time history data.
5. Select the **Loading Type** for your data:

   Acceleration

   or

   Force

   or

   Moment
6. Select the **From External File** option in the Function Options group.
7. Type the **File Name** (with or without file extension).
8. Click **Add**.

An example of an external data file:

```
0.0 1.0 1.0 1.2
2.0 1.8
3.0 2.2
4.0 2.6
```

If you need to specify a delta time spacing used for the external file data, this must be done using the STAAD.Pro Editor.

Note: You must define time history parameters to complete the time history load definition.

Related Links

- *G.17.3.5 Response Time History* (on page 2165)
- *TR.31.4 Definition of Time History Load* (on page 2441)
- *Add New Time History Definitions dialog* (on page 2907)

M. To define time history parameters

To define arrival times and damping used for time history loads, use the following procedure.

You must first define a time history type by one of the previously described methods.

One set of time history parameters can defined for your model for all time history load types.

1. On the Loading ribbon tab, select the **Time History** > **Parameters** tool in the Dynamic Specifications group.

   

   The **Define Param** dialog opens.
2. (Optional) Check the **Time Step** option and type the time step value.

   This is the solution time step used in step-by-step integration of the uncoupled equations. If not selected, the default value of 0.0013888 seconds is used.
3. Select the **Damping Type** to use and, if explicit **Damping** is selected, type the damping ratio to be used for all modes.
4. Type in one or more **Arrival Times** for the dynamic loads.

   Arrival time is the time at which a load type begins to act at a joint (forcing function) or at the base of the structure (ground motion).
5. Click **Add**.

The time history load parameters are added to the **Time History Definitions** in the **Load & Definition** dialog.

In order to use a time history load definition, you must add a time history load item to a primary load case.

Related Links

- *G.17.3.5 Response Time History* (on page 2165)
- *Define (Time History) Parameters dialog* (on page 2909)
- *TR.31.4 Definition of Time History Load* (on page 2441)

M. To add a time history load

To add a time history load to the current primary load case, use the following procedure.

Select the current load case in the program status bar.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group 

> **Tip:** This will add the load item to the currently selected load group selected in the program status bar.

or

In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**. The **Add New Load Items** dialog opens.

2. Select the **Time History** tab.
3. Select the **Load Type**:

   Time Load for a forcing function that applies forces or moments to joints

   or

   Ground Motion is applied global to all supports as an acceleration type
4. Select Direction in which the load is applied.

   Time Load types are applied in FX, FY, or FZ for forces and MX, MY, or MZ for moments. Ground motion types are applies in one of the three global directions.
5. Select the arrival time for this load from the arrival times in the time history definition parameters.
6. Select the load definition type from the Defined Types drop-down list.

   The list includes the definition number and function type.
7. (Optional) Select the results type from the Response Types drop-down list.
8. (Optional) Type a Force Amplitude Factor to multiply for the forces, moments, or accelerations at the joints.
9. Click **Add**.

You must assign the time history load to the joints to which it applies.

M. To define general pushover data

1. On the **Loading** ribbon tab, select the **Pushover** tool in the **Define Loading Systems** group.
   The **Create New Definitions / Load Cases / Load Items** dialog opens with only the Pushover tab displayed.
2. On the Define Input tab (on page 2900), select the **General Input Parameters** option.
3. (Optional) Select the **Type of Frame**
4. (Optional) Select **Include Effect Geometric Non-Linearity Effect**

Related Links

- *TR.37.7.7 End Pushover Data* (on page 2653)

M. To define member specific pushover data

Use the following optional procedure to specify parameters for individual members.

1. On the **Loading** ribbon tab, select the **Pushover** tool in the **Define Loading Systems** group.
   The **Create New Definitions / Load Cases / Load Items** dialog opens with only the Pushover tab displayed.
2. On the **Define Input** tab, select the **Member Specific Parameters** option.
3. (Optional) Set the **Expected Yield Stress**
4. (Optional) Set the **Effective Length Factor for Member (Y/Z)**
5. Click **Add.**
6. Once any other parameters have been added, click **Close**.
   Entries for the member parameters are added in the **Loads & Definitions** dialog in the **Definitions** > **Pushover Definitions** section.
7. Select one of the member parameters and click **Assign.**

> **Note:** Refer to Graphical Environment help for using the various assignment methods in the Loads & Definitions dialog.

Related Links

- *Define Input tab* (on page 2900)

M. To manually define and assign hinges

Use the following optional procedure to define parameters and assign hinges manually.

> **Note:** If the pushover analysis will make use of the built-in FEMA hinge properties for all members,

1. On the **Loading** ribbon tab, select the **Pushover** tool in the **Define Loading Systems** group.
   The **Create New Definitions / Load Cases / Load Items** dialog opens with only the Pushover tab displayed.

2. Select the **Define Hinge Property** tab.
3. Select the **Hinge Type**.

   Types **FEMA** or **Ignore** do not require any additional parameters.
4. (Optional) For user-defined hinge types only:
   a. Select an existing **Type ID** or select **New Type** to define a new hinge type.
   b. Specify a unique integer for the **Type Identifier**.
   c. Specify coordinate values for points C, D, and E in the **Load Deformation Curve Points** and IO, LS, and CP values in the **Acceptance Criteria**.

      These values are can be determined using Tables 5-6 and 5-7 in FEMA 356.
   d. Specify values for **Yield Moment (YR)** and **Yield Rotation (YR)**.
      These values are calculated per Section 5.5.2.2.2 of FEMA 365 (G.17.4.1.6 Frame element hinge properties (on page 2174)).
5. Click **Add**.
6. Once any other parameters have been added, click **Close**.
   Entries for the hinge types are added in the **Loads & Definitions** dialog in the **Definitions** > **Pushover Definitions** section.
7. Select one of the hinge types and click **Assign**.

> **Note:** Refer to Graphical Environment help for using the various assignment methods in the Loads & Definitions dialog.

Related Links

M. To define pushover spectral data

Use the following procedure to define the seismic hazard per FEMA 356.

1. On the **Loading** ribbon tab, select the **Pushover** tool in the **Define Loading Systems** group.
   The **Create New Definitions / Load Cases / Load Items** dialog opens with only the Pushover tab displayed.
2. Select the **Define Spectral Details** tab.
3. Specify up to four **Critical Damping** values for the 1st through 4th spectra.

   At least one is required, which has a default value of 5.0%.
4. (Optional) Select the **Site Category**

   Site Class D is used by default.
5. Specify the Mapped Spectral Acceleration **At Short Period**, S_S, to be used per Table 1-4 of FEMA 356.
6. Specify the Mapped Spectral Acceleration **At One-Second Period**, S_1, to be used per Table 1-5 of FEMA 356.
7. Click **Add**.

- *TR.37.7.6 Define Spectral Parameters* (on page 2652)
- *Define Spectrum Details tab* (on page 2904)

M. To add a pushover loading

Use the following procedure to define the pushover loading to be used in the pushover analysis.

1. On the **Loading** ribbon tab, select the **Pushover** tool in the **Define Loading Systems** group.
   The **Create New Definitions / Load Cases / Load Items** dialog opens with only the Pushover tab displayed.
2. Select the **Define Loading Pattern** tab.
3. (Optional) Select **User Defined**
   If the default Auto load pattern is used, the program will internally compute the gravity loads.
4. (Optional) Set the **Method for Lateral Load Calculation**
   TR.37.7.3 Define Loading Pattern (on page 2647) for additional information on each method.
5. (Optional) Set the **Total Base Shear to be Distributed Direction Total Base Shear**
6. (Optional) Specify a **Number of Push Load Steps**
7. Click **Add**.

> **Tip:** Only one pushover loading definition may be used for a model. If a different pushover loading definition is required, either change the individual parameters or delete them and create a new definition.

M. To define solution control

Use the following procedure to define at least one solution control method for the pushover analysis.

1. On the **Loading** ribbon tab, select the **Pushover** tool in the **Define Loading Systems** group.
   The **Create New Definitions / Load Cases / Load Items** dialog opens with only the Pushover tab displayed.
2. Select the **Define Solution Control** tab.
3. (Optional) Set the **Push Up to Defined Base Shear Direction Defined Base Shear**
4. (Optional) Set the **Push Up to Defined Displacement at Control Joint Direction Joint Displacement Value Joint Number**
5. Click **Add**.

M. To use starting vectors with load-dependent Ritz vectors

You must set the eignen method to use load-dependent Ritz (LDR) vectors in order to specify the starting vectors for that method. On the **Analysis and Design** ribbon tab, select the **Miscellaneous Commands** > **Set Eigen Method** tool in the **Analysis Data** group. Then select the **Load Dependent Ritz Vectors (LDR)** option and click **OK**.

Note: This method is used to specify starting mass loads only. In order to specify starting load from reference load cases, you must directly edit the STAAD input file.

1. Select the **Loading** page in the **Analytical Model** workflow.
2. Select **Starting Load Definition** under **Definitions** in the **Load & Definition** dialog and then click **Add**. The **Add New Define Starting Mass Load** dialog opens.
3. Select the directions you want to use for the starting mass load vectors.
4. (Optional) For each direction selected, enter the number of vectors to be extracted corresponding to that load.
5. Click **OK**.

M. Load Combinations

This section describes how to add load combinations to your STAAD.Pro results.

Note: Load combinations of primary load cases are algebraic combination of analysis results. Therefore, they are not applicable to nonlinear analyses.

Load Combinations with Loads from STAAD.Pro Physical Modeler

When you are creating load combinations using loads from STAAD.Pro Physical Modeler, there are two approaches:

1. Creating primary loads for each reference load generated from STAAD.Pro Physical Modeler. This will combine the analysis results of primary load cases and allow you to include the STAAD.Pro Physical Modeler loads in those results.
2. Using repeat load combinations. These load combinations will use the reference load cases generated by STAAD.Pro Physical Modeler (with any necessary load factors).

> **Note:** Do not use primary load cases with STAAD.Pro Physical Modeler reference loads *and* repeat style load combinations, or the results of those load cases will be included twice.

M. To define a new load combination

To manually define a load combination for post-processing, use the following procedure.

One or more primary load cases or load combinations must be defined in order to create a combination.

> **Note:** Load combinations are *not* directly processed by the analysis engine. Instead, their results are combined as specified by the combination method. In order to process combinations of load cases use either a Repeat Load or a Reference Load in a new Primary Load case.

1. On the **Loading** ribbon tab, select the **Combinations** tool in the **Loading** group.

   
   The **Define Load Combinations** dialog opens.
2. Type the **Load No** and load combination **Name**.
3. Select the combination Type to use:
   - **Normal -** a linear combination of a factor multiplied by a load result value
   - **SRSS -** a linear combination of either a Normal type or a square root of the sums squared (SRSS) combination. The factors for each control how each load component is added to the resulting combination
   - **ABS -** a linear combination of a factor multiplied by the absolute value of a load result
4. Select a Primary load case or existing load combination from the **Available Load Cases** list and then click **>** to add the load combination definition.

   The selected load case is added with the default type factors defined above. You can change the factors for an individual load combination component as needed.

   > **Moving Loads:** In order to include the individual load cases from a moving load generator, you must add these using the STAAD.Pro Editor. They cannot be entered using the dialog as they are not generated until the STAAD engine processes the input file.
5. Repeat step 4 for all load components to be added to this load combination.

   > **Tip:** Click **>>** to include all **Available Load Cases**, which will be use the default factors.
6. (Optional) To remove a load component from the **Load Combination Definition**, select the component in and then click **<**. To remove all load components, click **<<**.
7. Click **Add**.

Related Links

- *TR.35 Load Combination Specification* (on page 2616)
- *Define Load Combinations dialog* (on page 2836)

M. To define primary load type

To define or change the load type specified for a primary load case, use the following procedure.

You can define or change the load type for any previously added primary load case.

The load type is used for automatic load combinations.

1. On the **Loading** ribbon tab, select the **Primary Load Type** tool in the **Load Generation** group.

   The **Define Load Type** dialog opens.
2. For each primary load case, select the **Type** from the drop-down list in the cell.
3. (Optional) For Life or Roof Life load types, check the **Reducible-IBC 2003** if this particular load is considered a reducible live load per IBC.
4. Repeat steps 2 and 3 for all primary load cases.
5. Click **OK**.

Related Links

- *Define Load Type dialog* (on page 2871)
- *TR.32 Loading Specifications* (on page 2461)

M. To define automatic load combination rules

To define new or to edit existing rules for generating automatic load combinations, use the following procedure.

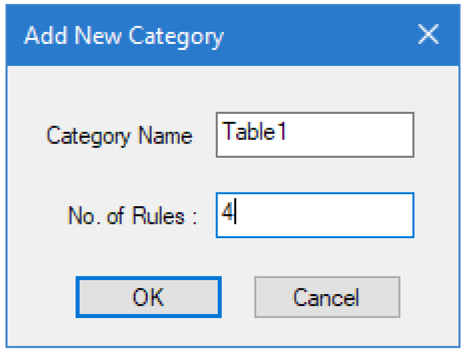
Note: In order to properly generate load combinations for Eurocode (unofficially referred to as EC0), the program contains a macro which allows for gamma inputs. For that code, refer to “ M. To generate load combinations per Eurocode (on page 890).”

1. On the **Loading** ribbon tab, select the **Automatic Combinations** > **Edit Auto Combination Rules** tool in the **Load Generation** group .

   
   The **Edit Loading Rules for Auto Load Combination Generation** dialog opens.
2. (Optional) To create a new Code and Category of load combinations:
   a. Click **New Code**.
      The **Add New Code** dialog opens.

   b. Type a **Code Name** and then click **OK**.
      A new, empty table is loaded.

c. Click **New Category**.
The **Add New Category** dialog opens.



d. Type the **Category Name** and the **No. of Rules** to initially create in the table.

You can add or remove table rows after you create the table.

e. Click **OK**.
The specified rows are added for the new table.

3. For each load type (i.e., column):
   a. Set the **Include Notional Loads?** check box to include notional loads in this type for direct analysis.

   Notional loads are included by default only in dead, live, roof life, snow, and ice load types.

   b. Select the appropriate **Combination Rule** option for this load type:

   - **Aggregate -** Combine all cases together: For each rule, a single combination will be created which will include all the load cases of that load category multiplied by the factor in the table.
   - **Separate -** Separate combination for each case: For each rule, multiple combinations will be created, each will include one of the load cases of that load category multiplied by the factor in the table.
   - **Matrix -** All possible combinations: For each rule, multiple combinations will be created which will include each of the load cases of that load category on their own and with each and every other load case of that category multiplied by the factor in the table.
4. For each combination (i.e., row) in the table, specify the load multiplier for the load types present in that load combination.

Tip: To add a new road, click **Add Row**. To remove a row, click the row number to highlight the entire row and then press **<Delete>**.

5. To save the changes to a table, click **Update Table**.
6. Repeat steps 3, 4, and 5 individually as needed to specify the load combinations for the code category.
7. Click **Close**.

You can now generate load combinations using this rule set.

M. To automatically generate load combinations

To automatically generate load combinations based on predefined rules for load types, use the following procedure.

In order to use this feature, one or more primary load cases must be created with a load type defined. A load type can be assigned to a primary load case either at the time when the load is being created or later.

If you want to customize the load combination rules or create your own for your organization, you must do this before creating the automatic load combinations.

Note: In order to properly generate load combinations for Eurocode (unofficially referred to as EC0), the program contains a macro which allows for gamma inputs. For that code, refer to " M. To generate load combinations per Eurocode (on page 890)."

1. On the **Loading** ribbon tab, select the **Automatic Combinations** > **Automatic Load Combinations** tool in the **Load Generation** group .

   

   The **Auto Load Combination** dialog opens.

   Note: If no load cases have yet been defined for the model, a warning message is displayed over the dialog and the parameters are inactive. Primary load cases are defined using the **Create Primary Load Case** dialog.
2. Choose the code to use from the **Select Load Combination Code** drop-down list.

   ACI:318-2002
   AISC 9th Ed
   ASCE 7-10
   BS:5950
   BS:8110
   GB:50009-2012
   GB:55002-2021
   IBC-2012
   IBC-1997
   NBCC-2005
   NBCC-1995
   IS:456 / IS:800
   SNiP 2.01.07-85
   UBC-1997
   ASCE 7-16
3. Chose the code-specific load combination table to use from the **Select Load Combination Category** drop-down list.
4. (Optional) Type the **Select Starting Combination No** to use for the first generated load combination.
5. (Optional) Check the **Create Repeat Load Cases** option to generate repeat load cases in place of results load combinations.

   Standard load combinations are algebraic combinations of results and therefore are not appropriate for second order effects. A repeat load case is a new primary load case which will re-use the loads from previously defined primary load cases in the analysis engine.
6. (Optional) Check the **Include Notional Load?** option to include notional loads (when notional loads have been specified) in the Repeat Load Cases.
7. Click **Generate Loads**.
   The load combinations based on the selected code and category are displayed in the **Selected Load Combinations** list.

8. Select any loads you do *not* want included in the load combinations and then click **<** to place them in the **Discarded Load Combinations** list.
9. Click **Add**.

M. To generate load combinations per Eurocode

To generate load combinations for the Strength limit state per *Eurocode - Basis of structural design, BS EN 1990:2002+A1:2005* (sometimes referred to as "Eurocode 0").

The load combination generator is capable of creating load combinations per equations 6.10, 6.10a, or 6.10b found in Cl. 6.4.3.2.

The load combination generator is capable of creating load combinations per equations 6.10, 6.10a, or 6.10b found in Cl. 6.4.3.2.

These equations specify the following combinations of loads:

$$\sum_{j\geq 1} \gamma_{G,j} G_{k,j} + \gamma_p P + \gamma_{Q,1} Q_{k,1} + \sum_{i>1} \gamma_{Q,1} \psi_{0,1} Q_{k,1}$$

Alternatively, for the strength limit state, the less favorable of equations 6.10a and 6.10b may be used:

$$\sum_{j\geq 1} \gamma_{G,j} G_{k,j} + \gamma_p P + \gamma_{Q,1} \psi_{0,1} Q_{k,1} + \sum_{i>1} \gamma_{Q,1} \psi_{0,1} Q_{k,1} \qquad (6.10a)$$

$$\sum_{j\geq 1} \xi_j \gamma_{G,j} G_{k,j} + \gamma_p P + \gamma_{Q,1} Q_{k,1} + \sum_{i>1} \gamma_{Q,1} \psi_{0,1} Q_{k,1} \qquad (6.10b)$$

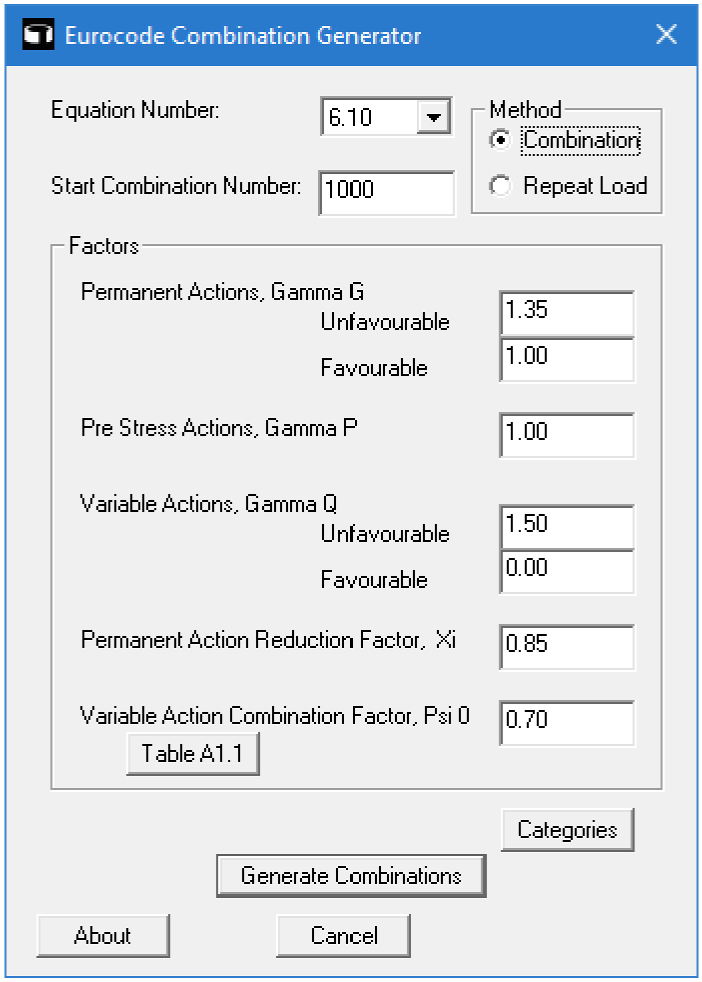
where

Gk	=	Permanent actions
P	=	Prestress actions
Qk	=	Variable actions

Note: The effects in each of the above equations are always additive. If any effect is negative (that is, would reduce the final sum), its effect is taken as zero.

1. On the **Utilities** ribbon tab, select the **User Tools** > **Euro Code Load Combination Generator** tool in the **User Tools** group.

   The **Eurocode Combination Generator** dialog opens.



2. Select the **Equation Number** to use for the generation of load combinations.
3. (Optional) Specify a **Start Combination Number**.
4. Select the **Method** as either:

   Combination to use post-analysis combination of results, which appropriate for linear elastic analysis

   or

   Repeat Load to generate repeat load cases from the primary load cases, which is appropriate for second order effects and dynamic analysis
5. (Optional) Specify load Factors for use in the combination equations.

Factor title	Equation notation
Permanent Actions, Gamma G	γ_G
Pre Stress Actions, Gamma P	γ_P
Variable Actions, Gamma Q	γ_Q
Permanent Action Reduction Factor, Xi	ξ

Factor title	Equation notation
Variable Action Combination Factor, Psi 0	ψ_0

Note: The default values are taken from those provided in EC0.

6. (Optional) Click **Table A1.1** to select one of the recommended values for the Permanent Action Reduction Factor, Psi (ψ_0).
7. Click **Categories** to specify in which load action classification each STAAD.Pro load category is to be assigned.

Action	Included Loads
(None)	Loads of this type will *not* be included in generated load combinations.
Permanent	Gk (permanent) By default, Dead loads are included. **Tip:** You may also want to include Mass or Gravity load.
Variable	Q (variable) By default, Live, Roof Live, Wind, and Snow are included. **Tip:** You may also want to include loads such as Seismic, Temperature, etc.
Pre Stress	P (prestress) No loads are included by default in this category. **Tip:** As STAAD.Pro does not use a load category for prestressing forces, a less-common load category such as **Imperfection** can be used for this action.

8. Click **Generate Combinations**.
A confirmation dialog box opens with the status of the export. Load cases are generated with the selection equation and load case number in the title.

M. To add a repeat load case

To create a primary load case using combinations of previously defined primary load cases, use the following procedure.

A repeat load case is treated as a new primary load. That is, it is processed by the analysis engine rather than being a combination of results. It is therefore applicable for P-Delta analysis.

A repeat load is added similar to a load item within a primary load case.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group 

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

The **Add New Load Items** dialog opens.

2. Select the **Repeat Load** tab.
   A list of the primary load cases which occur *before* the current primary load case is displayed.
3. Either:

   select a load case on the left and then click **>** to add it to the repeat load definition

   or

   click **>>** to add all the primary load cases to the repeat load definition
4. (Optional) Type a load Factor to use for each primary load case included in the repeat load definition.

   Note: The primary load case data is factored rather than results.
5. Click **Add**.
6. Click **Close**.

Related Links

- *TR.32.11 Repeat Load Specification* (on page 2595)
- *Repeat Load tab* (on page 2863)

M. To create a reference load

To define a reference load and add it to a reference load item, use the following procedure.

A reference load case allows you to construct a load case with load items but it will not be directly solved by the analysis engine. It is only solved when it is called by another load case. This allows you to limit the number of load cases analyzed.

Tip: A reference load of type Mass is especially useful to define the structure masses used for dynamic analyses. One reference load case can be used by each of those analysis commands.

1. In the **Load & Definition** dialog, select the **Definitions** > **Reference Load Definitions** entry and then click **Add**.
   The **Add New Reference Load Definitions** dialog opens.
2. (Optional) Type a Number for the load case.

   The program will increment the load case number based on existing load case numbers.
3. (Optional) Select the **Loading Type**.

   This selection is used when automatically generating load combinations. If you select a live load type, you may also indicated if the load is **Reducible per UBC/IBC**.

Dead	Soil	Ice
Live	Rain Water/ Ice	Wind on Ice
Roof Live	Ponding	Crane Hook
Wind	Dust	Mass (Notes (on page 2461))
Seismic-H (horizontal, Notes (on page 2461))	Traffic	Gravity

Seismic-V (vertical, Notes (on page 2461))	Temperature	Push
Snow	Accidental	None
Fluids	Flood	

4. Type a **Title** used to easily identify this load case.
5. Click **Add**.
   The reference load definition is added to the **Definitions** > **Reference Load Definitions** entry in the **Load & Definition** dialog.
6. Add load items to the reference load definition.

   This is done similar to how you would add load items to a primary load case. Reference load definitions can contain:

   selfweight loads
   nodal loads
   member loads
   physical member loads
   area loads
   floor loads
   plate loads
   surface loads
   solid loads
   temperature loads
7. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group 

   Tip: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.
8. Select the **Repeat Load** > **Reference Load** tab.
   A list of the reference load definitions is in the Available Load Cases list.
9. Either:

   select a reference load definition and then click **>** to add it to the Reference Load item

   or

   click **>>** to add all the available reference load definition to the Reference Load item.
10. Repeat Step 9 to add additional reference load definitions to the Reference Load item.
11. (Optional) Type a Factor to apply to each reference load definition in the Reference Load item as needed.
12. Click **Add**.

M. Damping Modeling

In STAAD.Pro, you can specify damping for the entire structure, composite damping for each material in the structure, or damping for each mode. Modal damping can be explicitly defined for each mode or calculated by the program based on the first two frequencies.

M. To assign a composite damping ratio

To assign a damping ratio to a model selection, use the following procedure.

This method assigns a composite damping ratio by a material constant.

Note: If you M. To assign material definitions (on page 797) to members, elements, or solids, then the critical damping ratio for that material will be used.

1. On the **Specifications** ribbon tab, select the **Constants** > **Damping Ratio** tool in the **Materials** group.

   The **Material Constant - Damping Ratio** dialog opens.
2. Select either:

   the **Enter Value** option and then type the composite damping ratio value (must be between 0.001 and 0.99)

   or

   one of the three predefined materials: **Aluminum**, **Concrete**, or **Steel**

Material name	Composite damping ratio value
Aluminum	0.03
Concrete	0.05
Steel	0.03

3. Select the **To Selection** option to limit the assignment to the selection set.
4. Click **OK**.

- *G.17.3.3.1 Composite Damping* (on page 2160)
- *Material Constant dialog* (on page 2809)
- *TR.26.2 Specifying Constants for Members and Elements* (on page 2305)

M. To explicitly define damping values for modes

To define damping values for modes for use with dynamic analysis, use the following procedure.

1. On the **Loading** ribbon tab, select the **Modal Damping** tool in the **Dynamic Specifications** group.

   
   The **Modal Damping** dialog opens.
2. Select the **Explicit** option.
3. Type a **Damping** ratio to use for each mode number.
4. Click **OK**.

Related Links
- *G.17.3.3.2 Modal Damping* (on page 2160)
- *Modal Damping dialog* (on page 2910)
- *TR.26.4 Modal Damping Information* (on page 2312)

M. To evaluate damping for modes

To instruct the program to evaluate the modal damping values from the first two

STAAD.Pro also has a similar method available for calculating the modal damping when provided the mass-proportional damping coefficient, α and the stiffness-proportional damping coefficient, β. This method must be input using the STAAD.Pro Editor.

1. On the **Loading** ribbon tab, select the **Modal Damping** tool in the **Dynamic Specifications** group.

   
   The **Modal Damping** dialog opens.
2. Select the **Evalute** option.
3. Type **Min** and **Max** values to evaluate damping values for each mode.

   The minimum damping value is used for the first two modes. This is also used to evaluate the damping coefficients for subsequent modes based on the first two modal frequencies. If any evaluated damping is greater than the specified maximum value, then the maximum damping is used instead. Refer to Evaluate Damping (on page 2162) for additional details.
4. Click **OK**.

Related Links
- *G.17.3.3.2 Modal Damping* (on page 2160)
- *Modal Damping dialog* (on page 2910)

M. Mass Modeling

Rules Used for Generation of Mass Models

The following rules are applied by the program when the **Mass Model Generator** tool is used to create equivelant

1. Only vertical load components are considered out of the selected loads.

   Typically, these are loads parallel to the global Y direction. In the case of Z Up, these are loads parallel to the global Z direction.
2. Only the user selected loads are considered, regardless of load item types and directions included in all load cases.
3. Only load items in global or projected directions are considered. Any load item in the local direction (typically those labeled X, Y, or Z; e.g., uniform member loads in local coordinate directions) are ignored.

   Note: Selfweight loads are by default applied in the global X, Y, and Z directions. So the vertical selfweight loads are considered.
4. Moment component of loads are ignored for generating equivalent gravity loads.
5. Repeat and reference loads are expanded into a set of internal loads and the rules are then recursively applied to these.
6. Additionally, some load types are ignored as they are not applicable to mass models. Please see the following table for additional details by load item category and load item type.

Table 39: Load Item Types Considered

Category	Type of LoadItem	Consider
Self-weight		Yes
Nodal Load	Node	Yes
	Support Displacement	No
Member Load	Uniform Force	Yes
	Uniform Moment	No
	Concentrated Force	Yes
	Concentrated Moment	No
	Linear Varying Load	No
	Trapezoidal Load	Yes
	Hydrostatic Load	Yes
	Pre/Post Stress Load	No
	Fixed End Load	No
Physical Member Load	Uniform Force	Yes

Category	Type of LoadItem	Consider
	Uniform Moment	No
	Concentrated Force	Yes
	Concentrated Moment	No
	Trapezoidal Load	Yes
Area Load	Area	No
Floor Load	Floor	Yes
Plate Load	Pressure on Full Plate	Yes
	Concentrated Load	Yes
	Partial Plate Pressure	Yes
	Trapezoidal	Yes
	Hydrostatic	Yes
	Element Joint Load	Yes
Solid Load	Solid Pressure Load	Yes
Temperature Load	Temperature	No
	Strain	No
	Strain Rate	No
Seismic Load	Seismic	No
Time History	Time History	No
Wind Load	Wind Load	No
	Wind Load Dynamic	No
Snow Load	Snow	No
Response Spectra	Response Spectrum	No
Repeat Load	Repeat Load	Yes
	Reference Load	Yes
	Notional Load	No
Frequency	Rayleigh Frequency	No

Category	Type of LoadItem	Consider
	Modal Calculation	No

Related Links

- *Create Mass Model dialog* (on page 2870)
- *M. To generate a mass model* (on page 899)

M. To generate a mass model

To automatically generate from existing primary load cases or reference load definitions, use the following procedure.

Your model must contain one or more primary load cases or reference load definitions as load sources. The load case types must be defined as: dead, live, snow, ice, crane hook, or dust.

Any load case or reference load of load type mass will automatically be included in the generated mass model. The generated mass model contains all load items from the included load sources. These load items are factored using the specified load factors and act in the global X, Y, and Z directions.

Tip: Use the **Primary Load Type** tool to quickly set the load types for multiple primary load cases.

1. On the **Loading** ribbon tab, select the **Mass Model Generator** tool in the **Load Generation** group.

   

   The **Create Mass Model** dialog opens.
2. Select the load case where the mass model will be generated as either:

   New Reference Load Case

   or

   Add into 1st Dynamic Load Case

   Note: Your model must contain at least one dynamic load case in order to use the second option.
3. Add the load cases to use in order to define the mass model.

   All primary load cases of the appropriate load types are automatically added to the **Selected Load Cases** list. Reference load cases of the appropriate load types are may be selected from the **Available Reference Load Cases** list as needed.

   Tip: You can remove any load cases from the **Selected Load Cases** list by selecting that item and then clicking the **<** button.
4. Click **Generate**.

- *Create Mass Model dialog* (on page 2870)

M. To add a mass model reference load

A mass model reference load is added in the same way as any other reference load, but with the Loading Type set to Mass.

1. Either:

   on the **Loading** ribbon tab, select the **Reference Load Case** tool in the **Loading Specifications** group

   

   or

   select the **Definitions** > **Reference Load Definitions** section of the **Load & Definition** dialog box and then click **Add**.

   or

   s

   The **Add New: Reference Load Definition** dialog box opens.
2. (Optional) Type a reference load identification number in the Number field.

   Tip: This number is incremented by one from any previously defined reference loads and typically does not need to be changed.
3. Select `Mass` as the **Loading Type**.
4. (Optional) Type a label in the **Title**
   For example, you may want to label the reference by typing `Mass Model`.
5. Click **Add**.
   The dialog box closes and a new reference load definition is added to the input file.

Related Links

- *TR.31.6 Defining Reference Load Types* (on page 2453)

M. To add mass loads to the mass model reference load

1. Select the mass Reference Load Case in the **Load & Definition** dialog box.
2. Click **Add**.
   The **Add New: Reference Load Items** dialog box opens.
3. Select the type of load you want to add from the tree.
4. Specify load parameters (e.g., magnitude, direction, etc.).
5. Click **Add**.
6. (Optional) Repeat steps 3 through 5 to add additional loads.
7. Click **Close**.

Related Links

- *TR.31.6 Defining Reference Load Types* (on page 2453)

M. To create a load envelope

To create a load envelope for grouping loads together in the analytical workflow, use the following procedure.

1. Select the **Load Envelopes** list on the **Load & Definition** dialog and then click **Add**.
   The **Add New Load Envelopes** dialog opens.
2. (Optional) Select an envelope **Type** from the drop-down list.

   Note: In the case of designing steel members for strength and serviceability, it is important to select the applicable load type.
3. Either:

   select a load case or load combination in the **Available** list and then click **>** to add that item to the envelope

   or

   click **>>** to add all the Available load cases and load combinations to the envelope
4. Repeat step 3 to add additional load cases or combinations to the envelope.
5. Click **Add**.
   The load envelope is added to the input file.
6. Repeat steps 2 through 5 to create additional load envelopes.
7. Click **Close**.

Related Links

M. To edit a previously assigned load

To modify the load magnitudes, direction, or assignments for existing load items, use the following procedure.

Loads can be changed within the Analytical Modeling workflow.

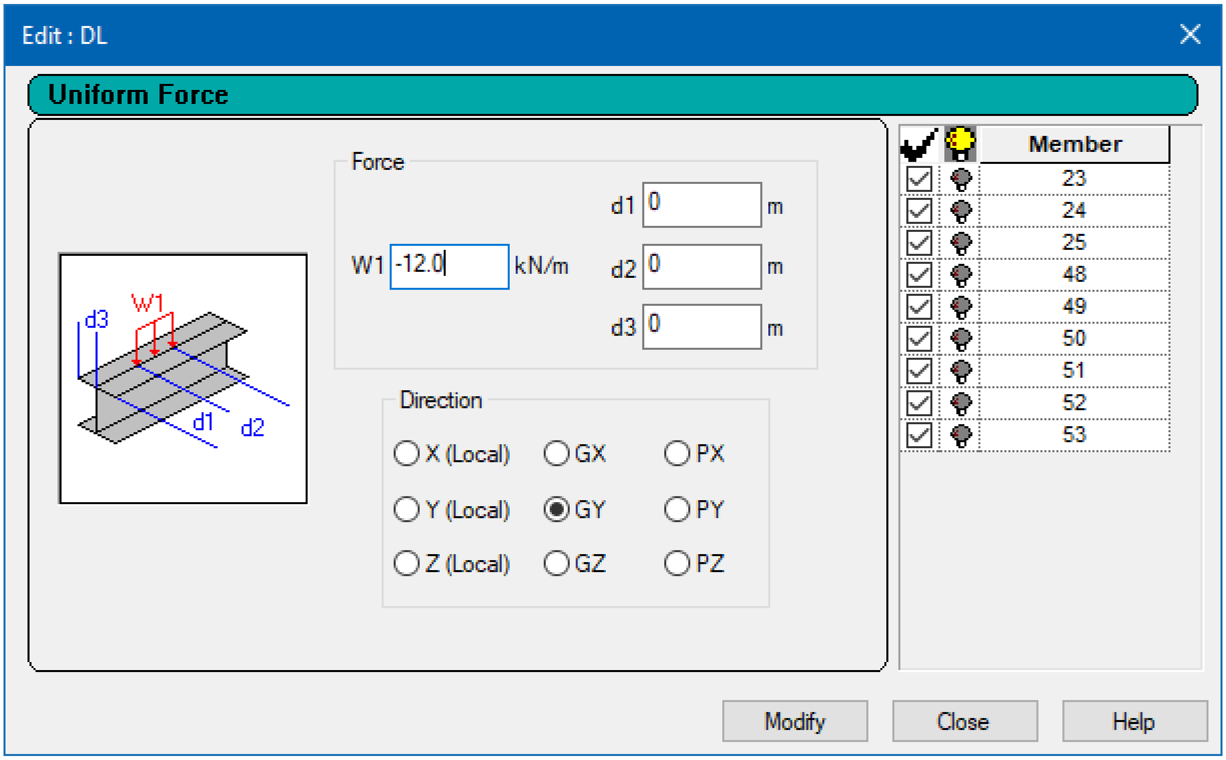
1. Select either:

   the **Loading** ribbon tab

   or

   the **Loading** page

   The **Load & Definition** dialog opens.
2. Expand the Loads section and load case containing the load item you wish to edit.
3. Select the load item you wish to edit.
4. Click **Edit**.
   A **Edit:** load item dialog specific to the defined load type opens.



This dialog is analogous to the **Add New Load Items** dialog, with additional controls included for editing the structural objects to which the load is assigned.

5. Make any changes necessary to magnitude, directions, or other load parameters entered when the load was created.

Tip: To aid in the load editing process, you can select the highlight option ( ) to select the corresponding structural object in the active view window.

6. Un-check individual rows for each structural object in the right-hand table to remove the load from this object.
7. Click **Modify** to save the changes.
8. Repeat steps 5 through 7 to make additional changes as needed.
9. Click **Close**.

M. Piping workflow

The STAAD.Pro Piping workflow is used to import piping support geometry and reactions from Bentley AutoPIPE.

The piping system in a plant model is supported by a number of structural components – such as pipe racks, cradles or shoes – constructed exclusively for that purpose or from the existing beams, columns and slabs of the structure. To facilitate the design of structures to sustain the loading imparted by the piping system, STAAD.Pro includes a seamless transfer of support reactions calculated from an AutoPIPE analysis to the structure modeled in STAAD.Pro.

M. Using the Piping Workflow

General Workflow

1. Import a piping model via the PipeLink utility.
2. Use the Support Connection Wizard to automatically assign connections between pipe nodes and structural entities.
3. Modify or add connections as necessary either graphically or via the Pipe Support table.
4. Transfer loads from the pipe stress model to the STAAD.Pro model.
5. Analyze the STAAD.Pro model for the new loads.
6. Export any changed or updated model data back to AutoPIPEvia the PipeLink utility or the Export Macro.

M. To import a piping model

Tip: The scale, orientation, and origin of both the piping model and structural model should be the same.

1. From within Bentley AutoPIPE, export the pipe stress model using the PipeLink utility.

   Note: Refer to the AutoPIPE documentation for additional assistance on using this product.
2. Open a corresponding model in STAAD.Pro.
3. Select the **Piping** workflow.
   The Piping ribbon tab and pages open.
4. Either:

   on the **Piping** ribbon tab, select **Interop** > **Import** in the **Models** group

   

   or

   click **Import** on the Pipe Model dialog (on page 2962).

   An **Open** dialog opens with the **Files of type** filter set for PipeLink files.
5. Select the **PipeLink file created from AutoPIPE** in the Files list box.
6. Click **Open**.

   A message dialog displays the status of the file import process.

   Note: If clashes are detected when importing, then the Merging Support Connection dialog (on page 2971) opens. This is used to specify if either the imported or local data should be used.
7. Click **OK** to dismiss the dialog.
   The **Support Connection Wizard** opens.

Tip: Multiple models can be imported to a single STAAD.Pro project. Any actions are performed on the current active model as selected in the **Pipe Model** dialog.

Tip: Imported data is saved with the structure upon exiting the Piping mode for later use.

Related Links

- *Pipe Model dialog* (on page 2962)

- *Support Connection Wizard* (on page 2964)

M. To use the Support Connection Wizard

1. Either:

   on the **Piping** ribbon tab, select the **Support Connection Wizard** tool in the **Connection** group

   

   or

   M. To import a piping model (on page 903) as described above.

   The **Move Pipe Model** dialog opens.
2. Enter the offset distance between pipe and structural models and the click the **Next >** button.

   The **Pipe Nodes** dialog opens.

   The filtering options are All, Connected, Unconnected, V-Stop, or Anchor (relating to whether a connection to the STAAD.Pro model has been defined). When support type information is available the filter will be expanded to include these as well.
3. Select which nodes will be used by adding them to the Selected list and click the **Next >** button.

   The **Structure Beams** dialog opens.

   The filtering options are implemented with two combo boxes, one for the category and one to identify the subset within that category. Available filtering options are All, Group, View and Property.
4. Select which structure elements will be used by adding them to the Selected list and click the **Next >** button.

   The **Structure Node** dialog opens.

   The filtering options are implemented with two combo boxes, one for the category and one to identify the subset within that category. Available filtering options are All, Group and View.
5. Select which structure nodes will be used by adding them to the Selected list and click the **Next >** button. The **Parameters** dialog opens.
6. Here you will set some parameters so the wizard can establish pipe connections and click the **Next >** button.

   The results of the Wizard will be displayed in the final dialog.

   See "Parameter Page / Connection Finder" for additional details on these settings.
7. Review these results and if changes are necessary, you may click the **< Back** button. Otherwise, click the **Finish** button to accept.

The results will be presented in a table with columns for pipe node id and for the structural item it is to be connected to. This second column will provide a drop list allowing the user to choose either “No connection” or one of up to 5 closest items. The items will be listed with the closest at the top. The initial state will be the closest item or ‘Ground’, if no good matches were found.

Tip: Manual connections can be generated using the following procedures.

Related Links

- *Support Connection Wizard* (on page 2964)

M. To draw connections between piping supports and the structure

1. On the **Piping** ribbon tab, select the **Connection Support** tool in the **Connection** group.

   
   The mouse pointer changes appearance to the Support Connection cursor ().
2. Click a piping model support.
   A dynamic line is now attaches this support to the cursor.
3. Click either a node or a beam element in the structural model.

   The support association is shown as a dashed, red line in the view window. The Pipe Supports table (on page 2968) is updated to reflect the **Connect To** structural entity.

   Note: You may wish to edit the **Dist. Along Beam** value in the Pipe Supports table to control the exact connection location.
4. Repeat steps 3 and 4 to connect as many supports as needed.
5. Press the **<ESC>** key to exit the Support Connection cursor.

Related Links

- *Pipe Supports table* (on page 2968)

M. To manually specify connections between piping supports and the structure

1. Select the **Supports** page in the **Piping** workflow.
   The Pipe Supports table (on page 2968) opens.
2. Select the row of the Pipe Support Node you wish to connect to the structure.
3. Select if the support is **Connected To** either a **Node** or **Beam**.

   Note: Ground supports are the default and are assumed to *not* be supported by the structural model.
4. Press **<Tab>**.
5. Type the connecting Beam or Node number in the **Structure Entity** cell for the Pipe Node.
   The connection association is shown as a dashed, red line in the view window.
6. Press **<Tab>** to update the model.
7. (Optional) (For Beam supports) Specify a distance along the beam, from the start node, to the connection point and then press **<Tab>**.
8. Repeat Steps 2 through 7 to connect as many supports as needed.

- *Pipe Supports table* (on page 2968)

M. To transfer load data for structural analysis

1. On the **Piping** ribbon tab, select the **Transfer Loadings** tool in the **Loading** group.

   
   The Transfer Pipe Reactions to Structure Model dialog (on page 2970) opens.
2. Make any changes to the load data as needed.
3. Click **OK**.
   A Transfer Loads summary dialog opens to inform you of the status of the load data transfer.
4. Click the **OK** button to dismiss the dialog.

   The loads from the pipe stress supports are now added to the **Load & Definition** dialog in the model.

> **Note:** The structure is now ready to be analyzed for the imported pipe support loads.

Related Links

- *Transfer Pipe Reactions to Structure Model dialog* (on page 2970)

M. To export model data for use in AutoPIPE

Before you export the model data, you should analyze the structural model. Select the **Analytical Modeling** workflow and then on the **Analysis and Design** ribbon tab, select the **Run Analysis** tool in the **Analysis** group. Return to the **Piping** workflow once the analysis is succesfully completed.

1. On the **Piping** ribbon tab, select **Interop** > **Export** in the **Models** group.

   
   The Export Revised Model dialog (on page 2961) opens.
2. (Optional) Edit **User Name**
3. Click **OK**.
   The **PipeLink for STAAD.Pro V8i** utility program opens.
4. Either:

   Select an existing data exchanger file (file extension `.pipelink`.) by clicking **[...]**.

   or

   Create a new file by clicking **Use Blank**.
5. Either:

   Select **Export** > **Start Run**.

   or

   Select the **Run** tool. 

   The progress of the export process is displayed in the Output window. A message dialog opens to provide you with the status of the export.
6. Click **OK**.

7. Review any error or warning messages as needed.
8. Select **File** > **Exit** to close the utility program.

Note: Refer to the documentation included with the PipeLink plug-in for additional help in using this utility.

Related Links

- *Export Revised Model dialog* (on page 2961)

M. To export STAAD.Pro model data into AutoPIPE

Tip: The macro `ToAutoPipePub.vbs` is included with STAAD.Pro for the purpose of creating structural support data in AutoPIPE from a STAAD.Pro model. The resulting file contains only the support frame data for the current STAAD input file.

1. On the **Utilities** ribbon tab, select **User Tools** > **Export Model to AutoPIPE** in the **User Tools** group.

   The Export STAAD Model to AutoPIPE (on page 2959) opens.
2. Select the AutoPIPE Neutral file (file extension `.NTL`) you wish to create or to which you wish to add data.

   Tip: Click **[...]** to select an existing AutoPIPE Neutral file.
3. Specify **Job Information** and **Header** data as necessary.
4. Select the appropriate system of **Units.**
5. Select an option for how the **Member Properties** are displayed in AutoPIPE.
6. Click **OK.**

   Note: If any invalid structural properties or specifications are found, a warning dialog opens to display these issues. Otherwise, a dialog opens to confirm the AutoPIPE Neutral file has been created.

Related Links

- *Export STAAD Model to AutoPIPE* (on page 2959)

M. Pages in the Piping Workflow

The Pages in the Piping workflow are described below in brief.

Table 40: Piping Page Controls in STAAD.Pro

Page	Purpose
Piping	Used to display piping models and select the active model when more than one piping model has been imported. When the **Piping** page is selected, the Pipe Model dialog (on page 2962) opens.
Supports	Used to review and edit support connections manually. When the **Supports** page is selected, the Pipe Supports table (on page 2968) opens.

M. Bridge Deck workflow

STAAD.beava (Bridge Engineering Automated Vehicle Application) mode is integrated into the Bridge Deck workflow. This facility is used for generating loads for use in the analysis of bridge structures.

Overview

The general philosophy governing the design of bridges is that, subject to a set of loading rules and constraints, the worst effects due to load application should be established and designed against. The process of load application can be complex as governing rules can impose interdependent parameters such as loaded length on a lane, lane factors, and load intensity. To obtain the maximum design effects, engineers have to try many loading situations on a trial and error basis.

This leads to the generation of many live load application instances (and a large volume of output data) that then must be combined with dead load and other effects, as well. Bridge Deck is used to minimize the load application process while complying with national code requirements.

The program is based on the use of influence surfaces, which are generated by STAAD.Pro as part of the loading process. An influence surface for a given effect on a bridge deck relates its value to movement of a unit load over the point of interest. The influence surface is a three-dimensional form of an influence line for a single member (or, in other words, it is a 2D influence function).

STAAD.Pro will automatically generate influence surfaces for effects such as bending moments for elements, deflection in all the degrees of freedom of nodes, and support reactions. You then instruct the program to utilize the relevant influence surfaces and, with due regards to code requirements, optimize load positions to obtain the maximum desired effects.

Once the influence surfaces have been generated, they are saved and can be reused for any further investigation that may be required. These remain valid as long as the you do not altered the structural model. Changes to the structural model can alter the pattern of the influence surfaces and you must ensure that a further analysis takes place before any further processing.

Your engineering knowledge and judgement is critical in deciding which effects are required and at what position to obtain them. This is where you can save a lot of processing time and also can ensure critical positions are not missed.

Bridge Standards

The Bridge Deck mode supports the following standards:

- UK: BS 5400 Specific Parameters (on page 2983)
- UK: BD21/01 BD21/01 Specific Parameters (on page 2984) and BD21/01 Annex D Specific Parameters (on page 2984)
- American: AASHTO Specific Parameters (on page 2985)
- American: AASHTO LRFD Specific Parameters (on page 2986)
- Indian: IRC Specific Parameters (on page 2986)

All the relevant code instructions for loading definitions and traffic lane calculations are incorporated in BEAVA and, in cases where vehicle axle arrangements are not standard, it is possible to define a vehicle and save it in the library for use it in the analysis.

Note: It is not uncommon for local authorities to have superseding documents or amendments to national documents. It is the responsibility of the engineer to be familiar with these codes and input the appropriate parameters for loads.

BEAVA is fully integrated in STAAD.Pro and utilizes the same GUI for all input and output data.

Roadway and Load Modeling

You must define the width of the Roadway as straight or curved parallel lines. BEAVA then automatically calculates the following in accordance with the selected code:

- Number of Notional Lanes (Traffic Lanes)
- Influence lines along the center line of notional lanes
- Loaded length along the Lanes
- Critical location of uniformly distributed load
- Critical location of knife edge load
- Critical location of vehicle load
- Maximum effect value
- Associates effects values

Once the program has completed calculating the above, a text file containing the results is displayed on the screen.You can also then examine the results graphically.

Loading arrangements for the effects requested can be displayed on the model and, for every loading arrangement produced, you can instruct the program to generate a STAAD.Pro load case. The added live load cases can be combined with dead loads using the normal STAAD.Pro load combination generation. The final model can then be analyzed in STAAD.Pro and then post-processed.

M. Using BEAVA

There are a number of distinct stages in the use of the program. It is strongly advised to follow this order when using the program.

Tip: It is recommended that you work through the EX. Bridge Deck Loading Example (on page 6988) to familiarize yourself with this process.

M. To open a model in the bridge deck workflow

1. Create a structural model –including member properties and support conditions– in STAAD.Pro.
2. Run an analysis on the structure.
3. Select **Bridge Deck** in the **Workflows** panel.

   Note: If you do not have a license for this module, you will not be able to proceed.

   The **Bridge Deck** ribbon tab opens.

M. To define a bridge deck

1. (Optional) If the mouse pointer is not already displayed as the Plate Cursor, in the **Analytical Modeling** workflow on the **Geometry** ribbon tab, select the **Plates Cursor** tool in the **Selection** group.

2. Select the elements and/or members that will be used to define the bridge deck area of the models.
3. In the **Bridge Deck** workflow on the **Bridge Deck** ribbon tab, select the **Create Deck** tool in the **Deck** group.

   The **Save Deck as** dialog opens.
4. (Optional) Type a **Name** for the deck.
5. Click **OK**.

M. To generate influence surfaces

To generate influence surfaces for the currently selected deck, do the following.

1. On the **Bridge Deck** ribbon tab, select the **Loading > Influence Surface Generator** tool in the **Loading** group.

   
   A temporary STAAD input file (`filename_deck.std`) is sent to the STAAD analysis engine for processing. The **STAAD Analysis and Design** dialog opens to display the progress. When the analysis is complete, the dialog closes automatically.

M. To define a roadway

To define a roadway (i.e., carriageway in some regions), do the following.

1. Either:

   Select a deck from the View window.

   or

   On the **Bridge Deck** ribbon tab, select the **Select Deck** tool in the **Deck** group and then select one of the defined decks from this list.

2. On the **Bridge Deck** ribbon tab, select the **Define Roadway** tool in the **Deck** group.

The Roadways dialog (on page 2974) opens.

3. Click **New**.
   The Define Roadway dialog (on page 2976) opens.
4. Specify the distances from the origin to each curb edge.
   The preview updates to display the roadway on the currently selected deck.
5. Click **OK**.
   A new roadway is now added to the Roadways list in the **Roadways** dialog and is outlined in blue on the deck in the active view window.
6. Click **Close**.

M. To generate loads on the roadway

1. On the **Bridge Deck** ribbon tab, select the **Loading** > **Run Load Generator** tool in the **Loading** group.
   The Load Generator Parameters dialog (on page 2981) opens.
2. On the **General** tab, select the appropriate **Design Code**.
   The ***<code>*** tab updates to reflect this selection.
3. Select the appropriate **Limit State**.
4. Select the ***<code>*** tab.
5. Make the code-specific selections for vehicles, road conditions, multiple presence factors, and impact factors.
6. Select the Node Displacements, Support Reactions, Beam End Forces, or Plate Center Stress tab.

   > **Note:** An action must be defined for which the maximum results determine the placement of the moving loads.

7. Specify a structural object number, direction of action, and sign of effect.
8. Repeat steps 6 and 7 as many times as needed.
9. Click **OK**.
   The program analyzes the deck to obtain the critical load positions for the specified action.

A summary of the analysis is opened in your default text editor (e.g., Notepad). The file (named `filename_deckx.out`) is saved in the same location as the input file. Close the text editor once you have completed reviewing this file.

The placement of the loads for each effect requested may be reviewed.

M. To transfer the loads to STAAD.Pro

To transfer the generated load cases to STAAD.Pro for analysis and design, do the following.

1. On the **Bridge Deck** ribbon tab, select the **Loading > Create Loading in STAAD Model** tool in the **Loading** group.
   A message dialog opens to confirm the load was successfully added in the STAAD input file.
2. Select the **Analytical Modeling** workflow.
3. On the **Loading** page, review the loads added to the input file in the **Load & Definitions** dialog.

   > **Note:** One load was added for each action requested in the **Load Generators Parameters** dialog.

4. (Optional) Specify additional analysis commands or design parameters as needed.

5. On the **Analysis and Design** ribbon tab, select the **Run Analysis** tool in the **Analysis** group.

M. Checking Your Model

STAAD.Pro comes with a number of tools used to check your structure and model objects.

M. To check for multiple structures

To check for multiple, independently defined set of entities in your model, use the following procedure.

The STAAD.Pro analysis engine can accommodate multiple structures in a single model. However, this check allows you to confirm the number of detected structures to prevent an unintentionally defined model.

1. On the Utilities ribbon tab, select the **Structure Tools** > **Multiple Structures** tool in the **Geometry Tools** group.

   The **List of Structures** dialog opens.
2. (Optional) Select a structure name in the list.
   The entities detected in this structure are selected in the view window.

M. To check for warped plates

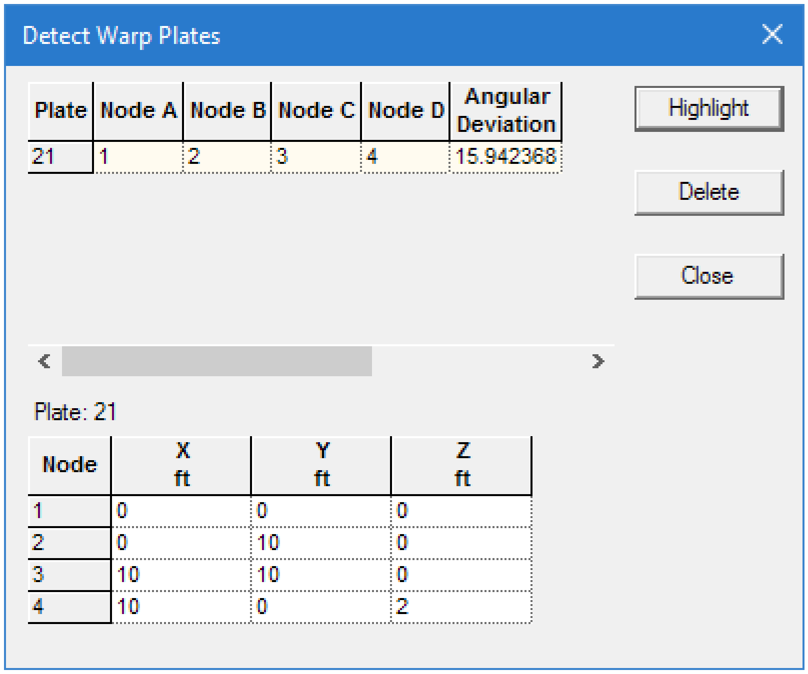
A warped plate is defined as a four-noded plate whose nodes do not lie on the same plane. This tool detects such plates.

You can set the tolerance for warped plates by first setting the **Tolerance for Warped Plate Element Detection** value on the **Options** dialog Tolerance tab. Only plates whose angular deviation exceeds this tolerance value will be displayed.

For this check, warping is defined as excessive angular deviation between all vertex normals.

1. Select one or more plates in the model.
2. Select the **Plate Tools** > **Check for Warped Plates** tool in the **Geometry Tools** group on the **Utilities** ribbon tab.

   If any warped plates are detected, the **Detect Warp Plates** dialog opens. A list of all selected plates and their maximum angular deviation is displayed. The global coordinates for a selected plate are displayed below.



3. (Optional) Click **Highlight**
4. (Optional) Click **Delete**

Tip: You can undo this action through the Undo tool in the main interface.

5. Click **Close** when you have completed reviewing warped plates.

An example of such an element is demonstrated in the following STAAD input.

```
STAAD SPACE
UNIT FEET KIP
JOINT COORDINATES
1 0 0 0; 2 0 10 0; 3 10 10 0; 4 10 0 2
ELEMENT INCIDENCES SHELL
21 1 2 3 4
FINISH
```

Nodes 1, 2, and 3 lie in the XY plane at Z = 0, but node 4 has a Z coordinate of 2, thereby causing the plate to become non-planar.

The warped plate check sub-divides the quad element into two sets of triangles: one with a diagonal from point 1 to point 3 and another diagonal from point 2 to point 4. These triangles do not lie in the same plane so an angle is formed between them at their shared edge. The largest angle between adjacent triangles in the warped quad element is compared against the tolerance threshold. If this tolerance angle is exceeded, then the plate is reported as excessively warped.

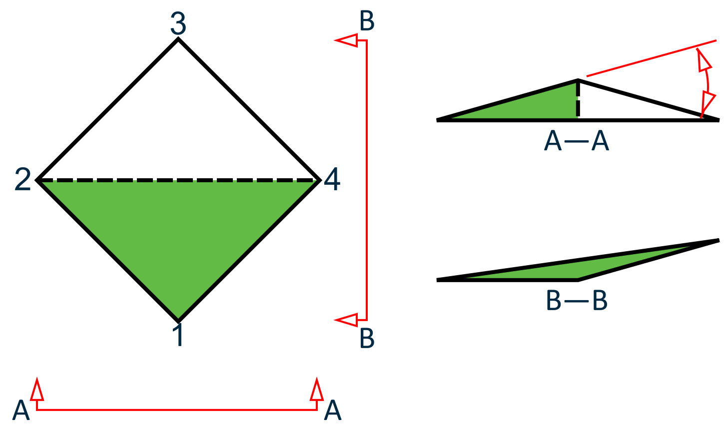


Figure 121: A) Checking triangles formed by the diagonal 2-4.

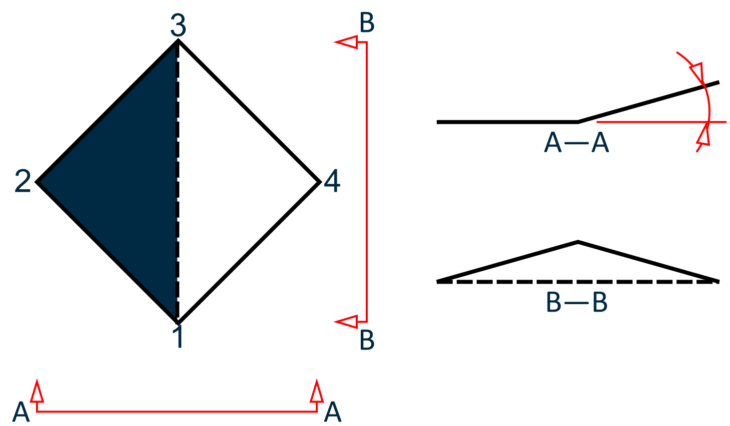

Figure 122: B) Checking triangles formed by the diagonal 1-3

M. To check for and remove duplicate entities

To detect the presence of and remove instances of nodes, beams, plates, etc. which are duplicates, use the following procedure.

One definition of duplicate nodes is that they are 2 or more nodes, having distinct node numbers, but the same X, Y, Z coordinates. For example, if node number 5 has coordinates of (7, 10, 0), and node 83 also has coordinates of (7, 10, 0), node 5 and 83 are considered duplicate. However, STAAD.Pro allows you to expand the definition of this term to include nodes separated by any distance. When this menu is selected, the following message box pops up, asking the user to specify a tolerance.

Duplicate members are 2 or more members, having distinct member numbers, but connected between the same 2 nodes. For example, if there are 3 members, say, 17, 46 and 75, all connected between the nodes 105 and 117, those 3 members are considered duplicate. The order of the node incidence is disregarded during this check. For example, if member 17 has 105 as its first node, 117 as its second, and member 46 has 117 as its first node, 105 as its second, they are still treated as duplicate.

A similar definition is applicable for duplicate triangular or quadrilateral plates. Plates are considered duplicates if they share the same vertex nodes, regardless of order.

1. Depending on the entity type you are checking, select one of the following tools from the **Utilities** ribbon tab in the **Geometry Tools** group:

To check for duplicate...	Select the following tool...
Nodes	**Node Tools** > **Duplicate Nodes**
Beams	**Beam Tools** > **Duplicate Beams**
Plates	**Plate Tools** > **Duplicate Plates**

   (Nodes only) The **Remove Duplicate Nodes** dialog opens.
2. (Nodes only) Type a distance in the **Enter Tolerance** field and click the **OK**.

   The tolerance is the value used to define the distanced at which nodes are to be considered separate or a duplicate. In some cases, the process of creating the model can result in nodes that a minuscule distance apart. Specifying a tolerance greater than zero allows the program to consider those nodes as duplicates and allows you to process them as needed.

   The program reviews the model for any duplicates of the selected model element type (using the tolerance for Nodes).

   If no duplicates are found, a message is displayed.

   If duplicates are detected, the **List of Duplicate Nodes / Members / Plates** dialog opens. Each entry in the list contains two or more entities that the program has detected to be duplicates.
3. Either:

   click **Remove All Duplicates** to remove the second and additional duplicate for item in the list and then click **OK** to confirm the deletion

   or

   select individual duplicate items to retain as follows:
   a. Select a duplicate set in the list and then click **Retain >>** to remove the duplicate from the model. The **Select Node / Member / Plate** dialog opens.
   b. Select which item to remove:

Options	Description
For nodes...	Either choose the node for deletion, either by clicking it, the first in the list, or the last in the list.
For beams and plates...	Select the **Member / Plate To Keep** drop-down list.

   c. Click **OK**.
      The remaining duplicates are removed and other model entities which refer to those duplicates now reference the selected (merged) entity.
   d. Repeat steps 3a through 3c as necessary to review all duplicates of the entity type selected.
4. Click **Close**.

Related Links

- *List of Duplicate Nodes / Beams / Plates dialog* (on page 2948)

M. To detect and remove zero length members

A zero length member is one of the undesirable consequences of having duplicate nodes in the structure. A member connected between duplicate nodes, which have the same (X,Y,Z) coordinates, will have a length of zero (or nearly zero).

1. On the **Utilities** ribbon tab, select the **Beam Tools** > **Check Zero Length Members** tool in the Geometry Tools group.
   The **Zero length beams** dialog opens.
2. (Optional) Type a different tolerance in the **Enter Tolerance** field.

   Since duplicate nodes can be two or more nodes separated by any user-defined distance, zero length members too can be defined as members of any user defined length. This distance is the tolerance used in the process of detection.
3. Click **OK**.

   If no members of zero length are detected a message is displayed.

   If one or more zero length members are detected, the **Detect Zero Length Member** dialog opens.
4. Select a zero length member in the list and then click **Delete** to remove the beam.

   Tip: You can click **Highlight** to select the member in the View window (though most zero length members are difficult to see unless at a very high magnification). Then select the **Properties** tool on the **Beam** ribbon tab to open the **Beam** dialog for the zero length member.
5. Repeat Step four as necessary until all zero length members are removed.
6. Click **Close**.

M. To check for overlapping collinear members

1. On the Utilities ribbon tab, select the **Beam Tools** > **Check Overlapping Colinear Members** tool in the **Geometry Tools** group.

   If no overlapping collinear members are detected, then a message dialog opens with that message.

   If one or more overlapping collinear members are detected, the **Overlapping Collinear Beams** dialog opens.
2. Select the overlapping members pair and the Highlight option to select the beam(s) in the Active View window.
3. The members in the Active View window can be manipulated or deleted as necessary while the **Overlapping Collinear Beams** dialog is open.

An example of 2 members which would qualify as overlapping collinear are:

```
STAAD SPACE
UNIT FEET KIP
JOINT COORDINATES
1 0 0 0; 2 0 10 0; 3 10 10 0; 4 10 0 0; 5 13 10 0; 6 -4 10 0;
MEMBER INCIDENCES
1 1 2; 2 2 3; 3 3 4;
101 5 6
FINISH
```

Here, members 2 and 101 are overlapping collinear. Member 2 is entirely confined within the span of member 101, and collinear, but they are not attached to each other.

Another example is:

```
STAAD SPACE
UNIT FEET KIP
JOINT COORDINATES
1 0 0 0; 2 0 10 0; 3 10 10 0; 4 10 0 0; 5 13 10 0; 6 -4 10 0;
MEMBER INCIDENCES
1 1 2; 2 2 3; 3 3 4;
101 2 5
FINISH
```

Here, again, members 2 and 101 are overlapping collinear. But even though they are connected to each other at node 2, again member 2 is entirely confined within the span of member 101, and collinear.

M. To change a beam incidence

To change the incidences of a selected set of beams, use the following procedure.

1. Select one or more members in the view window.
2. On the **Utilties** ribbon tab, select the **Beam Tools** > **Beam Incidence** tool in the Geometry Tools group.

   

   The **Redefine Incidence** dialog opens.
3. Select an incidence definition to use:

   Switch incidences of selected beams

   or

   Set the incidence order of the seleted beams so that the start node is close to the origin than end node

   or

   Set the incidence order of the seleted beams so that the start node is farther from the origin than end node
4. Click **OK**.

Related Links

- *M. Member Orientation* (on page 799)

M. To detect and remove orphan nodes

To detect and then remove nodes which are not connected to any other model entity (i.e., “orphan nodes”), use the following procedure.

In the process of modeling, disconnected nodes can be created in your model.

1. On the **Utilities** ribbon tab, select the **Node Tools** > **Oprhan Nodes** tool in the **Geometry Tools** group.

Any detected orphan nodes are selected in the view window.

2. To remove these orphan nodes, on the **Utilities** ribbon tab, select the **Node Tools** > **Remove Oprhan Nodes** tool in the **Geometry Tools** group.
   The detected orphan nodes are deleted.

M. To display the distance between two nodes

To temporarily display the dimension between two nodes in the active View window, use the following procedure.

1. On the **Utilities** ribbon tab, select the **Node Tools** > **Node to Node Distance** tool in the **Geometry Tools** group.

   The mouse pointer changes to the Node to Node Distance cursor ().
2. Click on any two nodes in succession in the active View window..
   A dimension call out is added between these two nodes.
3. Repeat step 2 to dimension as many distances as needed.
4. Either:

   Press the **<Esc>** key

   or

   Select the **Node to Node Distance** tool again

   The mouse pointer returns to the normal selection mode.

M. To display beam lengths

To display the lengths of each analytical member, use the following procedure.

To dimension only the members in a selection, select those members before starting this procedure.

1. On the **Utilties** ribbon tab, select the **Beam Tools** > **Dimension Beams** tool in the **Geometry Tools** group.

   

   The **Display/Remove Dimensions** dialog opens.
2. Select the option for which beams to be dimensioned:

To...	Select...
dimension all the beams in the current view window	**Dimension to View**
dimension only the beams you selected before step 1	**Dimension to Selected Beams**
dimension a comma separated list or range of beams	**Dimension to List**

3. Click **Display**.
4. (Optional) To remove the dimensions, select the **Remove** option and then click **Remove**.
5. Click **Close**.

Any new members will *not* be dimensioned. You must repeat this procedure to display their dimensions.

Related Links

- *Display/Remove Dimensions dialog* (on page 2949)

M. To check for negative volume solids

To check for solids that would result in a negative volume in the analysis, do the following.

This check uses the Jacobian matrix determinate to determine if any of the solids have a negative or indeterminate volume, which would result in an analysis error.

1. On the **Utilities** ribbon tab, select the **Solid Tools** > **Negative Volume** tool in the **Geometry Tools** group.

   

   The **List of Solids** dialog opens.
2. Select any solid number in the list to select it in the view window.
3. Click **Close**.

M. Physical Modeling workflow

You can use STAAD.Pro Physical Modeler to model a “physical” structure and then re-import that data back into the STAAD.Pro environment for loading, analysis, and design.

M. Using the Physical Modeler

You can model structure geometry, specifications, and many loads with the STAAD.Pro Physical Modeler.

You must being a physical model with an empty STAAD project. Existing analytical models cannot be opened in the physical modeler.

When you open a model that was created using the physical modeler, you will prompted if you want to open the model in the physical modeler environment.

1. Select the **Physical Modeling** workflow.

   
   The STAAD.Pro Physical Modeler window opens.

Refer to the STAAD.Pro Physical Modeler help for details on how to use that module to model your structure.

M. To drop the associated physical model

To remove the associated physical model from the current STAAD input file, use the following procedure.

Caution: This procedure cannot be undone. Once a physical model has been dropped, that model can no longer be opened within the **Physical Modeling** workflow.

When a physical model is associated with a STAAD input file, many tools in the **Analytical Modeling** workflow as well as portions of the input file in the STAAD.Pro Editor are disabled. This is intended to prevent making changes which would potentially corrupt the association between the physical and analytical models. However, there are times when you may need to drop this association to make changes to the analytical model.

1. Select the **Analytical Modeling** workflow in STAAD.Pro.
2. On the **Utilities** ribbon tab, select the **Drop Physical Model** tool in the **Physical Model** group.

   A warning dialog opens asking you to confirm you want to break this link.
3. Click **Yes**.

The input file is re-opened in STAAD.Pro as a analytical model only.

M. Building Planner workflow

The **Building Planner** workflow integrates STAAD Building Planner into STAAD.Pro. This is used to generate concrete building models which can then be analyzed in STAAD.Pro and detailed using the **Advanced Concrete Design** workflow.

M. To start a STAAD Model in the Building Planner workflow

1. On the Start page, select **New**.
   The New page opens to the **Model Info** tab.
2. Specify the **File Name**, **Location**, and **Units** as necessary.
3. Select the **Building** option for the **Type** of model.
4. (Optional) Select the **Job Info** tab to add project member names, dates, project description data, etc.

   You can also associate your STAAD project with a ProjectWise Project here.
5. Click **Create**.

   The STAAD.Pro window closes and the STAAD Building Planner application opens. The **Start** dialog opens.
6. Enter the project details, including **No of Levels** and **Founding Depth**.
7. Click **Create Project**.
   The **New Plan** dialog opens.

You are now ready to start adding details for the first floor plan and modeling your building structure.

Related Links

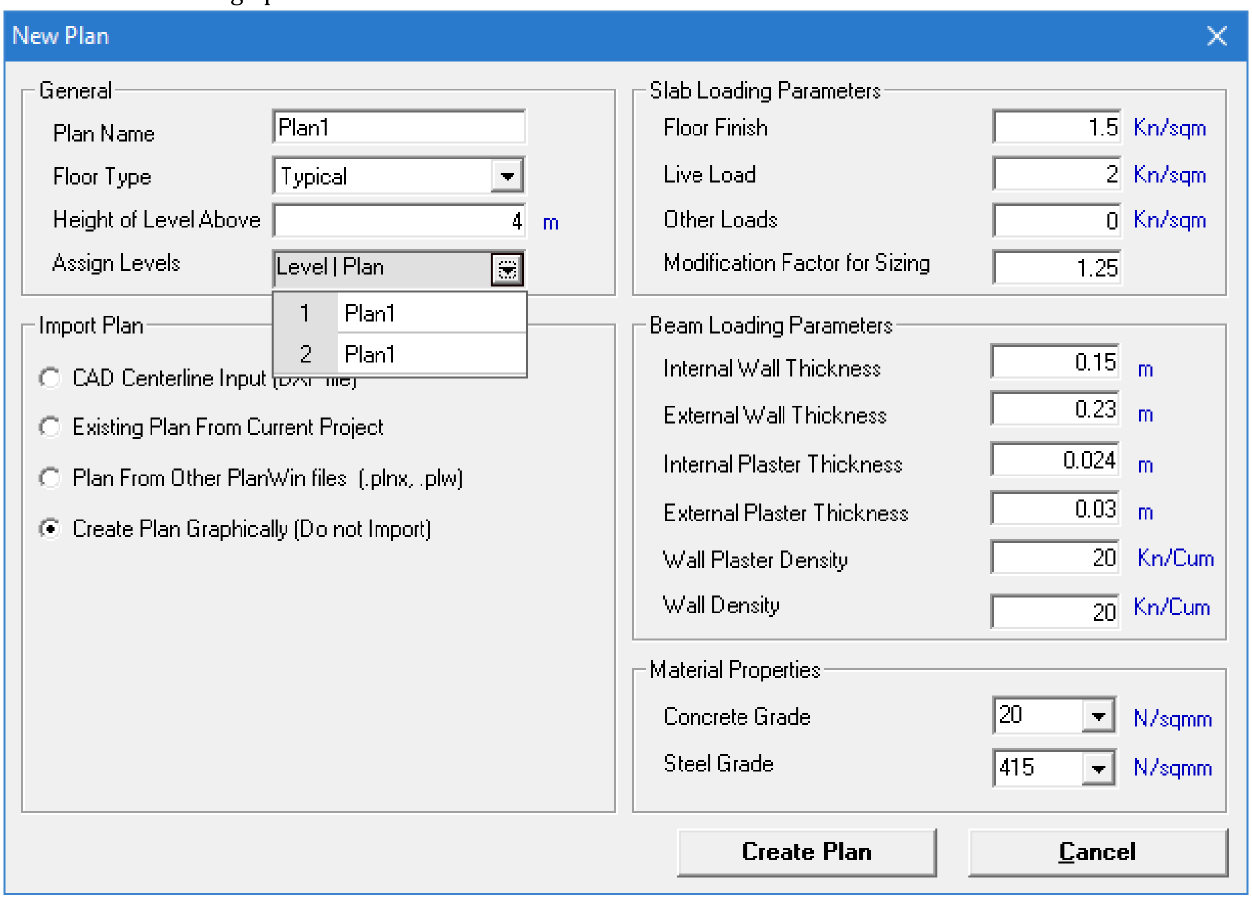
- *GS. Start Page* (on page 54)

M. Plans

Plans are building floor layouts (slabs, columns, and beams) which can be used for one or more floors in your building model. This allows you to rapidly model a building in which multiple floors have the same geometry, structure, and loads.

M. To Create a New Building Plan

1. Select **Workspace** > **New Plan**.
   The **New Plan** dialog opens.

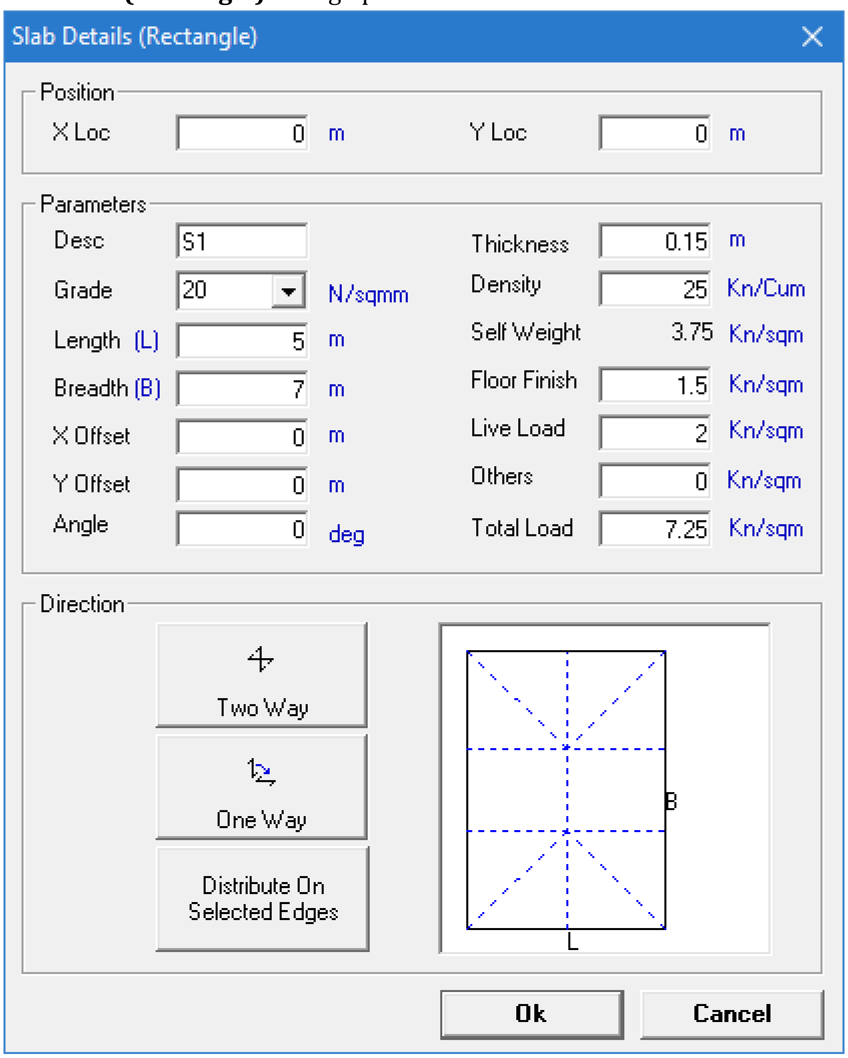


2. Specify the general details:
   a. Type a **Plan** name.
   b. (Optional) Select a **Floor type**
   c. Type the **Height of Level Above** (floor-to-floor height).
   d. Click the **Assign Levels** drop-down to assign plan names to each level of the building.

Note: The number of levels is specified in the **Start** dialog.

3. Select the **Create Plan Graphically (Do not import)** option to create a new plan

   Optionally, you may M. To Import a Building Plan (on page 923), a PlanWin file, or from another plan in this project (if there is another).
4. Specify the plan details and source (i.e., CAD file, drawing an plan in STAAD, or PlanWin plan).
5. Specify the loads on this plan:
   a. Enter the Slab Loading Parameters.
   b. Enter the Beam Loading Parameters.
6. Select the **Concrete Grate** and **Steel Grade** used in this plan.
7. Click **Create Plan**.
   If the plan was not assigned to any levels in Step 2d, then a warning message displays. Click **Yes** to proceed. Otherwise, the **Slab Details (Rectangle)** dialog opens.



8. Specify the slab details:
   a. Type coordinates for the Position

Tip: Leave default to accept origin.

  b. Type material, geometry, and loading parameters.
  c. Specify the direction the slab spans: Two Way, One Way, or Distribute on Selected Edges.

  Tip: The Length and Breadth values specified determine the recommended default direction.

9. Click **OK**.
   The slab is drawing in the graphical view.

M. To Import a Building Plan

The Building Planner can import plan data from other sources, such as PlanWin files or CAD drawings.

Note: The plan data must be in the correct format in a CAD drawing (`.dxf` file format). The correct units and scale must used in the drawing.

- Slab data must be in a layer named "Slab". Only closed polylines or light weight polylines can be imported.
- Column data must be in a layer named "Column". Use circles of any appropriate radius to mark the columns.
- Beam data must be in a layer named "Beam". Use lines to mark the beam centerlines.

1. Select **Workspace** > **New Plan**.

   If you have not yet specified project details, the **Start** dialog opens. Otherwise, the **New Plan** dialog opens.

   Note: Alternately, you can select **Edit** > **Import Plan File** to replace the current plan with imported plan data using the **Import Plan File** dialog.
2. Specify the general details:
   a. Type a **Plan** name.
   b. (Optional) Select a **Floor type**
   c. Type the **Height of Level Above** (floor-to-floor height).
   d. Click the **Assign Levels** drop-down to assign plan names to each level of the building.

   Note: The number of levels is specified in the **Start** dialog.
3. Select either:

   CAD Center line Input (DXF)

   or

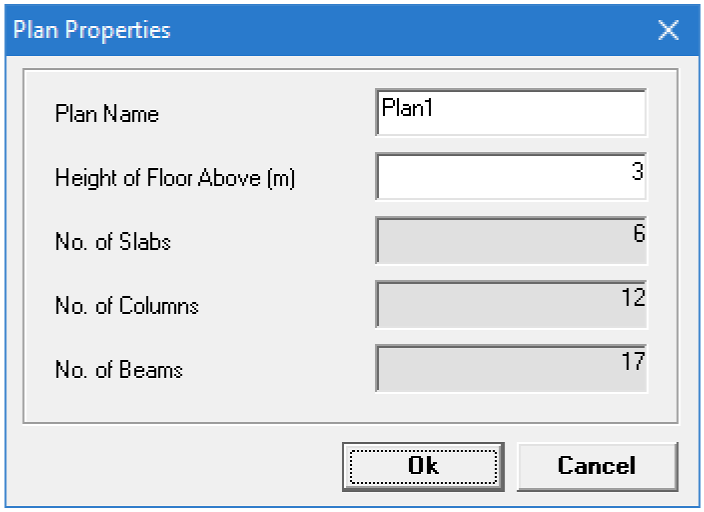
   Plan from PlanWin file

   or

   Existing plan from current project
4. Navigate to and select the file you want to use for either CAD or PlanWin file options and click **Open**.
5. If the selected PlanWin file has multiple plans, select the plan name you want to import.
6. Click **OK**.

M. To Edit Plan Properties

1. Select **View** > **Plan Properties**.
   The **Plan Properties** dialog opens.



2. Type a new **Plan Name** or **Height of Floor Above** value.
3. Click **OK**.

M. Slabs

Parametric slabs are used to model portions of physical slabs in a building floor. This allows you to model thickened slabs or other complex layout geometry easily.

M. To Add a Rectangular Slab

To add a rectangular slab to the current plan, use the following steps.

1. In a plan workspace, select **Slab** > **Create Slab Rectangle**.
2. Click a start and end corner for the slab in the graphics window.

   The start corner “snaps” to the nearest existing slab corner. You can input any corner using the X and Y offsets in t

   A gray rectangle connects the initial point to your mouse pointer to indicate the general direction of the slab. Exact slab dimensions are specified in the next steps, though.

   The **Slab Details (Rectangle)** dialog opens.
3. Specify the slab details:
   a. (Optional) Type **X Offset Y Offset**

   Tip: You may use negative numbers here.

   b. Type material, geometry, and loading parameters.
   c. Specify the direction the slab spans: **Two Way**, **One Way**, or **Distribute on Selected Edges**.

   Tip: The Length and Breadth values specified determine the recommended default direction.

   Tip: Cantilevered slabs can be specified using the **Distribute on Selected Edges** option and clicking a single, supporting edge.
4. Click **OK**.

The slab is drawn in the Plan | Slab page graphical view.

Tip: If the slab has been drawn beyond the extents of the window, right-click anywhere *not* on a slab and select **Zoom Extend** from the pop-up menu.

Describe the results of the action.

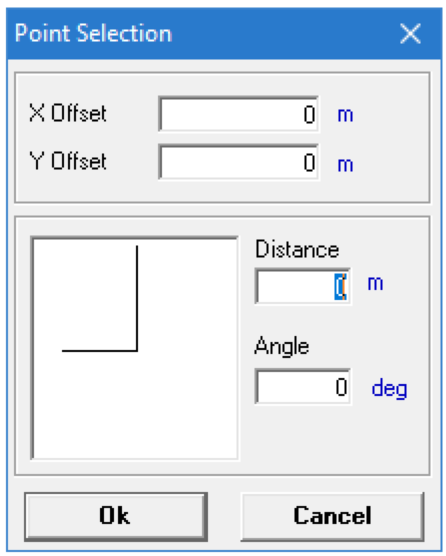
5. Repeat Steps 2 through 4 as necessary to continue drawing slabs.

Tip: Press **<Esc>** to quit using this tool.

M. To Add an Irregular Shape Slab

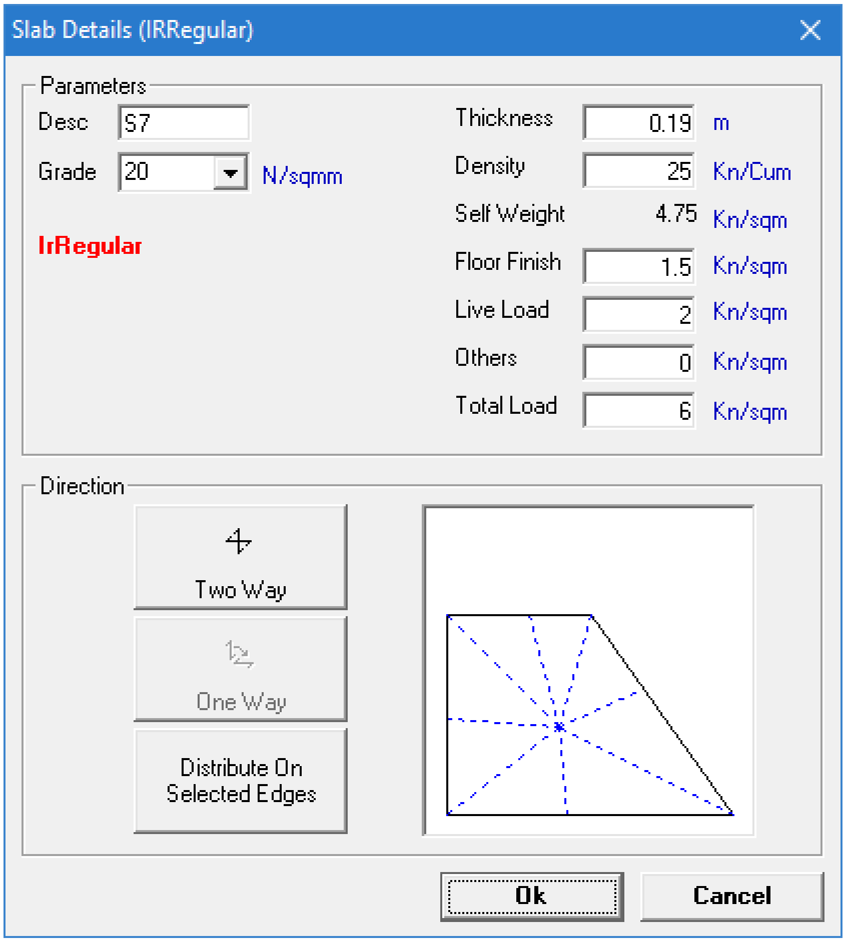
To add an irregularly shaped slab to the current plan, use the following steps.

1. In a plan workspace, select **Slab** > **Create Irregular**.
2. Click an initial corner for the slab.
3. Click another corner in either a clockwise or counterclockwise progression from the previous corner.
   The **Point Select** dialog opens.



Tip: The **Point Selection** dialog will not open if the program detects you have indicated an existing slab corner.

4. (Optional) Specify an X Offset and Y Offset value (relative to the point highlighted in a red circle), Distance, and Angle value to place the point at another location.
5. Click **OK**.
6. Repeat steps 3 through 5 to select each additional vertex point on the slab.
7. Right-click to stop adding corners.
   The **Slab Details (Irregular)** dialog opens.



8. Specify the slab details:
   a. Type label, material, geometry, and load parameters.
   b. Specify the direction the slab spans: **Two Way**, **One Way**, or **Distribute on Selected Edges**.

   Tip: The resulting dimensions determine the recommended default direction. If one or more slab spanning directions is determined to be unsuitable based on the dimensions, it is disabled.

   Tip: Cantilevered slabs can be specified using the **Distribute on Selected Edges** option and clicking a single, supporting edge.

9. Click **OK**.
   The slab is drawn in the Plan | Slab page graphical view.
10. Repeat Steps 2 through 9 to continue drawing irregularly shaped slabs.

Tip: Press **<Esc>** to quit using this tool.

M. To Edit Slab Properties

To edit the parameters of an existing slab, use the following steps.

Note: The label or material and load parameters of a slab may be edited. To edit they geometry, you must deleted and redraw a slab.

1. In a plan workspace, select **Slab** > **Select/Unselect**.

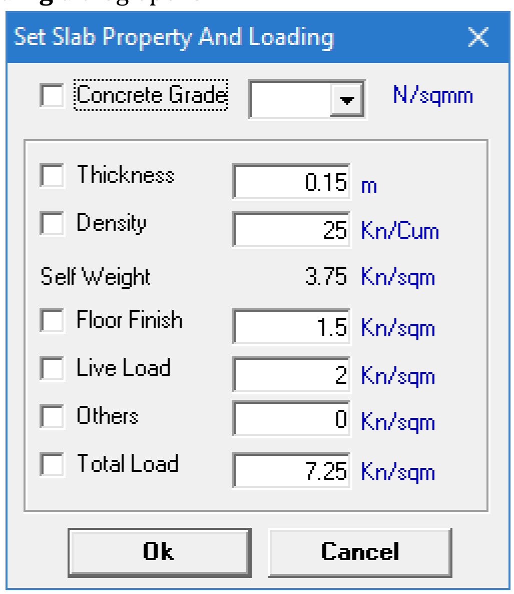
   Tip: You can use some of the other selection tools to refine your selection of slabs as necessary.
2. Select a slab in the graphical view.

   Tip: Hold **<Ctrl>** to select multiple slabs.
3. Either:

   Select **Slab** > **Set Property and Loads for Selected Slab/s**

   or

   Right-click and select **Set Property and Loads for Selected Slab/s** from the pop-up menu.
   The **Set Slab Property and Loading** dialog opens.



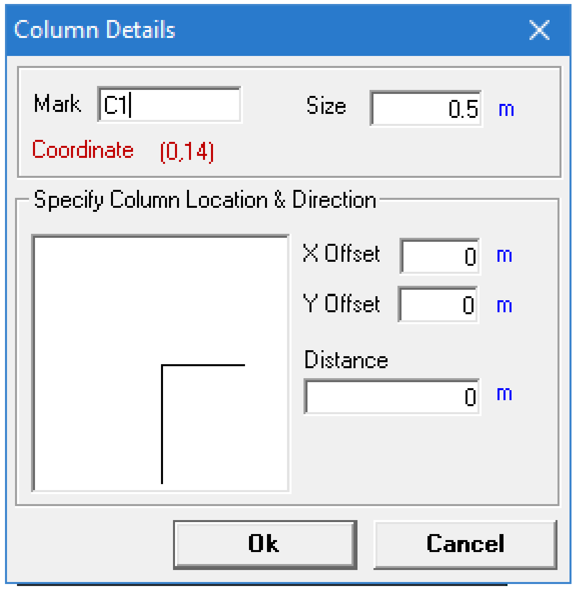
4. Check the options for each parameter you want to edit for all selected slabs and then type or select the value.
5. Click **OK**.

M. Columns

M. To Add a Column

To add a single column, use the following steps.

1. In a plan workspace, select **Column** > **Create Column**.
2. Click the nearest slab corner or edge where you want to place a column.
   The nearest slab corner is highlighted with a red circle. The **Column Details** dialog opens.



3. Type column details:
   a. (Optional) Type a custom **Mark**

   > **Note:** This must be unique to the plan.

   b. Type a face **Size** (square column).

      All initial column sizes are assumed to be square. Columns can later be resized manually or designed.

   c. (Optional) Type an **X Offset Y Offset**

      The coordinates of the column are displayed for reference.

   d. (Optional) Type an **Angle Distance**
4. Click **OK**.
   The column is drawn in dark blue on the graphical view.
5. Repeat Steps 2 through 4 to continue placing columns.

M. To Add Columns Automatically to the Entire Plan

To place columns automatically at detected points on the entire plan, use the following steps.

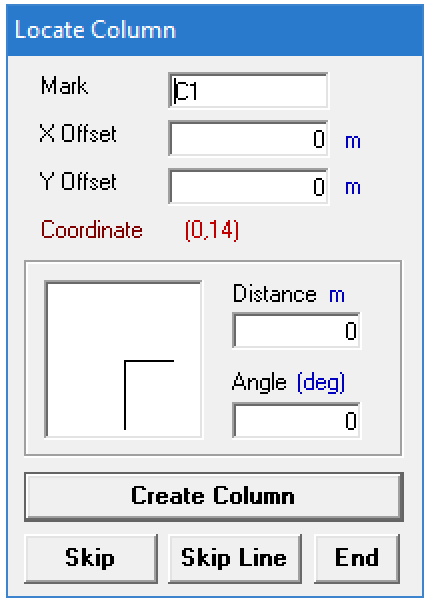
1. In a plan workspace, either:

   select **Column** > **Auto Column**, or

   or

   select **Column** > **Locate Column**.

   Columns are added at all slab corners on the floor, unless you selected the Locate Column option. In that case, the first detected column location is selected and the Locate Column dialog opens.



2. (Optional) If you selected the Locate Column feature, either:

   Specify the current column mark, offset, and orientation, or

   or

   click **Skip** to skip to the next detected column location, or

   or

   click **Skip Line** to skip all the detected locations in the current column line, or

   or

   click **End** to stop adding columns.
3. Repeat Step 2 as needed until you have reached the end of the detected column locations.

If you used the auto column feature or if you neglected to skip a location, you may need to delete any unwanted columns (e.g., those added at the end of a slab intended to cantilever), move columns, or edit the parameters of columns which are different than the default values for the plan.

M. Beams

M. To Create a Beam

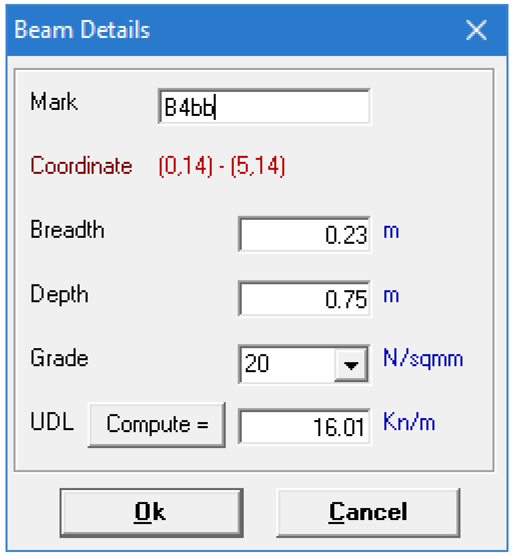
To add a single beam, use the following steps.

> **Note:** The **Auto Beam** tool will delete any existing beams on the plan. You may want to use use the Auto Beam feature prior to drawing individual beams.

1. In a plan workspace, select **Beam** > **Create Beam**.
2. Select the start and end support points for the beam.

If beams are drawing over columns or existing beams, the new beam will be broken into separate objects once placed.

The nearest slab corners are highlighted with red circles. The **Beam Details** dialog opens.

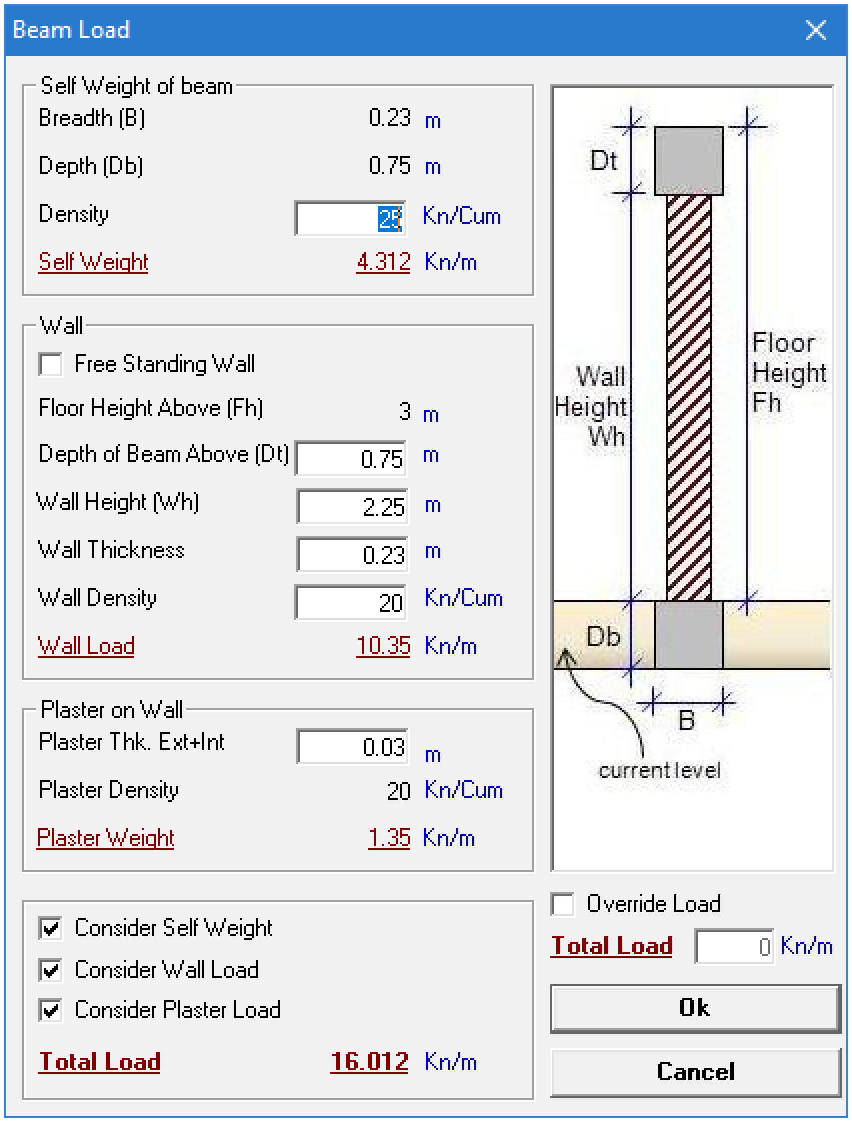


3. Type the beam details:
   a. (Optional) Type a custom **Mark**

   > **Note:** This must be unique to the plan. If you are drawing multiple beams over columns or existing beams, the mark will be incremented for the additionally created beams.

   b. Type a **Breadth** and **Depth** for the beam size.
   c. Select the **Grade** of material.
   d. (Optional) To include the uniform dead load for the beam, type a value or click **Compute Beam Load**

   > **Note:** If Compute is used, the Beam Load dialog opens with the specified beam dimensions. You can specify a material Density and include options for walls supported by the beam.



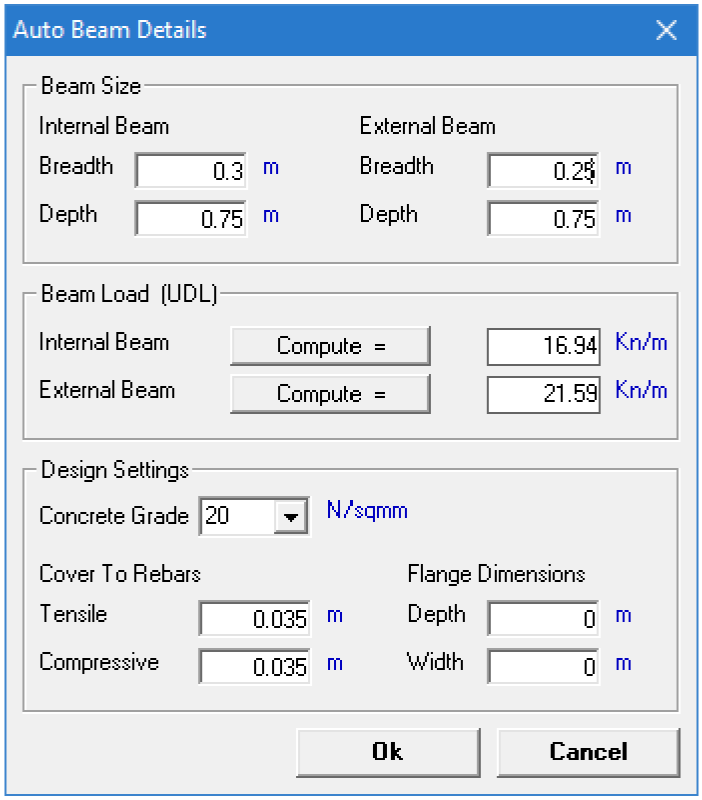
4. Click **OK**.
   The beam is drawn in green on the graphical view.
5. Repeat Steps 2 through 4 to continue placing beams.

M. To Add Beams Automatically to an Entire Plan

To place beams automatically at detected points on the entire plan, use the following steps.

1. In a plan workspace, select **Beam** > **Auto Beam**.
   If there are any existing beams, a warning message that they will be deleted opens.
2. Click **OK**.

   The **Auto Beam Details** dialog opens.

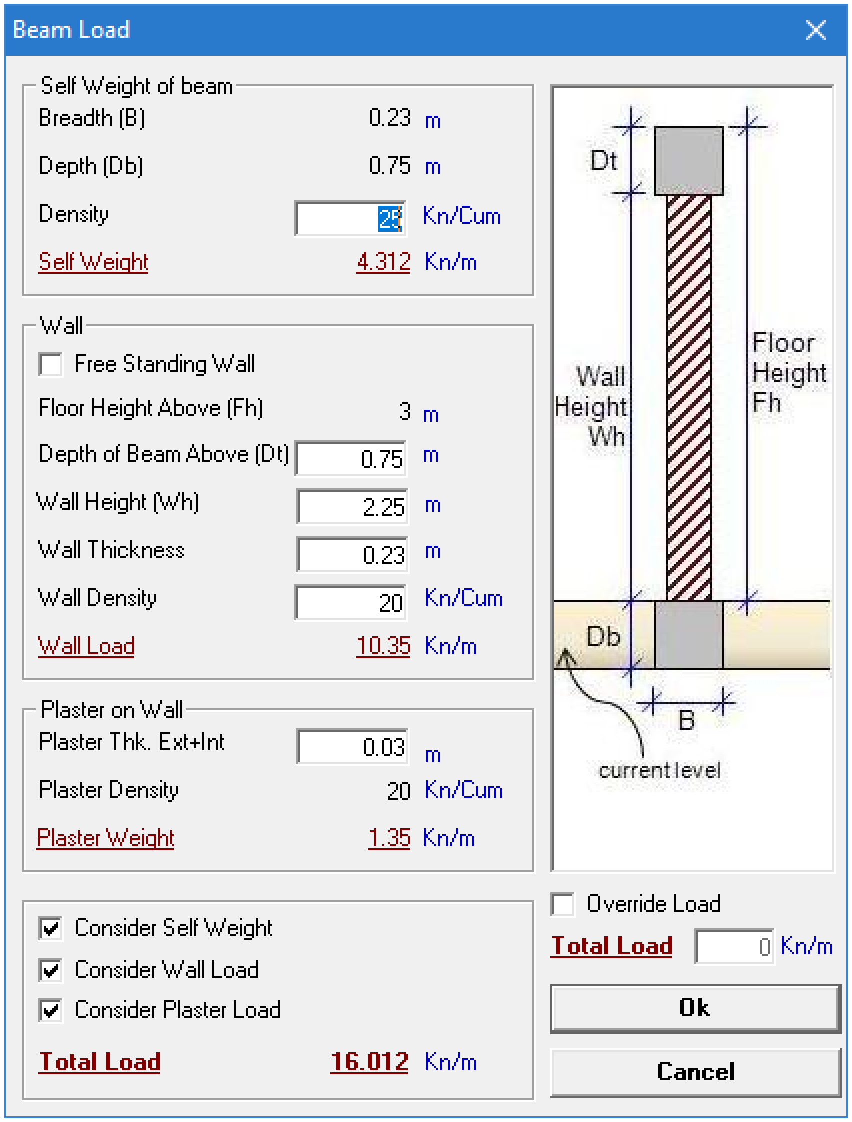


3. Type the beam details:

Note: The internal and external (exterior slab edge) beams can be specified separately.

- **a.** Type a **Breadth** and **Depth** for the beam sizes.
- **b.** (Optional) To include the uniform dead load for the beam, type a value or click **Compute Beam Load**

Note: If Compute is used, the Beam Load dialog opens with the specified beam dimensions. You can specify a material Density and include options for walls supported by the beam.



c. Select the **Grade** of material.

d. Type the **Cover to Rebars** and **Flange Dimensions** used for design.

4. Click **OK**.
   Beams are added at all slab edges on the floor.

M. To Specify Beam Continuity

To specify continuous beams over supports, use the following steps.

Building Planner uses a window to specify continuous beams for the entire plan. It is typically best practice to draw all beams for the plan before performing this procedure.

1. Select **Beam** > **Modify Beam Continuity**.
   The **Continuous Beam** window opens.
2. You can specify continuous beams individual for finer control or allow the program to autodetect all continuous beams:

To...	Select...
select individual beam segments to create continuous beams manually	**Modify Data** > **Mark/Unmark**
allow the program to detect all continuous beams automatically	**Modify Data** > **Auto Mark Continuous Beam**

If you used the auto mark option, then all beams that the program detects as having possible continuity over supports are marked in light purple. Proceed to Step 5.

3. Click a series of beams you want to mark as continuous.
   Each beam selected is highlighted in light red. You can click a beam segment again to unmark it.
4. Select **Modify Data** > **Create**.
   The selected beam segments are marked in light purple.
5. Repeat Steps 2 through 4 as necessary to continue to mark individual beam lines as continuous.
6. When you are finished marking continuous beams, either:

   click the **X** in the top,right-corner of the **Continuous Beam** window, or

   or

   press **<Alt+F4>**

If you have marked beams as continuous, you must finalize the plan including continuity.

M. To Edit Beam Properties

To change beam properties, use the following steps.

> **Tip:** If the **Beam Loading Errors** window indicates that beams intended to be cantlievered are not supported, simply right-click on the beam and select **Cantilever** from the pop-up menu.

1. Select **Beam** > **Select/Unselect**.

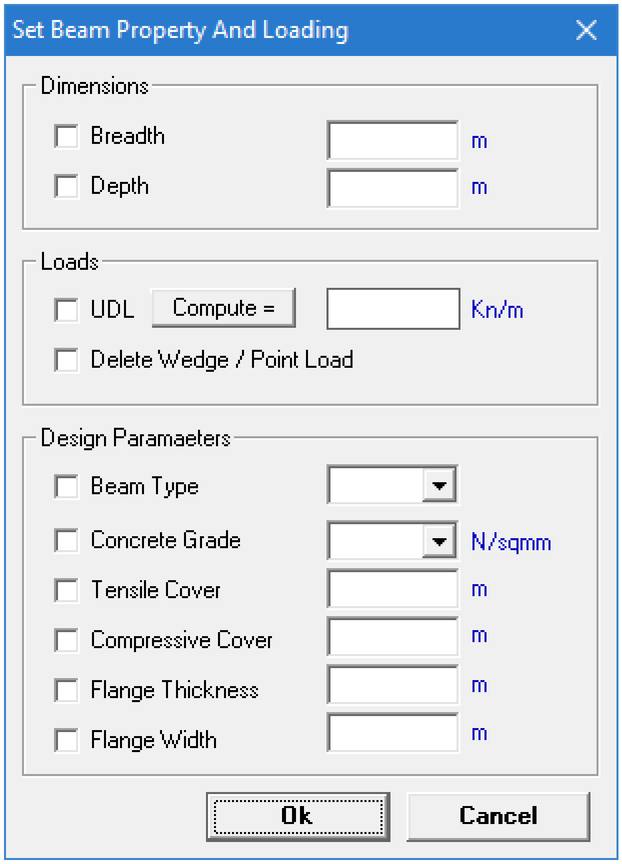
   > **Tip:** You can use some of the other selection tools to refine your selection of beams as necessary.
2. Select a beam in the graphical view.

   > **Tip:** Hold **<Ctrl>** to select multiple beams.
3. Either:

   select **Beam** > **Set Property and Loads for Selected Beam/s**, or

   or

   right-click and select **Set Property and Loads for Selected Beam/s** from the pop-up menu
   The **Set Beam Property and Loading** dialog opens.



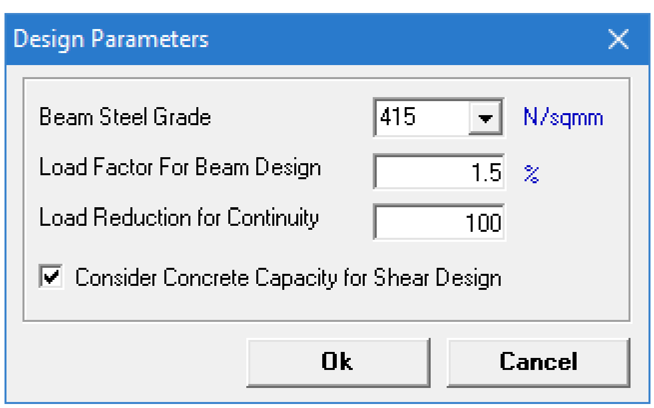
4. Check the options for each parameter you want to edit for all selected beams and then type or select the value.
5. Click **OK**.

M. To Specify Beam Design Parameters

To control some of the various design parameters, use the following procedure.

1. In a plan workspace, select **Analysis** > **Design Parameters**.

   The **Design Parameters** dialog opens.



2. Make changes to the design parameters as necessary.

3. Click **OK**.

M. Frames

M. To Finalize a Plan

To finalize a plan for use in a building frame, use the following steps.

In order to complete a 3D frame model using the plan data, you must first finalize the layout of a plan. if you select the Frame page without having finalized plans, a warning message is displayed.

1. In the plan workspace, either:

   select **Analysis** > **Finalize Plan (with Continuity)**, or

   or

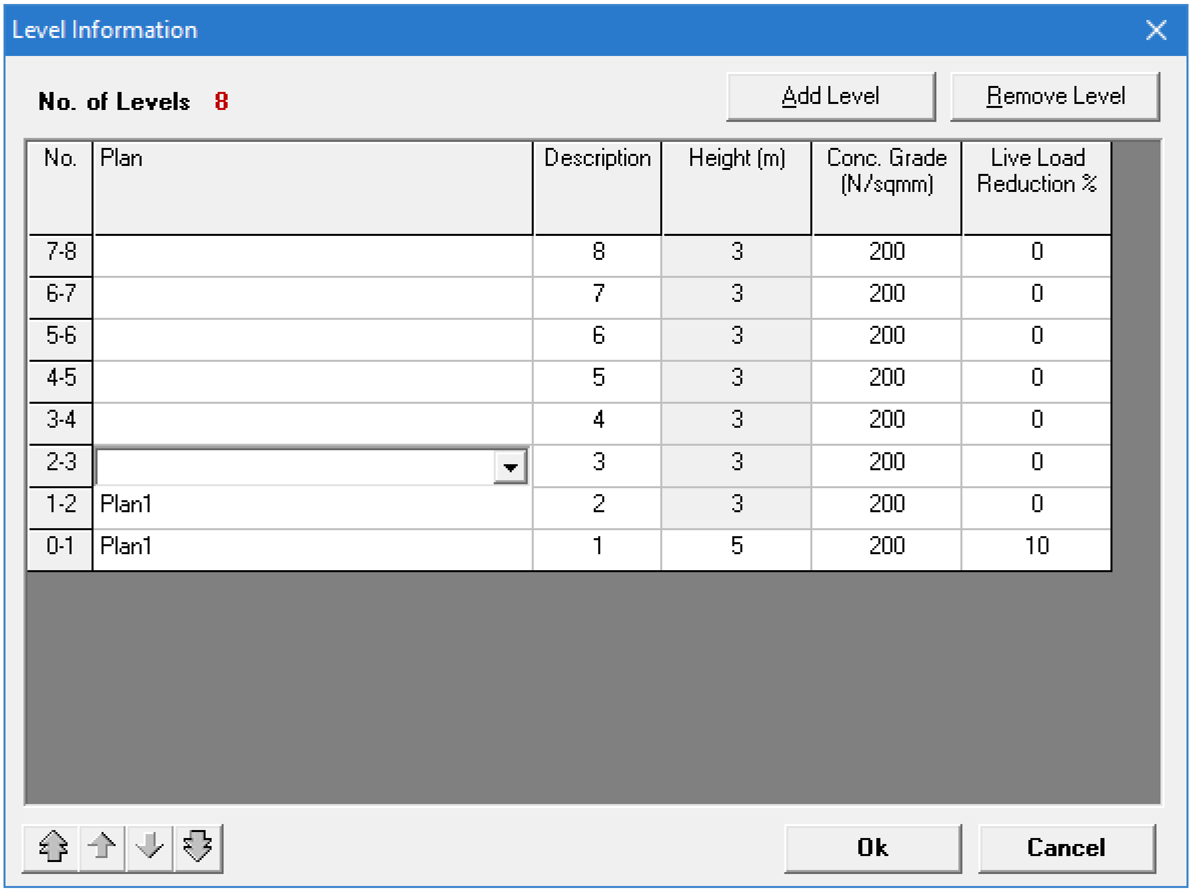
   select **Analysis** > **Finalize Plan (without Continuity)** to ignore continuity between beams, or
   A message dialog opens to indicate the plan was finalized. If any errors are detected, they will be highlighted in a pop-up window.

If any changes are made to the plan, you must repeat this procedure.

M. To Create a 3D Frame

In order to create or edit 3D frames, any changes to plans must first be finalized.

1. In the 3D Frame workspace, select **Assign** > **Level Properties**.
   The **Level Information** dialog opens.



2. Click **Add Level** to add another level and then click **OK** to confirm.
3. For each level, click in the Plan column to select a plan name from the drop-down list.

   Tip: Use the autofill arrows below the table to copy the plan name to rows above or below a selected row, or to all rows above or below.

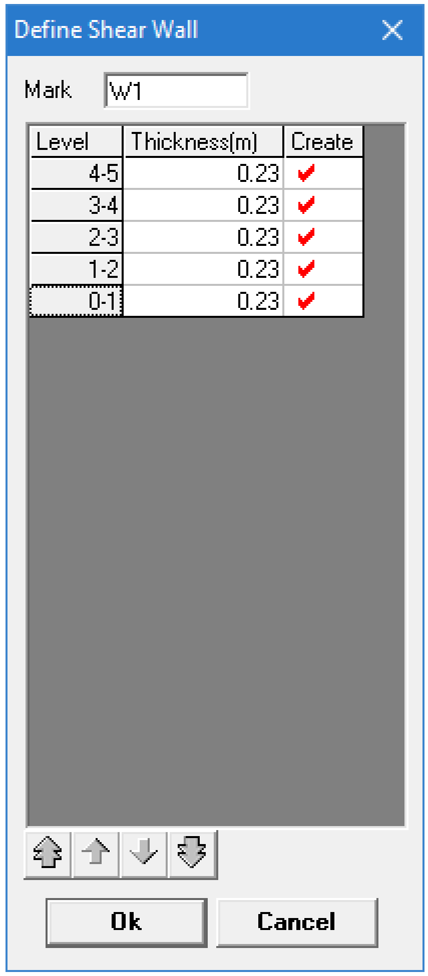
4. Click **OK**.
   The 3D Frame is created.
5. (Optional) Select **View** > **3D View**.

M. To Create a Shear Wall

Shear walls created by the Building Planner are analytically columns with the dimensions of the wall they represent.

1. Select **Assign** > **Define Shear Wall**.
2. Click the columns or slab corners to define the start and end of the shear wall in plan.

   The points are highlighted with gray-filled, red circles in the view window. The **Define Shear Wall** dialog opens.



3. Specify the shear wall parameters: as necessary
   a. Type a Mark to label the wall.
   b. If a shear wall is *not* continuous from base to roof, clear the check mark in the Create column for that level.
   c. Type an X Offset and Y Offset value to move the wall with respect to the selected start point.
   d. Type B and D dimensions to specify a wall size.
4. Click **OK**.
   The shear wall is drawn in dark red in the plan.
5. Repeat Steps 2 through 4 as necessary to continue adding shear walls.

Tip: Press **<Esc>** to quit using this tool.

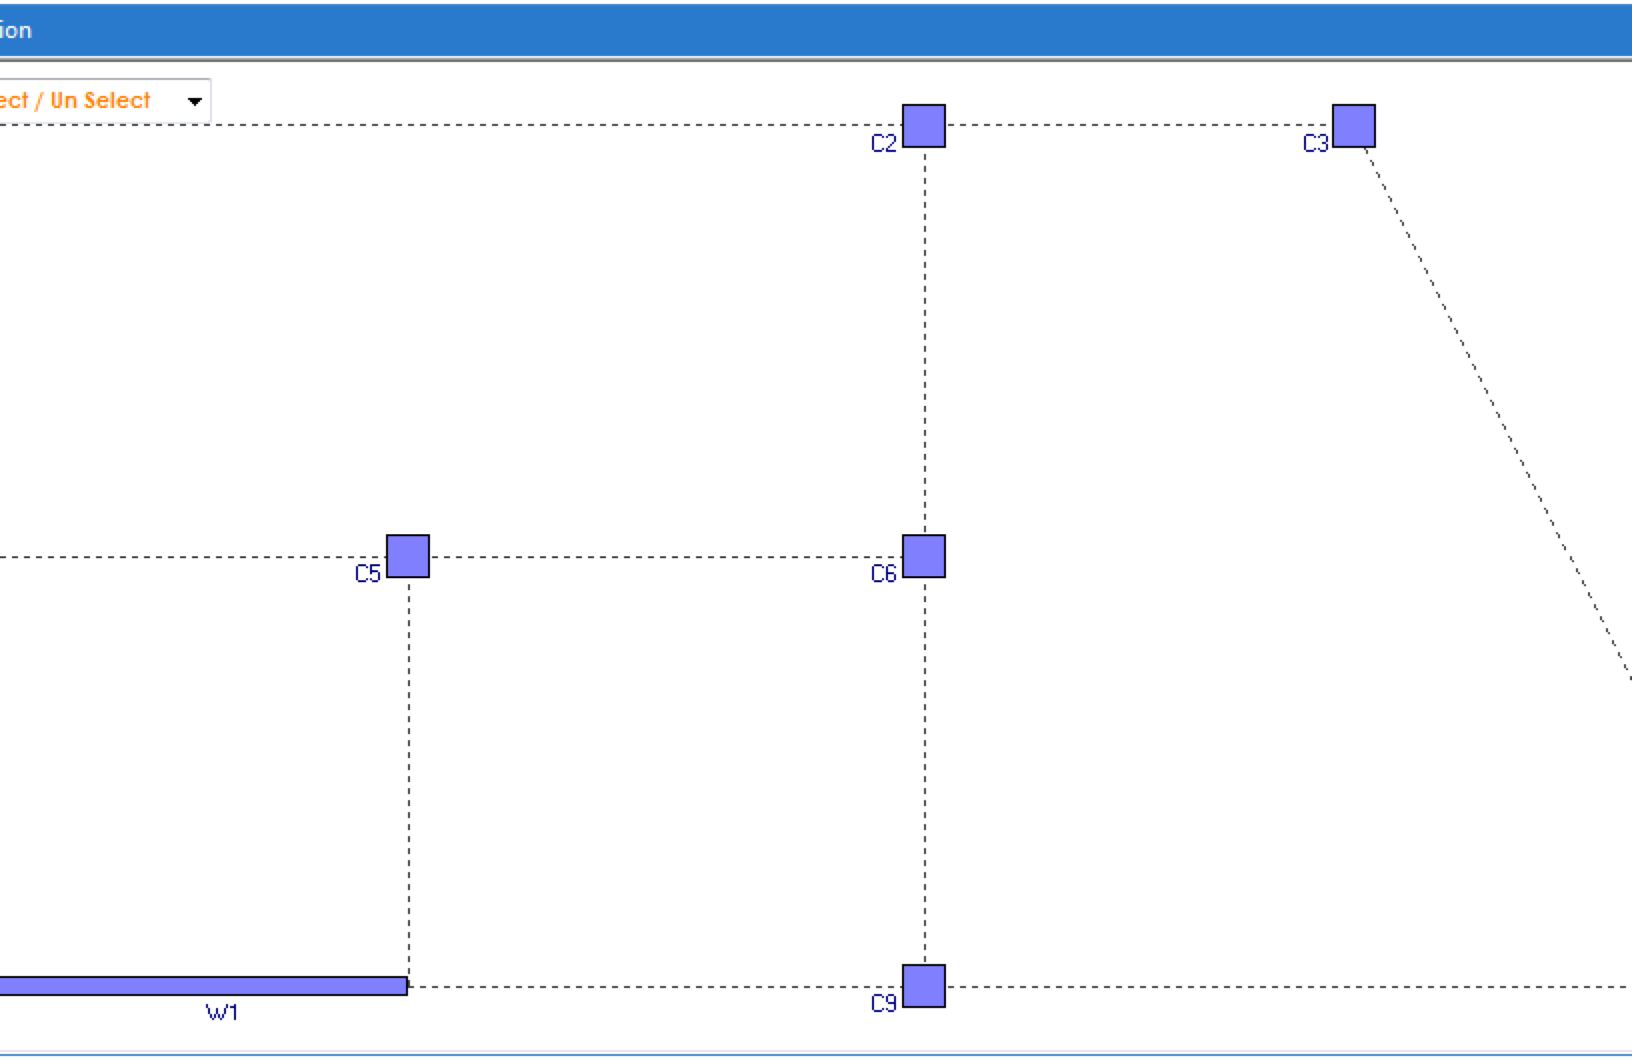
M. To Change Supports

To change boundary conditions for the 3D frame, use the following steps.

The supports are at each column or wall base at the first (lowest) level in the building frame. Initially, all supports are assumed as Fixed.

1. Select **Assign** > **Support Specification**

The **Support Specification** dialog opens.

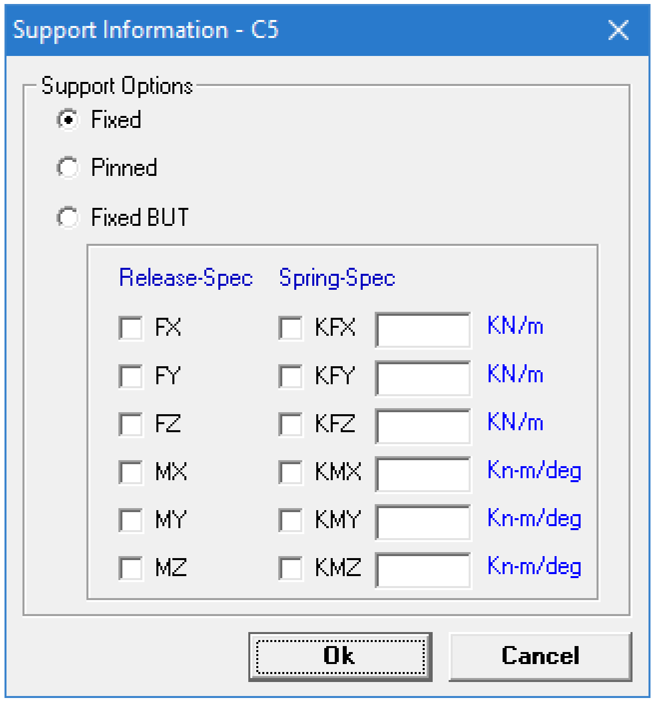


2. Select the one or more columns or walls.

Tip: Use the Selection drop-down list to change the selection method.

3. Right-click on a column or wall and select **Support Condition -** ***mark*** from the pop-up menu.

   The **Support Information** dialog opens.



4. Select the **Support Options** to use.
5. For **Fixed But** option, either:

   specify the **Release-Spec**

   or

   Spring-Spec and spring constant for each degree of freedom as necessary.
6. Click **OK**.
7. Repeat Steps 3 through 6 for each support you want to change.

Tip: The support type is color-coded in the **Support Specification** dialog.

8. Click the **X** in the top,right-hand corner of the **Support Specification** dialog when you are finished making changes to the supports.
   The **Support Details** table updates with the changes.

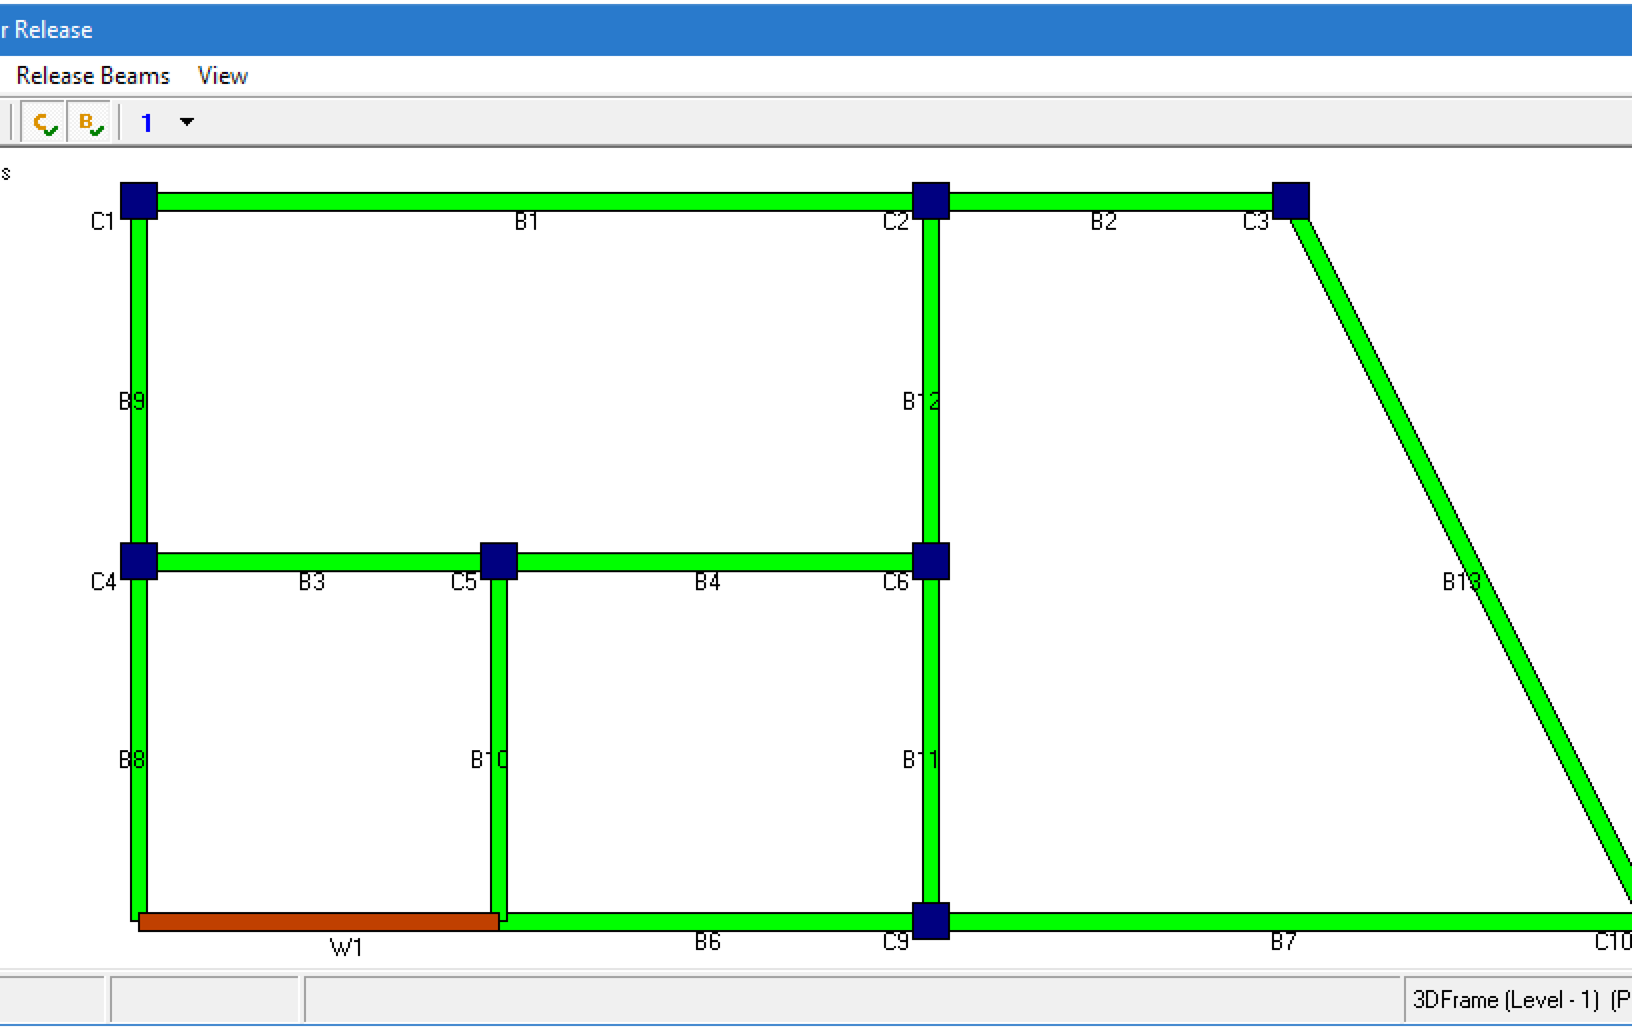
M. To Specify Member Releases

To change member end release details for the 3D frame, use the following steps.

All beams are initially assumed as fully fixed at both ends.

1. Select **Assign** > **Member Release (Beams)**.

   The **Member Release** dialog opens.



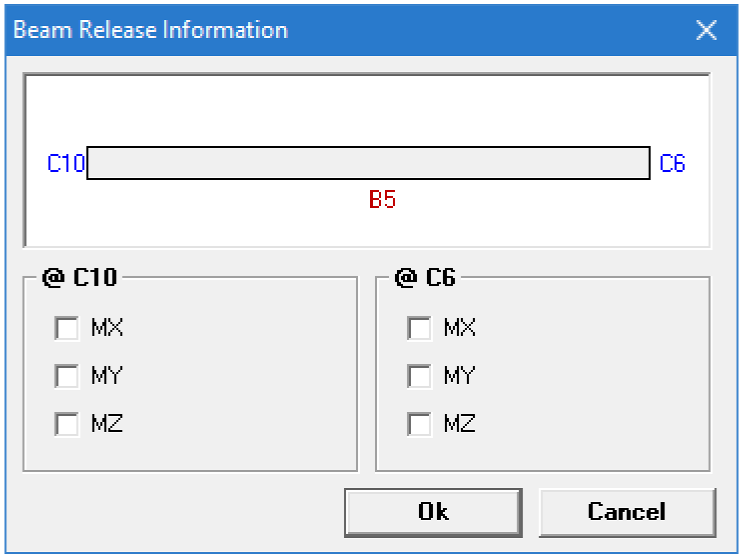
2. (Optional) Select the level from the drop-down list of level numbers in the tool bar.

   Tip: The current level and plan name are displayed in the status bar.

3. Right-click on a beam and select **Release Details-** ***mark*** from the pop-up menu.

   Tip: The **Member Release** dialog contains some tools to select and make release changes to multiple members, such as all primary or secondary beams or all beams along a column line. These tools allow you to select the levels to which you want to apply these release specifications as well.

   The **Beam Release Information** dialog opens.



4. Check the boxes for each degree of freedom to release at either end of the member and type a percent release value for each release direction.

    Tip: The default release of 99% is intended to represent a full member release.

5. Click **OK**.
6. Repeat Steps 2 through 6 for each member you want to edit release specifications.

    Tip: The member release specifications are color-coded in the **Member Release** dialog and indicated with dots on each member.

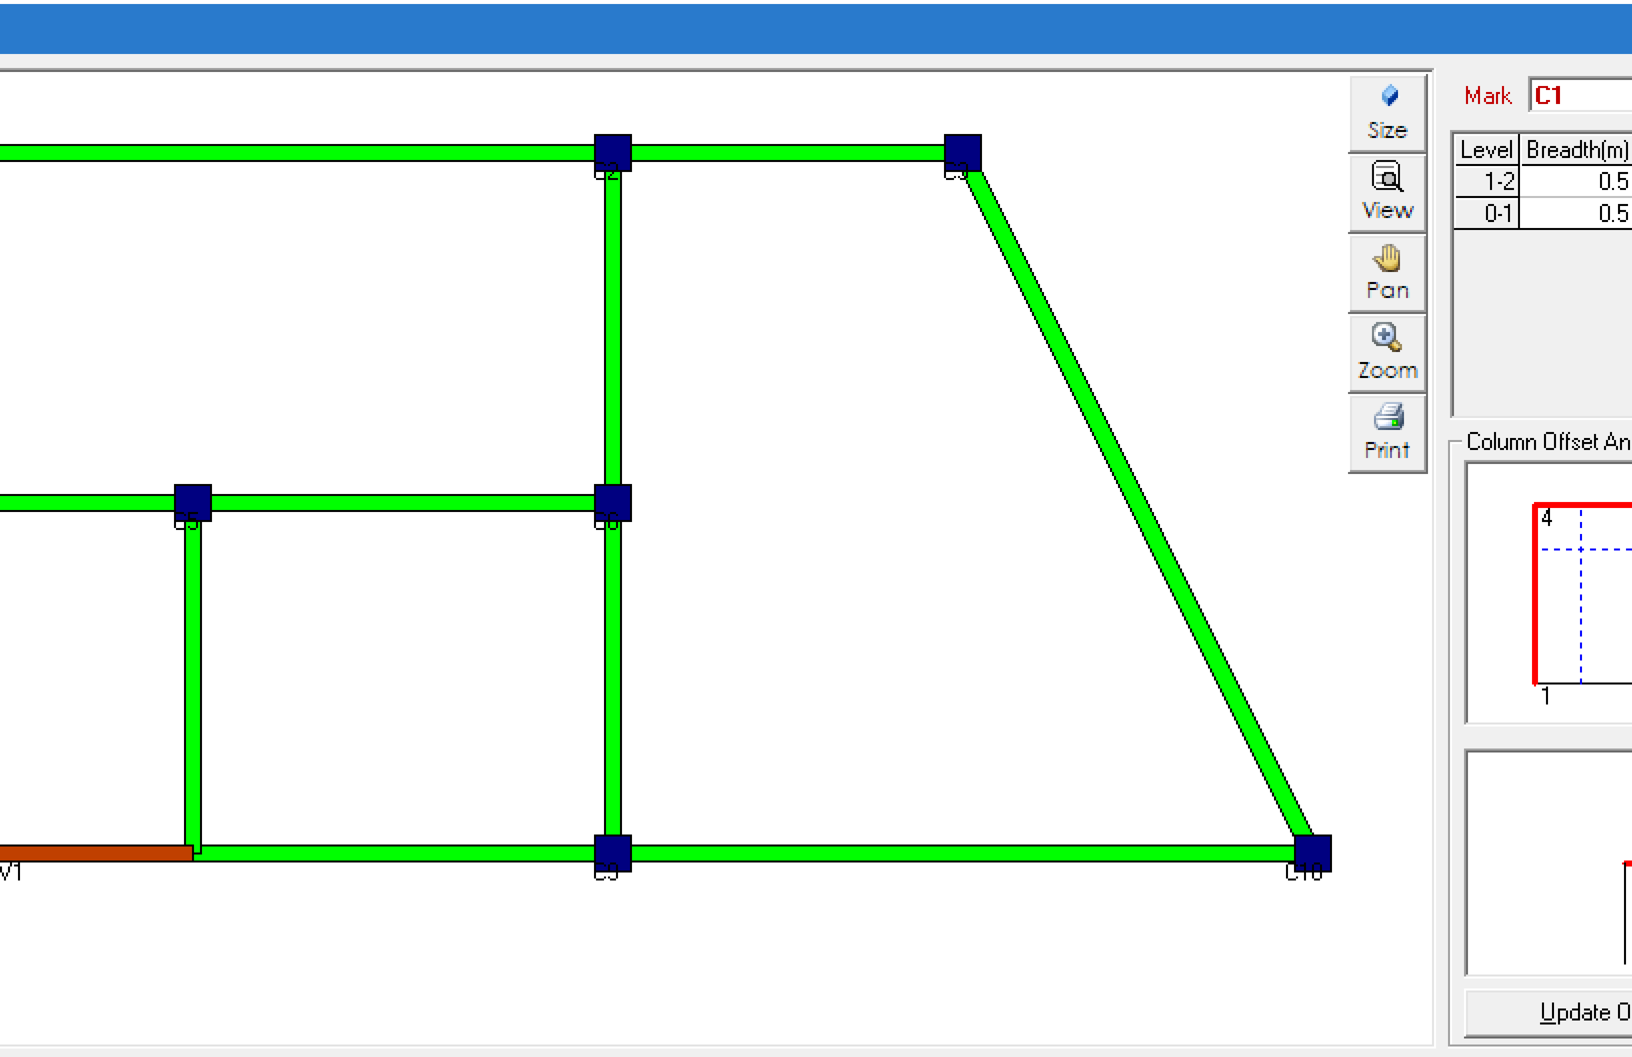
7. Click the **X** in the top,right-hand corner of the **Member Release** dialog when you are finished making changes to the member releases.
    The **Beam Release Details** table updates with the changes.

M. To Change Column Size, Orientation, and Alignment

To change a column size and orientation, use the following steps.

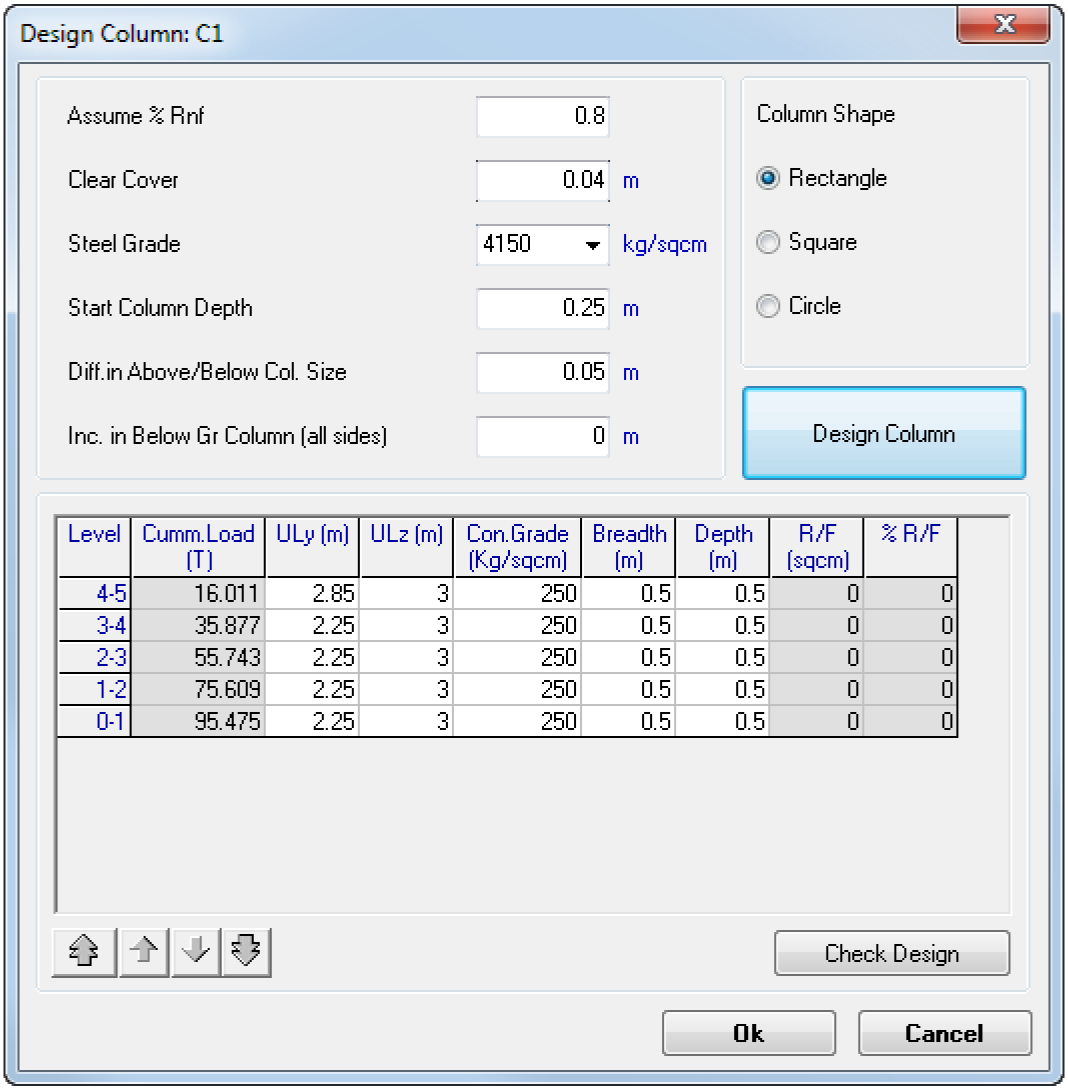
1. Select **Assign** > **Column Sizing and Orientation**.

    The **Column Sizing** dialog opens.



2. Select a column in the main graphical view.
   The selected column is highlighted in a red circle and the Mark is displayed. The column orientation and offset are displayed in the right-hand views.
3. To change the column orientation (i.e., Beta angle):
   - **a.** Click a different axis of orientation in the lower, right-hand graphic or click **+90** to rotate the column 90°
   - **b.** Click **Update Offset Data & Beta Angle**.
4. To change the column offset:
   - **a.** Click one of the column faces in the middle, right-hand graphic.
   - **b.** Type an offset value in the indicated units.
   - **c.** Repeat steps 4a and 4b to specify offsets in a different axis.
   - **d.** Click **Update Offset Data & Beta Angle**.
5. To change a column size:
   - **a.** Click **Re-Size Column.**

     The **Design Column: <mark>** dialog opens.



b. Type initial design parameters in the fields.

> **Tip:** You can use the **Check Column** feature to perform a design check on the current column size.

c. Select a **Column Shape**.

d. Click **Design Column**.
The column size (Breadth and Depth) at each floor are updated based on the design parameters and specified building loads.

e. (Optional) You can manually type changes to the table values to further refine the design.

> **Tip:** Use the automatic fill buttons below the table to copy values up or down the currently selected row.

f. Click **OK**.
The column diagrams are updated in the **Column Sizing** dialog.

6. Repeat Steps 2 through 5 for each column you want to change.
7. Click the **X** in the top,right-hand corner of the **Column Sizing** dialog when you are finished making changes to the column sizes and orientation.
The **Beam Release Details** table updates with the changes.

M. To Modify Wind Parameters

To specify parameters for lateral wind loads, use the following steps.

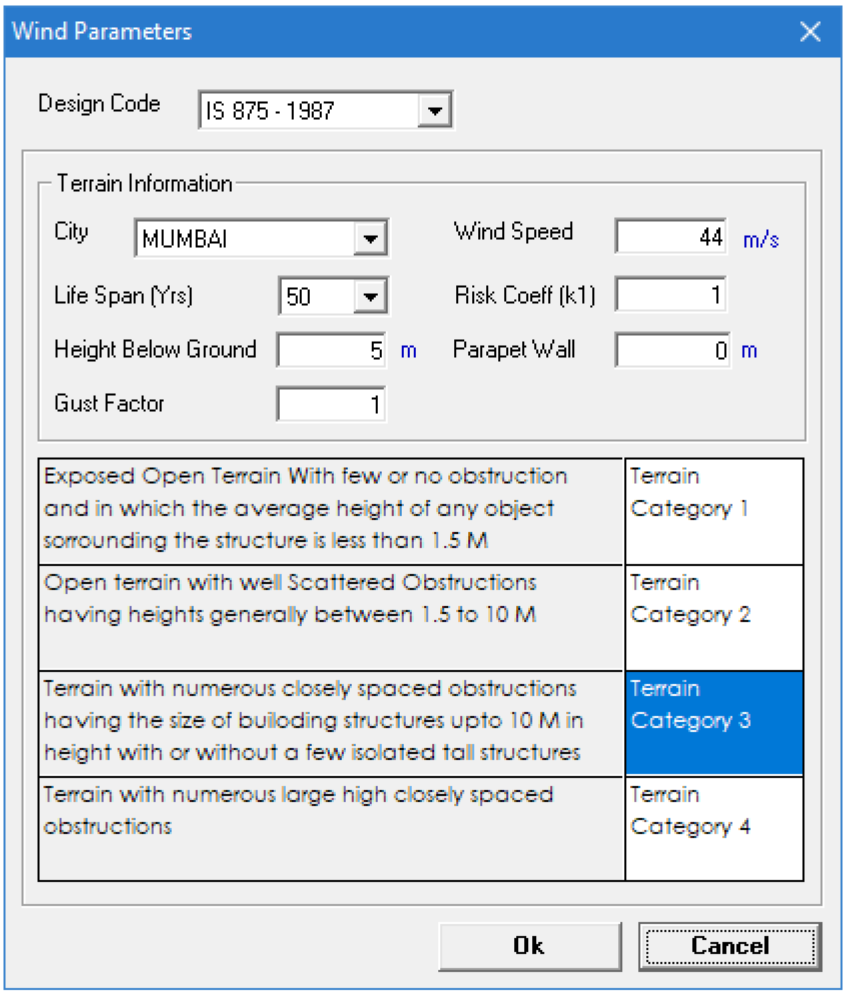
The wind load parameters are input per the following codes:

- UBC 97
- IS 875-1987
- ASCE7

1. Select **Assign** > **Wind Parameters**.

   Tip: You can also double-click any of the wind load parameters in the **Lateral Load** dialog.

   The **Wind Parameters** dialog opens.



2. Select the **Design Code** from the drop-down list.
3. Either:

   Select the appropriate **City** in the drop-down list (recommended)

   or

Type a **Wind Speed** value directly.

4. Either:

   Select the **Life Span (yrs)** for which the building is to be designed from the drop-down list (recommended)

   or

   Type a **Risk Coeff (K1)** value directly.
5. Type **Height Below Ground** and **Parapet Wall** values, in the units indicated.
6. Type a **Gust Factor** value.
7. Select the Terrain Category from the description list.
8. Click **OK**.

You can now review the calculated wind loads by selecting **Frame** > **Wind Effect**. In the Wind Effect dialog, select the different directions to see the distributed wind intensity on each floor. Selecting a column in the table displays the wind intensity values at the top and bottom of each floor along that column.

M. To Modify Seismic Parameters

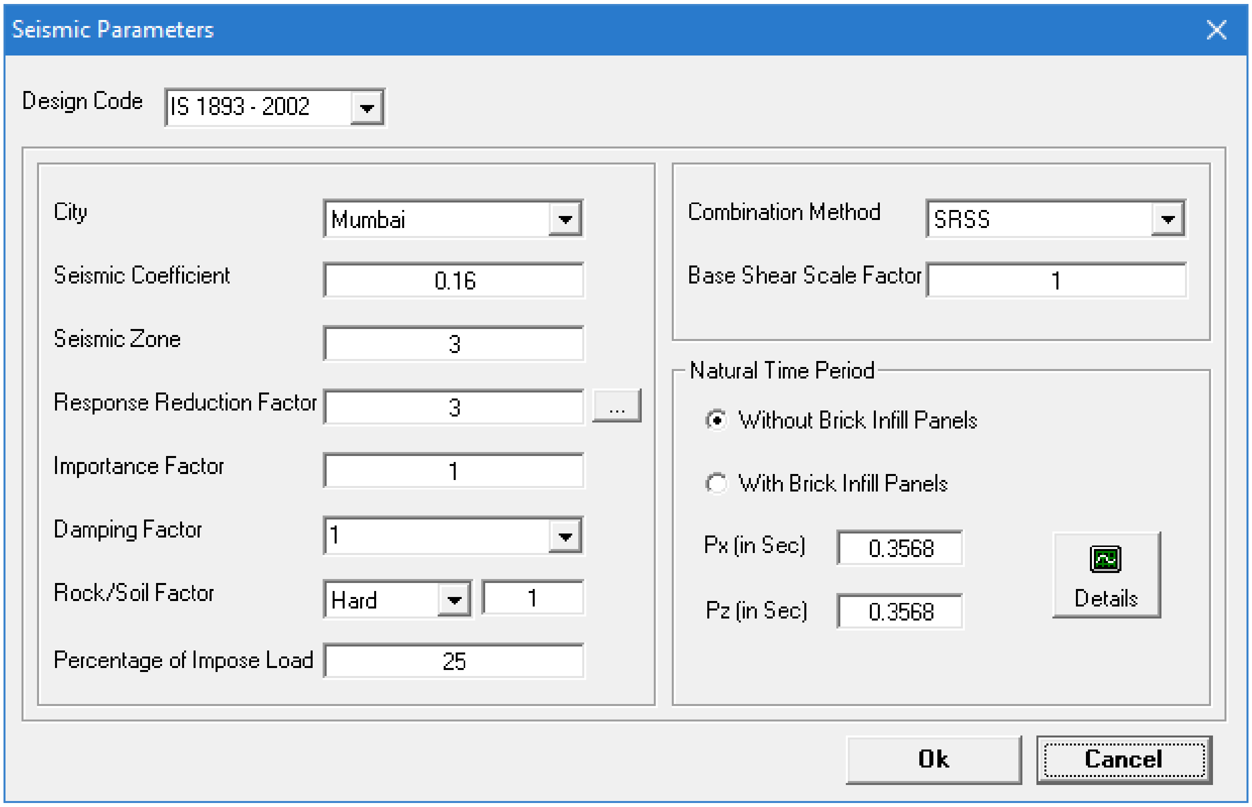
To specify parameters for lateral seismic loads, use the following steps.

The seismic load parameters are input per the following codes:

- UBC 97
- IS 1893-2002

1. Select **Assign** > **Seismic Parameters**.

   The **Seismic Parameters** dialog opens.



2. Either:

   Select the appropriate **City** in the drop-down list (recommended)

   or

   Type **Seismic Coefficient** and **Seismic Zone** values directly.
3. Specify a Response Reduction Factor for the building:
   a. Click **[...]** adjacent to the Response Reduction Factor field.
      The Response Reduction Factor dialog opens.
   b. Select the appropriate row in the **Building Frame Systems** description list.
   c. Click **OK**.
      The Response Reduction Factor is updated.
4. (Optional) Specify or select additional seismic parameters as necessary:
   a. Type an **Importance Factor** value.
   b. Type a **Damping Factor** value.
   c. Select the type of soil on site from the **Rock/Soil Factor** drop-down list.
   d. Select the **Combination Method** from the drop-down list.
   e. Type the **Base Shear Scale Factor** value.
5. Select if brick infill panels are present in the building structure to determine the **Natural Time Period**.

   Tip: Click **Details** to see the values used in evaluating Px and Pz.
6. Click **OK**.

M. To Modify the Load Combinations

The Building Planner mode uses building combinations per the Indian code by default. You can modify, remove, or add individual load combinations as necessary.

1. Select **Tools** > **Load Combination**.
   The **Loading Combination** dialog opens.
2. Make any changes to the load combinations necessary:

To…	Do the following…
change the load factor on a load type for a particular load combination	type the new load factor in the corresponding cell
add a new load combination	click **Add** and type the load factors for each load type
remove an existing load combination	select the load combination row and click **Remove**
set the current load combinations as the default in Building Planner mode	click **Set as Default**
restore the default load combinations (i.e., the code load combinations)	click **Load Default Combinations**

3. Click **Update**.
4. Click **[X]** to close the **Loading Combination** dialog.

M. Analysis and Design

M. To Generate a STAAD.Pro Model

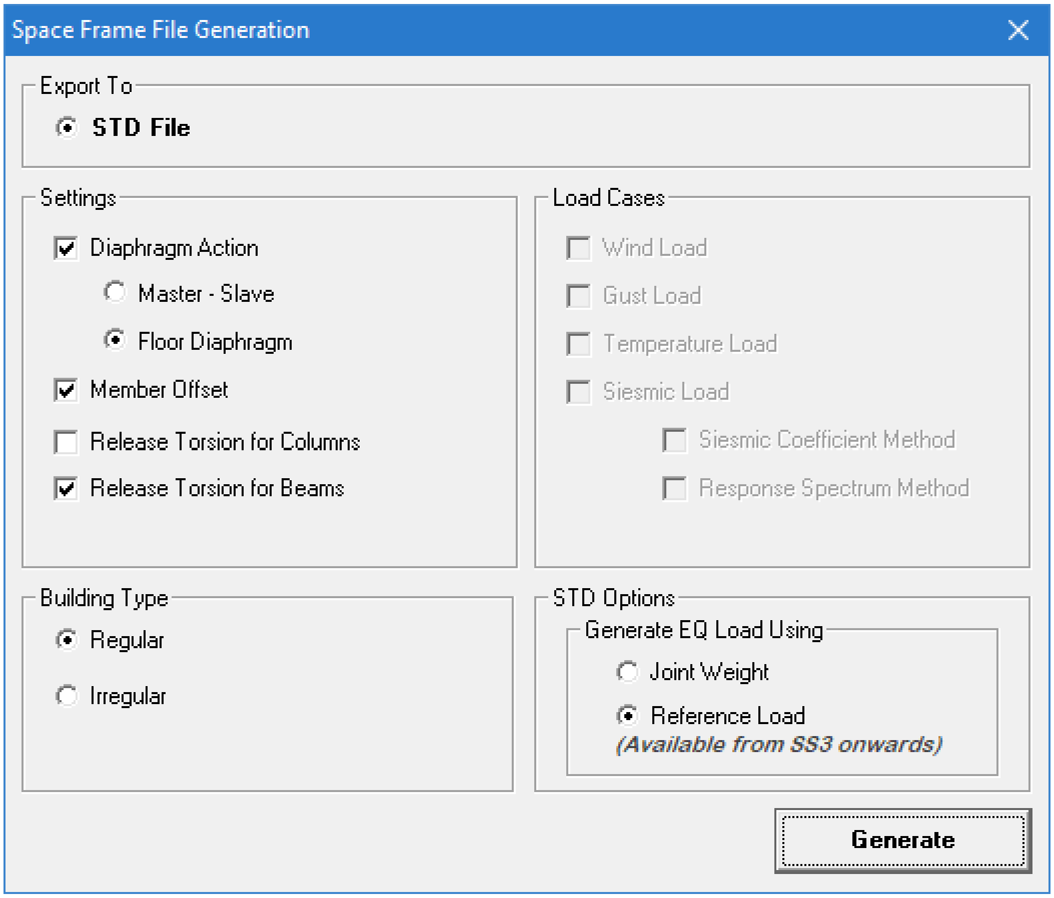
To generate a STAAD.Pro input file from your Building Planner workflow physical model, use the following procedure.

The physical model created using the Building Planner workflow can export an equivalent STAAD.Pro input file for use with the analysis and design capabilities in STAAD.Pro.

Tip: You must perform an analysis using STAAD.Pro in order to perform design in the Building Planner or Advanced Concrete Design workflows.

1. In the 3D Frame workspace, select **Analysis** > **Generate Analysis File**.
2. Click **OK**.

   The **Space Frame File Generation** dialog opens.



Caution: Do *not* close the dialog by clicking X as this will result in an invalid STAAD input tile.

3. Specify the parameters to use for the STAAD input file:
   a. Select the **Settings** to use for diaphragms, beams, and columns.
   b. Select the load cases to use, including if the seismic load should be (static) **Seismic Coefficient Method** or **Response Spectrum Method**.
   c. Select the **Building Type**.
      For **Irregular** buildings, both positive and negative direction load cases are generated.
   d. Select whether to **Generate EQ Load** Using by Joint Weight or Reference Load.
4. Click **Generate**.
   A warning message opens to inform you that the existing STAAD.Pro model will be overwritten.
5. Click **Yes**.
   The STAAD.Pro input file is created and opens in the Analytical Modeling workflow.

You can now make changes to the STAAD.Pro file as necessary. You can perform an analysis by selecting the **Run Analysis** tool on the **Analysis** ribbon tab or by pressing **<Ctrl+F5>**.

- *Space Frame File Generation dialog* (on page 950)

Space Frame File Generation dialog

Used to specify analytical model settings, building details, and load cases to use for a STAAD input file (file extension `.std`) generated from the 3D building frame in Building Planner.

Dialog Controls

Control	Description
Settings group	**Control** / **Description** **Diaphragm Action** — Check this option to include a diaphragm definition in the analysis model. Select the method to use for defining the diaphragm: • Control - Dependent (formerly referred to as Master / Slave) • Floor Diaphragm **Member Offset** — Used to consider Member offset in the model. **Release Torsion for Columns** — Releases columns for torsion. **Release Torsion for Beams** — Releases beams for torsion.
Load Cases group	**Control** / **Description** **Wind Load** — Wind load will be applied to the analytical model using the load parameters indicated in the **Wind Parameters** dialog. **Gust Load** — Gust (wind) load will be applied to the analytical model using the load parameters indicated in the **Wind Parameters** dialog. **Temperature Load** — **Note:** This option is currently inactive. **Seismic Load** — Earthquake Load per IS 1893 will be applied to the analytical model using the load parameters in the **Seismic Parameters** dialog.
Building Type	This option is used to create appropriate load combinations. • For **Irregular** buildings, both positive and negative direction load cases are generated. • For **Regular** buildings, only positive direction load cases are generated.
Generate EQ Load Using	Specifies that earthquake load are created using either **Reference Load** or by **Joint Weight**.
Generate	Click generate the STAAD input file and open in Modeling mode.

M. To Design Slabs

You must have STAAD RCDC installed to perform slab design from the Building Planner mode.

You must perform a successful analysis of the generated STAAD.Pro input file prior to performing design.

1. Select **RCDC** > **Slab**.
   STAAD RCDC opens and reads the analysis results for the associated STAAD.Pro input file.
2. In STAAD RCDC, select the slab and perform the design.

   Tip: Refer to the STAAD RCDC help for details.
3. Close STAAD RCDC when you have completed the slab designs for the selected building level.

M. To Design Beams

You must have STAAD RCDC installed to perform beam design from the Building Planner mode.

You must perform a successful analysis of the generated STAAD.Pro input file prior to performing design.

1. Select **RCDC** > **Beams**.
   STAAD RCDC opens and reads the analysis results for the associated STAAD.Pro input file.
2. In STAAD RCDC, select the beam and perform the design.

   Tip: Refer to the STAAD RCDC help for details.
3. Close STAAD RCDC when you have completed the beam designs for the selected building levels.

M. To Design Columns

You must have STAAD RCDC installed to perform column design from the Building Planner mode.

You must perform a successful analysis of the generated STAAD.Pro input file prior to performing design.

1. Select **RCDC** > **Columns**.
   STAAD RCDC opens and reads the analysis results for the associated STAAD.Pro input file.
2. In STAAD RCDC, select the column and perform the design.

   Tip: Refer to the STAAD RCDC help for details.
3. Close STAAD RCDC when you have completed the column designs.

5
Analysis

This section of the help describes the analysis methods, data print commands, and how to perform analysis in STAAD.Pro

A. Types of Analysis

A. To specify a linear elastic analysis

To instruct the program to perform a first-order, linear elastic analysis of the structure, use the following procedure.

1. Either:

   select the **Analysis** page

   or

   on the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group

   

   The **Analysis/Print Commands** dialog opens.
2. Select the **Perform Analysis** tab.
3. Select the **Print Option** you want to use.
4. Click **Add**.
   The perform analysis command is added to the input file.

Related Links

- *TR.37.1 Linear Elastic Analysis* (on page 2620)
- *Perform Analysis tab* (on page 2917)

A. To specify a P-Delta analysis

To instruct the program to perform a second-order, P-Delta analysis, use the following procedure.

1. Either:

   select the **Analysis** page

or

on the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group

The **Analysis/Print Commands** dialog opens.
2. Select the **PDelta Analysis** tab.
3. Type the **Number of Iterations** to use.
4. (Optional) Check the **Use Geometric Stiffness (Kg)** option to include stiffening effects of the KG matrix.

   Refer to Notes for Stress Stiffening Matrix (Option 2) (on page 2623) for details on this option.
5. Check the **Small Delta** option to include effects of member deflection (i.e., P-δ effects).

   This option is recommended. Clear this option to only consider effects of structure drift (i.e., P-Δ effects).
6. Select the **Print Option** you want to use.
7. Click **Add**.
   The PDetla Analysis command is added to the input file.

- *G.17.2.1 P-Delta Analysis* (on page 2141)
- *P Delta Analysis tab* (on page 2917)
- *TR.37.2 P-Delta Analysis Options* (on page 2621)

A. To specify a direct analysis

To instruct the program to perform a direct analysis as per AISC 360, use the following procedure.

Note: You must have one or more members with Direct Analysis parameters defined in order to use a direct analysis.

This is a non-linear, iterative analysis as the stiffness of the members is dependent upon the forces generated by the load. The analysis will iterate in each step, changing the member characteristics until the maximum change in any τ_b is less than the tau tolerance (τ_{tol}), If the maximum change in any τ_b is less than $100 \times \tau_{tol}$ *and* the maximum change in any displacement degree of freedom is less than the displacement tolerance (δ_{tol}); then the solution has converged for this case.

1. Either:

   select the **Analysis** page

   or

   on the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group

   The **Analysis/Print Commands** dialog opens.
2. Select the **Perform Direct Analysis** tab.
3. Select to use either the **LRFD** or **ASD** design method.

4. Type values for both **Tau** and **Displacement** Tolerances.

   Note: Leave either field empty to use the default tolerances of 0.01 for Tau and 0.01 inches and 0.01 radians for displacement.
5. Type the **Number of Iterations** to use.

   Leave this field empty (zero) to use the default of one iteration.
6. Select the number of **PDelta Iterations** to perform in the iterative PDelta with small delta analysis procedure with a direct analysis.

   The default value of 15 is recommended.
7. (Optional) Clear the **Reduced EI** option to use the full EI for member section moment and section displacement calculations.
8. (Optional) Clear the **Perform Tau-b Iteration** option prevent the program from iterating τ_b.
9. Select the **Print Option** you want to use.
10. Click **Add**.
    The perform direct analysis command is added to the input file.

Related Links

- *G.17.2.1.4 AISC 360 Direct Analysis* (on page 2144)
- *Perform Direct Analysis tab* (on page 2920)
- *TR.37.5 Direct Analysis* (on page 2630)

A. To specify a nonlinear analysis

To instruct the program to perform a static, geometric nonlinear analysis of the structure, use the following procedure.

Note: This requires a STAAD.Pro Advanced license.

The following limitations should be noted regarding static, geometrically nonlinear analyses:

- Large rotations in one step should be avoided by using more steps.
- Very large displacements, unstable structures, and/or post-buckling should be avoided.
- Geometrically nonlinear only. No tension/compression or contact is considered. No yield, plastic moment hinges or bilinear behavior is considered.
- Solids cannot be used for this analysis method.
- Temperature loads are *not* supported for geometric nonlinear analysis.

1. Either:

   select the **Analysis** page

   or

   on the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group

   

   The **Analysis/Print Commands** dialog opens.
2. Select the **Nonlinear Analysis** tab.

3. (Optional) Specify the nonlinear analysis parameters as necessary:
   a. Type a absolute displacement limit for the first analysis step in the **ARC** field.
   b. Type the maximum number of **Iterations** to use to achieve equilibrium in the deform position within the specified tolerance value.
   c. Type the **Tolerance** to use for achieving convergence between two sequential iterations.
   d. Type the number of **Load Steps** to use for applying load in stages.
   e. Type frequency of **Rebuild Steps** of the tangent K matrix.
4. Check the **KG** option to add the geometric stiffness to the stiffness matrix.
5. (Optional) Check the **Set Displacement Limit** option to specify a target displacement:
   a. Either:

      type a **Node** number

      or

      click **[...]** to select a node in the view window
   b. Select a **DOF** (degree of freedom from the drop-down list).
   c. Type a **Target Value** distance for the displacement limit.
6. Select the **Print Option** you want to use.
7. Click **Add**.
   The perform nonlinear analysis command is added to the input file.

The maximum displacement should be reviewed for nonlinear analyses because this analysis type may result in buckling or large displacements.

A. To specify a nonlinear cable analysis

To specify a nonlinear cable analysis using the advanced features in STAAD.Pro, use the following steps.

You must specify at least one member with a nonlinear cable specification.

Note: Use of the Advanced Cable analysis feature requires the STAAD.Pro Advanced License.

Only one primary load case is permitted for a nonlinear cable analysis. A `CHANGE` command must be used with a new nonlinear cable analysis for each additional primary load case to be analyzed.

1. Either:

   select the **Analysis** page

   or

   on the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group

The **Analysis/Print Commands** dialog opens.
2. Select the **Perform Cable Analysis** tab.
3. Select the **Advanced Cable Analysis** option.
4. (Optional) Set the options for **Use Modified Newton-Raphson** method and **Use Geometric Matrix (Kg)** as needed.
5. (Optional) Type values for the **Steps**, **Eq-Iterations**, and **Eq-tolerance** fields as needed.
   Default values are assumed for each when not specified.
6. Select the **Print Option** you want to use.
7. Click **Add**.
   The advanced cable analysis command is added to the input file.

A. To add a change command (on page 958) and M. To create a new primary load case (on page 830) to analyze additional load cases using a nonlinear cable analysis. Then repeat this procedure to specify another nonlinear cable analysis.

Tip: You can select to add the cable sag values for a nonlinear cable analysis to the output file in the post-analysis **Analysis/Print Commands** dialog.

A. To specify an imperfection analysis

To instruct the program to perform an imperfection analysis, use the following procedure.

This analysis is used when member imperfection specifications are included in the model to define camber or drift.

1. Either:

   select the **Analysis** page

   or

   on the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group

   The **Analysis/Print Commands** dialog opens.
2. Select the **Perform Imperfection Analysis** tab.
3. Select the **Print Option** you want to use.
4. Click **Add**.
   The perform imperfection analysis command is added to the input file.

Related Links

- *G.17.2.4 Imperfection Analysis* (on page 2148)
- *TR.37.9 Imperfection Analysis* (on page 2657)
- *Perform Imperfection Analysis tab* (on page 2924)

A. To specify buckling analysis

To instruct the program to perform a buckling analysis on the structure, use the following procedure.

This analysis type is used to calculate the buckling factor for a load case. This is the load case multiplier at which global buckling of the structure would occur for that load case.

1. Either:

   select the **Analysis** page

   or

   on the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group

   

   The **Analysis/Print Commands** dialog opens.
2. Select the **Perform Buckling Analysis** tab.
3. Select the method for the buckling analysis:

   Iterative method

   or

   Eigen method - available for STAAD.Pro Advanced only
4. (Optional) If the iterative method is used, type the maximum **Number of Iterations** to use in the analysis.

   It not specified (i.e., left as zero), 20 iterations are used as the default value. 15 is recommended.

   Note: MAXSTEPS input is ignored when using the eigen method.
5. Select the **Print Option** you want to use.
6. Click **Add**.
   The perform buckling analysis command is added to the input file.

Related Links

- *G.17.2.2 Buckling Analysis* (on page 2145)
- *TR.37.4 Buckling Analysis* (on page 2628)

A. To specify a pushover analysis

To instruct the program to perform a pushover analysis, use the following procedure.

You mush first define pushover data and the pushover loading.

Note: This requires a STAAD.Pro Advanced license.

1. Either:

   select the **Analysis** page

   or

   on the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group

   

   The **Analysis/Print Commands** dialog opens.
2. Select the **Perform Pushover Analysis** tab.
3. Click **Add**.
   A message dialog opens to confirm you want to add this command.

Once you have successfully performed a pushover analysis, you can review the pushover results in the Postprocessing workflow.

Related Links

- *TR.37.7 Pushover Analysis* (on page 2643)
- *G.17.4 Pushover Analysis* (on page 2168)
- *M. Pushover Loads* (on page 881)
- *Perform Pushover Analysis tab* (on page 2926)

A. To add a change command

To add a change command which is required for performing a subsequent analysis command, use the following procedure.

A change command is only added *after* an analysis command.

In addition to being used for a new analysis, the change command is used to change the support conditions, active/inactive member status, load conditions, etc. The stiffness matrix being solved will be reset when a change command is used.

1. Either:

   select the **Analysis** page

   or

   on the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group

   

   The **Analysis/Print Commands** dialog opens.
2. Select the **Change** tab.
3. (Optional) Check the **After Current** option if you previously selected the analysis command in the input file list within the **Analysis - Whole Structure** dialog.

This option allows you to specify specifically where the command is added. Otherwise it will be added to the end of the input file.

4. Click **Add**.
   The change command is added to the input file.

You can now add an additional analysis command to the input file. A change command with no subsequent analysis command has no effect.

Related Links

- *G.19 Multiple Analyses* (on page 2194)

A. To generate a floor spectrum

To calculate the floor spectra from time history acceleration, use the following procedure.

This procedure should only be used if a time history load case is being solved by the analysis engine.

Note: The floor response spectrum command must immediately follow an analysis command. Therefore, it is helpful to select the corresponding analysis command prior to starting this procedure.

Note: That analysis can only contain a single time history load case.

This command is used to specify the calculation of floor and/or joint spectra from time history results.

Note: This requires a STAAD.Pro Advanced license.

1. Either:

   select the **Analysis** page

   or

   on the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group

   

   The **Analysis/Print Commands** dialog opens.
2. Select the **Generate Floor Spectrum** tab.
3. For every group and direction that is necessary:
   a. Check one or more global directions in a table row: **GX**, **GY**, and **GZ**.
   b. Type a **Title** used to identify the spectrum.
   c. Use the drop-down to select the **Node Groups** which are included in this direction.

   You may include as many directions as needed.
4. (Optional) Type frequency options to use for the spectra (all are optional inputs):
   a. Type the **Lowest Frequency** (in Hz) to be in the calculated spectrum.
      This should be at least 0.0 Hz.
   b. Type the **Highest Frequency** (in Hz) to be in the calculated spectrum

   c. Type the number of **Frequency Interval** to use between the lowest and highest frequency.
5. (Optional) Type up to ten **Damping Ratios** to use as a ratio.
   (e.g., 3% damping is `0.03`)

   One spectrum will be generated for each damping ratio for each global direction requested for each floor defined. The spectrum will be based on these damping ratios. Is not entered, the default of 5% (0.05) damping will be used as a single damping ratio.
6. Check the **Relative Acceleration?** option if there is ground motion defined and you wan tthe spectrums based on the relative acceleration of the floor to the ground acceleration.

   Otherwise, the acceleration is assumed to be an absolute acceleration.
7. (Optional) Select the print parameters as needed (both are optional):
   a. Check the **Print Time History Acceleration used?** option to include this in the output.
   b. Check the **Print Calculated Spectrum?** option to include this in the output.
8. Select the **Print Option** you want to use.
9. Click **Add**.

> **Tip:** The **After Current** option is helpful to make sure this is added immediately following the analysis command if you selected prior to this procedure.

   The generate floor spectrum command is added to the input file.

Related Links

- *TR.37.10 Floor Spectrum Command* (on page 2657)
- *TR.37.10 Floor Spectrum Command* (on page 2657)

A. To specify pre-analysis commands

To instruct the program to include model input data in the STAAD output file (`.anl`), use the following procedure.

1. On the **Analysis and Design** ribbon tab, select the **Pre Analysis Commands** tool in the **Analysis Data** group.

   

   The **Pre Analysis Print - Whole Structure** dialog opens.
2. Click **Define Commands**.
   The **Analysis/Print Commands** dialog opens.
3. Select the tab corresponding to the print command you want to add to the output file.

   Problem Statistics
   Joint Coordinates
   Member Information
   Material Properties
   Support Information
   All
   Element Information

Solid Information
Member Properties

4. Click **Add**.

> **Note:** If you selected a portion of the model prior to opening the **Analysis/Print Commands** dialog, you can click **Assign** to assign the command to those model objects.

The selected print command is added to the input file.

5. Repeat Steps 3 and 4 to add additional print commands.
6. Click **Close**.

You must assign most print commands to portions of the model using one of the standard assignment methods.

- *Analysis/Print Commands dialog (Pre Print)* (on page 2926)

A. To create a load list

To create an active list of load cases for use with subsequent print and design commands, use the following procedure.

A load list is used to control the loads that are included with following print and design specifications.

> **Note:** All load cases are considered by analysis commands. You just a `CHANGE` command to make changes to the loads considered for analysis.

1. On the **Analysis and Design** ribbon tab, select the **Load List** tool in the **Analysis Data** group.

The **Load List** dialog opens.

2. Either:

select one or more items in the **Load Cases** list and then click **[>]** to include them in the **Load List**

or

click **[>>]** in include all load cases

> **Tip:** Including all load cases is the same as not using a load list at all.

3. Click **OK**.

Related Links

- *Load List dialog* (on page 2931)

A. To check for soft stories and seismic code irregularities

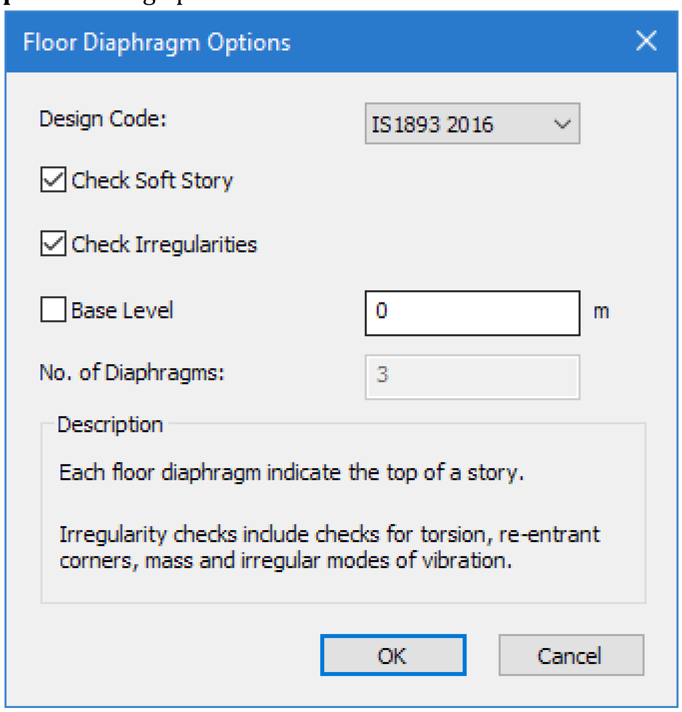
To check for soft stories and other seismic code irregularities in rigid diaphragm structures, use the following procedure.

Note: Soft story checks and plan irregularities are applicable to structures with rigid floor diaphragm definitions. Refer to M. To assign nodes to a floor diaphragm (on page 818).

The `CHECK SOFT STORY` option may added to a `FLOOR DIAPHRAGM` command set to check for soft stories per either IS 1893 2002, IS 1893 2016, or ASCE 7-05 codes. The `CHECK IRREGULARITIES` command may be added to check plan irregularities for the IS 1893 2016 or ASCE 7-05/10/16 codes.

Tip: You can check plan and vertical irregularities and structure stiffness per EC8 using P. Using the Earthquake Workflow (on page 2032).

1. On the **Analysis and Design** ribbon tab, select the **Miscellaneous Commands** > **Floor Diaphragm Options** tool in the **Analysis Data** group.
   The **Floor Diaphragm Options** dialog opens.



2. Select the building code for which you want to perform earthquake checks:

   IS1893 2002

   or

   IS1893 2016

   or

   ASCE7-05/10/16
3. Check the option **Check Soft Story** to perform this check.

4. (IS 1893 - 2016 or ASCE 7 only) To check for plan and other vertical irregularities, check the option **Check Irregularities**.

   For IS 1893 2016, the program can check horizontal irregularities (torsional and reentrant corners) per Table 5 and vertical irregularities (mass irregularities and irregular modes of oscillation) per Table 6.

   For ASCE 7-05/10/16, the program can check horizontal irregularities (torsional and reentrant corners) and vertical irregularies (mass). Irregular modes of oscillation are not considered for this code.
5. (Optional) If the base of the structure is not the minimum global Y coordinate defined in the structure, then check the **Base Level** option and then type the height of the structure base in the adjacent field.
6. Click **Add**.

Note: Additionally, the story stiffnesses used in calculating story drift or checking soft stories can be added to STAAD.Pro output by including the command `PRINT STORY STIFFNESS` in the post analysis print commands section.

A. To specify post-analysis print commands

To include additional analysis results in the STAAD output (`.anl`) file, use the following procedure.

Note: All output values will be available in the postprocessing workflow, regardless of whether you add them to the output file. Similarly, you can add post-analysis output to a report even if not included in the output file.

1. Select the **Post Analysis Commands** tool in the **Analysis Data** group on the **Analysis and Design** ribbon tab.

   

   The **Analysis/Print Commands** dialog for post-analysis commands opens.

> **Tip:** If the dialog does not immediately open, click **Define Commands** on the **Post Analysis Print - Whole Structure** dialog.

2. Select the tab pertaining to the output you want to add to the output file.
3. Check the **After Current** option to insert the print command following the currently selected command within the **Post Analysis Print - Whole Structure** dialog.

   Otherwise, the print command will be added to the end of the STAAD input file.
4. Click **Add**.
   The command is added to the STAAD Input file.
5. (Optional) Repeat steps 2 through 4 to add additional print commands as needed.
6. Click **Close**.

> **Note:** Some print commands require a assignment. These will be marked with question mark (?) in **Post Analysis Print - Whole Structure** dialog. Use the **Assignment Method** tools to assign these to the appropriate model objects.

Related Links

- *Analysis/Print Commands dialog (Post Print)* (on page 2927)

A. To output the center of rigidity

To instruct the program to include the center of rigidity of each rigid diaphragm in the analysis output, use the following procedure.

The lateral force at each floor, as generated by earthquake and wind loading, acts at the center of rigidity of each floor which is modeled as rigid floor diaphragm. The center of mass of each floor is defined as the mean location of the mass system of each floor. The mass of the floor is assumed to be concentrated at this point when the floor is modeled as rigid diaphragm. The distance between these two is the lever arm for the natural torsion moment for seismic loads when that option is used.

1. Select the **Post Analysis Commands** tool in the **Analysis Data** group on the **Analysis and Design** ribbon tab.

   

   The **Analysis/Print Commands** dialog for post-analysis commands opens.

   > **Tip:** If the dialog does not immediately open, click **Define Commands** on the **Post Analysis Print - Whole Structure** dialog.

2. Select the **Dia CR** tab in the **Analysis/Print Commands** dialog.
3. Check the **After Current** option to insert the print command following the currently selected command within the **Post Analysis Print - Whole Structure** dialog.

   Otherwise, the print command will be added to the end of the STAAD input file.
4. Click **Add**.
   The command is added to the STAAD Input file.
5. Click **Close**.

Related Links

- *TR.42 Print Specifications* (on page 2666)

A. To report cable sag from an advanced cable analysis

To include the cable sag in the output from an advanced cable analysis, use the following procedure.

Tip: Cable sag is only available for advanced nonlinear analysis. If requested for a standard cable analysis, a warning message will be reported in the output.

An advanced cable analysis can also report the deflected shape of the sag in the cable using the `PRINT CABLE SAG` command.

1. On the **Analysis and Design** ribbon tab, select the **Post Analysis Commands** tool in the **Analysis Data** group.

   

   The **Post Analysis Print - Whole Structure** dialog opens.
2. Click Define Commands in the **Post Analysis Print - Whole Structure** dialog.
   The **Analysis/Print Commands** dialog opens.
3. Select the **Cable Sag** tab.
4. Click **Add**.
   The `PRINT CABLE SAG` command is added to the input file.

The output of a successful advanced cable analysis will report the cable sag in local XYZ coordinates. Post-analysis print will calculate the actual, nonlinear cable displacements along the length of cable.

A. To check for inter-story drift

To instruct the program to check the drift between adjacent stories against a code-defined ratio, use the following procedure.

Story drift is calculated as the relative horizontal displacement of two adjacent floors in a building. Inter-story drift can also be expressed as some factor times the story height. The allowable factor generally varies from one country code to another and may also vary depending on the type of loading. For example, in IS 1893: 2002 for seismic loading the allowable limit for inter-story drift is 0.004 times the story height whereas in IS 875 for wind loading it is 0.002 times the story height.

The drift at a particular story level in either lateral direction is calculated as the average of all the joint displacements present in that floor level. However if floor diaphragm is present, the drift is calculated at the center of mass (i.e,. control joint) of the floor.

Note: Additionally, the story stiffnesses used in calculating story drift or checking soft stories can be added to STAAD.Pro output by including the command `PRINT STORY STIFFNESS` in the post analysis print commands section.

Refer to TR.42 Print Specifications (on page 2666) for additional information.

Note: For dynamic IS 1893: 2002 response spectrum, the story drift check is performed by adding a command line within the load case, rather than in the post-analysis print commands. Refer to TR.32.10.1.7 Response Spectrum Specification per IS: 1893 (Part 1)-2002 (on page 2534) for additional information.

1. Select the **Post Analysis Commands** tool in the **Analysis Data** group on the **Analysis and Design** ribbon tab.

   

   The **Analysis/Print Commands** dialog for post-analysis commands opens.

   Tip: If the dialog does not immediately open, click **Define Commands** on the **Post Analysis Print - Whole Structure** dialog.
2. Select the **Story Drift** tab in the **Analysis/Print Commands** dialog.
3. Enter an **Allowable Drift Factor** value.

   This is the drift ratio value as specified by the applicable building code.
4. Check the **After Current** option to insert the print command following the currently selected command within the **Post Analysis Print - Whole Structure** dialog.

   Otherwise, the print command will be added to the end of the STAAD input file.
5. Click **Add**.
   The command is added to the STAAD Input file.
6. Click **Close**.

Related Links
- *TR.42 Print Specifications* (on page 2666)

A. To perform an analysis in STAAD.Pro

Once you have completed the input file, use the following procedure to perform an analysis and optional design.

The STAAD analysis engine performs analysis and design sequentially with a single click. In order to carry out the design, these design parameters must be specified along with geometry, properties, etc. in the input file (this is referred to as a “batch” design). Also, note that you can change the design code used for design and code check before performing the analysis and design.

The Analytical Modeling and Physical Modeling of the STAAD.Pro user interface are used to prepare the structural input data which is then passed to the STAAD analysis engine for general purpose structural analysis and design.

1. Either:

   Select the **Run Analysis** tool in the **Analysis** group on the **Analysis and Design** ribbon tab.

   

   or

Press **<CTRL+F5>**

The **STAAD Analysis and Design** dialog opens.

During the analysis (and design, if specified), an output file is generated. This file may contain selected input data items, results and error messages. Optional print specifications can be used to include additional information in the output file.

2. Select an option for what action occurs when the dialog is closed:

   Open the output file

   or

   go to the post-processing mode

   or

   remain in the analytical modeling mode
3. Click **Done**.
4. (Optional) To review the output file is this option was not selected in the **STAAD Analysis and Design** dialog, either:

   Select the **STAAD Output** tool in the **Utilities** group on the **Utilities** ribbon tab

   

   or

   Select the **View STAAD Output File** tool on the Quick Start toolbar.

A. To run analysis on the cloud

To use Bentley's Scenario Services to perform analysis and design on your model, use the following procedure.

Note: Requires you to be logged into your valid CONNECT account.

Technical Preview:  This feature is part of a Technical Preview. It has not been reviewed per Bentley's standard quality assurance program and should be considered for review only.

1. On the **Analysis and Design** ribbon tab, select the **Run Cloud Analysis** tool in the **Cloud Analysis Services** group.

   

   The **Run Cloud Analysis** dialog opens.

2. If your STAAD model is not already associated with a CONNECT Project, you will be prompted to select one now.
3. (Optional) To create a new solution for use with the analysis:
   a. Click **Create**.
      The **Create New Solution** dialog opens.
   b. Type a **Solution Name**.
   c. (Optional) Type a **Solution Description**.
   d. Select the **Unit Convention** to use for this solution.
   e. Select the **Analysis Engine** to use.

      The various releases of STAAD.Pro are included in the drop-down list.
   f. Select the **Summary Indicators** you want to use for ranking the performance of this scenario.
   g. Select any optional **Other Indicators** you would also like to use for scenario comparisons.
   h. Click **Create Solution**.
      You are notified once the solution has been successfully created.
   i. Click **OK**.
4. Select the solution to use from the **Select Solution** drop-down list.

   The details of the selected scenario are displayed.
5. Type a **Scenario Name**.

   This must be a unique name.
6. Click **Submit**.
   You are notified once the analysis job has been successfully created and queued.

Once the analysis job is complete, you will be notified with a message from the Windows task area.

You can use the **Download Results** tools to either open the results for postprocessing STAAD.Pro or to save to your local computer for review or other postprocessing later.

6 Design

This section contains information on designing structural elements, organized by material type.

D. Batch Design versus Interactive Design Workflows

STAAD.Pro has two means by which structural members can be designed.

Batch Design

Using this method, code checks and/or member selection is performed directly by the analysis and design engine when an analysis is performed.

Interactive Design Workflow

Concrete code checks and member selection are performed in a post-processing workflow Advanced Concrete Design. This workflow is available in the Workflows panel.

D. Steel Design

D. Available Steel Design Codes

All steel design codes are available using the batch design method in the Analytical Modeling workflow (e.g., via the STAAD input file) where not specifically stated otherwise in the workflow column.

Note: Design per the Chinese steel code GB 50017-2017 is available through the **Chinese Steel Design** workflow.

Batch Design

Table 41: Steel design codes available in batch design

Country/Region	Code	Title
Australia	D2.B. Australian Codes - Steel Design per AS 4100 - 1998 (on page 1356)	Standards Australia - Steel Structural Design, including Amendment 1 (2012)
Belgium	D5.D.10 Belgian National Annex to EC3 (on page 1563)	Belgian National Annex (EC3)
Canada	D4.B. Canadian Codes - Steel Design per CSA Standard CAN/CSA-S16-01 (on page 1419)	Limit States Design of Steel Structures
	D4.C. Canadian Codes - Cold Formed Steel Design per S136-94 (on page 1434)	Specification for the Design of Cold-Formed Steel Structural Members
	D4.E. Canadian Codes - Steel Design per CAN/CSA-S16-09/14/19 (on page 1447)	Limit States Design of Steel Structures (2009, 2014, and 2019 editions)
Europe	D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478)	Eurocode 3: Design of steel structures Part 1.1 General rules and rules for buildings
Finland	D5.D.7 Finnish National Annex to EC3 (on page 1543)	Finnish National Annex (EC3)
France	D6.A. French Codes - Steel Design per CM66-1977 (French) (on page 1592)	Regulations for the calculation of steel structures and Design rules for structural steelwork, Addendum 80

D.Batch Steel Design Operations

STAAD.Pro contains a broad set of facilities for designing structural steel members as individual components of an analyzed structure. The member design facilities provide you with the ability to carry out a number of different design operations. These facilities may be used selectively in accordance with the requirements of the design problem.

D.Steel Design Overview

The design of steel members in STAAD.Pro can be achieved in the following three methods:

- check that the member meets the requirements of the design code using the Code Check command.
- for the forces resulting from the current set of loading, determine the most efficient size of section that would meet the requirements for the design code using the Select command.
- determine the optimum size for all members in the model that would meet the requirements for the design code for the current loading set using the Select Optimized command.

Each design follows the rules as defined in a published design code specification. The list of available codes currently supported can be found at D. Available Steel Design Codes (on page 969).

In order to determine the design code and code edition to which the members will be designed, the design command is preceded by a definition of the code and a series of code-related parameters. Each collection of these parameters is referred to as a “parameter block.” In the STAAD.Pro input file, this is initiated with the command `PARAMETER` and then typically terminated with the design command (e.g., `CHECK CODE`).

The parameter block provides the means by which you specify design-related member attributes required for the specified design code that have not been specified in the analytical model thus far. Each parameter has a default value which is ascribed to members to which a design command applies. When you assign a parameter to a given member, any design command that follows this assignment will use the specified parameter in the design. The default value of each design code parameter is listed in the appropriate section of the documentation.

```
PARAMETER
CODE design code/version
parameters modified from default values
design command
```

It is possible to define multiple design command and parameter blocks :

```
PARAMETER 1
CODE design code/version
parameters modified from default values
design command 1
design command 2
design command 3
...
PARAMETER 2
CODE design code/version
parameters modified from default values
```

```
design command 4
design command 5
design command 6
```

Also, each design command can be defined for different sets of members and different design commands:

```
PARAMETER 1
CODE design code/version
parameters modified from default values
CHECK CODE MEMBER 1 TO 10
SELECT MEMBERS 5 TO 20
```

D. To specify steel design code and parameters

To initiate the design of steel members and specify the code parameters, use the following procedure.

Note: To reduce the number of load cases used in design operations, you may want to create a load envelope or load list prior to specifying the design.

Batch mode design is specified and performed in the Analytical Modeling workflow.

1. On the **Analysis and Design** ribbon tab, select **Steel** in the **Design** group gallery.
   The **Steel Design - Whole Structure** dialog opens.
2. In **Steel Design - Whole Structure** dialog, select the applicable steel design code from the **Current Code** drop-down list.
3. Click **Define Parameters**.
   The **Design Parameters** dialog opens.
4. Specify a value or option for each required parameter for a set of members and then click **Add**.

   You only need to specify parameters that require a different value from the default value. Repeat this step for all non-default parameters.

   Note: Different parameters can be used for different member type designs (e.g., columns, beams, composite floor girders, braces, etc.). Alternatively, you can use a separate set of parameters for different member types.
5. Click **Close**.

   The design parameters are marked with an  icon. This indicates that the need to be assigned to members.
6. Use one of the STAAD.Pro assignment methods to assign each parameter to the applicable members.

You will now need to instruct the program to perform a design command on these members.

D. To design steel members in groups

To design members as a group, use the following procedure.

In many situations, it is preferable to have only a few different member sizes for many members rather than each member size be different, even if this would result in some members being underutilized. You can group members in the batch design to instruct the program to replace the member sizes in the group with the highest capacity member of the existing sizes in that group. You can also instruct the program to use a specified section property for the grouping or even group based on a specific member number, regardless of property specifications.

For example, in a floor bay with 5 beam members the edge members were selected as W12x14 shapes and the interior members were selected as W14x22 shapes. Grouping these members will immediately instruct the program to use W14x22 for all members for any subsequent instructions (i.e., analysis, design, take-off, etc.).

Note: All members within a group must be of the same cross section type. If one or more of the members has a different cross-setion type, the grouping is ignored by the program.

1. On the **Steel Design - Whole Structure** dialog, click **Commands**.
   The **Design Commands** dialog opens. The tabs (if any) available in this dialog are dependent on the current design code selection. Not all commands are available for every design code.
2. If you want to retain the member groups for all subsequent commands, select the **FIXED GROUP** tab and then click **Add**.

   If you do not use the FIXED GROUP option, then the members are grouped once and then this grouping is ignored for subsequent commands. If you do add the FIXED GROUP command, then all subsequent member selection commands will apply to the group again.
3. Select the **GROUP** tab.
4. (Optional) Select the **Property Specification** to use for grouping shapes.
5. (Optional) Check the **Same as Beam #** option and then select a member number from the drop-down list.
6. Click **Add**.
7. Click **Close**.
8. Assign the group command to all the members you want to group together.

You can repeat this procedure to create as many design groups as necessary.

Once you have created a group, you will typically want to perform a code check or member selection on the members.

D. To specify steel design commands

To specify the code checking or design commands to be used for the steel design operation, use the following procedure.

1. On the **Steel Design - Whole Structure** dialog, click **Commands**.

The **Design Commands** dialog opens. The tabs (if any) available in this dialog are dependent on the current design code selection. Not all commands are available for every design code.

2. To perform a design action, select one of the following options (as they are available for the code selection):

To...	Select...
check the capacity of the current member sizes	the **CHECK CODE** tab
select a member size based on the last analysis results	the **SELECT** tab
select a member size based on iterating the analysis for updated member sizes	the **SELECT OPTIMIZED** tab

3. Click **Add**.
4. Click **Close**.
5. Assign the design commands to the appropriate members.

Related Links

- *TR.49.2 Member Selection by Optimization* (on page 2679)

D. To generate steel take off

To generate a summary of all steel sections with their lengths and weights for the whole structure or a list of members, use the following procedure.

1. On the **Steel Design - Whole Structure** dialog, click **Commands**.
The **Design Commands** dialog opens. The tabs (if any) available in this dialog are dependent on the current design code selection. Not all commands are available for every design code.
2. Select the take off table you want to include:

To...	Select...
generate a list of sections used including total length and weight	the **TAKE OFF** tab
generate a list sorted by members including the length and weight of the member and section used	the **MEMBER TAKE OFF** tab

3. Click **Add**.
4. Click **Close**.
5. Assign the take off commands to members or to a named group of members.

D. Chinese Steel Design

The SSDD application for steel design to the Chinese code is integrated as the Chinese Steel Design workflow.

D. To open a model in the Chinese Steel Design workflow

To design steel members per the Chinese GB 50017-2017 code, use the following procedure.

In order to use the Chinese steel design workflow, the steel sections must be from the steel section table or from a user-provided table. Refer to Member Properties (on page 985) for details.

Note: In previous versions, wind and response spectra load cases per the Chinese code were applied within the SSDD application. These loads are now applied in the analytical modeling workflow within STAAD.Pro:

- M. To add a GB50009 wind load definition (on page 848)
- M. To add a seismic load definition (on page 857) (static load per GB50011-2010)
- M. To add a GB 50011-2010 response spectrum (on page 869)

Load combinations should be generated per the GB 50009-2012 specification.

- M. To automatically generate load combinations (on page 888)

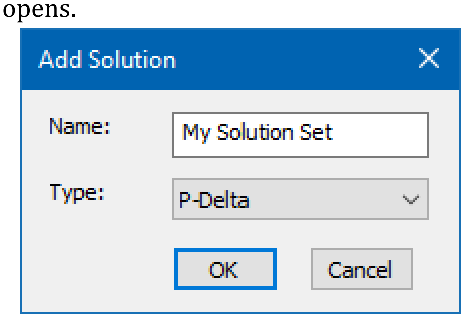
1. Open an input file in STAAD.Pro which contains the steel sections to be designed.
2. Perform a successful analysis.
3. Select **Chinese Steel Design** in the Workflows panel.

D. To add a new solution set

To add a new set of parameters in a solution set for comparing different designs, use the following procedure.

1. On the **Chinese Steel Design** ribbon tab in the **Solution** group, select the **Configuration** tool.

   The **Configure Solution** dialog opens.
2. Add a new solution set:
   a. Click **Add**.
      The **Add Solution Name** dialog opens.



b. Type a **Solution Name**.
c. Select the analysis **Type** to use with this solution set from the drop-down list.

> **Note:** The solution set is bound to an analysis method: **First-order** (elastic) or **P-Delta**.

d. Click **OK**.
The dialog closes.

The new solution set is added and is selected in the **Select Solution** drop-down list.

3. Click **OK**.
The dialog closes.
4. In the **Chinese Steel Design** ribbon tab **Solution** group, select the new solution set name from the drop-down list.
5. Add one or more design parameters.

> **Note:** The name of the current selection solution is displayed in the **Design Parameters** dialog. The analysis type associated with the solution set is also displayed in this dialog.

6. On the **Chinese Steel Design** ribbon tab in the **Solution** group, select the **Configuration** tool.

The **Configure Solution** dialog opens.
7. Select the new solution set name from the **Select Solution** drop-down list.
8. Add parameter sets to the **Used** list by either:

To...	Do the following...
add a single parameter	select a parameter name in the **Unused** list and then click **>**
add all available parameters	click **>>**

9. Click **OK**.

To design with a solution set, select the solution set name from the drop-down list in the **Chinese Steel Design** ribbon tab **Solution** group.

Related Links

- *Configure Solution dialog* (on page 3019)

D. To add a parameter set

To a set of design parameters to one or more members, use the following procedure.

A parameter set is specific to a solution set and the associated analysis type. Select the correct solution set before adding a parameter set.

A parameter set is used to assign a collection of steel design parameters (grade, seismic detailing, etc.) to one or more members.

> **Note:** Many of the parameters do have default values, so they do not all need to be specified for every member. However, any member to be designed in the Chinese Steel Design workflow does require a parameter set assigned to it.

1. In the Chinese Steel Design workflow, select the **Parameters** page.

The **<solution set name> - Design Parameters** dialog opens.

> **Note:** The type of analysis associated with the current solution set is displayed at the top of the dialog.

2. In the **<solution set name> - Design Parameters** dialog, click **Add**.
   The **Add New Chinese Steel Design Parameters** dialog opens.
3. Select and specify the parameters on each of the dialog tabs for this set as needed.
4. Click **OK**.

Parameter sets associated with a STAAD input file are stored in a `.gsp` with the same file name as the input file and in the same file location. These are plain text files.

- *Design Parameters* (on page 988)

D. To assign secondary members

To assign members to be considered as "secondary" members per the Chinese steel code, use the following procedure.

The members into which a secondary member frame will *not* be considered as restrained when determining automatic effective length calculations.

1. On the **Chinese Steel Design** ribbon tab, select the **Secondary Member** tool in the **Settings** group.

   

   The **Assign Secondary Member** dialog opens.
2. Use one of the following methods to select members for assignment:

Options	Description
To assign to a selection	select one or more members in the model view window and then select the **Assign to Selected Beams** option
To assign to all the members in the current view	select the **Assign to View** option
To assign to a list of members	select the **Assign to Edit List** option and then type the member numbers in the text field

> **Tip:** You can use tools found in the **Beams** group on the **Select** ribbon tab (e.g., **Parallel** tools) to easily select members for the Assign to Selected Beams option.

3. Click **Assign**.

> **Note:** You can remove unwanted secondary member assignments by repeating step1 and then using the **Remove** button to remove assignments for all or selected members.

Related Links

- *Assign Secondary Member dialog* (on page 3012)

D. To specify brace angle threshold values

To specify angle values used as the limit when auto-detecting brace members, use the following procedure.

Note: The default brace angle values (1 = 60°, 2 = 60°, and 3 = 10°) are recommended. These values typically only need to be changed when the program does not automatically identify a brace member as such.

1. Select the **Parameters** page.
2. On the **Chinese Steel Design** ribbon tab, select the **Secondary Member** tool in the **Settings** group.

   

   The **Brace Angle** dialog opens.
3. Type the values for the angle thresholds as necessary:

   1 and 2 are the angle between the brace and the major or minor axis of the member, respectively.

   3 is the angle between adjacent brace members considered to be collinear.
4. Click **OK**.

Re-perform the design procedure to have the changes reflected in the brace detection.
Related Links

- *Brace Angle dialog* (on page 3013)

D. To add a custom material definition

To add a user-defined steel material definition for use with the Chinese Steel Design workflow, use the following procedure.

The standard steel values for Chinese steel design from Table 4.4.1 of GB50017-2017 are included in the STAAD.Pro material definitions for use in the analytical modeling workflow. The material yield stress (*fy*) used for the design parameter should match that in the STAAD.Pro analytical model. Otherwise, a warning is produced in the member check report.

If a custom material definition is used in the analytical model, then you can add a custom material definition for the Chinese steel design workflow as well.

1. On the **Chinese Steel Design** ribbon tab in the **Settings** group, select the **Material** tool.

   

   The **Material Parameter** dialog opens.
2. Click **Add**.
   A new row labeled "USERDEFINE*n*" is added to the bottom of the table.
3. Select the new row.

   Note: The default material values are "read only" (marked in gray). These cannot be edited or deleted.

   The material values are populated with the defaults.

4. Type a **Material Name**.
5. Type a **Max Thickness** for which these values will apply.

   The same material name can have different Max T values.
6. Type the strength values which apply for this material name and max. thickness.

   Yield Strength (fy)
   Tensile Strength (f)
   Shear Strength (fv)
   Section Bearing Strength (fce)
   Ultimate Tensile Strength (fu)
7. Repeat steps 2 through 6 to add additional material definitions.
8. Click **Close**.

You can now select this material name in the parameter definition.

Related Links

- *Material Parameter dialog* (on page 3013)

D. To perform steel design per the Chinese code

To perform steel design per the GB 500017 code, use the following procedure.

1. On the **Chinese Steel Design** ribbon tab, select the **Design** tool in the **Design** group.

   

   The **Chinese Steel Design** dialog opens.
2. (Optional) On the **Structure** tab, set the following options as needed:
   a. Click **Default** to make any changes to the default design parameter.

      This parameter set is used for any members which do not have a named parameter set assigned.

      Tip: Any members without a parameter set name associated with it in the view window will use the default parameter set.
   b. Select the **Design Range** option: all members or on those selected.
   c. Check the **Seismic Design** option to include seismic design and then select the **Seismic Precautionary Intensity** level from the drop-down list.
   d. Select the optimization options applicable.
3. Click **Design**.
   The design and optimization process is displayed.
4. Click **Done**.
   The **Results** page opens. The members are color-coded by design status in the view window as well as in the Summary Results table.

   Tip: If you would like to change or add to the design result columns displayed in the Summary Results table, select the **Table Settings** tool in the **Results** group on the **Chinese Steel Design** ribbon tab (active when the Results page is selected). From there you can make changes to the table columns.

5. Select a member either in the view window or in the table to display design results in the Member Detail Result table.

D. Chinese Steel Design Technical Reference

General Description

The design philosophy embodied in this specification is based on the concept of limit state design. Structures are designed and optimization designed taking into consideration the limit states, and two major categories of limit-state are recognized: ultimate and serviceability. The primary considerations in ultimate limit state design are strength and stability, while that in serviceability is deflection. Appropriate load and resistance factors are used so that a uniform reliability is achieved for all steel structures under various loading conditions and the design strength of each structural component should equal or exceed the required strength determined according to the load combinations.

In the STAAD.Pro implementation, members are proportioned to resist the design loads without exceeding the limit states of strength, stability, and serviceability. Accordingly, the most economic section is selected based the least weight criteria as augmented by the designer in specification of allowable member depths, desired section type, or other such parameters. The code checking portion of the program checks whether code requirements for each selected section are met and identifies the governing criteria.

The following sections describe the salient features of the STAAD.Pro implementation of GB 50017-2017. A detailed description of the design process along with its underlying concepts and assumptions is available in the specification document.

Analysis Methodology

Elastic analysis method is used to obtain the forces and moments for design. Analysis is done for the primary and combination loading conditions provided by the user. Therefore, it is your responsibility to enter all necessary loads and load combination factors for design in accordance with the Building Structure Loadings Code GB 50009-2012, Building Structures Seismic code GB 50011-2010, or other relevant design codes. You are allowed complete flexibility in providing loading specifications and using appropriate load factors to create necessary loading situations. This process is completed in the STAAD.Pro Analytical Modeling or Physical Modeling workflows.

Depending upon the analysis requirements, a regular (elastic) stiffness analysis or P-Delta analysis may be specified. Dynamic analysis may also be performed and the results combined with static analysis results.

Member Properties

For specification of member properties, either the steel section library available in STAAD.Pro or user-provided table sections may be used.

For code check and Section optimization, the Chinese Steel Design workflow supports:

- Chinese - Rolled Steel table
  - I shapes
  - H shapes
  - T shapes
  - Channels
  - Double Channels
  - Angles
  - Double Angles
  - Tube
  - Pipe
- User-defined table
  - composite sections

Note: Prismatic sections and other special composite section can only be used with the Code Check facility. Furthermore, the design of laced and battened members is not considered. The program does not support the design of tapered section profiles per Chinese code.

Section Classification

The occurrence of local buckling of the compression elements of a cross-section prevents the development of full section capacity. It is therefore imperative to establish this possibility prior to determining the section capacities. Cross sections are classified in accordance with their geometrical properties and the stress pattern on the compression elements. For each load case considered in the design process, the program determines the section class and calculates the capacities accordingly. It is worth noting that the section class reported in the design output corresponds to the most critical load case among those being considered for design.

The program can design members with all section profiles that are of Class 1, 2, 3, or 4 as defined in section 3.5.1 of the code. However, the design of members that have a Class 5 section profile are limited to:

- H-sections
- Wide flange (with equal flanges or unequal flanges)
- Tube sections

Member Capacities and Deflection Check

Member Capacities

The bearing capacity of a member is the allowable stress under various load conditions, such as allowable tensile stress, allowable compressive stress, etc. The bearing capacity of a member depends on various factors, such as the cross-section characteristics, slenderness ratio and the ratio of unsupported width to thickness.

Due to the limitation of space and the complexity of GB 50017-2017, we can only briefly introduce the main specification inspection conditions for the above types of components in the program.

Strength and Stability Checks of Various Components

For different types of components, the program will check the strength and stability of components and select the section according to the relevant provisions of GB 50017-2017. The following will introduce the relevant code terms considered in the inspection of various types of components in the program.

In the following clauses, the numbers in the opening brackets are consistent with the corresponding clauses in the original GB 50017-2017 specification. In the following formula, the meaning of each symbol is the same as that in GB 50017-2017.

Flexural Members

1. The flexural strength of the solid web member bending in the main plane is as follows:

   $$\frac{M_z}{r_z W_{nz}} + \frac{M_y}{r_y W_{ny}} \le f \tag{6.1.1}$$

   In code inspection, the default component is static load or indirect dynamic load. In the calculation and test of the program, the values of parameters and forces are obtained from the data structure of components.
2. The shear strength of the solid web member bending in the main plane is as follows:

   $$\tau = \frac{VS}{It_w} \le f_v \tag{6.1.3}$$

3. 1. At the edge of the calculation height of the web of composite beam, if there are large normal stress, shear stress and local compressive stress at the same time, or bear large normal stress and shear stress at the same time (such as the support of continuous beam or the change of flange section of beam, etc.), the converted stress is as follows:

   $$\sqrt{\sigma^2 + \sigma_c^2 - \sigma\sigma_c + 3\tau^2} \le \beta_1 f \tag{6.1.5}$$

4. The global stability of the I-section bending in two main planes is calculated as follows:

   $$\frac{M_z}{\phi_b W_x} + \frac{M_y}{r_y W_y} \le f \tag{6.2.3}$$

5. Height thickness ratio of Web:

   Calculated value = web height / web thickness (I-beam, H-beam, channel steel...)

   =Diameter / wall thickness (round pipe)

   =Short leg length / short leg thickness (angle steel)

   See table 3.5.1 of GB 50017-2017 for calculation limit.
6. Flange width thickness ratio:

   Calculated value = flange width / flange thickness (I-beam, H-beam, channel steel...)

   =Diameter / wall thickness (round pipe)

   =Long leg length / short limb thickness (angle steel)

See table 3.5.1 of GB 50017-2017 for calculation limit.

Axially Loaded Members

1. The strength calculation formula of axially loaded members is as follows:

$$\sigma = \frac{N}{A} \le f \tag{7.1.1-1}$$

$$\sigma = \frac{N}{A_n} \le 0.7 f_u \tag{7.1.1-2}$$

2. The stability checking formula of axial compression member is as follows:

$$\frac{N}{\phi A} \le f \tag{7.2.1}$$

   For the stability factor ϕ, the program is obtained according to “Appendix D stability coefficient of axial compression members”in the code.
3. Slenderness ratio of compression member

   Refer to article 7.2.2 of GB 50017-2017 for calculation value. After calculation of Y-axis and z-axis, take the maximum value.

   If the program automatically calculates the limit value, the default value is 150, and then according to the seismic code, the requirements of axial force members are adjusted and modified.
4. Slenderness ratio of tension member

   Refer to article 7.2.2 of GB 50017-2017 for calculation value. After calculation of Y-axis and z-axis, take the maximum value.

   If the program automatically calculates the limit value, the default value is 300, and then according to the seismic code, the requirements of axial force members are adjusted and modified.
5. Height thickness ratio of Web:

   The calculated value is the same as that of flexural member.

   For the calculation limit, see article 7.3.1 of GB 50017-2017.
6. Flange width thickness ratio

   The calculated value is the same as that of flexural member.

   For the calculation limit, see article 7.3.1 of GB 50017-2017.

Members Subject to Combined Axial Loading and Bending

1. The strength of tension (compression) bending members with bending moment acting on the main plane is as follows:

$$\frac{N}{A_n} \pm \frac{M_z}{r_z W_{nz}} \pm \frac{M_y}{r_y W_{ny}} \le f \tag{8.1.1}$$

2. Stability:

   A. The stability of solid web compression and bending members with bending moment acting in the plane of symmetry axis is considered as follows.

      a. When the bending moment acts on the plane, the stability calculation formula is as follows:

$$\frac{N}{\psi_z A} + \frac{\beta_{mz} M_z}{r_z w_{1z}\left(1 - 0.8\frac{N}{N'_{Ez}}\right)} \le f \tag{8.2.1-1}$$

When the bending moment acts in the plane of the symmetrical axis and the larger flange is pressed, it should be calculated according to the above formula, and also meet the following requirements:

$$\left| \frac{N}{A} - \frac{\beta_{mz} M_z}{\gamma_z w_{2z}\left(1 - 1.25\frac{N}{N'_{Ez}}\right)} \right| \le f \qquad (8.2.1\text{-}4)$$

b. When the bending moment acts outside the plane, the stability calculation formula is as follows:

$$\frac{N}{\phi_y A} + \frac{\beta_{mz} M_z}{\phi_b w_{1z}} \le f \qquad (8.2.1\text{-}3)$$

B. When the bending moment acts on the imaginary axis direction of the lattice compression bending member, the calculation formula of the overall stability in the bending moment action plane is as follows:

$$\frac{N}{\psi_z A} + \frac{\beta_{mz} M_z}{w_{1z}\left(1 - \frac{N}{N'_{Ez}}\right)} \le f \qquad (8.2.2\text{-}1)$$

C. The stability of biaxially symmetric solid web I-shaped and box shaped members with bending moment acting on two main planes is calculated according to the following formula:

$$\frac{N}{\phi_z A} + \frac{\beta_{mz} M_z}{\gamma_z w_{1z}\left(1 - 0.8\frac{N}{N_{Ez}}\right)} + \frac{\beta_{ty} M_y}{\phi_{by} W_{1y}} \le f \qquad (8.2.5\text{-}1)$$

$$\frac{N}{\phi_y A} + \frac{\beta_{my} M_y}{\gamma_y w_{1y}\left(1 - 0.8\frac{N}{N_{Ey}}\right)} + \frac{\beta_{tz} M_z}{\phi_{bz} W_{1z}} \le f \qquad (8.2.5\text{-}2)$$

D. For the double leg lattice beam columns with bending moment acting on two main planes, the overall stability is calculated by the following formula:

$$\frac{N}{\phi_z A} + \frac{\beta_{mz} M_z}{w_{1z}\left(1 - \frac{N}{N'_{Ez}}\right)} + \frac{\beta_{ty} M_y}{W_{1y}} \le f \qquad (8.2.6\text{-}1)$$

3. Shear strength

The calculation method is the same as that of flexural member.

4. Local stability (width thickness ration / height thickness ratio)

The calculated value is the same as that of flexural member.

See table 3.5.1 of GB 50017-2017 for calculation limit.

5. Slenderness ratio

The calculation method is coaxial center stress member

Deflection Check

In the process of deflection test, various conditions in Chapter 3, section 3 of the code are considered. If you need to consider the provisions of member deflection in the process of specification inspection and component selection, it is also necessary to consider the control by design parameters `DFF`, `DJ1`, and `DJ2`.

Design Parameters

You can completely control the whole design process by modifying the design parameters.

These parameters are used by design engineers to communicate their design decisions to computer programs. The default values of all these parameters are selected as the common values which are more inclined to the security design. For a specific design requirement, some or all of the parameters need to be changed to meet the actual design requirements.

Member Type

In GB 50017-2017, members are divided into three categories: flexural members, axially loaded members, and tension (compression)+ bending members. You can force some components to be any of the above types. In this case, the program will check according to the type specified regardless of the geometry or stress. You can also let the program judge automatically. When the program judges automatically, there are two judging principles: according to the geometric position or according to the force characteristics. If you do not specify the component type, the default setting of the program is automatic judgment. The classification principles of various components are described below.

1. According to the geometric conditions

The flexural member	member is located in the horizontal plane of XZ
The axial force member	member is defined as the member truss
Tension (compression) + bending member	other members

2. According to the actual stress situation of members

The flexural member	member with axial force = zero
The axial force member	member with bending moment = zero
Tension (compression) + bending member	other members

Flexural Member

The flexural members are beam members. The judgment principle used in the program is: if the vertical coordinate difference between the two ends of the component is zero, it is regarded as a flexural member; if the axial force of the component is zero, it is regarded as a flexural member. The clause of flexural member shall be used in code inspection.

Axially Loaded Members

The axially loaded members are column members or truss members. The judgment principle adopted in the program is: when judging by geometry, the axial force member will not be generated; if the bending moment of the member is zero, that is, it is not subjected to bending moment, it is regarded as the axial force member. In the standard inspection, the axial force member clause is used.

Tension (Compression) Bending Member

In addition to the above-mentioned flexural members and axially loaded members, all other members in geometric or stress states are regarded as tension (compression) bending members in the program. In the standard inspection, the terms of tension bending and compression bending members are used.

Custom Component

You can choose the inspection terms freely by crossing, and can mix different types of component terms.

Steel Grade

From the following table, the design values of tensile, compressive and bending strength f and shear strength V_f are obtained respectively:

Table 42: Design value of steel strength (N/mm²)

Steel Grade		Thickness or diameter (mm)	Design Value of Strength			Yield strength f_y	Tensile strength f_u
			Tension, compression ,bending f	Shear f_v	End bearing (planed and closely fitted) f_{ce}		
Carbon structural steel	Q235	≤16	215	125	320	235	370
		>16~40	205	120		225	
		>40~100	200	115		215	
Low alloy high strength structural steel	Q345	≤16	305	175	400	345	470
		>16~40	295	170		335	
		>40~63	290	165		325	
		>63~80	280	160		315	
		>80~100	270	155		305	
	Q390	≤16	345	200	415	390	490
		>16~40	330	190		370	
		>40~63	310	180		350	
		>63~100	295	170		330	
	Q420	≤16	375	215	440	420	520
		>16~40	355	205		400	
		>40~63	320	185		380	
		>63~100	305	175		360	
	Q460	≤16	410	235	470	460	550
		>16~40	390	225		440	
		>40~63	355	205		420	

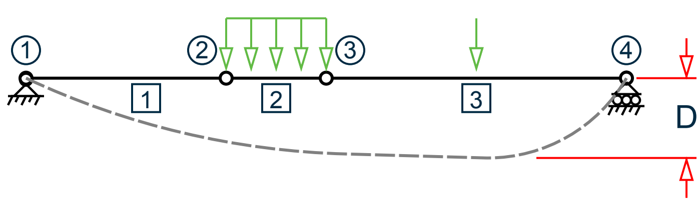
Steel Grade		Thickness or diameter (mm)	Design Value of Strength			Yield strength f_y	Tensile strength f_u
			Tension, compression ,bending f	Shear f_v	End bearing (planed and closely fitted) f_{ce}		
		>63~100	340	195		400	

In each inspection clause in the specification, the value of material strength used is extracted from the data specified here.

You can define a certain steel type manually, as long as the corresponding strength index can be specified. If you do not define and select the steel type, the program default value is set to Q235 steel.

Deformation Parameters

In the process of deflection inspection, various clauses in Appendix B of GB 50017-2017 are considered. If you need to consider the provisions of member deflection in the process of specification inspection and component selection, it can be controlled by three parameters `DFF`, `DJ1`, and `DJ2`. The `DFF` parameter takes the ratio of span to maximum allowable deformation as the limit value of deformation, which is called “deflection length”. The “flexure length” is the length of the member used to calculate the local deformation between the two ends. In most cases, the length of the member is equal to the length of the member. However, in some special cases, the “flexural length” may be different from the member length. For example, the beam shown in the following figure has 4 nodes and 3 members (in this case, two nodes are added in the middle of the component). In this case, for all three beam members, the “flexural length” is defined as the total length of the beam. Parameters `DJ1` and `DJ2` can be used to define this situation. At the same time, the connecting line between `DJ1` and `DJ2` is also the reference line for measuring the local deflection of the rod. Therefore, for all three members, `DJ1` should be node 1 and `DJ2` should be node 4. If `DJ1` and `DJ2` are not defined, the default value of “flexural length” is the length of the member (`DJ1` and `DJ2` take the end node of the member respectively), and the local displacement will be calculated along the line (i.e. axis) of the two ends of the member.



D = Maximum local deflection for members 1, 2, and 3.

The default setting value of the program is DFF = 400; DJ1 and DJ2 are the end nodes of components respectively. For DFF, you should take the denominator value of the corresponding type of allowable deflection in Appendix B according to the provisions of the code GB 50017-2017, and consider the provisions of other clauses.

Plastic Development Coefficients γ_x, γ_y, γ_{sharp}

The plastic development coefficient is a coefficient related to the shape of the section. The coefficient can be according to "specification" the provisions of article 6.1.2 8.1.1, table, through the STAAD/CHINA specification of CHINA steel structure design parameters γ_z, γ_y, γ_{limb} pointed to determine.

The program can automatically determine these coefficients according to the section type of the designed member, namely:

For I - section, take $\gamma_z = 1.05$, $\gamma_y = 1.20$;
For box section, take $\gamma_z = 1.05$, $\gamma_y = 1.05$;
For T steel limb tip parts $\gamma_{sharp} = 1.2$;
For other sections, use table 8.1.1.

If you enter the design parameters γ_z, γ_y, γ_{sharp}, the program will utilize those values. If you select to use automatic calculation, the program will be in accordance with your choice of sectional form, automatic computing (select) γ_z, γ_y, γ_{sharp}. Parameter γ_z, γ_y, γ_{sharp} the default value for the automatic calculation.

Stability Coefficient

The stability coefficient is divided into overall stability coefficient of flexural member (beam) and stability coefficient of axial compression member (truss). The program can automatically judge the coefficient according to the section type and force characteristics of the designed member. The built-in judgment principles in the program are as follows.

1. The overall stability coefficient of flexural members (beams) is calculated by the approximate calculation method in Appendix C of the code.

   For I-section and $\lambda_y > 120\varepsilon_k$

   $$\phi_b = \beta_b \frac{4,\ 320}{\lambda_y} \frac{Ah}{W_x} \left[\sqrt{1 + \left(\frac{\lambda_y t_1}{4.4h} \right)^2} + \eta_b \right] \varepsilon_k$$

   For I-section and $\lambda_y \le 120\varepsilon_k$

   a. When the cross section is biaxially symmetric:

   $$\phi_b = 1.07 - \frac{\lambda_y^2}{44,\ 000} \frac{f_y}{235}$$

   b. When the cross section is uniaxially symmetric:

   $$\phi_b = 1.07 - \frac{W_{1z}}{(2a_b + 0.1)Ah} \frac{\lambda_y^2}{14,\ 000} \frac{f_y}{235}$$

   T-section (moment acting on the plane of symmetry axis):

   a. When the flange is in compression by bending moment: double angle steel

   $$\phi_b = 1 - 0.0017\lambda_y \sqrt{\frac{f_y}{235}}$$

   Two board combination

   $$\phi_b = 1 - 0.0022\lambda_y \sqrt{\frac{f_y}{235}}$$

   b. When the flange is tensioned by bending moment: $\phi_b = 1.0$

When the value calculated by the formula is greater than 1.0, take 1.0.

2. For the axial compression member (truss), the calculation method of Appendix D in the code is used. It is related to the section type and slenderness ratio. The classification of section types is shown in table 7.2.1-1. You can also input data to specify the stability coefficient of the component. The default value of the program is automatic calculation, that is, the program automatically calculates the stability coefficient of the component according to the section type and force characteristics of the designed member.

Equivalent Moment Coefficient

The equivalent moment coefficient is used to “correct” the bending moment when checking the stability of the solid web bending member with bending moment acting on the symmetry axis plane, so it is divided into in-plane equivalent moment coefficient and out of plane equivalent moment coefficient. These coefficients can be calculated automatically by program or manually input.

In the dialog box of the program, the default value is 1.0. You can also specify them as other values or as automatic calculation. If the you specify automatic calculation, the program will automatically calculate the equivalent moment coefficient of the member according to the specification in 8.2.2.

Note: When members are pure and weakly braced frames without considering second-order analysis, the coefficient should be taken as 1 without reduction.

At the same time, it is necessary to specify whether there is lateral load in the direction of the main shaft.

Unsupported Effective Length and Effective Length Coefficient

The unsupported effective length and effective length coefficient are the calculation parameters needed to check the stability of members.

The direction of the strong axis and the weak axis of the principal inertial axis should be considered respectively. For complex spatial structures, it is very difficult to select the effective length and effective length coefficient of members. For the convenience of users, the function of automatically calculating these coefficients is set up in the program. Of course, users can also input these coefficients themselves. When these coefficients are automatically calculated by the program, they are calculated according to the following principles.

The general calculation length formula of members is as follows:

$$l_o = \mu l$$

For the principal inertial axis (the strong axis is the local Z-axis and the weak axis is the local Y-axis), the effective length of the member can be expressed as follows:

$$l_{zo} = l_z \mu_z$$

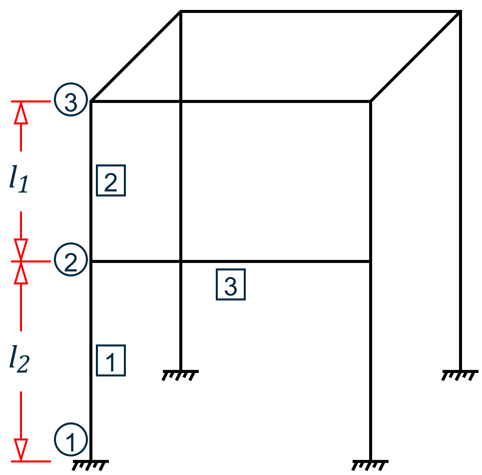
$$l_{yo} = l_y \mu_y$$

where

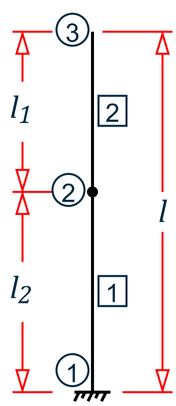
l_{zo} and l_{yo}	=	the effective lengths of the stability analysis along the strong axis (local Z axis) and weak axis (local Y axis) around the principal inertial axis, respectively;
μ_z and μ_y	=	the effective length coefficients in the strong axis direction and the weak axis direction, respectively; For P-Delta solution sets, the effective length coefficients are always taken as 1.0.

l_z and l_y	=	the unsupported lengths in the strong axis direction and the weak axis direction, respectively.

In the Chinese Steel Design workflow, the structure is divided into element and member system, and analyzed and calculated by finite element method. In some cases, it is possible that only one direction (such as the main axis direction) is supported at the node, while the other direction (such as the weak axis direction) is not supported. In this case, l_z and l_y are not equal, and they are not necessarily the distance between two nodes. For example, for the element [1] in the figure below, there is a horizontal member (unit 3) supporting at node 2 in the direction of the main axis, while there is no support at node 2 in the direction of the secondary axis. Therefore, the unsupported length of the member [1] in the direction of the principal axis $l_z = l_1$ and the unsupported length $l_y = l_1 + l_2$ in the secondary axis direction.



In some cases, you may add several nodes between members, and these nodes are only used for calculation, not nodes in the geometric sense. For example, as shown in the figure below, if a node (node 2) is added in the middle of a vertical column, then the unsupported length of element [1] and element [2] should be l instead of l_1 or l_2 during stability check.



For this kind of component, there is no problem in the structural analysis. But for the component design, it must be considered.

According to the provisions of GB 50017-2017, the members requiring stability analysis and calculation can be divided into three categories (the following are divided into three categories A, B and C).

Truss Chords and Single Web Members

For this kind of member, the provisions in table 7.4.1-1 in the specification can be adopted μ_z and μ_y.

For example, the Chord in the plane of the truss, $\mu_z = \mu_y = 1$,and web in the plane of the truss $\mu_z = \mu_y = 0.8$.

For this kind of component, you need to input the calculated length.

Uniform Section Column of Single or Multi Story Frame

For frame columns, the ratios K1 and K2 of the sum of the linear stiffness of the beams intersecting the upper and lower ends of the column and the sum of the linear stiffness of the column are required, and then the following equation is solved

For non-sway frame columns:

$$\mu = \sqrt{\frac{7.5K_1K_2 + 4(K_1 + K_2) + 1.52}{7.5K_1K_2 + K_1 + K_2}}$$

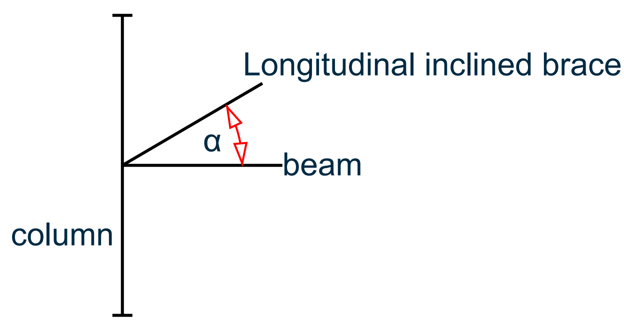
For sway frame columns:

$$\mu = \sqrt{\frac{(1 + 0.41K_1)(1 + 0.41K_2)}{(1 + 0.82K_1)(1 + 0.82K_2)}}$$

In the Chinese Steel Design workflow, you can input the length coefficient and unsupported length of members, and it can also be calculated automatically by the program. In this case, it is necessary to specify the supporting condition of the component (whether the two principal axes belong to the component with or without lateral displacement respectively).

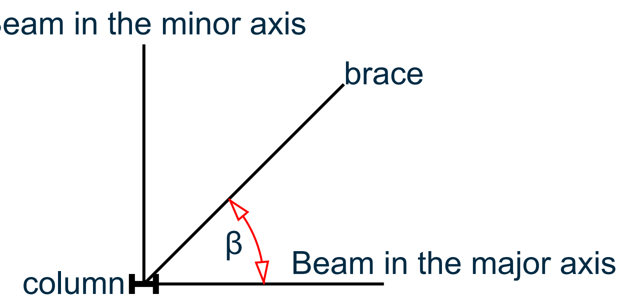
For the calculation of unsupported length, there are several cases as follows:

1. The longitudinal inclined strut is shown in the figure below.



In this case, the program will judge whether the constraint effect of the bar on the column should be considered according to the size of α angle. If $\alpha \leq 60$ ° (this can be specified), the program considers that the strut has constraint on the corresponding main axis direction of the column, and the linear stiffness of the strut is added to the total linear stiffness of the beam in proportion to calculate the value of K1 or K2.

2. Horizontal non principal inertial axis direction strut, as shown in the following figure:



In this case, the program will also automatically judge whether the constraint of the bar to the main axis of the column should be considered according to the size of the β angle.

If β is less than 60 °, which you can be specify, the strut is considered as a constraint on the strong axis direction of the column, and the linear stiffness of the strut is added to the total linear stiffness of the beam in the strong axis direction of the column.

3. The column extension angle is used to allow the engineer to set the maximum angle if the column is not on the same line but has an included angle when calculating the unsupported length of the column. Note that the angle should not exceed 30 degrees.

   Finally, the unsupported length (l_z and l_y) and the effective length coefficient of the column in the strong axis and weak axis direction ($\mu_z = \mu_y$) are calculated automatically

Rigid Fixed Stepped Column at the Lower End of Frame of Single Story Workshop

This kind of column is mostly used in the concrete column of heavy workshop. Generally, there are single and double order columns. Because in the steel structure, this kind of stepped column is not very useful. Therefore, for this kind of component, the user should input it manually after calculation according to 8.3.2 and 8.3.3 of the specification.

For single angle steel, when the length coefficient is calculated automatically, you can select to calculate by parallel limb (Y-Z axis) or strong weak axis (U-V axis) in the Design Parameters dialog box.

Allowable Slenderness Ratio

The allowable slenderness ratio of a member is the limit of the ratio between the effective length and the radius of rotation. The actual slenderness ratio of a member must be less than or equal to the allowable slenderness ratio.

7.2.2 the slenderness ratio of solid web member shall be determined by the following formula according to its instability mode:

1. For members whose section centroid coincides with shear center:
   a. When calculating the bending buckling, the slenderness ratio is calculated as follows:

$$\lambda_x = \frac{l_{ox}}{i_x} \qquad (7.2.2\text{-}1)$$

$$\lambda_y = \frac{l_{oy}}{i_y} \qquad (7.2.2\text{-}1)$$

where

l_{ox} and l_{oy}	=	the effective lengths of members to the section principal axis X and Y respectively, in accordance with section 7.4 of this specification;

i_x and i_y	=	the radius of rotation of the member section to the principal axis X and Y respectively.

b. When calculating torsional buckling, the slenderness ratio shall be calculated according to the following formula. If the width thickness ratio of biaxially symmetric cross-section plate does not exceed $15\varepsilon_k$, torsional buckling may not be calculated.

$$\lambda_z = \sqrt{\frac{I_0}{I_t / 25.7 + I_\omega / l_\omega^2}} \quad (7.2.2\text{-}3)$$

where

I_0, I_t, and I_ω	=	polar moment of inertia (MM4), free torsion constant (MM4) and sectorial moment of inertia (MM6) of the shear center of the member's gross section, respectively. For the cross section, $I_\omega = 0$ can be approximately taken;
l_ω	=	the effective length of torsional buckling, if both ends are hinged and the end section can be warped freely, the geometric length l is taken; if both ends are clamped and the warpage of end section is completely constrained, it is taken as $0.5l$.

2. Members with uniaxial symmetry section:

a. The slenderness ratio should be determined by formula (7.2.2-1) and formula (7.2.2-2) when calculating the bending buckling around the asymmetric principal axis. The slenderness ratio should be determined according to the following formula when calculating the bending torsional buckling around the symmetric principal axis:

$$\lambda_{yz} = \frac{1}{\sqrt{2}}\left[(\lambda_y^2 + \lambda_z^2) + \sqrt{(\lambda_y^2 + \lambda_z^2)^2 - 4\left(1 - \frac{y_s^2}{i_0^2}\right)\lambda_y^2\lambda_z^2}\right] \quad (7.2.2\text{-}4)$$

where

y_s	=	the distance from the centroid of the section to the shear center;
i_0	=	the polar radius of rotation of the cross-section of the shear center, for uniaxially symmetric section, $i_o^2 = i_x^2 + i_y^2$
λ_z	=	the equivalent slenderness ratio of torsional buckling is determined by formula (7.2.2-3).

b. When the effective length of the equal leg single angle steel axial compression member is equal, the bending torsion buckling can be omitted. The single angle strut of tower shall comply with the relevant provisions in section 7.6 of this specification.

c. The equivalent slenderness ratio λ_{yz} of T-section members with double angle steel combination around the axis of symmetry can be determined by the following simplified formula:

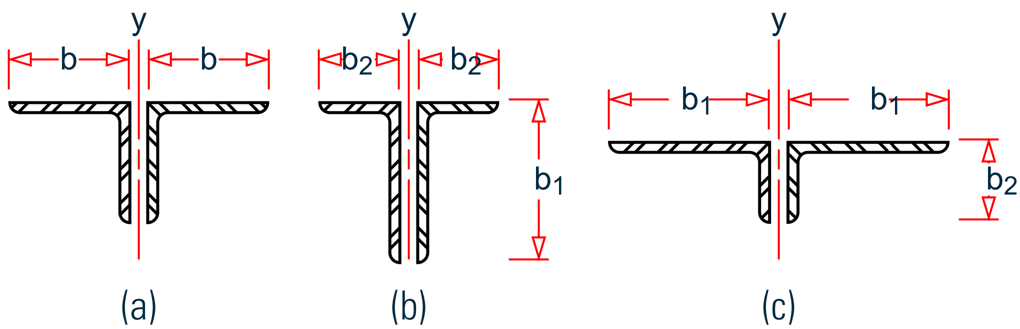


Figure 123: Double angle steel combined T-section (Figure 7.2.2.-1)

where

b	=	the leg width of equal angle;
b_1	=	the long leg width of unequal angle;
b_2	=	the short leg width of unequal angle;

Equal double angle steel [Fig. 7.2.2-1 (a)]

- When $\lambda_z \geq \lambda_y$

$$\lambda_{yz} = \lambda_y\left[1 + 0.16\left(\frac{\lambda_z}{\lambda_y}\right)^2\right] \quad (7.2.2\text{-}5)$$

- When $\lambda_z < \lambda_y$

$$\lambda_{yz} = \lambda_z\left[1 + 0.16\left(\frac{\lambda_y}{\lambda_z}\right)^2\right] \quad (7.2.2\text{-}6)$$

$$\lambda_z = 3.9\frac{b}{t} \quad (7.2.2\text{-}7)$$

Unequal double angle steel with parallel long legs [Fig. 7.2.2-1 (b)]:

- When $\lambda_z \geq \lambda_y$

$$\lambda_{yz} = \lambda_y\left[1 + 0.25\left(\frac{\lambda_z}{\lambda_y}\right)^2\right] \quad (7.2.2\text{-}8)$$

- When $\lambda_z < \lambda_y$

$$\lambda_{yz} = \lambda_z\left[1 + 0.25\left(\frac{\lambda_y}{\lambda_z}\right)^2\right] \quad (7.2.2\text{-}9)$$

$$\lambda_z = 5.1\frac{b_2}{t} \quad (7.2.2\text{-}10)$$

Unequal double angle steel with parallel short legs [Fig. 7.2.2-1 (c)]:

- When $\lambda_z \geq \lambda_y$

$$\lambda_{yz} = \lambda_y\left[1 + 0.06\left(\frac{\lambda_z}{\lambda_y}\right)^2\right] \quad (7.2.2\text{-}11)$$

- When $\lambda_z < \lambda_y$

$$\lambda_{yz} = \lambda_z\left[1 + 0.06\left(\frac{\lambda_y}{\lambda_z}\right)^2\right] \tag{7.2.2-12}$$

$$\lambda_z = 3.7\frac{b_1}{t} \tag{7.2.2-13}$$

d. The members without symmetrical axis and the shear center and centroid do not coincide are not considered in the current program, and are treated as (7.2.2-1) and (7.2.2-2)

e. The conversion slenderness ratio of axially compressed members with unequal angle steel can be determined according to the following simplified formula (Fig. 7.2.2-2)

- When $\lambda_z \geq \lambda_y$

$$\lambda_{xyz} = \lambda_v\left[1 + 0.06\left(\frac{\lambda_z}{\lambda_v}\right)^2\right] \tag{7.2.2-20}$$

- When $\lambda_z < \lambda_y$

$$\lambda_{xyz} = \lambda_v\left[1 + 0.06\left(\frac{\lambda_v}{\lambda_z}\right)^2\right] \tag{7.2.2-21}$$

$$\lambda_v = 4.21\frac{b_1}{t} \tag{7.2.2-22}$$

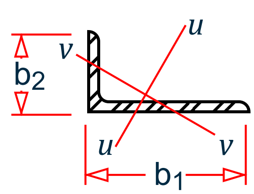

Figure 124: Unequal angle steel (Figure 7.2.2-2)

Note: V axis is the weak axis of angle steel, b_1 is the long leg width of angle steel.

The allowable slenderness ratio is the allowable slenderness ratio of compression member and tension member. You should select the correct value according to the provisions in 7.4.6 and 7.4.7 of the specification. The default values of the program are: allowable slenderness ratio of 150 under compression and 300 under tension. The slenderness ratio of components mainly includes the following situations:

1. Non-seismic:

   a. The slenderness ratio of compression members should not exceed the allowable values given in Table 7.4.6

Table 43: Allowable values of slenderness ratio for compression members (Table 7.4.6)

Nomenclature of members	Allowable values
Columns, members of trusses and monitors.	150
Lacing of columns, column bracings beneath crane girders or crane trusses	150
Bracings	200

Nomenclature of members	Allowable values
Members used to reduce the slenderness ratio of compression members	200

Notes:

i. A slenderness ratio of 200 may be allowed for compression web members in trusses (including space trusses) when they are stressed to or under 50% of their capacities.
ii. For single angle compression members, the least radius of gyration shall be used for calculation of slenderness ratio, but the radius of gyration about the axis parallel to the leg may be used for calculation of the out-of-plane slenderness ratio in the case of cross diagonals interconnected at the crossing point.
iii. For trusses with span length equal to or larger than 60m, the allowable slenderness ratio should be taken as 100 for compression chords and end posts, and 150 (when subjected to static or indirect dynamic load), or 120 (when subjected to direct dynamic load) for other web members in compression.
iv. In case member section is governed by allowable slenderness ratio, the effect of twisting may be neglected in calculating the slenderness ratio.

b. The slenderness ratio of tension members should not exceed the allowable values given in table 7.4.7.

Table 44: Allowable values of slenderness ratio for tension members (Table 7.4.7)

Nomenclature of members	Structures subject to static or indirect dynamic loading			Structures subject to direct dynamic loading
	Common buildings	chord that provides out of plane support for web	Mill buildings with heavy duty crane	
Members of Trusses	350	250	250	250
Column bracings beneath crane girders or crane trusses	300	-	200	-
Other tension members, bracings and ties (except pretensioned round bars)	400	-	350	-

Notes:

i. For structures subject to static loading, slenderness ratio of tension members may be checked only in vertical planes.
ii. For structures subject to direct or indirect dynamic loading, the slenderness ratio of a single angle tension member is calculated similarly to Note 2 of Table 7.4.6.
iii. The slenderness ratio of bottom chord of crane trusses for medium and heavy duty cranes should not exceed 200.

- **iv.** In mill buildings equipped with soaking pit cranes and stripper cranes or rigid claw cranes, the slenderness ratio of the bracings (except Item No.2 in the Table) should not exceed 300.
- **v.** When tension members change into compression ones under the combined action of dead and wind loads, their slenderness ratio should not exceed 250.
- **vi.** For trusses with span length equal to or larger than 60m, the slenderness ratio of tension chords and tension web members should not exceed 300 (when subjected to static or indirect dynamic loading) or 250 (when subjected to direct dynamic loading).

2. Seismic code clause 8.3, 8.4:

Section 8.3.1 states that the slenderness ratio of frame columns shall not be greater than $60\sqrt{235 / f_{ay}}$ for first grade seismic, shall not be greater than $80\sqrt{235 / f_{ay}}$ for second grade seismic, shall not be greater than $100\sqrt{235 / f_{ay}}$ for third grade seismic, and shall not be greater than $120\sqrt{235 / f_{ay}}$ for fourth grade seismic.

Section 8.4.1 The slenderness ratio and the width-to-thickness ratio of the epicenter diagonal brace shall comply with following requirements:

The slenderness ratio of the epicenter diagonal brace which is designed as compress member shall not be greater than $120\sqrt{235 / f_{ay}}$, and the epicenter diagonal brace of the first, second and third seismic grade shall not be designed as tension member, and the slenderness ratio of the epicenter diagonal brace which is designed as tension member shall not be greater than 80 for fourth seismic grade.

3. Seismic code clause 9.2.13:

The slenderness ratio of the frame column of the single-story steel factory, which should not be greater than 150 when the axial compression ratio is less than 0.2, and it should not be greater than $120\sqrt{235 / f_{ay}}$ when the axial compression ratio is not less than 0.2.

The limit of slenderness ratio of the supporting members between columns should meet the requirements of the steel code GB 50017-2017.

4. Seismic code clause H.2.8, for multistory factory structures

H.2.8 the basic anti-seismic structural measures of multi-story steel structure workshop should also meet the following requirements:

- **I.** The slenderness ratio of frame column should not be greater than 150; when the axial compression ratio is greater than 0.2, it should not be greater than $125(1 - 0.8N / A_f)\sqrt{235 / f_{ay}}$.
- **II.** The width thickness ratio of the frame columns and beams of the workshop shall meet the following requirements:
  - **i.** The single-layer part and the multi-layer part with height greater than 40m can be implemented according to Section 9.2 of this specification;
  - **ii.** When the total height of the multi-layer part is greater than 40m, the provisions in section 8.3 of this specification can be followed.
- **III.** In the maximum stress area of frame beam and column, the flange section shall not be changed suddenly, and the upper and lower flange shall be provided with lateral support. The relationship between the support point and the adjacent support point shall meet the relevant requirements of plastic design in steel structure code GB 50017-2017.
- **IV.** The supporting members between columns should meet the following requirements:
  - **i.** The column bracing of multi-storey frame should form X-shape or other anti-seismic forms with frame beam, and its slenderness ratio should not be greater than 150;

ii. The width thickness ratio of the supporting member shall meet the requirements of Section 9.2 of this specification.

When the program is selected to automatically calculate the slenderness ratio limit, the program will calculate according to the rules in the dialog box. You can select all of them to meet the requirements, or you can specify the filtering calculation rules.

Construction Requirements

The structural requirement parameters specified here refer to the limits of flange width thickness ratio and web height thickness ratio, as well as the section type of axial compression members. Generally, this parameter is automatically calculated by the program. However, in order to make it easier for users to design the program more flexibly, you can also set the parameters required here.

Flange Width Thickness Ratio / Web Height Thickness Ratio

The local stability inspection of components must meet the requirements of table 3.1.5 and 7.3.1 of steel code (GB 50017-2017).

When considering earthquake resistance, it should also meet the seismic code.

For the framed structures, the width-to-thickness ratio of the elements of beam and column shall conform to the requirements in Table 8.3.2.

Table 45: Width-to-thickness ratio limit of the elements of beam and column (Table 8.3.2)

Element Name		Grade 1	Grade 2	Grade 3	Grade 4
column	Flange overhanging part of I-section	10	11	12	13
	Web of I-section	43	45	48	52
	Plates of box-section	33	36	38	40
Beam	Flange overhanging part of I-section or box- section	9	9	10	11
	Flanges between both webs of box-section	30	30	32	36
	Webs of I-section or box-section	72-120Nb /(Af) £60	72-100Nb /(Af) £65	80-110Nb /(Af) £70	85-120Nb /(Af) £75

Note:

i. the values listed in the table is applicable to Q235 steel, other steel types shall multiply by $\sqrt{235 / f_{ay}}$.

ii. $N_b / (Af)$ is the axial compression ratio of the beam.

In the program, it is necessary to specify the seismic design or seismic grade to consider the restrictive provisions of the seismic code. For the members using seismic design (specified in the **Chinese Steel Design** dialog), their strength and stability should be reduced according to the code, and specified in the **Reduction Factor of Bearing Capacity**.

Note: When the circular pipe is a beam, the diameter thickness ratio is not specified, and the value shall be taken according to the column in table 3.5.1.

When the seismic option is selected, the program will check the provisions in the Table 8.3.2 and 8.4.1 of the seismic code.

When checking the seismic height thickness ratio of beam webs, when the tested load combination does not include seismic conditions, the seismic height thickness ratio limits of beam webs shall meet the requirements of grade I ≤ 60, grade II ≤ 65, grade III ≤ 70 and grade IV ≤ 75 respectively.

Section Coefficient

The net section coefficient refers to the ratio of net section to gross section area and section modulus (temporarily replaced by net section modulus coefficients an, WNZ and wny). The default value is 1.0.

The reduction coefficient of seismic bearing capacity of bracing is to reduce the bearing capacity of members in the presence of seismic load. The effective section coefficient of axially loaded members refers to (considering article 7.1.3 of code GB 50017-2017) that for axial tension and axial compression members, the area of dangerous section is multiplied by the effective section coefficient h in case of indirect force transmission.

D. Chinese Steel Design Parameter File Format

The parameters for steel design per GB 50017-2017 are stored in a separate file (file extension `.gsp`).

Example GSP File

Click the **Edit Parameters (Text)** button in the **Chinese Steel Design Parameters - Whole Structure** dialog to open and edit this file.

Note: No data validation of any kind is performed in the plain text editor. Therefore, the accuracy and validity of these changes is dependent upon the user to verify.

Code Checking and Member Selection

Code Checking

The purpose of code checking is to check whether the provided section properties of the members are adequate to carry the forces transmitted to it by the loads on the structure. The adequacy is checked per the GB 50017-2017 requirements.

Code checking is done using forces and moments at specified sections of the members. General they are calculated at every twelfth point along the beam. The code checking output labels the members as PASSED or FAILED. In addition, the critical condition, governing load case, location (distance from start joint) and magnitudes of the governing forces and moments are also printed.

Member Selection

The member selection process basically involves determination of the least weight member that PASS the code checking procedure based on the forces and moments of the most recent analysis. The section selected will be of the same type as that specified initially. For example, a member specified initially as a channel will have a channel selected for it. Selection of members whose properties are originally provided from a user table will be limited to sections in the user table.

Note: Member selection can not be performed on TUBES, PIPES, or members listed as PRISMATIC.

Use of Design Parameters

Users can modify the design parameters and control the whole design process by checking the specified parameters before. These parameters are used by design engineers to communicate their design decisions to computer programs. The default values of all these parameters are selected as the common values which are more inclined to the security design. For a specific design requirement, some or all of the parameters need to be changed to meet the actual design requirements. Therefore, specifying design parameters is often an indispensable step.

Assumptions

There are some default assumptions in the program when performing specification checking.

1. Biaxial symmetry and uniaxial symmetry are specified in the code. When different terms are adopted, the proportion of area difference between upper and lower flanges shall be taken as the judgment basis for H-section program judgment (mainly for H-section with unequal upper and lower flange and H-section with adhesive plate). When the area difference is less than 30%, the cross section is considered to be biaxially symmetric.
2. When calculating the post buckling strength of H-section with plate, the program considers that the laminate on the compression side is invalid, and the effect of the veneer is not considered when calculating the effective section.

Tabulated Results of Steel Design

For code checking or member selection, the program produces the results in a tabulated fashion. The items in the output table are explained as follows:

Member No.	refers to the member number for which the design is performed
Solution	Lists the solution set associated with this design.
Check	refers to steel design limit state, which has been checked against the steel code or has been selected.
Actual Value	prints the actual stresses for the critical condition, which is calculated by the analysis results and design parameters.
Failure Ratio Above	prints the allowable stresses for the critical condition. Normally which is related to the steel grade.
Normalized Ratio	prints the ratio of the actual stresses to allowable stresses for the critical condition. Normally a value of 1.0 or less will mean the member has passed.
Load case	provides the load case number, which governed the design.

D. Steel Connection Design

D. Connection Design workflow

D. Getting Started

The following concepts will help you understand how to use Connection Design in STAAD.Pro for the design of steel connections in your engineering practice.

D. Overview

Purpose

The Connection Design mode in STAAD.Pro is used to dynamically link structural model data —including section properties and analysis results— to the Connection Design application in order to check connection designs for code compliance. The resulting data and diagrams of the connection can also be included in the User Report.

Note: Not all options described here will be available for versions of Connection Design prior to release 7.0.

Note: Full use of the Connection Design mode in STAAD.Pro requires a valid RAM Connection license. The RAM Connection mode will run with a limited set of steel connections available with only a standard STAAD.Pro license. Please contact your Bentley account manager to have a Connection Design license added to your SELECT licenses.

Description

Connections are designed in the Connection Design Mode by creating “Joints” from the geometry and section properties. Forces resulting from the analysis are used in this mode by assigning a load envelope. A set of connection templates is then assigned to the joint. A suitable connection design, if one is available, will be reported once you have selected the appropriate connection templates.

Any number of joints may be selected and designed. Further, connection design is performed automatically for you once appropriate templates have been selected for the selected joints. These enhancements greatly reduce the time required for connection design in models of all sizes.

Tip: The selected load envelope is now used for all connection designs, instead of per design brief as in previous versions of STAAD.Pro.

Refer to the following procedures and interface elements used in designing steel connections with RAM Connection within STAAD.Pro. For specific information regarding RAM Connection templates, refer to the documentation with RAM Connection.

D. Full vs. Free Connection Sets

Basic connection templates are available to users with a valid STAAD.Pro license. The following connections templates are available when using a standard STAAD.Pro license.

- Basic DA BCF Bolted
- Basic DA BCF Welded
- Basic EP BCF Bolted
- Basic EP BCF Welded
- Basic DA BCW Welded
- Basic EP BCW Welded
- Basic SP BCF
- Basic SP BCW

Note: In order to use all connection templates (including Smart and Gusset connections), a valid RAM Connection license is required.

For a detailed explanation of connections available, refer to AD.2007-1001.5.1 in the What's New section.

D.Steel Connection Design Codes and Connection Types

The following tables indicate the allowable member types per connection for supported steel design codes in RAM Connection.

Steel design codes in RAM Connection:

Table 46: AISC 360 (on page 1017)
Table 47: BS5950 (on page 1020)
Table 48: GB 50017-03 (on page 1022)
Table 49: EN 1993-2005 (on page 1023)
Table 50: IS 800-2007 (on page 1025)
Table 51: AS 4100-1998 (on page 1027)
Table 52: NZS 3404-1997 (on page 1029)
Table 53: CSA S16-14 (on page 1030)

RAM Connection Section Type	STAAD.Pro Section Type	Notes
I	Wide Flange[a]	
T	Wide Flange (cut into tee; T type specification)	Tee sections
HSS_Rect	Tube	Rectangular hollow sections
HSS_Circ	Pipe	Circular hollow sections
C	Channel	
I2C	Channel (double back-to-back; D type specification)[b]	
L	Angle	Single angles
T2L	Angle (back-to-back; LD or SD type specification)[b]	Double angles

a. Wide flange sections that have been assigned a cover plate (top, bottom or both, with the options: TC, BC, or TB), as a composite beam with the CM option, or a double profile with the D option will be designed using the base profile only.

b. Channel sections and angle sections are only designed with the options defined above. Channels front-to-front (type specification FR) and double angle star arrangement (heel-to-heel; type specification SA) are not designed.

Refer to TR.20.1 Assigning Properties from Steel Tables (on page 2257) for details on STAAD.Pro steel section options.

D. Using the RAM Connection mode

This section provides you with some common procedures used in design steel connections in the Connection Design mode.

D. To assign member type attributes

To assign the member type to consider for steel connection design in the Connection Design workflow, use the following procedure.

The member type attribute is *only* used for steel connection design in RAM Connection. It has no effect for members of other materials or other workflows.

Note: To assign a member as a truss type for analysis, you must M. To assign axial action members (on page 803). This process only affects the member type used for connection design.

1. Select one or members that will share the same attribute.

2. Either:

   on the **Beam Tools** ribbon tab, select the **Add Attribute** tool from the **Plugins** group

   or

   right-click and then select **Add Member Attribute** from the pop-up menu
   The **Member Attribute** dialog opens.
3. Select **MEMBTYPE** from the **Attribute Name** drop-down list.
4. Select the most appropriate member type from the **Attribute Value** drop-down list.
   - column
   - primary beam
   - brace
   - rafter
   - girt
   - purlin
   - eave-strut
   - secondary-beam
   - tertiary-beam
   - chord
   - branch
5. Click **Apply**.

Related Links
- *TR.29.3 Member Type Attribute* (on page 2343)
- *Member Attribute dialog* (on page 3057)

D. To edit the RAM Connection settings

1. Click the **RAM Settings** tool 
   The **RAM Connection Settings** dialog opens.
2. Select the default **Design Code** from the drop down list.
3. (Optional) For AISC codes, select the **Consider AISC 341-05 and AISC 358-05 Seismic Provision** option to include these seismic checks in design of connections by default for AISC codes.
4. (Optional) Select the **Design multiple selected connections individually** option to disable grouping of connections into same templates.
5. Check the country names to include various section catalogs in the **Sections Add to RAM** list.
6. Click **OK** to save the changes.

- *D. RAM Connection Settings dialog* (on page 1043)

D. To design steel connections

Before performing a connection design, you should select the appropriate design code and options in the **RAM Connection Settings** dialog.

1. Run an analysis.

   Tip: The Connection Design workflow is only available after the completion of a successful analysis.
2. Select **Connection Design** in the Workflows panel.

   

   The **RAM Connection Validation** dialog opens.
3. Click **Close**.
   The **RAM Connection Input** dialog opens.
4. Select the **Add Load Envelope** tool 
   The D. Load Envelope dialog (on page 1042) opens.
5. Select the loads you wish to use for design and then click **OK**.

   This can be an existing load envelope or a selection of loads and load combinations.
6. Select the joint(s) you wish to add connections to.

   Note: Use the selection tools on the **Connection Design** ribbon tab in the **Assign Connections** group to assist selecting the intended joints.

   Selected joints are highlighted with red dots.
7. In the **Connection Design** ribbon tab in the **Assign Connections** group, select the appropriate tool corresponding to the connection assignment you want to make:

   D. To select a basic connection template (on page 1033) 
   or

   D. To Select a Smart Connection Template (on page 1034) 
   or

   D. To Select a Gusset Connection Template (on page 1034)    In the corresponding Connection dialog, you can select which design code and the connection template you wish to use for the selected joint's design brief.
8. Click **OK** to assign the templates and design the connections.

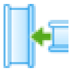
   The Connection Design dialog will display a list of all connection assignments.
9. Click **Close** to dismiss the dialog.
   A list of connections and basic information is displayed in the D. RAM Connection Input table (on page 1040).

D. To select a basic connection template

An appropriate set of joints must be selected in order to assign basic connections.

1. Either:

on the **Connection Design** ribbon tab, select the **Basic Connection** tool in the **Assign Connection** group



or

in the **RAM Connection Input** dialog, select the **Basic Connections** tool 
The **Basic Connection** dialog opens.

2. You may specify design code or grouping overrides here.
3. Select a connection class from the drop-down list.
   All available connections are displayed in the **Available** list box below.
4. Select one or more connections and add them to the **Selected** list box by clicking the **[>]** (add) button.

> **Tip:** You may add all connections in the list by clicking the **[>>]** (add all) button.

5. Click **OK** to accept and design the selected joints using these connections.

Related Links

- *Basic Connections dialog* (on page 3032)

D. To Select a Smart Connection Template

An appropriate set of joints must be selected in order to assign smart connections.

1. Either:

   Click the **Smart Connections** tool 
   or

   Select **Connection Design** > **Assign Smart Connection**

   The Smart Connections (on page 3035) opens.
2. You may specify design code or grouping overrides here.
3. (Optional) For AISC codes, select the option for **Consider AISC 341-05 Seismic Provisions**
   Select a load cases from the drop-down list which represents the gravity load.
4. (Optional) For BS5950 code, select the option to **Consider Structural Integrity** if necessary.
5. (Optional) For Base Plates, select a **Seismic Category** site class from the drop down list.
6. Select a connection class from the drop-down list.

   All available connections are displayed in the **Available** list box below.
7. Select the connection you wish to use and add it to the Selected list box by clicking the Add (**>**) button.
8. Click **OK** to accept and design the selected joints using these connections.

Related Links

- *Smart Connections* (on page 3035)

D. To Select a Gusset Connection Template

An appropriate set of joints must be selected in order to assign gusset connections.

1. Either:

Click the **Gusset Connections** tool 
or

Select **Connection Design** > **Assign Gusset Connection**

The Gusset Connections dialog (on page 3037) opens.

2. You may specify design code or grouping overrides here.
3. Select a connection class from the drop-down list.
   All available connections are displayed in the **Available** list box below.
4. Select the connection you wish to use and add it to the Selected list box by clicking the Add (>) button.
5. Click **OK** to accept and design the selected joints using these connections.

- *Gusset Connections dialog* (on page 3037)

D. To design an HBBB connection
To design a horizontal brace-beam-beam gusset connection, use the following procedure.

HBBB connections apply to joints with the following conditions:

- no column at the joint
- two perpendicular beams with H section and one brace with an angle section
- beams should be parallel with the ground (X-Z plane when Y is up)
- the brace should be in the same plane with the beams, with the angle between the brace and either beam between 30° and 60°

1. Start the **Connection Design** workflow and select the applicable load envelope.
2. Select a joint that matches the joint requirements.
3. On the **Connection Design** ribbon tab, select the **Gusset Connection** tool in the **Assign Connections** group.

   
   The **Gusset Connection** dialog opens.
4. Select an AISC design code from the **Design Code** drop-down list.
5. Select **Gusset Plate HBBB** from the connection template drop-down list.
6. Double-click the **HBBB_CA** template to add it to the selected list.
7. Click **OK**.
8. Double-click the connection list view to review the connection design.
   The connection pad opens.
9. (Optional) If the girder and beam have been incorrectly specified, they can be changed:
   a. On the **Connection Design** ribbon tab, select the **Beam and Girder Identification** tool in the **Frames** group.
      The **Beam-Girder Identification** dialog opens.
   b. Check the Swap option for the beam-girder connection you want to switch.
   c. Click **Switch**.
   d. Click **OK**.
   e. Repeat step 8 to open the connection design again.

D. To design an HCBB connection
To design a horizontal brace-column-beam gusset connection, use the following procedure.

HCBB connections apply to joints with the following conditions:

- at least one column with an H section at the joint
- column is vertical (perpendicular to beams)
- two perpendicular beams with H section and one brace with an angle section
- beams should be parallel with the ground (X-Z plane when Y is up)
- the brace should be in the same plane with the beams, with the angle between the brace and either beam between 30° and 60°

1. Start the **Connection Design** workflow and select the applicable load envelope.
2. Select a joint that matches the joint requirements.
3. On the **Connection Design** ribbon tab, select the **Gusset Connection** tool in the **Assign Connections** group.

   

   The **Gusset Connection** dialog opens.
4. Select an AISC design code from the **Design Code** drop-down list.
5. Select **Gusset Plate HCBB** from the connection template drop-down list.
6. Double-click the **HCBB_CA** template to add it to the selected list.
7. Click **OK**.
8. Double-click the connection list view to review the connection design.
   The connection pad opens.
9. (Optional) If the girder and beam have been incorrectly specified, they can be changed:
   a. On the **Connection Design** ribbon tab, select the **Beam and Girder Identification** tool in the **Frames** group.
      The **Beam-Girder Identification** dialog opens.
   b. Check the Swap option for the beam-girder connection you want to switch.
   c. Click **Switch**.
   d. Click **OK**.
   e. Repeat step 8 to open the connection design again.

D. To edit steel connections

1. Either:

   On the **Connection Design** ribbon tab, select the **Joint Cursor** tool in the **Assign Connections** group and then double-click on any connection in the View window.

   

   .

   or

   Select the entry for the connection row in the **RAM Connection Input** table and then click **Edit**

   The **Connection Pad** opens displaying the design information for this joint.

2. Make the desired changes to the connection input data.
3. Select the **Save** tool to save any changes .
   Changes made to the connection pad are saved back to the connection design in STAAD.Pro.
4. Click the **[X]** to close the Connection Pad window.

D. Selecting Joints & Connections

The Select Nodes tool is used to select nodes in the View window for assigning connection templates.

The **Select Joints** tool  (found in the Selection toolbar or from the **Select** menu) is used to select connections in the View window. Typical STAAD.Pro graphical selection rules apply.

The Select menu contains tools to select different connections and joints based on logical criteria:

- The **Select** > **Select Joints** sub-menu contains tools which logically select joints based on the connecting members.
- The **Select** > **Select Connections** sub-menu contains tools which aide in selecting joints for grouping.

D. Design Connections Individually

Any time multiple connections fitting the same template are selected and a template is applied, these will be grouped to the template meeting the minimum requirement of the entire group.

If you wish to design each connection to an optimized (and likely different) template, then select the **Design Connections Individually** option in the Connection assignment dialog before clicking **OK.**

This option can be selected in the D. RAM Connection Settings dialog (on page 1043) to disable the grouping feature.

Related Links

- *Basic Connections dialog* (on page 3032)

D. To delete steel connections

1. Select the connection(s) you wish to remove in the **RAM Connection Input** table.
2. Either:

   press **<Delete>**

   or

   click **Delete**
3. Click **Yes** to confirm the deletion.

Tip: You may need to Refresh the display (press **<F5>**) to see the connection icon removed in the View window.

D. To Export Connection Designs to a Report

To export the connection design results to a Microsoft® Office Word® document report, use the following procedure.

You must perform connection design on one or more connections to generate a report.

1. Either:

   On the **RAM Connection Input** Table, select the **Export Connection Reports** tool 
   or

   Select **Connection Design** > **Export Connections report**.

   The **RAM Report Export** dialog opens.
2. Select the connections you want to include in the report.

   > **Tip:** Click **Select All** to quickly include all connection design into the report.
3. (Optional) Select or clear options to include **Data Report Result Report forumla**
4. Select to output multiple connections to either **Individual Reports** (separate file for each connection) or a **Merged Report** (single file containing all selected connections).
5. Click **OK**.
   The report is generated and saved in the same folder as the STAAD.Pro input file.

Related Links

- *RAM Report Export dialog* (on page 3041)

D. To add connection designs to your report

To add a summary of steel connection design results to your STAAD.Pro report, use the following procedure.

1. Select the **Postprocessing** workflow.
2. Either:

   select the **Reports** page

   or

   select the**File** ribbon tab and then select **Report** > **Setup** in the backstage view

   The **Report Setup** dialog opens.
3. Select the **Items** tab.
4. In the **Available** topics drop-down list, select **RAM Connection Summary Report**.
5. Double-click the **RCNX Report** entry to add it to the **Selected** list.
   The connection design summary is now included in the report.
6. Either:

   click **Print** to generate a copy of the report

   or

   click **OK** to dismiss the dialog and review the report on screen.

D. Custom Connection Templates

You can create and use your own connection templates.
D. To create a custom template file

Custom template files are created in the **Connection Design** workflow.

1. On the **Connection Design** ribbon tab, select the **Connection Database** tool in the **Configure** group.

The connection database dialog opens.

2. Click **New group**.
3. Type a New group name then click the X to close the dialog.
   The new group is created and selected as the current group.
4. Click **New table**.
   The new table dialog opens.
5. Specify the table parameters:
   a. Select the **Design code** to use for these connections.
   b. Select the **Connector type** from the drop-down list.
   c. Select the **Joint type** for the connections.
   d. Select the **Connector name** for the connection.
   e. The context-sensitive help panel provides additional information on the connector name selection.
   f. Click **OK**.

   The new table is saved to the custom group.
6. (Optional) Repeat Steps 4 and 5 to create additional tables as needed.

D. To add a connection template to a table
To add a custom connection template to a database table, use the following procedure.

> **Tip:** One of the simplest methods to get started is to copy factory installed templates to your new group and edit those to suite your needs.

1. On the **Connection Design** ribbon tab, select the **Connection Database** tool in the **Configure** group.
   The connection database dialog opens.
2. Select **Custom** in the **Groups** drop-down list.
3. Click **New Item**.
   The **Connection Pad** window opens.
4. Specify the connection parameters:
   a. Type the connection **Name**.
   b. Update the connection parameters for this connection type.
   c. Click **Save**.
   d. Close the window.

   The new connection name is added to the items list. A list of the connection tables where you can add this connection type are also listed.
5. Click **>>** to add the new connection to the connection database file.

The new connection type is available for use in design in this connection database.

> **Note:** When the connection database is selected in the connection database dialog, you can click **Reset** to remove any custom items and restore the database to the default values.

D. Pages in the Connection Design workflow

The page control bar in Connection Design workflow contains the following pages:

D. Connections page

Used to select, assign, design, and edit steel connections. The Connection page is where connections are defined and designed.

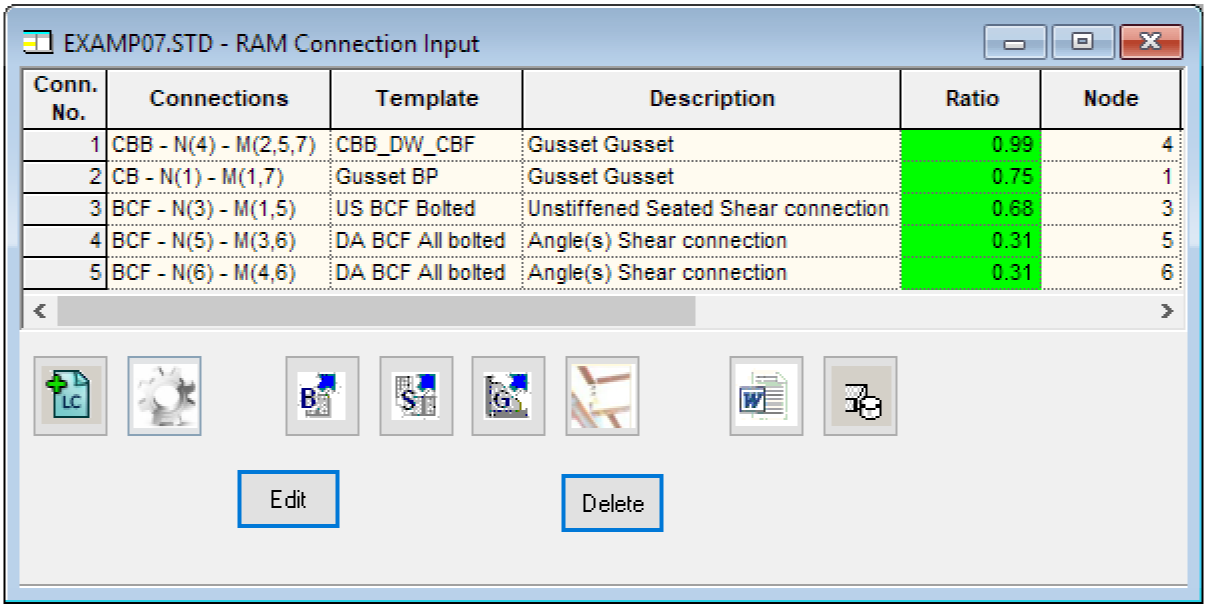
When the **Connections** page is selected, the **RAM Connection Input** table opens.

The **Whole Structure** view window displays the structure (or a portion thereof), which is used to graphically select joints for connection assignment and connections for editing.

> **Tip:** When a table row(s) is selected in the **RAM Connection Input** table, the corresponding Joint(s) will be highlighted in the view window.

D. **RAM Connection Input** table
Contains tools to generate new connection designs and contains all previously designed connections.

Opens when the D. Connections page (on page 1040) is selected.



Tools

Icon	Description	Same Effect as Selecting
 **Load Envelope**	Opens the D. Load Envelope dialog (on page 1042), which is used to select load cases and combinations to include in the load envelope for steel connection design.	**Connection Design > Load Envelope For Connection**
 **RAM Connection Settings**	Opens the D. RAM Connection Settings dialog (on page 1043), which is used to set the default design code and grouping toggle.	**Connection Design > Assign RAM Connection Settings**
 **Assign Basic Connections**	Opens the Basic Connections dialog (on page 3032), which is used to assign basic connection templates to selected joints.	**Connection Design > Assign Basic Connections**
 **Assign Smart Connections**	Opens the Smart Connections (on page 3035), which is used to assign smart connection templates to selected joints.	**Connection Design > Assign Smart Connections**
 **Assign Gusset Connections**	Opens the Gusset Connections dialog (on page 3037), which is used to assign gusset connection templates to selected joints.	**Connection Design > Assign Gusset Connections**

Icon	Description	Same Effect as Selecting
 **Show RAM Database**	Opens the RAM Connection Material Database dialog (on page 3042), which is used to review additional material data required by RAM Connection for the design of steel connections.	**Connection Design** > **Assign RAM Materials**
 **Identify Beam-Girder**	Opens the Beam-Girder Identification dialog (on page 3040), which is used to switch beam and girder assignments in a Beam-Girder connection.	**Connection Design** > **Identify Beam and Girder**
 **Export Connection Reports**	Opens RAM Report Export dialog (on page 3041), which is used to manage connections and other report details to include in an report.	**Connection Design** > **Export Connections report**

Table

Once a Connection is established the following information will be displayed in the Input grid:

- Connection Name
- Template used for the Connection
- Description of the Connector
- Node (where the Joint is created)
- Members which participated in the connection

D. **Load Envelope** dialog
Used to specify the loads which will be included in the Load Envelope used for steel connection design.

Opens when the **Add Load Envelope** tool is selected in the **Connection Design** workflow.

Loads Select the source of connection design load envelopes:

- **Defined Envelopes -** Select this option to use a load envelope which has been previously defined for this model. A list of all defined envelopes is then available in the drop-down list.
- **Envelope of Load Cases in Selected List -** The option will be inactive if no load envelopes have been defined.

Loads Use the controls to populate the selected load list for a new load envelope.

Click this button...	to...
>	Add the selected load case to the Selected list
>>	Add all load cases to the Selected list.
<<	Remove all entries in the Selected list, load combination is placed back in the Available list.
<	Remove the selected entry from the Selected list.

The **Selected** list displays load cases that have been selected.

OK Click this button to accept changes made to the Load Envelope.

Cancel Click this button to close the dialog with no changes saved.

Apply Click to apply the changes without closing the dialog.

Help This button opens the online documentation.

D. **RAM Connection Settings** dialog
Used to set the default design code and grouping toggle.

Opens when the **RAM Settings** tool  is selected in the RAM Connection input dialog.

Design Code Specify the default design code to be used from the drop-down list. The following codes are currently available in Connection Design in STAAD.Pro:

AISC 360-10 (ASD) — Allowable Stress Design per AISC 360-10
AISC 360-10 (LRFD) — Load Resistance Factor Design per AISC 360-10
AISC 360-05 (ASD) — Allowable Stress Design per AISC 360-05
AISC 360-05 (LRFD) — Load Resistance Factor Design per AISC 360-05
AS 4100 1998
BS 5950-01:2000
CSA S16-14 — Limit States Design of Steel Structures (2014 editions)
EN 1993-1-7 — Eurocode 3
IS 800-2007
GB50017-2003 — "Design of Steel Structures" Chinese code
NZS 3404-1997

Consider AISC 341-05 and AISC 358-05 Seismic Provision (AISC codes only) Select this option to direct the program to consider seismic provisions per AISC 341-05 “Seismic Provisions for Structural Steel Buildings” and AISC 358-05 “Prequalified Connections for Special and Intermediate Steel Moment Frames for Seismic Applications ” in the design of connections of members in a designated seismic frame.

Design multiple selected Select this option to disable grouping of connections into same templates

connections individually	
Sections Add to RAM	Check the boxes associated with country section catalog to include in the RAM Connection catalog.

OK	Accepts the settings changes and closes the dialog.
Cancel	Closes the dialog without saving changes.
Help	Opens the Help window.

Related Links

- *D. To edit the RAM Connection settings* (on page 1032)
- *D. To edit the RAM Connection settings* (on page 1032)

D. Results page

Used to review steel connection designs. The **Results** page displays the summary, layout, and results of the connection designs.

View Window

When a row of a RAM Connection Result table is selected, the DXF drawing and the Report will be displayed in the View window.

RAM Connection Results table

Contains the following items for each connection (upon successful connection design):

- Joint Name
- Template
- Design Code
- Ratio (Critical Strength Ratio)
- Status — Possible values:

    OK (Critical Strength Value < 1),
    No Good (Critical Strength Value > 1), or
    Warning (This connection may require additional review)

D. Seismic Frames page

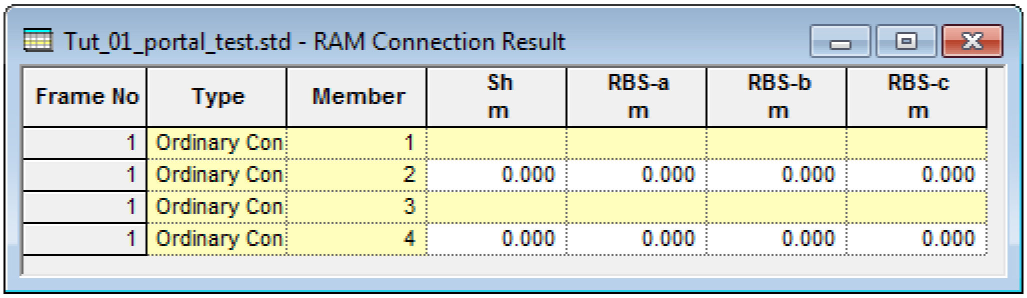
Used to assign and review seismic frames for connection design.

When the **Seismic Frame** page is selected in the **Connection** workflow, the **RAM Connection Result frames** table opens.

D. **RAM Connection Result** frames table
Used to review frame member assignments and specify reduced section (induced plastic hinge) parameters for beam members within a frame.

Note: A column member may be used in multiple frames but a beam member can only be used in a single frame definition.

Opens when the D. Seismic Frames page (on page 1044) is selected in the **Connection** workflow.



Frame No	Type	Member	Sh m	RBS-a m	RBS-b m	RBS-c m
1	Ordinary Con	1				
1	Ordinary Con	2	0.000	0.000	0.000	0.000
1	Ordinary Con	3				
1	Ordinary Con	4	0.000	0.000	0.000	0.000

The table rows are grouped first by **Frame No** and then by **Member** number. The **Type** of lateral seismic resisting is also displayed. These elements (shaded in yellow) may not be edited. The location and dimensions of reduced beam sections (RBS) for forming plastic hinges may be specified here for beam members.

Where:

Sh is the distance to the Hinge Location
RBS-a is the horizontal distance to locate the reduce beam section
RBS-b is the length of the reduced section of the flange of the beam
RBS-c is the depth of the reduced section of the flange

D. Application Window Layout

After entering the Connection Design Mode is entered, some of the menus change to offer some additional tools.

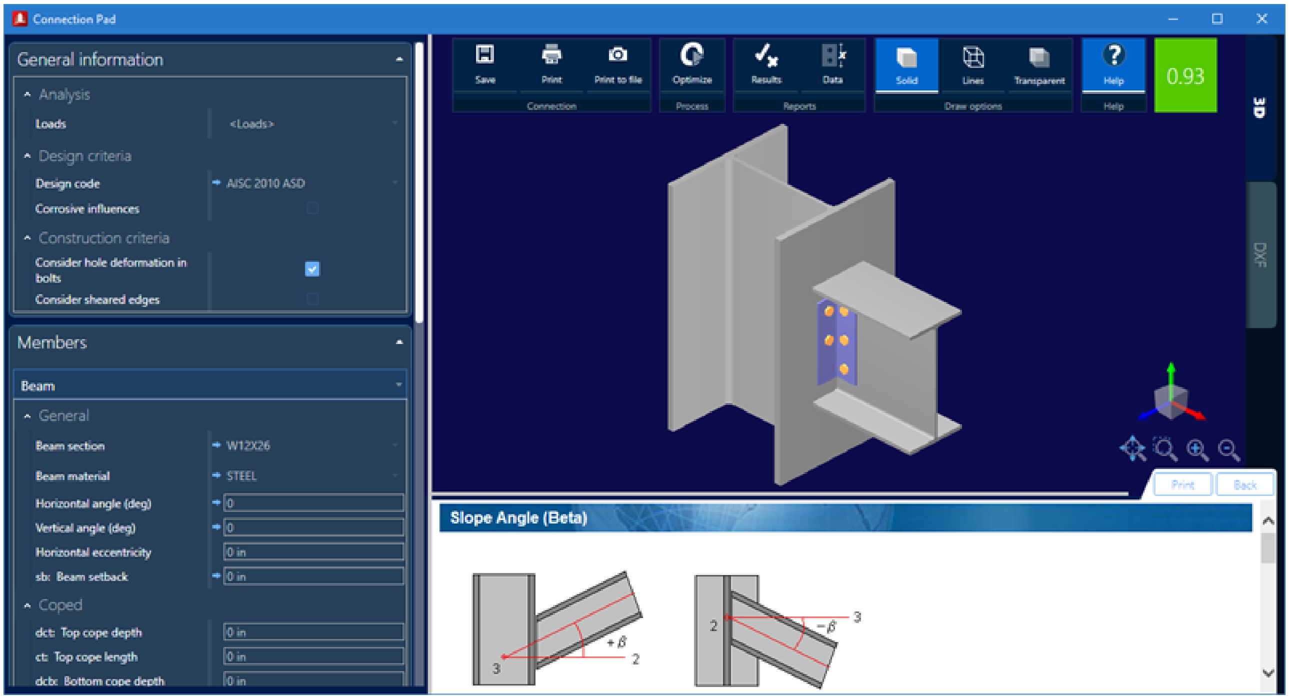
Note: For help with all other application window elements, please refer to the M. Creating Model Objects (on page 653) .

D. RAM Connection pad

Used to inspect connection details, edit a connections input, and access steel connection design results.

Opens when a connection icon is double clicked in the View window.

Note: The appearance and layout of the Connection pad varies depending on which version of **RAM Connection** is installed. The tools and operation remain essentially the same.

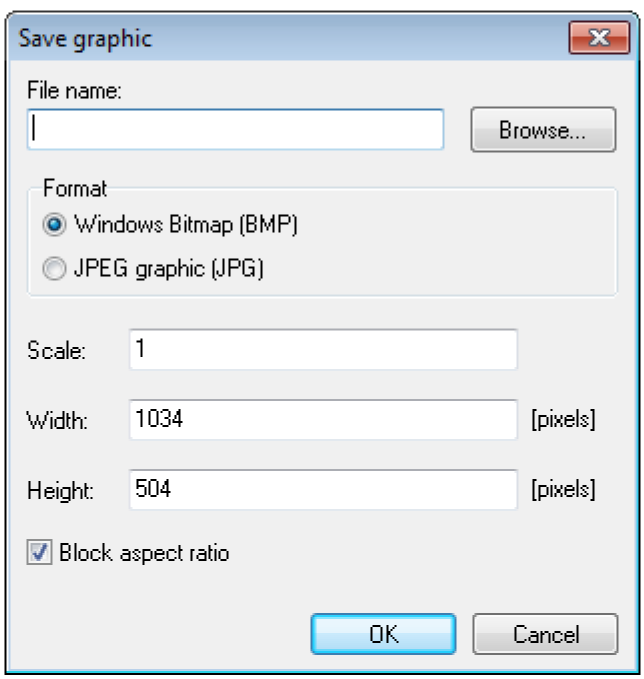


The connection pad is required for the creation of templates for the database and also to review/edit a model connection, or many model connections with the connections detailer. It is accessed when any template of the database is edited, when the user double clicks a model connection, or when several identical model connections are selected and the detailing command is invoked from the main menu.

D. **Save Graphic** dialog

Used to save a connection drawing to an external image file.

Opens when the **Print to File** tool is selected in the **Connection Pad Drawing** window.



File name Specify a name for the image file.

Browse Opens a Windows Save As dialog, which is used to specify a drive, directory, and file name for the image file.

Format Select one of the following common image file formats:

- Windows Bitmap (BMP) - An uncompressed image file format. These are very common and readable by most image editing tools. Many word processing or spreadsheet programs can import these image files for re-use. These files can be very large for even relatively short reports (approximately 20x the size of a JPEG).
- JPEG graphic (JPG) - A compressed image format commonly used for photographic images. These are also readable by a wide variety of programs, including web browsers, image editors, and office programs. JPEG is not recommended for line drawings or text due to the blurring that may result from its compression algorithm.

Scale Specify a scale factor to be used with the image file.

Width Specify a width (in pixels) for the image file.

Height Specify a height (in pixels) for the image file.

Block aspect ratio Selecting the is option will scale the height or width such that the aspect ratio of the original drawing is constant in the image file.

OK Create the image file with the selected options and close the Save Graphic dialog.

Cancel Close the dialog without saving an image file.

D. Connection Tags

Connection tags are used to associate connection data included in an XML file with members. This data can be exchanged with other programs via the ISM link. The connections can also be checked by defined capacities in the XML file.

Connection tags consist of two pieces of data:

i. A Connection Tags XML file, which contains the connection categories, tag names, and member end releases for the connection tag. Connection capacities are also specified for each combination of member and connecting member which may utilize a connection tag. Refer to D. Connection Tags XML File Schema (on page 1052) for additional information on the required structure of this XML file.

ii. Assignments of connection tags to members are stored in the STAAD input file. Though this is done within the `DEFINE MEMBER ATTRIBUTE` command, it is strongly recommended that the user interface features be used to make connection tag assignments as these must utilize only the connection categories and tag names in the associated XML file. Refer to TR.29.2 Connection Tag Member Attribute (on page 2341) for additional information on this command.

D. To create a connection tag

To create a new connection tag for use in the current STAAD model, use the following steps.

Note: You must have a Connection Tags XML file containing appropriate connection capacities with members used in the model. A default XML file is included with the program that contains a minimal amount of connection data.

A connection tag is added to the model to define the type of connection (e.g., shear or moment) and the associate attributes of that connection (e.g., end releases or capacities associated with the connection).

1. Select one or more members in the view window.
2. Either:

   on the **Beam Tools** ribbon tab, select the **Assign** tool in the **Connection Tags** group

   or

   right-click and select **Connection Tags** > **Assign Connection Tags** from the pop-up menu

   Note: If you have not specified a Connection Tags XML data file, then the Select Connection Tag File dialog opens prompting you to select an appropriate XML file.

   The **Assign Connection Tags** dialog and **New Connection Tag** dialog open.
3. If the **New Connection Tag** dialog did not already open, then click the **New** tool in the dialog toolbar 
4. On the **New Connection Tag** dialog, select the category to use from the **Select Categories** drop-down list.
5. Select the Tag to use from the selected category from the **Select Tags** drop-down list.
6. Either:

   set the option to **Assign Beam End Releases** to the use the end releases in the connection tag definition

   or

   clear the **Assign Beam End Release** option and manually select the end releases you want for this connection
7. Select either the **Start** or **End** Location option (or both).

   Note: Selecting both Start and End locations creates two distinct connections, which must both be assigned.
8. Either:

   click **Add** to add this connection to the connection tags list in the Assign Connection Tags dialog

   or

   click **Assign** to assign the connection tag to the current member selection

Related Links

- *Assign Connection Tags dialog* (on page 3053)
- *New Connection Tag dialog* (on page 3055)

D. To delete a connection tag

To remove a connection tag entirely from the STAAD model, use the following steps.

This procedure will remove the connection from the model. To remove the assignment of a connection tag from one or more members, see D. To remove connection tag assignments (on page 1049).

1. Select one or more members in the view window.
2. Either:

   on the **Beam Tools** ribbon tab, select the **View** tool in the **Connection Tags** group

   or

   on the **Utilities** ribbon tab, select the **Connection Tags** > **View Tags** tool in the **Tools** group

   or

   right-click and select **Connection Tags** > **View Connection Tags** from the pop-up menu.

   The **Assign Connection Tags** dialog opens.
3. Select the row in the Connection Tags table for the connection tag you want to remove.
4. Select the **Remove** tool in the dialog toolbar. 
   A confirmation dialog opens to confirm you want to delete the connection tag.
5. Click **OK**.
   A confirmation dialog opens in the STAAD.Pro user interface window to confirm you want remove the associated STAAD input command for the member attribute definition.
6. Click **Yes**.
   The row is removed from the Connection Tags table.

D. To remove connection tag assignments

To remove the connection tag assignments from members, use the following steps.

This procedure will disassociate a connection tag with a member end. If you want to complete remove a connection tag from the STAAD.Pro model, see D. To delete a connection tag (on page 1048).

1. Select one or more members in the view window.
2. Either:

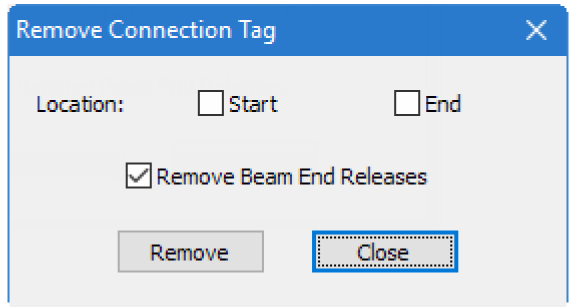
   on the **Beam Tools** ribbon tab, select the **Remove** tool in the **Connection Tags** group

   or

   right-click and select **Connection Tags** > **Remove Connection Tags** from the pop-up menu

   The **Assign Connection Tags** and the **Remove Connection Tag** dialogs open.



3. Select either the **Start** or **End** (or both) corresponding to the member end from which you want the connection tag removed.
4. (Optional) If you do not want the beam end releases for this beam end changed, then clear the option **Remove Beam End Releases**.

> **Tip:** By default, this option is set so the member end releases for this end are returned to their defaults (i.e., fully fixed).

5. Click **Remove**.
   A confirmation dialog opens.
6. Click **OK**.
   A confirmation dialog opens in the STAAD.Pro user interface window to confirm you want remove the associated STAAD input command for the member attribute definition.
7. Click **Yes**.

   The member number is removed from the Assigned Beams cell of the Connection Tags table.

> **Note:** If the tag selected was only assigned to a single member end, then the row is removed from the Connection Tags table.

Related Links

- *Remove Connection Tags dialog* (on page 3057)

D. To check connection tags

To check the assigned connection tags capacity using the STAAD.Pro analysis results, use the following steps.

Prior to checking connections, you must perform a successful analysis on the model so analysis results at member ends can be compared to connection capacities.

Additionally, each beam and connecting member (beam or column) must have a connection capacity for the sections used in the associated Connection Tags XML file to facilitate checking connections.

1. Select one or more members in the view window.
2. Either:

   on the **Beam Tools** ribbon tab, select the **Check** tool in the **Connection Tags** group

   or

on the Utilities ribbon tab, select the **Connection Tags** > **Check Tags** in the Tools group

or

right-click and select **Connection Tags** > **Check Connection Tags** from the pop-up menu

The **Assign Connection Tags** dialog and **Check Connection Tags** dialog open.

3. Select the load case types you want to use in the **Select Load Case Types** drop-down list.
   The load cases list displays only the type or types selected.
4. Either:

   select load cases individually by setting their check boxes on in the list

   or

   set the **Select All** option check box on.
5. Click **Check**.
   The **Connection Tag Check Results** table opens. This table displays the connection tag data from the Connection Tag XML file capacity used checked against the critical load case at each member end with a connection tag. The status of the check (i.e., Pass or Fail) is listed in the Remarks column.

D. Connection Tags Capacity Checks

The rules for checking the connections are dependent on the whether the connection is typed as moment or shear.

Moment Connections

Shear Capacity Check **-** The shear capacity for a given beam/column combination present in the `ConnectionTagFile.xml` is checked against the demand taken as the absolute value of the major axis shear value, Fy, from each of the load cases included and the maximum value reported.

If the shear capacity in the XML file is 207.345 kN, then:

- when Fy = ±208.0 kN > 207.345 kN, the connection check is failed.
- when Fy = ±200.0 kN < 207.345 kN, the connection check is passed.

Moment Capacity Check **-** The moment capacity check for a given beam/column combination is based on both the major axis moment and axial force. For each load case, the maximum demand is taken from the end moment plus the axial force multiplied by a specified alpha factor and compared against the given moment capacity.

If the moment capacity in the XML file is 35.951 kN·m and the tension force factor, alpha, is 0.09565, then demand = $|Mz| + a \cdot |Fx|$:

- when Mz = 30 kN·m and Fx = -50 kN, then demand is 30 + 0.09565(50) = 34.7825 kN·m < 35.951 kN·mm, the connection check is passed.
- when Mz = 32 kN·m and Fx = -50 kN, then demand is 32 + 0.09565(50) = 36.7825 kN·m > 35.951 kN·mm, the connection check is failed.

Shear Connections

The shear capacity for a given beam/column combination present in the `ConnectionTagFile.xml` is checked against the demand taken as the major axis shear value, Fy, and a proportion of the axial force, Fx, from each of the load cases included and the maximum value reported.

If the shear capacity in the XML file is 15.538 kN and the tension force factor, alpha, is 0.2016, then demand = $|Fy| + a \cdot |Fx|$:

- when Fy = 12 kN and Fx = -25 kN, then demand = 12 + 0.2016(25) = 17.04 kN > 15.538 kN, the connection is failed.
- when Fy = 10 kN and Fx = 25 kN, then demand = 10 + 0.2016(25) = 15.04 kN < 15.538 kN, the connection is passed.

Note: There are no moment capacity checks for a shear connection.

D. Connection Tags XML File Schema

A simple schema is used to define the data for a Connection Tags XML file used for storing connection tag data for STAAD.Pro.

When you initiate a connection tags action for the first time from the right-click pop-up menu, you will be prompted to select a Connection Tags XML file for use with creating and checking connection tags.

Figure 125: A diagram representation of the XML schema used

ConnectionTagFile

The `<ConnectionTagFile>` element is the root element for a STAAD.Pro Connection Tags file. Within a ConnectionTagFile element two types of data: connection categories and connection tags.

Table 54: ConnectionTagFile model details

Contains	(File Version then Categories then Equations then Tags then RCNXTemplates)
Contained by	n/a (*root element*)
Attributes	

FileVersion

The `<FileVersion>` element is indicate the file version used.

Table 55: FileValue model details

Contains	n/a (*empty element*)
Contained by	ConnectionTagFile
Attributes	value (required, decimal)

Categories

The `<Categories>` element contains individual connection categories. Typically a connection tags file contains both Moment and Shear categories.

Table 56: Categories model details

Contains	(Category) (*one or more*)
Contained by	ConnectionTagFile
Attributes	none

Category

The `<Category>` element defines a connection category.

Table 57: Category model details

Contains	(CategoryDesc)

Contained by	Categories
Attributes	CategoryName (required, restricted string data, no default); values are: MOMENT SHEAR

CategoryDesc

The `<CategoryDesc>` element is used to provide a human readable description for the parent connection category. It can contain any alpha-numeric string.

Table 58: CategoryDesc model details

Contains	text data
Contained by	Category
Attributes	none

Equations

The `<Equations>` element contains individual equations.

Table 59: Categories model details

Contains	(Equation) (*one or more*)
Contained by	ConnectionTagFile
Attributes	none

Equation

The `<Equation>` element contains a user-defined equation.

Table 60: Capacity model details

Contains	n/a (*empty element*)
Contained by	Equations

Attributes	EquationID (required, string), Equation (required, string), Condition (required, string), Limit(required, decimal) See " Equations Guidelines (on page 1059) " for details on writing equation and condition values.

Tags

The `<Tags>` element contains the connection tag data in a series of child elements.

Table 61: Tags model details

Contains	(Tag) (*one or more*)
Contained by	ConnectionTagFile
Attributes	

Tag

The `<Tag>` element contains an end release definition and a set of connection capacities to be used for checking connection tags.

Table 62: Tag model details

Contains	(EndRelease then Capacities)
Contained by	Tags
Attributes	TagName (required, string, no default), CategoryName (required, restricted string data, no default); values are: MOMENT SHEAR

EndRelease

The `<Tag>` element is used to specify the end release conditions to be used with a connection tag.

Table 63: EndRelease model details

Contains	n/a (*empty element*)
Contained by	Tag

Attributes	FX (required, restricted integer), FY (required, restricted integer), FZ (required, restricted integer), MX (required, restricted integer), MY (required, restricted integer), MZ (required, restricted integer) The range for these attributes is: 0 - restrained 1 - full release

Capacities

The `<Capacities>` element contains one or more connection capacity value sets for a specific system of units.

Table 64: Capacities model details

Contains	(Capacity) (*one or more*)
Contained by	Tag
Attributes	UnitSystem(required, restricted string data, no default); values are: METRIC IMPERIAL

Beam

The `<Beam>` element contains one or more beam or column sections.

Table 65: Beam model details

Contains	BeamOrCol (*one or more*)
Contained by	Capacities
Attributes	Name (required, string)

BeamOrCol

The `<BeamOrCol>` element is used to specify connection capacity bending and shear capacities for a specific member, or for the default member.

Table 66: BeamOrCol model details

Contains	n/a (*empty element*)
Contained by	Beam
Attributes	Name (required, string), Mz.cap (required, decimal), Fx.cap (required, decimal), Fz.cap (required, decimal) alpha (required, decimal) See D. Connection Tags Capacity Checks (on page 1051) for details on how these values are used. See " Use of Wild Cards (on page 1059) " for details on using defaults.

Checks

The `<Checks>` element contains one or more check.

Table 67: Checks model details

Contains	(Check) (*one or more*)
Contained by	Tag
Attributes	none

Check

The `<Check>` element is used to specify connection capacity between specified members required for checking connections.

Table 68: Check model details

Contains	n/a (*empty element*)
Contained by	Checks
Attributes	Type (required, string), Desc (required, string), EquationID (required, string) - reference to equation IDs.

RCNXTemplates

The `RCNXTemplates` element contains one or more RAM Connection template.

Table 69: RCNXTemplates model details

Contains	(RCNXTemplate) (*one or more*)
Contained by	Tag
Attributes	none

RCNXTemplate

The `RCNXTemplate` element is used to map a connection tag to a RAM Connection template.

Table 70: RCNXTemplate model details

Contains	n/a (*empty element*)
Contained by	RCNXTemplates
Attributes	TagName (required, string), Code (required, string), Template (required, string) - the RAM Connection template name, File (required, string) - the RAM Connection template file name

Use of Wild Cards

Instead of specifying the capacities and other details for each individual beam or column section, “wild card” entries can be used. This is particularly useful when the remaining attributes are the same for multiple sections.

Example using the `Default` wild card:

```
<Beam  Name="UB203x102x23">
      <BeamOrCol Name="Default" Mz.cap="35.9156" Fx.cap="207.3451" Fz.cap="" />
</Beam>
```

Equations Guidelines

The following table contains the expressions that can be evaluated for user-defined equations:

Digits/ Characters	0	1	2	3	4	5	6	7	8	9	.	,

Binary Operators	+	-	*	/								
Unary Operators	+	-										
Parenthesis	(	)										
Symbols	PI											
Functions	ABS	POW	ROUND	SQRT								
	MAX	MIN	SIN	COS	TAN	ASIN	ACOS	ATAN	LN	LOG	EXP	
Reserved Keywords (variables)	[MZ.CAP]	[FX.CAP]	[FZ.CAP]	[FX]	[FY]	[FZ]	[MX]	[MY]	[MZ]			

Notes:

- "," (comma) can only be used with the POW function
- The ROUND function rounds off to the nearest integer, not to a certain decimal place
- Condition attributes should include any one of the following:
  - EQ - equal to
  - LT - less than
  - LE - less than or equal to
  - GT - greater than
  - GE - greater than or equal to
- Reserved keywords should be specified with square brackets
- Reserved keywords, symbols, functions, and conditions are *not* case sensitive.

Example of an equation:

```
<Equation EquationID="Eq1" Equation="Abs([MZ])/[MZ.CAP]+Abs([FX])/[FX.CAP]"
Condition="LT" Limit="1.0" />
```

- *D. Connection Tags XML File Schema* (on page 1052)

D. Connection Tags sub menu

These sub-menu items are available under **Connection Tags** on the right-click pop-up menu when a member is selected.

Menu item	Description
Assign	Opens the **Assign Connection Tags** dialog and **New Connection tag** dialog, which are used to assign existing connection tags to member ends in the model and to create new connection tags, respectively.
Remove	Opens the **Assign Connection Tags** dialog and initiates the remove connection tag tool for the connections on the selected member. A confirmation dialog opens to confirm the remove action.
View	Opens the **Assign Connection Tags** dialog.
Check	(Active only after a successful analysis has been performed) Opens the **Assign Connection Tags** dialog and **Check Connection Tags** dialog, the latter of which is used to check the load case results from the analysis against the defined connection capacities in the Connection Tags XML data file.

D. Concrete Design

D. Available Concrete Design Codes

The following concrete design codes are available in the batch design mode and in the interactive design mode.

Batch Design

Table 71: Concrete design codes available in Batch design

Country	Code	Title
Australia	D2.A. Australian Codes - Concrete Design per AS 3600 - 2001 (on page 1350)	Australian Standard - Concrete Structures
Canada	D4.A. Canadian Codes - Concrete Design per CSA Standard A23.3-94 (on page 1413)	Design of Concrete Structures
India	D8.E. Indian Codes - Concrete Design per IS 456 (on page 1669)	Code of Practice for Plain and Reinforced Concrete (2000 edition)
	D8.G. Indian Codes - Concrete Design per IS 13920-1993 (on page 1697)	Code of Practice for Ductile Detailing of Reinforced Concrete Structures Subjected to Seismic Forces (1993 edition)
	D8.F. Indian Codes - Concrete Design per IS 13920-2016 (on page 1683)	Ductile Design and Detailing of Reinforced Concrete Structures Subjected to Seismic Forces - Code of Practice
Japan	D9.A. Japanese Codes - Concrete Design per 1991 AIJ (on page 1713)	Architectural Institute of Japan Standards for Structural Calculation of Steel Reinforced Concrete Structures
Mexico	D10.A. Mexican Codes - Concrete Design per MEX NTC 1987 (on page 1743)	Normas Técnicas Complementarias para Diseño y construcción de Estructuras de Concreto
Russia	D13.A. Russian Codes - Concrete Design Per SNiP 2.03.01-84* (on page 1866)	Building Regulations: Concrete and Reinforced Concrete Construction
	D13.D. Russian Codes - Concrete Design Per SP 63.1330.2012 (on page 1918)	Concrete and Reinforced Concrete Structures. Basic Provisions
South Africa	D14.A. South African Codes - Concrete Design per SABS-0100-1 (on page 1949)	The structural use of concrete Part 1:Design
United Kingdom	D3.D. British Codes - Design per BS8007 (on page 1403)	Design of concrete structures for retaining aqueous liquids

Country	Code	Title
United States	D1.F. American Codes - Concrete Design per ACI 318 (on page 1198)	Building Code for Structural Concrete (2014 edition). Building Code for Structural Concrete (2011 edition). Building Code for Structural Concrete (2008 edition). Building Code for Structural Concrete (2005 edition). Building Code for Structural Concrete (2002 edition). Building Code for Structural Concrete (1999 edition).

Advanced Concrete Design Workflow

Table 72: Available Concrete Design Codes in RCDC

Country	Code	Title
Europe	EN 02 2004	Eurocode 2: Design of concrete structures. General rules and rules for buildings
India	IS 456 + IS 13920 - 2016	Code of Practice for Plain and Reinforced Concrete & Ductile Design and Detailing of Reinforced Concrete Structures Subjected to Seismic Forces (2016 edition)
	IS 456 + IS 13920 - 1993	Code of Practice for Plain and Reinforced Concrete & Ductile Design and Detailing of Reinforced Concrete Structures Subjected to Seismic Forces (1993 edition)
Malaysia	EN 02 2004 + MS National Annex	Malaysian National Annex to Eurocode 2: Design of concrete structures
Singapore	EN 02 2004 + SS National Annex	Singaporean National Annex to Eurocode 2: Design of concrete structures
United Kingdom	BS 8110 97	Structural use of concrete. Code of practice for design and construction

Country	Code	Title
	EN 02 2004 + UK National Annex	UK National Annex to Eurocode 2: Design of concrete structures
United States	ACI 318 2014	Building Code for Structural Concrete (2014 edition), Imperial and Metric
	AC 318 2011	Building Code for Structural Concrete (2011 edition), Imperial and Metric

- *D. Batch Design versus Interactive Design Workflows* (on page 969)

D. Batch Member and Element Design Operations

How to perform concrete member and slab design in the Analytical Modeling workflow using batch operations.

D. To specify concrete design code and parameters

To initiate the design of concrete members and specify the code parameters, use the following procedure.

Note: To reduce the number of load cases used in design operations, you may want to create a load envelope or load list prior to specifying the design.

Batch mode design is specified and performed in the Analytical Modeling workflow.

1. On the **Analysis and Design** ribbon tab, select **Concrete** in the **Design** group gallery.
   The **Concrete Design - Whole Structure** dialog opens.
2. In the **Concrete Design - Whole Structure** dialog, select the applicable concrete design code from the **Current Code** drop-down list.
3. Click **Define Parameters**.
   The **Design Parameters** dialog opens.
4. Specify a value or option for each required parameter for a set of members and then click **Add**.

   You only need to specify parameters that require a different value from the default value. Repeat this step for all non-default parameters.

   Note: Different parameters can be used for different member type designs (e.g., columns, beams, etc.). Alternatively, you can use a separate set of parameters for different member types.
5. Click **Close**.
   The design parameters are marked with an icon. This indicates that the need to be assigned to members.
6. Use one of the STAAD.Pro assignment methods to assign each parameter to the applicable members.

You will now need to instruct the program to perform a design command on these members.

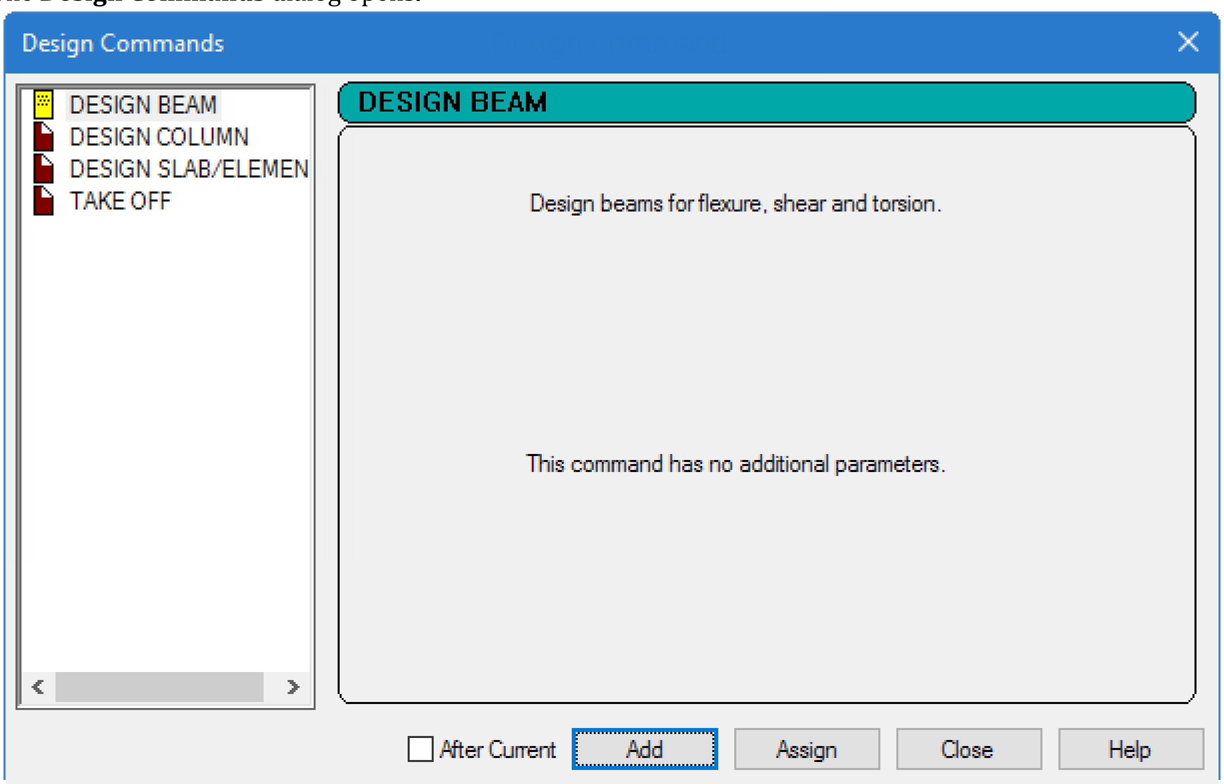
- *TR.53.5 Concrete Design Terminator* (on page 2686)

D. To specify concrete beam design command

To specify the design commands for concrete beams, use the following procedure.

1. On the **Concrete Design - Whole Structure** dialog, click **Commands**.
   The **Design Commands** dialog opens.
   


2. To perform a design action for concrete members, select one of the following options based on the member type:

To...	Select...
design members acting as beams	the **DESIGN BEAM** tab
design members acting as columns	the **DESIGN COLUMN** tab

3. Click **Add**.
4. Click **Close**.
5. Assign the design commands to the appropriate members.

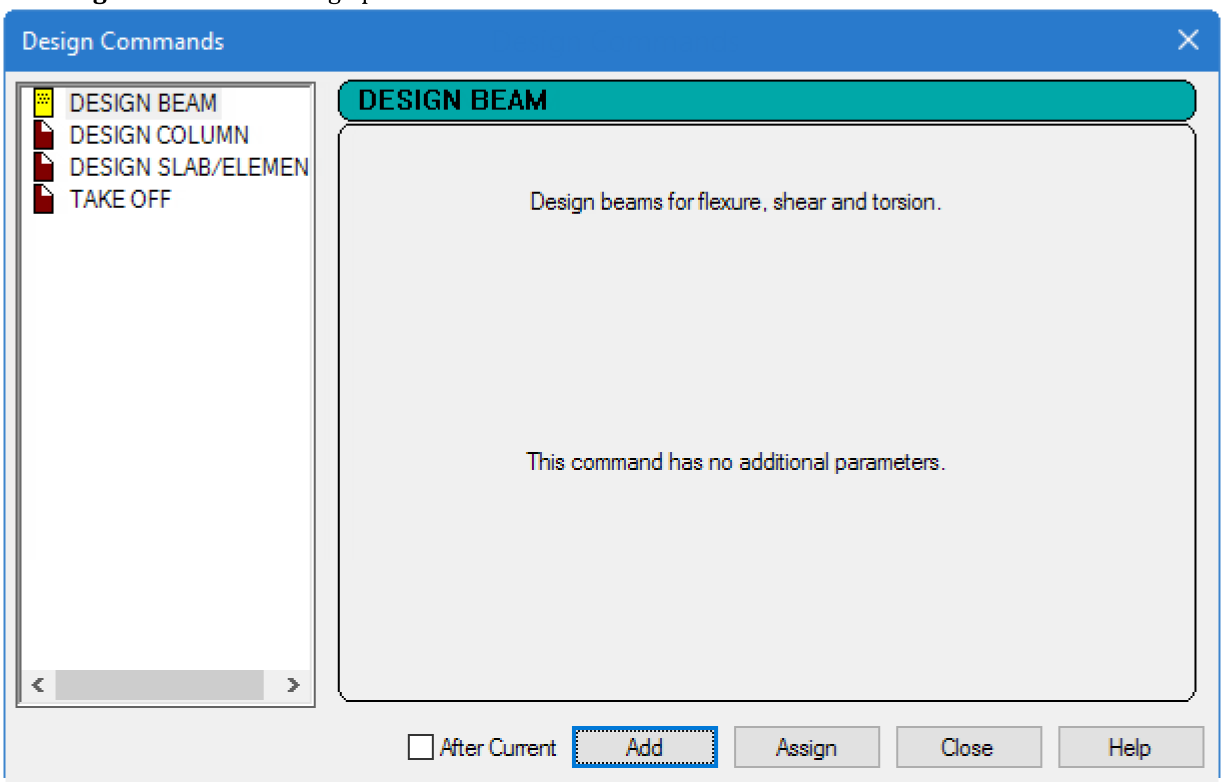
D. To generate concrete take off

To generate a summary of the total concrete volume along with the reinforcing steel bar numbers and weights for the design concrete members, use the following procedure.

1. On the **Concrete Design - Whole Structure** dialog, click **Commands**.
   The **Design Commands** dialog opens.



2. Select the **TAKE OFF** tab.
3. Click **Add**.
4. Click **Close**.
5. Assign the take off commands to members or to a named group of members.

D. Advanced Concrete Design

This workflow launches the STAAD.Pro Advanced Concrete Design (RCDC) program, which is used for the design and detailing of reinforced concrete building structures.

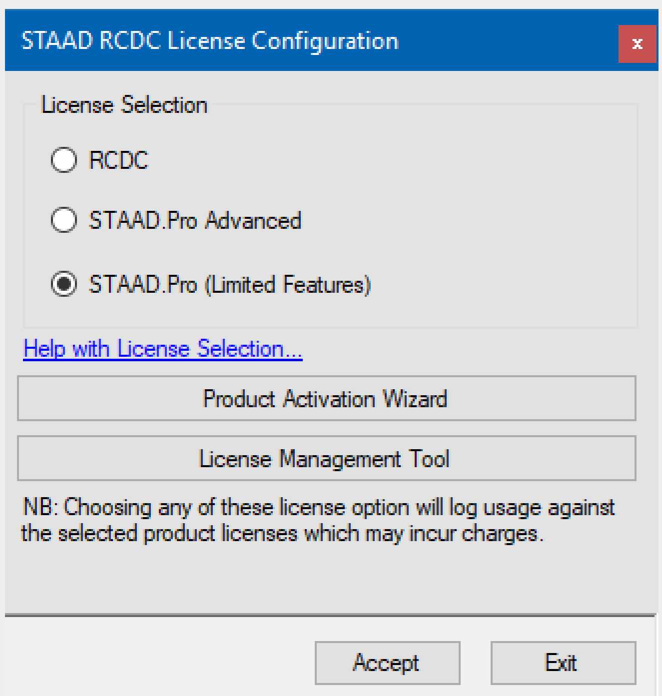
The Advanced Concrete Design workflow provides direct access for STAAD.Pro models to leverage the power of the RCDC application. This is a standalone application, which is operated outside the STAAD.Pro environment, but requires a model and results data from a suitable analysis.

The model should typically be formed from beams and columns (plates are currently not supported). RCDC can be used to design the following objects:

- Pile Caps
- Footings
- Columns and walls (note walls are determined from a STAAD model as very wide columns, see the RCDC documentation for more details)
- Beams
- Slabs (zones defined by a loop of beams, not plates, see RCDC documentation for more details)

As projects progress, each design created in RCDC is retained and displayed when RCDC is reentered so that previous designs can be recalled and/or continued. If any analysis is performed on the STAAD.Pro model from when the RCDC document was last edited, this is identified as an old document and should be reviewed again to ensure that the results of the design are still valid.

Note: When using the model in STAAD.Pro Advanced, access to RCDC will be provided using the same STAAD.Pro Advanced license and no other license is required. If using STAAD.Pro (basic), then the Advanced Concrete Design workflow will still allow access to RCDC, but this will allow only a limited feature set without the use of an additional license. This could either be a STAAD.Pro Advanced license or a STAAD Advanced Concrete license. Please check which licenses are available to you before attempting to use this and ensure that you use the correct license.



D. Advanced Slab Design

The STAAD.Pro Advanced Slab Design workflow is an integrated tool that works from within the STAAD.Pro environment. Concrete slabs can be defined and the data can be transferred to RAM Concept .

The data passed into RAM Concept includes the geometry, section and material properties, loads and combination information, and analysis results.

Note: Beginning with STAAD.Pro CONNECT Edition, direct export to ADAPT-Builder® has been deprecated.

D. Using the Advanced Slab Design workflow

Note: A successful analysis of a STAAD.Pro input file is required before initiating and using the Advanced Slab Design workflow.

D. To open the Advanced Slab Design workflow

1. Open an input file (containing the slab to be designed) in STAAD.Pro.
2. Perform a successful analysis.
3. Select **Advanced Slab Design** in the **Workflows** panel.

D. To create a load envelope

1. Select the **Envelopes** page in the **Advanced Slab Design** page control bar.
   The **Envelopes** table.

   Tip: This page is typically open by default.
2. Click **New Envelope** on the **Envelopes** table.

   workflow.

   The **Load Envelope** dialog opens.
3. (Optional) Type a title for the load envelope.

   A Load Envelope name should be entered, being defined by the chosen load cases by clicking the check boxes corresponding to each load case.
4. Select the load cases or combinations to be included in the design load envelope.

   Tip: Check the **Select All Load Cases Shown Below** option to add all available load cases to the envelope.
5. For each load case included, select a **Load Type** to describe the nature of that load.
6. Click **OK**.
   The new load envelope is added to the **Envelopes** table.

Related Links

- *D. Envelopes table* (on page 1075)

- *D. Load Envelope dialog* (on page 1076)

D. To create a slab definition

Note: A maximum of 10 holes can be defined per slab when exporting to RAM Concept.

1. Select the **Slab Design** page in the **Advanced Slab Design** page control bar.
   The **Geometry Cursor** tool is selected.
2. Select the structure geometry which will form the slab.

   Note: The slab geometry should include all plate elements which form the slab, as well as column members both above and below the slab, beam members framing the slab, and wall plate elements which are connected both above and below to the slab.
3. Click **New Slab** on the **Slabs** table.
   The **Slab Definition** dialog opens.
4. Select the **Load Envelope** with which to associate the slab definition.
5. Click **OK**.

   The new slab definition is added to the **Slabs** table.

   Note: If the selection of plates is such that the plates form two separated entities (e.g., plates that form parallel floors) then STAAD.Pro will create multiple separate slab entities.

Related Links
- *D. Slabs table* (on page 1076)
- *D. Slab Definition dialog* (on page 1077)

D. To export slab definitions to RAM Concept

1. Select the slab design definition(s) in the **Slabs** table.
2. Select the **Export** > **Export RAM Concept Information** tool in the **RAM Concept** group on the **Advanced Slab Design** ribbon tab.

   A dialog opens to confirm that the data files were created.

D. To open the STAAD.Pro slab data in RAM Concept

1. Select the slab design definition(s) in the **Slabs** table.
2. Either:

   Select the **Export** > **Run RAM Concept** tool in the **RAM Concept** group on the **Advanced Slab Design** ribbon tab.

or

Right-click on the **Slabs** table and select **Run** > **RAM Concept** from the pop-up menu.

RAM Concept launches and The **Concept import** dialog opens.

3. Leave all structure geometry element types selected (default) and click **OK.**

   Upon the completion of a successful import, a message dialog opens to inform you of the total number of structural elements and loads created.

Refer to the RAM Concept documentation for assistance performing analysis and design operations.

D. Pages in the Advanced Slab Design workflow

The Pages in the Advanced Slab Design workflow are described below in brief.

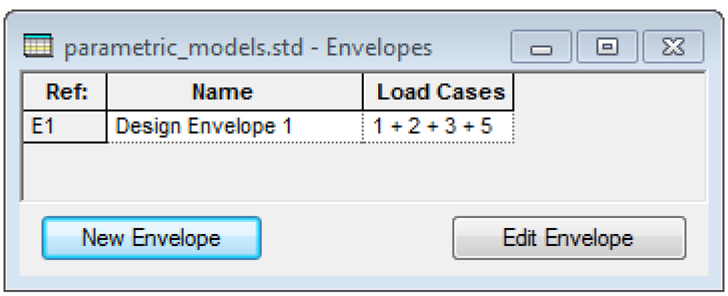
Table 73: Page Controls in the Advanced Slab Design workflow

Page	Purpose
Envelopes	Used to create set(s) from available Primary and Combination Loads defined in the current STAAD.Pro file for which analysis results are already available. When the **Envelopes** page is selected, the **Envelopes** table opens.
Slab Design	Used to create Slab definitions for slab design. When the **Slab Design** page is selected, the **Slabs** table opens.

D. **Envelopes** table

Used to view a table containing all the load envelopes created by the user for the current model. This table will also open even if there is no load envelope created yet.

Opens when the **Envelopes** page is selected in the **Advanced Slab Design** workflow.



Envelopes list Contains a list of all Envelopes available for Slab Design, along with the component load cases.

New Envelope Opens the D. Load Envelope dialog (on page 1076), which is used to create a load envelope from defined loads.

Edit Envelope Opens the **Load Envelope** dialog for editing the selected envelope.

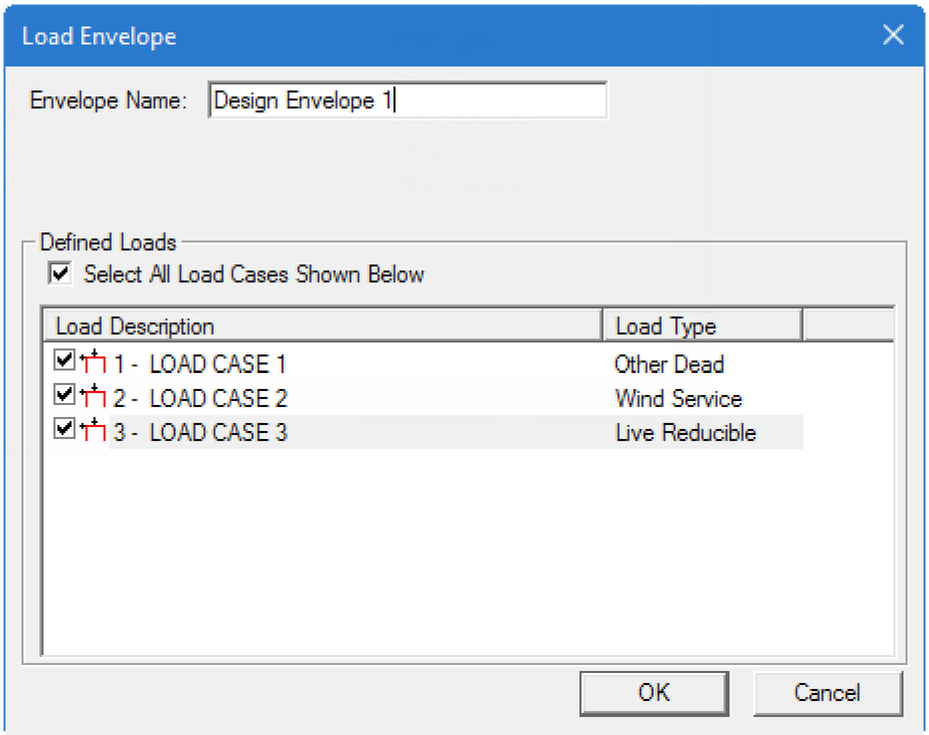
Related Links

- *D. To create a load envelope* (on page 1073)

D. **Load Envelope** dialog

Used to define an envelope of primary and combined load cases used in the analysis that will then be used by RAM Concept for performing code checks or member selections

Opens when **New Envelope** is clicked on the D. Envelopes table (on page 1075) .



Envelope Name	Specify a title for the load envelope. The default title uses an incremented id number.
Select All Load Cases Shown Below	Select this option to add all load cases in the Defined Loads list to the new load envelope.
Defined Loads list	Lists all previously defined load cases in the input file. For each load selected for the Load Envelope, the Load Type must be defined. The Load Type describes the nature of the load. Clicking in the cell for a Load Case opens a drop-down list containing all load types. Select the most appropriate type to make the assignment.
OK	Creates a new Load Envelope with the selected parameters and closes the dialog.
Cancel	Closes the dialog without creating a new load envelope.

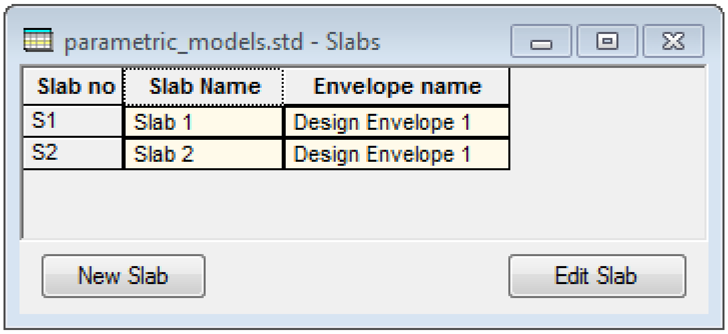
Related Links

- *D. To create a load envelope* (on page 1073)

D. **Slabs** table

Contains the slabs already defined along with the associated design load envelope.

Opens when the **Slab Design** page is selected in the **Advanced Slab Design** workflow.



Slab no	Lists sequential slab reference numbers (S1, S2, etc.)
Slab Name	Name of the Slab definition.
Envelope name	The load envelope associated with the slab.

New Slab Opens the D. Slab Definition dialog (on page 1077), which is used to create a slab definition from a set of selected plate elements.

Edit Slab Opens the **Slab Definition** dialog to edit or rename the currently selected slab.

Related Links

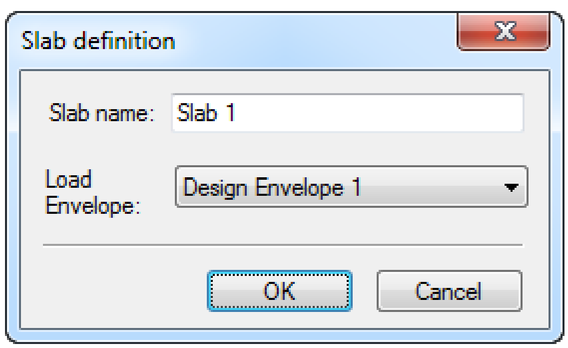
- *D. To create a slab definition* (on page 1074)

D. **Slab Definition** dialog

Used to create a slab definition from a set of selected geometry.

Opens when **New Slab** is clicked on the D. Slabs table (on page 1076) .

Note: A maximum of 10 holes can be defined per slab when exporting to RAM Concept.



Slab name	(Edit mode only) Enter the name of the Slab definition. Slab definitions are automatically named with incrementing numbers when they are created.
Load Envelope	Select a previously defined design load envelope from the list.
OK	Closes the dialog and creates a slab from the selected geometry.
Cancel	Closes the dialog without creating a slab definition.

Related Links

- *D. To create a slab definition* (on page 1074)

D. Foundation Design

The Foundation Design workflow integrates STAAD Foundation Advanced into STAAD.Pro. In this workflow, you can select loads and geometry to pass to a new STAAD Foundation Advanced project.

Note: This feature requires STAAD.Pro V8i (SELECTseries 2) (release 20.07.07) or higher.

Tip: Models containing a large number of supported nodes or load cases may result in slow performance on older computer hardware. Exporting a limited set of data can be used to improve performance in STAAD Foundation Advanced in these cases.

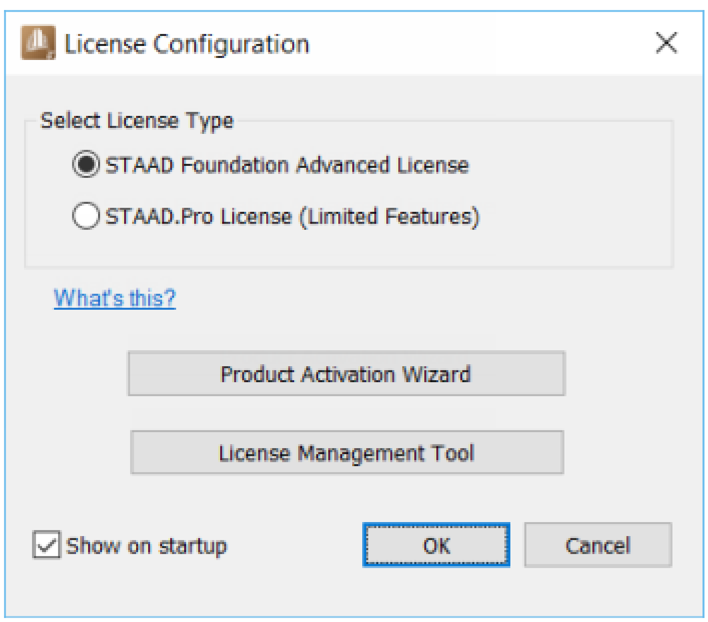
D. Using the Foundation Design workflow

Note: See Limited Versus Full Licensed Versions of STAAD Foundation Advanced (on page 1078) for details on the two license options available and the foundations that can be designed using those licenses.

Limited Versus Full Licensed Versions of STAAD Foundation Advanced

STAAD Foundation Advanced is available in two forms:

- licensed version
- a limited version which may be used with a STAAD Foundation Advanced license



Note: This limited version requires a license for STAAD.Pro but not a separate license for STAAD Foundation Advanced.

When you launch the program with STAAD Foundation Advanced installed, you are given a choices to select one of these in the **License Configuration** dialog. If you select the limited version option, then you only have access to the items as indicated in the following table. If you have purchased a license then you will have access to all the modules in STAAD.Pro.

Note: All available design codes are included for each feature.

Table 74: Items included in the free, limited version of STAAD Foundation Advanced

Items indicated with a "✔" are available with a free, limited version license. Items indicated with an "X" require a license to use.

Mode	Feature Name	Limited Version (license free)
Toolkit	All modules	X
General	Isolated footings	✔
General	Combined footings	✔
General	Pilecaps	✔
General	Mat foundations	X
General	Octagonal footings	X
General	Strap footings	X
General	Vibrating machine foundations	X
General	Combined with rib	X
Plant	All modules	X

Tip: If you uncheck the **Show on startup** option but need to access the **License Configuration** dialog, you can select the **License Configuration** tool in the **Settings** group on the **Home** ribbon tab. 

D. To open the Foundation Design workflow

1. Perform a successful analysis.
2. Select **Foundation Design** in the **Workflows** panel.

   The **Foundation Design** dialog opens.

D. To export all of the structure data to a STAAD Foundation Advanced project

This is the typical method of transferring data. Keep in mind that you can set up multiple jobs in STAAD Foundation Advanced, each containing some or all of the STAAD.Pro supports or load cases.

1. In the **Foundation Design Options** dialog, select the **All Supports** option is it is not already selected.
2. Click **Include All** to transfer all available load cases to the list of load cases To be included in design.
3. Click **STAAD Foundation Advanced**.
   STAAD Foundation Advanced opens and the STAAD.Pro support data and results are imported.

D. To export a limited set of structure data to a STAAD Foundation Advanced project

1. Either:

   Use the **Node Cursor** tool (selected by default with then Foundation Design workflow is selected) to graphically select the support nodes you want to transfer. The **Selected Supports** option will be selected automatically in the **Foundation Design** dialog.

   or

   Select the **Listed Supports** option in the **Foundation Design** dialog and then type a list of node numbers.
2. Either:

   Select one or more load cases in the **Excluded from design** list and click **Include** to transfer them to the **To be included in design** list.

   or

   Select the **Select Envelope** option and then select a load envelope from the drop-down list.
3. Click **STAAD Foundation Advanced**.
   STAAD Foundation Advanced opens and the STAAD.Pro support data and results are imported.

Tip: To change the loads or update the STAAD Foundation Advanced model per any geometry changes to your STAAD.Pro model, simply re-perform the steps involved in exporting the data.

D. **Foundation Design** dialog

Used to specify the supports and results to be exported to a STAAD Foundation Advanced project.

Opens when the **Foundation Design** workflow is selected.

Supports for Foundation Design

- **All Supports** – All supports in the structure will be exported to the STAAD Foundation Advanced project.
- **Selected Supports** – Only supports which are selected in the Active view window will be included. Use the **Nodes Cursor** tool to make selections.
- **Listed Supports** – List the support numbers of supports to included.

Load Cases and Combinations

Select the load cases to be included in the export to STAAD Foundation Advanced project:

- **Select Envelope** – select a load envelope from the drop-down list.

  Tip: You can create envelopes in the Analytical Modeling workflow. Refer to M. To create a load envelope (on page 901) for details.

- **Select Load Cases and Combinations** – select this option to choose load cases and combinations to include in the design.

  Excluded from design — All primary load cases and load combinations are listed here. Any that remain in this list are not exported to the

Table 75: Load Selector tools

Click this button	To
Include	Include load cases selected in the Excluded from design list in the To be included in design list below.
Include All	Include all available load cases in the To be included in design list below.
Exclude	Remove the selected load cases from the To be included in design list below.
Exclude All	Remove all load cases in the To be included in design list below.

To be included in design Loads included here will be exported to the STAAD Foundation Advanced project.

STAAD Foundation Advanced Starts STAAD Foundation Advanced and imports the structural data selected in this dialog into a new project file.

D. Aluminium Design

D. Available Aluminum Design Codes

The following aluminum design code is available in batch mode in STAAD.Pro.

Table 76: Aluminum Design codes available in STAAD.Pro

Country	Code	Title
US	D1.H. American Codes - Aluminum Design per 1994 ADM (on page 1264)	Specifications for Aluminum structures

Related Links

- *D. To specify aluminum design code and parameters* (on page 1083)
- *D. Batch Design versus Interactive Design Workflows* (on page 969)

D.Aluminum Design Overview

The design of aluminum members in STAAD.Pro can be achieved in the following two methods:

- check that the member meets the requirements of the design code using the Code Check command.
- for the forces resulting from the current set of loading, determine the most efficient size of section that would meet the requirements for the design code using the Select command.

Each design follows the rules as defined in a published design code specification. The list of available codes currently supported can be found at D. Available Aluminum Design Codes (on page 1081).

In order to determine the design code and code edition to which the members will be designed, the design command is preceded by a definition of the code and a series of code-related parameters. Each collection of these parameters is referred to as a “parameter block.” In the STAAD.Pro input file, this is initiated with the command `PARAMETER` and then typically terminated with the design command (e.g., `CHECK CODE`).

The parameter block provides the means by which you specify design-related member attributes required for the specified design code that have not been specified in the analytical model thus far. Each parameter has a default value which is ascribed to members to which a design command applies. When you assign a parameter to a given member, any design command that follows this assignment will use the specified parameter in the design. The default value of each design code parameter is listed in the appropriate section of the documentation.

```
PARAMETER
CODE design code/version
parameters modified from default values
design command
```

It is possible to define multiple design command and parameter blocks :

```
PARAMETER 1
CODE design code/version
parameters modified from default values
design command 1
design command 2
design command 3
...
PARAMETER 2
CODE design code/version
parameters modified from default values
design command 4
design command 5
design command 6
```

Also, each design command can be defined for different sets of members and different design commands:

```
PARAMETER 1
CODE design code/version
parameters modified from default values
CHECK CODE MEMBER 1 TO 10
SELECT MEMBERS 5 TO 20
```

D. To specify aluminum design code and parameters

To initiate the design of aluminum members and specify the code parameters, use the following procedure.

Note: To reduce the number of load cases used in design operations, you may want to create a load envelope or load list prior to specifying the design.

Batch mode design is specified and performed in the Analytical Modeling workflow.

1. On the **Analysis and Design** ribbon tab, select **Aluminium** in the **Design** group gallery.
   The **Aluminum Design - Whole Structure** dialog opens.

   Note: Only the US Aluminum code is available for design of aluminum members.
2. Click **Define Parameters**.
   The **Design Parameters** dialog opens.
3. Specify a value or option for each required parameter for a set of members and then click **Add**.

   You only need to specify parameters that require a different value from the default value. Repeat this step for all non-default parameters.

   Note: Different parameters can be used for different member type designs (e.g., columns, beams, etc.). Alternatively, you can use a separate set of parameters for different member types.
4. Click **Close**.

   The design parameters are marked with an icon. This indicates that the need to be assigned to members.
5. Use one of the STAAD.Pro assignment methods to assign each parameter to the applicable members.

You will now need to instruct the program to perform a design command on these members.

- *Aluminum Design - Whole Structure dialog* (on page 2937)
- *Design Parameters dialog* (on page 2934)
- *TR.48.1 Parameter Specifications* (on page 2676)

D. To specify aluminum design commands

To specify the code checking or design commands to be used for the aluminum design operation, use the following procedure.

1. On the **Aluminum Design - Whole Structure** dialog, click **Commands**.
   The **Design Commands** dialog opens.
2. To perform a design action, select one of the following options (as they are available for the code selection):

To...	Select...
check the capacity of the current member sizes	the **CHECK CODE** tab

To...	Select...
select a member size based on the last analysis results	the **SELECT** tab

3. Click **Add**.
4. Click **Close**.
5. Assign the design commands to the appropriate members.

Related Links

- *TR.49.1 Member Selection Specification* (on page 2678)

D. To generate aluminum take off

To generate a summary of all aluminum sections with their lengths and weights for the whole structure or a list of members, use the following procedure.

1. On the **Aluminum Design - Whole Structure** dialog, click **Commands**.
   The **Design Commands** dialog opens.
2. Select the **TAKE OFF** tab.

   This will generate a list of sections used including total length and weight.
3. Click **Add**.
4. Click **Close**.
5. Assign the take off command to members or to a named group of members.

- *D. To specify timber design code and parameters* (on page 1085)
- *D. Batch Design versus Interactive Design Workflows* (on page 969)

D. To specify timber design code and parameters

To initiate the design of timber members and specify the code parameters, use the following procedure.

Note: To reduce the number of load cases used in design operations, you may want to create a load envelope or load list prior to specifying the design.

Batch mode design is specified and performed in the Analytical Modeling workflow.

1. On the **Analysis and Design** ribbon tab, select **Timber** in the **Design** group gallery.
   The **Timber Design - Whole Structure** dialog opens.
2. In the **Timber Design - Whole Structure** dialog, select the applicable concrete design code from the **Current Code** drop-down list.
3. Click **Define Parameters**.
   The **Design Parameters** dialog opens.
4. Specify a value or option for each required parameter for a set of members and then click **Add**.

   You only need to specify parameters that require a different value from the default value. Repeat this step for all non-default parameters.

   Note: Different parameters can be used for different member type designs (e.g., columns, beams, etc.). Alternatively, you can use a separate set of parameters for different member types.
5. Click **Close**.

   The design parameters are marked with an icon. This indicates that the need to be assigned to members.
6. Use one of the STAAD.Pro assignment methods to assign each parameter to the applicable members.

You will now need to instruct the program to perform a design command on these members.
Related Links

- *D. Available Timber Design Codes* (on page 1084)
- *Timber Design - Whole Structure dialog* (on page 2939)
- *Design Parameters dialog* (on page 2934)

D. To specify timber design commands

To specify the code checking or design commands to be used for the timber design operation, use the following procedure.

1. On the **Timber Design - Whole Structure** dialog, click **Commands**.
   The **Design Commands** dialog opens. The tabs (if any) available in this dialog are dependent on the current design code selection. Not all commands are available for every design code.
2. To perform a design action, select one of the following options (as they are available for the code selection):

To...	Select...
check the capacity of the current member sizes	the **CHECK CODE** tab
select a member size based on the last analysis results	the **SELECT** tab (AITC 1984 code only)

3. Click **Add**.
4. Click **Close**.
5. Assign the design commands to the appropriate members.

Related Links

- *Timber Design - Whole Structure dialog* (on page 2939)

D. Design Codes

This section contains engineering reference material and input commands for structural design using batch mode. The codes are organized by country, material, and edition.

Effort has been made to provide some basic information about the analysis considerations and the logic used in the design approach. A brief outline of the factors affecting the design along with references to the corresponding clauses in the codes is also provided. Examples are provided at the appropriate places to facilitate ease of understanding of the usage of the commands and design parameters. You are urged to refer to the Examples Manual for solved problems that use the commands and features of STAAD.Pro. Since the STAAD.Pro output contains references to the clauses in the code that govern the design, we recommend that you consult the documentation of the code of that country for additional details on the design criteria.

D1. American Codes

D1.A. American Codes - Steel Design per AISC 360 Unified Specification

Steel member design per ANSI/AISC 360-05, 360-10, and 360-16 *Specifications for Structural Steel Buildings*, is available in STAAD.Pro. These specifications are published as part of the AISC *Steel Construction Manual*. Since the ASD and the LRFD method are both addressed in those specifications, they are referred to as `UNIFIED`.

To use the 2016 edition (default), specify the command:

```
CODE AISC UNIFIED
```

or

```
CODE AISC UNIFIED 2016
```

To use the 2010 edition, specify the command:

```
CODE AISC UNIFIED 2010
```

To use the 2005 edition, specify the command:

```
CODE AISC UNIFIED 2005
```

Tip: Either method may be selected in the user interface using the **Steel Design - Whole Structure** dialog.

Design can be performed according to the provisions for **Load and Resistance Factor Design** (LRFD) or to the provisions for **Allowable Strength Design** (ASD), as per section B3 of the code. This selection of the design methodology can be done through the `METHOD` parameter. The full list of parameters is given in D1.A.6 Design Parameters (on page 1100).

Related Links

- *G.17.2.1.4 AISC 360 Direct Analysis* (on page 2144)

D1.A.1 General Comments on Design as per AISC Unified Code

Both Allowable Stress Design and Load Resistance Factor Design methods are implemented in STAAD. The selection of the method can be done through the `METHOD` parameter explained in the parameter list. This Unified Code allows the designer to design the member as per LRFD as well as ASD method.

Design for Strength Using Load and Resistance Factor Design (LRFD)

Design according to the provisions for Load and Resistance Factor Design (LRFD) satisfies the requirements of the AISC 360 Unified Code Specification, when the design strength of each structural component equals or exceeds the required strength determined on the basis of the LRFD load combinations.

Design shall be performed in accordance with Equation B3-1 of the Code:

$$R_u \le \phi R_n$$

where

R_u = required strength (LRFD)
R_n = nominal strength
φ = resistance factor
φR_n = design strength

Design for Strength Using Allowable Strength Design (ASD)

Design according to the provisions for Allowable Strength Design (ASD) satisfies the requirements of the AISC 360 Unified Code Specification when the allowable strength of each structural component equals or exceeds the required strength determined on the basis of the ASD load combinations.

Design shall be performed in accordance with Equation B3-2 of the Code:

$$R_a \le R_n/\Omega$$

where

R_a = required strength (ASD)
R_n = nominal strength
Ω = safety factor

R_n/Ω	=	allowable strength

D1.A.2 Section Classification

The LRFD specification allows inelastic deformation of section elements. Thus local buckling becomes an important criterion. Steel sections are classified as compact, non-compact or slender element sections depending upon their local buckling characteristics. This classification is a function of the geometric properties of the section. The design procedures are different depending on the section class. STAAD.Pro is capable of determining the section classification for the standard shapes and design accordingly.

The Section Classification is done as per section B4 and Table B4.1, for Stiffened and Un-Stiffened Elements of a section.

D1.A.3 Member Properties

For specification of member properties of standard American steel sections, the steel section library available in STAAD.Pro may be used. The syntax for specifying the names of built-in steel shapes is described in the next section.

D1.A.4 Built-in Steel Section Library

The following sections describe specification of steel sections from the AISC Steel Tables.
Related Links
- *G.6.2 Built-In Steel Section Libraries* (on page 2116)

D1.A.4.1 AISC Steel Table

Almost all AISC steel shapes are available for input. Following are the descriptions of all the types of sections available:

Wide Flanges (W shapes)

All wide flange sections as listed in AISC are available the way they are written, e.g., W10X49, W21X50, etc.

```
20 TO 30 TA ST W10X49
33 36 TA ST W18X86
```

C, MC, S, M, HP Shapes

The above shapes are available as listed in AISC (9th Edition) without decimal points. For example, C8X11.5 will be input as `C8X11` and S15X42.9 will be input as `S15X42`, omitting the fractional portion of the weight past the decimal.

Note: Exception: `MC6X151` for MC6X15.1 and `MC6X153` for MC6X15.3.

```
10 TO 20 BY 2 TA ST C15X40
1 2 TA ST MC8X20
```

Double Channels

Back to back double channels, with or without spacing between them, are available. The letter D in front of the section name will specify a double channel.

```
21 22 24 TA D MC9X25
55 TO 60 TA D C8X18
```

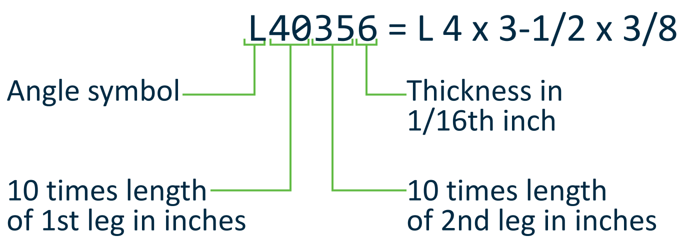
Front to front channel steel sections can be defined by using the FR (Double Channel – Front to Front) option and any spacing required between the channels are specified with the SP designation.

```
61 62 TABLE FR C4X5 SP 0.5
```

Note: The SP parameter is optional, but if it is not set, the section will not be assumed to be a closed box for torsional calculations.

Angles

Angle specifications in STAAD.Pro are different from those in the AISC manual. The following example illustrates angle specifications.



Similarly, `L505010` = L 5 x 5 x 5/8 and `L904016` = L 9 x 4 x 1

At present, there are two ways to define the local y and z-axes for an angle section. To make the transition from the AISC Manual to the program data easy, the standard section for an angle is specified:

```
51 52 53 TA ST L40356
```

This specification has the local z-axis (i.e., the minor axis) corresponding to the Z-Z axis specified in the steel tables. Many engineers are familiar with a convention used by some other programs in which the local y-axis is the minor axis. STAAD provides for this convention by accepting the command:

```
54 55 56 TA RA L40356
```

Note: RA denotes reverse angle

Double Angles

Short leg back to back or long leg back to back double angles can be specified by inputting the word SD or LD, respectively, in front of the angle size. In case of an equal angle either LD or SD will serve the purpose.

```
14 TO 20 TA LD L35304 SP 0.5
```

Long leg back to back L3-1/2x3x1/4 with 0.5 space.

```
23 27 TA SD L904012
```

Short leg back to back L 9x4x3/4

Tees

Tees are not input by their actual names, as they are listed in the AISC manual, but instead by designating the beam shapes (W and S) from which they are cut. For example

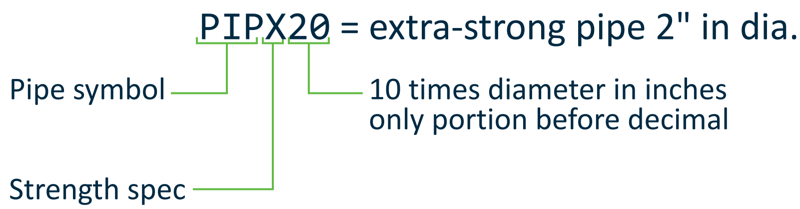
```
1 2 5 8 TA T W8X24
```

Tee cut from W8x24, or a TW4x12.

Pipes

Two types of specifications can be used for pipe sections. Pipe sections listed in the AISC manual can be specified as follows.

```
5 TO 10 TA ST PIPX20
```



Where the strength spec is one of the following:

S = standard
X = extra-strong
D = double extra-strong

General pipe sections may be input by their outer and inner diameters. For example,

```
1 TO 9 TA ST PIPE OD 2.0 ID 1.875
```

Indicates a pipe with an outer diameter of 2.0 and inner diameter of 1.875 in current input units.

Round HSS

Round hollow structural sections listed in the AISC manual can be specified as follows.

```
5 TO 10 HSS16X0.438
11 TO 12 HSS14X0.5_A1085
```

Indicates members 5 through 10 as 16" outer diameter and a nominal wall thickness of 7/16" (0.4375"). Members 11 and 12 have a 14" outer diameter and a 1/2" nominal wall thickness and use A1085 grade material.

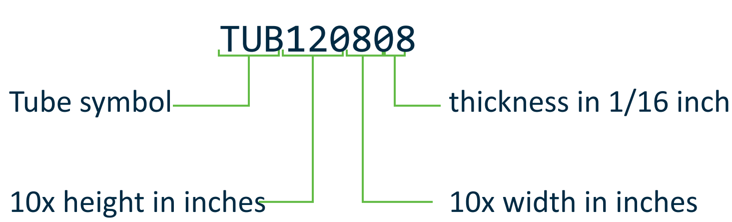
Notes:

- AISC codes require that the design of HSS sections use section properties calculated based on a reduced wall thickness. The STAAD.Pro database values incorporated a design thickness of 0.93× the nominal thickness.
- HSS sections using A1085 grade material per the AISC 360-16 and 360-10 codes are designed using section properties with the full nominal wall thickness. Thus, a separate set of tables is available to specify this material grade as these use different section properties.

Tubes

Two types of specifications can be used for tube sections. Tube sections from the AISC tables can be specified as follows.

```
5 TO 10 TA ST TUB120808
```



General tube sections may be input by their dimensions (height, width, and thickness) as follows.

```
6 TA ST TUBE DT 8.0 WT 6.0 TH 0.5
```

Indicates a tube that has a height of 8, a width of 6, and a wall thickness of 0.5 in the current input units.

Note: Member Selection cannot be performed on tubes specified by their dimensions. Only code checking can be performed on these sections.

Rectangular HSS

Rectangular hollow structural sections listed in the AISC manual can be specified as follows.

```
5 TO 10 HSST14X10X0.313
11 TO 12 HSST6X3X0.375_A1085
```

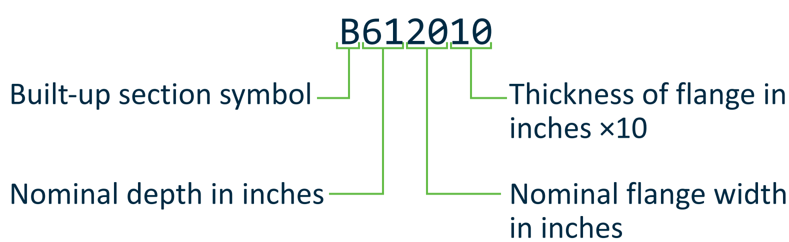
Indicates members 5 through 10 as a 14" x 10" tube with a nominal wall thickness of 5/16" (0.3125"). Members 11 and 12 are a 6" x 3" tube with a 3/8" nominal wall thickness and use A1085 grade material.

D1.A.4.2 Welded Plate Girders

The AISC welded plate girder shapes (pages 2-230 and 2-231 – AISC 9th edition) are available in the Steel Section library of the program.

```
1 TO 10 TA ST B612010
15 16 TA ST B682210
```

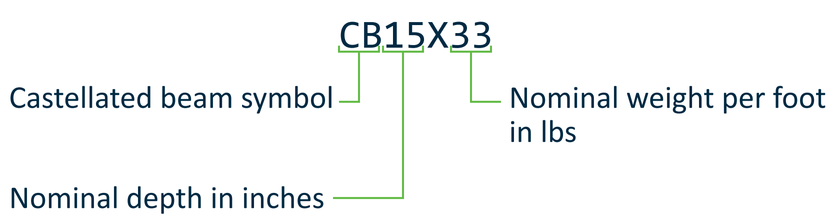
Nomenclature



D1.A.4.3 Castellated Beams Section Sizes

STAAD.Pro incorporates the non-composite castellated beam tables.

All castellated beams are listed with their nominal depth and their nominal weight per foot (i.e., similar to the nomenclature used for American wide flange shapes).



Tip: You can click **View Table** in the **Section Profile Tables** dialog to view the properties table, which includes the root beam profile size used for each castellated beam.

```
10 TO 20 TA ST CB15X33
2 TA ST CB27x40
```

D1.A.5 Limit States

Slenderness

The slenderness check is *not* used as a critical member ratio check. If a slenderness check is included and exceed unity (1.0), then it may be reported as the governing criteria. However, if it is less than unity, it will be reported but will not be used as the governing ratio.

D1.A.5.1 Axial Tension

The criteria governing the capacity of tension members are based on:

- Tensile Yielding in Gross Section and
- Tensile Rupture of Net Section.

The limit state of yielding in the gross section is intended to prevent excessive elongation of the member, and the corresponding check is done as per section D2-(a) of the code.

The second limit state involves fracture at the section with the minimum effective net area, and the corresponding check is done as per section D2-(b) of the code.

STAAD.Pro calculates the tension capacity of a given member based on these two limit states.

The Net Section Area may be specified by the user through the use of the parameter `NSF` (see D1.B.1.2 Design Parameters (on page 1134)). The Effective Net Area of tension members can be determined by using the Shear Lag Factor. You can also input the shear lag factor through the use of the parameter `SLF`.

D1.A.5.2 Axial Compression

The Design Compressive Strength (LRFD), $\phi_c \times P_n$, and the Allowable Compressive Strength (ASD), P_n / Ω_c , are calculated by the program.

The Nominal Compressive Strength, P_n, shall be the minimum value obtained according to the Limit States of:

- Flexural Buckling,
- Torsional Buckling, and
- Flexural-Torsional Buckling.

The Nominal Compressive Strength, P_n, for a particular member is calculated by STAAD.Pro according to the procedure outlined in Chapter E, section E3 to E5, of the unified code specifications. For slender elements, the procedure described in section E7 is used.

For single angle members in compression designed per AISC 360-16, the conditions in E5 for use of the modified slenderness ratio in Cl. E5.(a) are assumed to be met by default. However, the engineer can specify these conditions by use of the `E5P` parameter. Further, the modified slenderness ratio for box or space trusses can be utilized by using the `IMM` parameter.

Effective length for calculation of compression resistance may be provided through the use of the parameters KY and KZ. If not provided, the entire member length will be taken into consideration.

In addition to the compression resistance criterion, compression members are required to satisfy slenderness limitations which are a function of the nature of use of the member (main load resisting component, bracing member, etc.). In both the member selection and code checking process, STAAD.Pro immediately does a slenderness check on appropriate members before continuing with other procedures for determining the adequacy of a given member.

D1.A.5.3 Flexural Design Strength

The Design Flexural Strength (LRFD), $\phi_b \cdot M_n$, and the Allowable Flexural Strength (ASD), M_n / Ω_b , are being calculated by the program.

The Nominal Flexural Strength, M_n, is determined according to Sections F2 through F12 of unified code specifications, for different types of rolled sections.

Doubly symmetric, I-shaped sections with slender flanges are also checked, as per Section F3 of AISC 360-10.

The Nominal Flexural Strength of a member is determined by the limit states of Yielding (Y), Lateral-Torsional Buckling (LTB), Flange Local Buckling (FLB), Web Local Buckling (WLB), Tension Flange Yielding (TFY), Leg Local Buckling (LLB), and Local Buckling (LB).

The program internally calculates the Lateral-Torsional Buckling Modification Factor (C_b) for non-uniform moment diagrams when both ends of the unsupported segment are braced. The purpose of this factor is to account for the influence of the moment gradient on lateral-torsional buckling. Alternatively, this can be directly specified using the CB parameter.

To specify laterally unsupported length of member flanges, the parameters UNB, UNL, UNR, and UNT can be used. By default, these take the value of the member length.

D1.A.5.4 Design for Shear

The Design Shear Strength (LRFD), $Q_v \times V_n$, and the Allowable Shear Strength (ASD), V_n / Ω_v , are calculated by the program, as per section G2 of the unified code specifications.

The Nominal Shear Strength, V_n , of un-stiffened or stiffened webs, is calculated taking care of limit states of shear yielding and shear buckling. The sections G4 to G7 of the code specifications are used to evaluate Nominal Shear Strength, V_n for different types of rolled sections.

Shear Capacity Along the Major Axis

For determining shear capacity, Vc in the major axis Clause G2, G3, G4 are followed based on the different shapes.

Note: For user-defined sections the value of shear area will be used instead of the term 'Aw' in the equation in the above-mentioned clauses.

Shear Capacity Along the Weak Axis

The nominal shear strength, V_n, for each shear resisting element in doubly symmetric and singly symmetric shapes loaded in the weak axis (minor axis, or along the flanges) without torsion in is determined per AISC 360-16 G6 as follows:

$$V_n = 0.6F_y b_f\, t_f C_{v2} \tag{G6-1}$$

The use of the section dimensions[1] bf& tf in the above equation will be based on the section profile type. The following table lists the value of the terms bf, tf , kv, Cv2 that are used in the calculation of shear capacities for various section profile shapes, when subject to shear along the z-axis of the section.

Shape	Use of terms $b_f t_f$ in eqn G6-1	Dims used to calculate shear buckling coeff. Cv2 (Ref Cl G.2)	Ceoff kv used to calculate Cv2
Built Up Box	bf = 2.0 × (B – 2×wall thickness) & tf = flange thickness	h = (B – 2×wall thickness) & t = flange thickness	5.0
HSS Box	bf = 2.0 × Width between fillets & tf = wall thickness	h = Width between fillets & t = wall thickness	5.0
Rolled/ Channel	bf = 2.0 × Flange width & tf = flange thickness	h = Flange Width & t = Flange thickness	1.2
Rolled / Built Up I	bf = 2.0 × Flange width & tf = flange thickness	h = Flange Width & t = Flange thickness	1.2
I With Cover Plate(s)[2]:	Bf×tf = 2.0 × Flange width × flange thickness + width of top cover plate × thickness of top plate + width of bottom plate × thickness of bottom plate	h = Flange Width & t = Flange thickness for the base I shape & h = width of plate and t = thickness of plate	1.2
L- Section	bf = Length of leg along the X -axis & tf = thickness	h = Length of leg along the X -axis & t = thickness	1.2
T – Section	bf = Flange width & bf = flange thickness	h = Flange width (bf) & t = flange thickness (tf)	1.2
Solid bar / rod[3]	Bf×tf = 0.5 × section area	1.0	-

Notes:

1. For the shear in the weak axis, the value is determined using Bf and Tf alone. AZ cannot be used.
2. The shear capacities of the base I section and the top and / or bottom cover plates are evaluated separately using the dims shown and a Kv = 1.2. These values are then added to get the final section shear strength.

3. For solid rectangular bars and rods, half the total section area is assumed to resist the shear along the vertical axis and the other half to resist the shear along the horizontal axis. This could lead to conservative results in some cases.

D1.A.5.5 Design for Combined Forces

The interaction of flexure and axial forces in singly and doubly symmetric shapes is governed by sections H1 and H3. These interaction formulas cover the general case of biaxial bending combined with axial force and torsion. They are also valid for uniaxial bending and axial force.

D1.A.5.6 Design for Torsion

Stresses due to torsion in non-HSS sections are considered per AISC 360-10 Section H3.3. This section states that the available torsional strength for non-HSS members shall be the least value obtained according to the limit states of yielding under normal stress, shear yielding under shear stress, or buckling:

$$\phi_t = 0.9 \text{ (LRFD)}, \Omega_t = 1.67 \text{ (ASD)}$$

For the limit state of yielding under normal stress (H3-7):

$$F_n = F_y$$

For the limit state of shear yielding under shear stress (H3-8):

$$F_v = 0.6F_y$$

The calculation of F_v and F_n is based on AISC Design Guide 9 *Torsional Analysis of Structural Steel Members* (DG-9). In general terms, in case of shear stress, F_v will comprise of components of shear stress due to shear about both axes, warping shear stress and shear stress due to pure torsion. In case of normal stress F_n , stress due to axial force and stress due to flexure about both axes is considered. For some sections, like Single Angles and Tees, the component due to warping is negligible with respect to stress for pure torsion (Ref. Section 4.2 and 4.3 of Design Guide 9).

Notes

- STAAD.Pro will perform these torsion design checks when the `TORSION` parameter has been set to `1` (these are *not* checked by default).
- When torsion checks are performed, `TRACK 3` output may be used to provide detailed torsion design output for Design Guide 9 checks.

- The torsion checks per Design Guide 9 require additional analysis to calculate Θ (rotation of the element due to applied torsion; refer to the following sections) at the 13 design segments along the member. Thus there is a performance cost for each torsion check. Therefore, it is recommended that torsion checks only be performed on the necessary members (rather than all members).

Pure Torsional Shear Stress

These shear stresses are always present in the cross-section of a member subjected to torsional moment. They are in plane shear stresses which vary linearly along the thickness of an element.

$$\tau_t = Gt\Theta'$$

where

where

τ_t	=	the pure torsional shear stress at the element edge
G	=	the shear modulus of elasticity of steel
t	=	thickness of the element
Θ'	=	first derivative of rotation expressed as a function of local x (distance from start end to point where rotation is calculated)

In the case of an element with a rectangular cross section:

$$\tau_t = T_u t/J$$

In the case of a hollow circular element or a pipe section with an inner radius of R:

$$\tau_t = T_u R/J$$

In the case of a tube section:

$$\tau_t = T_u/(2bht)$$

where

where

T_u	=	the total torsional moment action at any location along the beam

Shear Stress Due to Warping

When warping in a member is restrained, in plane shear stresses are developed which are constant along thickness of the element but vary along the length of the element.

$$\tau_{ws} = -ES_{ws}\Theta'''/t$$

where

where

τ_{ws}	=	shear stress at a point,s, due to warping
E	=	the modulus of elasticity of steel
t	=	thickness of the element
S_{ws}	=	warping statical moment at a point, s
Θ'''	=	third derivative of rotation expressed as a function of local x (distance from start end to point where rotation is calculated)

Note: The shear stress due to warping is neglected for angle, tee, tube, or pipe sections.

Normal Stress Due to Warping

When warping in a member is restrained, direct stress acting perpendicular to the cross-section of the element is generated. These stresses are constant along the cross-section but vary along the length of the member.

$$\sigma_{ns} = EW_{ns}\Theta''$$

where

where

σ_{ns}	=	normal stress at a point,s, due to warping
E	=	the modulus of elasticity of steel
W_{ns}	=	normalized warping function at a point, s
Θ''	=	second derivative of rotation expressed as a function of local x (distance from start end to point where rotation is calculated)

Note: Point s refers to a point on the cross section area of a particular section as explained in Section 3.2.2 of Design Guide 9.

Combined Stresses due to Axial, Bending, and Torsional Stresses

Under section 4.6 of Design Guide 9, the combined stress in a section due all the stresses as explained in sections 4.1, 4.2, 4.3, and 4.4 is

$$f_n = \sigma_a + \sigma_{bz} + \sigma_{by} + \sigma_s$$

$$f_v = \tau_{sz} + \tau_{sy} + \tau_t + \tau_{ws}$$

These stresses are calculated at 13 sections along the beam length.

Considered Loads

Only member loads of the following types are considered in these checks:

- concentrated torque (moment about local x axis)
- concentrated force eccentric from the member shear center
- uniformly distributed torque (full or partial)
- uniformly distributed force eccentric to the member shear center
- end torques (only considered when end supports are fixed)

Linearly varying torque is *not* considered in the torsion checks. Joint loads are also *not* considered in the torsion checks.

The boundary conditions for torsional analysis and the method to calculate rotation,Θ , and its derivatives are used as described in DG-9.

STAAD.Pro calculates the stresses due to flexure, pure torsion, and warping torsion at 13 different sections along the member length. The total stress is the vector summation at each location.

D1.A.5.7 Design of Web-Tapered Members

AISC 360 05/10 specifications have been incorporated into STAAD.Pro to perform code checking on web tapered wide flange, square, and round shapes.

Note: Member selection cannot be performed on web-tapered members. That is, `SELECT ALL`, `SELECT OPTIMIZE`, and `PROFILE` are *not* applicable to web-tapered members.

The section properties used for web-tapered members are based on interpolated values between the start and depths of the member. Similar interpolation of values from start and end values is done for square and round tapered members.

Related Links

- *TR.20.3 Tapered Member Specification* (on page 2266)

D1.A.5.8 Design of I-Section with Cover Plates

STAAD.Pro can design I-sections with cover plates per AISC 360-05 and AISC 360-10.

According to B4.2(c) (p.16.1-15) of the AISC 360-05 specification, the cover plate is taken as a stiffened element and the width of a flange plate in a built-up section is taken between as the distance between lines of fasteners or welds. For the compression flange, the appropriate classification in Table B4.1 is that of case 12, which explicitly includes "flange cover plates and diaphragm plates between lines of fasteners or welds." The section classification limits for this case are:

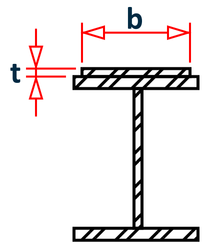
$$\lambda = b/t$$

$$\lambda_p = 1.12\sqrt{\frac{E}{F_y}}$$

$$\lambda_r = 1.40\sqrt{\frac{E}{F_y}}$$

where

b	=	width of the cover plate
t	=	thickness of the cover plate



Similarly, according to B4.2(c) of the AISC 360-10 specification, the cover plate is taken as a stiffened element and the width of the flange plate in a built-up section is taken as the distance between lines of fasteners or welds. For the compression flange, case 7 is used.

$$\lambda = b/t$$

$$\lambda_r = 1.40\sqrt{\frac{E}{F_y}}$$

For flexure, case 18 is used.

$$\lambda = b/t$$

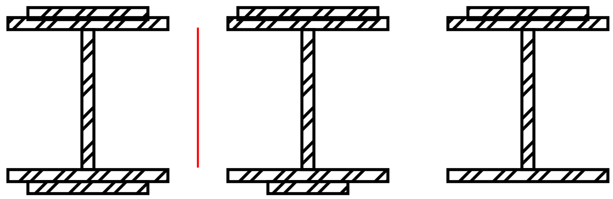
$$\lambda_p = 1.12\sqrt{\frac{E}{F_y}}$$

$$\lambda_r = 1.40\sqrt{\frac{E}{F_y}}$$

The section classification is included in the STAAD.Pro output listed as UNSTIFFENED / STIFFENED elements of the shape, along with the classification limits calculated as above and the element slenderness ratio, λ.

In addition to the limit states described elsewhere in this section, I-sections with cover plates have the following considerations for code checking per AISC 360-05/10:

- For Section E4, the program determines if the section is doubly or singly symmetric. Based on this, E.4-4 or E. 4-5 is used for the compression code check, respectively. An I-section with the same cover plate top and bottom remains doubly symmetric. An I-section with differing top and bottom plates or only a top or a bottom cover plate is singly symmetric.



- For lateral-torsional buckling calculations, the values of r_t and a_w are calculated as described in F4.2 for the effective radius of gyration in section ii.
- For shear, the minimum of all b/t ratios - including the flanges and top and bottom cover plates - is used for the web slenderness in the horizontal direction.
- For shear, the cover plates are checked for tension field action.
- The cover plates are considered in the seismic classification of the section.

It is assumed that the section classifications are for I-section flanges, web, and cover plates but not for parts of elements (i.e., outstanding flange).

Note: The following two items are *not* checked for I-sections with cover plates:

- The effects of the cover plates for flange local buckling of the section. Only the I-section flanges are considered in the FLB calculation.
- AISC Design Guide 9 is not incorporated.

D1.A.6 Design Parameters

Design per AISC 360-05, 360-10, and 360-016 (Unified) specifications is requested by using the CODE parameter. Other applicable parameters are summarized in the following Table. These parameters communicate design decisions from the engineer to the program and thus allow you to control the design process.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements, some or all of these parameter values may be changed to exactly model the physical structure.

Note: For AISC 360-2016, a maximum of nine (9) design commands may be specified in a parameter block.

Table 78: AISC 360-05, 360-10, and 360-16 Design Parameters

Parameter Name	Default Value	Description

CODE	AISC UNIFIED	Used to designate this code (default is the 2016 edition).
		`CODE AISC UNIFIED (2016)`
		`CODE AISC UNIFIED 2010`
		`CODE AISC UNIFIED 2005`

ALH (AISC 360-16 only)	0.5	Distance of applied point torsion from start of member as a fraction of member length. Represented by " a " in the torsional case options in Appendix B of AISC Design Guide 9. To be used with `TND` values of 3, 6, or 9. (0<ALH<1). Set `TORSION 1` to enable Torsion check as per DG9.
BEAM	1.0	See Note 9 below. 0.0 = design at start and end nodes and those locations specified by the `SECTION` command. 1.0 = design at 13 evenly spaced points (i.e., 1/12th points) along member length, including start and end nodes.
BRC (AISC 360-05 and 360-10 only)	1	Specifies the bracing type for the member used for seismic provision checks: 1 = Relative bracing 2 = Nodal bracing
CAN	0	0 = deflection check based on the principle that maximum deflection occurs within the span between DJ1 and DJ2. 1 = deflection check based on the principle that maximum deflection is of the cantilever type (see D1.B.1.2 Design Parameters (on page 1134))
CB [2]	1.0	Coefficient C_b per Chapter F. If C_b is set to 0.0, it will be calculated by the program. Any other value will be directly used in the design. See Note 2 below.
CSPACING	12 in	Spacing between connectors in current length units. Refer to Section E6.1 and E6.2 of AISC 360.
DFF	none (mandatory for deflection check)	"Deflection Length" / Maximum allowable local deflection. See TR.40 Load Envelope (on page 2663) for deflection checks using serviceability load envelopes.
DJ1	Start Joint of member	Joint No. denoting starting point for calculation of "Deflection Length" (see D1.B.1.2 Design Parameters (on page 1134))

Parameter Name	Default Value	Description
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length" (see D1.B.1.2 Design Parameters (on page 1134))
DMAX	1000.0 mm	Maximum allowable depth for member selection.
DMIN	0.0 mm	Minimum allowable depth for member selection.
DUCT (AISC 360-16 only)	0	The ductile category of the member as per AISC 341-16: 0 = non-ductile 1 = moderately ductile 2 = highly ductile
E5PROVISION (AISC 360-16 only)	0	Specifies whether the requirements for single angle members in compression in sections E5.(1) to E5.(3) are met for this member. 0) All requirements are satisfied. Thus the modified slenderness approach of E5 is used. 1) One or more are not satisfied See Note 11 below for details.
FLX	1	Parameter for specifying the lateral-torsional restraint condition for a single angle. Refer to Section F10 of AISC 360-05, 360-10, and 3601-16. 1 = Member does not have continuous lateral-torsional restraint along the length. 2 = Member has continuous lateral-torsional restraint along the length. 3 = Lateral-torsional restraint is provided at the point of maximum moment only. **AISC 360-16:** If FLX 2 is used, then any values assigned to parameters UNB, UNL, UNR, or UNT are ignored and zero is used for the member length for lateral torsional buckling.
FRM (AISC 360-05 and 360-10 only)	0	Specifies the seismic force-resisting system used in seismic provision checks: 0 = Ordinary Moment Frame (OMF) 1 = Intermediate Moment Frame (IMF) 2 = Special Moment Frame (SMF)
FU	400 MPa	Ultimate strength of steel. **AISC 360-16:** This value is ignored if SGR specified other than 0. Refer to Note 10 for details.

Parameter Name	Default Value	Description
FYLD	250 MPa	Yield strength of steel. The program considers a valid range of input values between 10 ksi - 100 ksi (69 MPa - 689 MPa). **AISC 360-16:** This value is ignored if SGR specified other than 0. Refer to Note 10 for details.
IMM (AISC 360-16 only)	0	Truss type of single angle members: 0) E5(a): Individual / web member of a planar truss 1) E5(b): Web member of a box or space truss **Note:** For the default case, a single angle is assumed to be an individual or web member of a planar truss [E5(a)] with adjacent web members attached to the same side of the gusset plate or chord. See Note 11 below for additional details.
KX	1.0	K value for flexural-torsional buckling.
INTERACTION	0	Directs the program which interaction equations to check per section H1: 0 = Checks both H1.1 and H1.3 and reports the lower ratio as critical 1 = Check both H1.1 and H1.3 and reports the higher ratio as critical 2 = Always checks per H1.1 even when H1.3 may be applicable 3 = Checks H1.3 in lieu of H1.1 when applicable
KY	1.0	Effective length factor to calculate slenderness ratio for compression buckling about local y-axis. Usually this is the minor axis.
KZ	1.0	Effective length factor to calculate slenderness ratio for compression buckling about local z-axis. Usually this is the major axis.
LBRC (AISC 360-16 only)	1	Type of flange lateral bracing: 0 = none 1 = panel bracing 2 = point bracing 3 = special bracing Used to calculate bracing requirements as per seismic provisions in AISC 341-16.

Parameter Name	Default Value	Description
LEG	0	This parameter is meant for plain angles (Section E5). 0 = The angle is connected by the longer leg. 1 = The angle is connected by the shorter leg.
LX	Member Length	Length for flexural-torsional buckling. See Note 8 below.
LY	Member Length	Length to calculate slenderness ratio for buckling about local y-axis.
LZ	Member Length	Length to calculate slenderness ratio for buckling about local z-axis.
MAIN	200	Allowable slenderness limit for compression members. A value of 1 suppresses this check. Any value greater than 1 is used as the compression slenderness check value.
METHOD	LRFD	Used to specify LRFD or ASD design methods.
MTYP	1	Specifies whether the member is a beam or column. Used for seismic provisions checks. 1 = Beam 2 = Column For AISC 360-16 only: 3 = Beam-column
NBRC (AISC 360-16 only)	1	Number of braced points within the span. Represented by "n" in Appendix 6.3.2(a) of AISC 360-16. Required for Seismic Provisions.
NSF	1.0	Net Section Factor for tension members, equal to A_n/A_g ,used to account for reduction in section used for tension checks (clause B 4.3b.) combined with the SLF parameter to determine the rupture strength. (see also SLF parameter)
PROFILE		Used in member selection. Refer to TR.48.1 Parameter Specifications (on page 2676) for details.
RATIO	1.0	Permissible ratio of actual load to allowable strength.

Parameter Name	Default Value	Description

SEISMIC	0	Used to instruct the program to add additional checks per the AISC 341, *Seismic Provisions for Structural Steel Buildings*.
		
		0 = Do not check seismic provisions
		
		AISC 360 – 05, check according to AISC 341 – 05
		
		AISC 360 – 10, check according to AISC 341 – 10
		
		AISC 360 – 16, check according to AISC 341 – 16
		
		See section D1.A. American Codes - Steel Design per AISC 360 Unified Specification for more details.
		
		1 = Check seismic provisions
		
		See D1.A.9 Seismic Provision Checking per AISC 341 (on page 1112) for details.
		
		Note: These additional parameters that should be set when using the seismic option:
		• AISC 360-05 and AISC 360-10
		  • MTYPE
		  • FRM
		  • BRC
		• AISC 360-16
		  • MTYPE
		  • DUCT

31 = A1085

The yield stress and ultimate stress will be auto-calculated based on the grade selected. Note that any SGR value greater than 0 will take priority when calculating the yield stress and ultimate stress over any supplied FYLD and FU value.

AISC 360-16: Refer to Note 10 for details.

Note: “HSS Rectangle A1085” and “HSS Round A1085” profiles steel grade will always be considered as A1085 irrespective of any value assigned to SGR.</td></tr>
</table>

Parameter Name	Default Value	Description
SLF	1.0	Shear Lag Factor, value "U" normally taken from table D3.1, combined with the NSF parameter to determine the net effective area used to calculate the section rupture strength. (see also NSF parameter)
SNUG	1	Type of connection for the built-up members: 0 = Welded or pretensioned bolts 1 = Bolted snug-tight
SOE (AISC 360-16 only)	0	Second Order Effects have been considered in analysis forces or not: 0 = Have not been considered 1 = Have been considered By default, Second Order Effects are not considered in the analysis forces. This is related to Torsion checks as per DG9. Set `TORSION 1` to enable Torsion check as per DG9.
SRT (AISC 360-16 only)	0	Used for tension slenderness checking. 0 = Checks slenderness design for tension member in conventional way. 1= Checks slenderness design for tension member as per CL D1. For default case, tension slenderness check is made by dividing the TSL value by Rmin. For SRT value 1, slenderness design for tension member will be done by taking maximum length out of LZ, LY and member length.
STFB (AISC 360-16 only)	0.0	Stiffener width for one-sided web stiffeners, twice the individual stiffener width for pairs of stiffeners. Represented by "bs" in Appendix 6.3.2(a) of AISC 360-16. Required for Seismic Provisions.
STFT (AISC 360-16 only)	0.0	Thickness of web stiffeners. Represented by "tst" in Appendix 6.3.2(a) of AISC 360-16. Required for Seismic Provisions.
STIFF	Member Length or depth of beam, whichever is greater	Spacing of stiffeners for plate girder design.

Parameter Name	Default Value	Description
STP	1.0	Section Type used for design 1 = Rolled section 2 = Welded section **Note:** If a UPT Wide flange section with different top & bottom flange dimensions have been specified for a member, the AISC360-16 module will ignore the value of STP and consider the section as a Welded/Built-Up section.
TBRC (AISC 360-16 only)		Type of torsional bracing: 0 = None 1 = continuous bracing 2 = point bracing 3 = special bracing Used to calculate bracing requirements as per seismic provisions in AISC 341-16.
TFA (AISC 360-16 only)	0	Tension field action to be considered in shear design: 0 = do not consider 1 = consider
TSL (AISC 360-16 only)	Member Length	The length used in tension slenderness checks.
TMAIN	300	Allowable slenderness limit for tension members. A value of 1 suppresses this check. Any value greater than 1 is used as the tension slenderness check value.

Parameter Name	Default Value	Description
TND (AISC 360-16 only)	1	Torsion loading and end condition as in Table in Appendix C.4 of AISC Design Guide 9: 1 = Equal concentrated end torques. Both ends free. 2 = Equal concentrated end torques. Both ends fixed. 3 = Concentrated Torque. Both ends pinned. 4 = Uniformly distributed torque. Both ends pinned. 6 = Concentrated Torque. Both ends fixed. 7 = Uniformly distributed torque. Both ends fixed. 9 = Concentrated Torque. One end fixed, another end free. 10 = Partial uniformly distributed torque. One end fixed, another end free. 12 = Uniformly distributed torque. One end fixed, another end pinned. The number corresponds to the case number of the case chart in Appendix B of DG9. Set `TORSION 1` to enable Torsion check as per DG9.
TORSION (AISC 360-10 and 360-16 only)	0	Specifies design for torsion per AISC Design Guide 9. See D1.A.5.6 Design for Torsion (on page 1096) 0 = Do not perform torsion checks 1 = Perform torsion checks **Note:** When torsion checks are performed, `TRACK 3` output may be used to provide detailed torsion design output for Design Guide 9 checks.
TRACK	0	Specifies the amount of detail included in design output 0 = Suppress all member capacities 1 = Print all member capacities 2 = Print full member design details
UNB	Member Length	Unsupported length of the bottom flange for calculating flexural strength. Will be used only if compression is in the bottom flange. See Note 3 below.
UNL	Member Length	Unsupported length of left extreme flange for LTB that will be used as lateral-torsional buckling length for the section with the vertical axis as major principal axis and where the left extreme fiber is in compression. If member is assigned with any value of UNL and FLX=2 concurrently, LTB length of the member will be treated as zero.

Parameter Name	Default Value	Description
UNR	Member Length	Unsupported length of right extreme flange for LTB that will be used as Lateral-torsional buckling length for the section with the vertical axis as major principal axis and where the right extreme fiber is in compression. If member is assigned with any value of UNR and FLX=2 concurrently, LTB length of the member will be treated as zero.
UNT	Member Length	Unsupported length of the top flange for calculating flexural strength. Will be used only if compression is in the top flange. See Note 3 below.
WTYPE (AISC 360-05 and 360-10 only)	0	Weld type for HSS per Sect. B3.12 (AISC 360-05) or Sect. B4.12 (AISC 360-10): 0 = Electric resistance welding 1 = Submerged arc welding For HSS Rectangle and Round profiles from AISC databases, the weld type will always be determined based on profile table (grade A1085 or not). `WTYP` will have no effect on these. For any other hollow profiles (pipe, tube, box, etc.) from AISC databases, all hollow profiles from any other country databases, and User Provided tables, the weld type must be specified using the `WTYP` parameter.

Notes

1. For the AISC 360 unified code, an angle is automatically checked for geometric axis bending (in addition to principal axis bending) provided one of the following conditions is met:
   i. The `FLX` parameter is set to 2 for that member. The section could be an equal or an unequal legged angle.
   ii. The angle is equal-legged, has bending moment only about one of its geometric axes, and is not subjected to axial compression.

   The `AXIS` parameter is only used by the deprecated AISC 360-05 code checking method (`CODE AISC UNIFIED OLD`). If this code is used, then AXIS 1 specifies design based on principle axes, where AXIS 2 specifies design based on geometric axes.
2. Non-default values of `CB` must be re-entered before every subsequent `CHECK CODE` or `SELECT` command.
3. Top and Bottom represent the positive and negative side of the local Y axis (local Z axis if `SET Z UP` is used).
4. For a description of the deflection check parameters `DFF`, `DJ1`, `DJ2` see the Notes section of D1.B.1.2 Design Parameters (on page 1134) of this manual.
5. `NSF` is the Net Section Factor as used in most of the steel design codes in STAAD.Pro. It is defined as the Ratio of “Net cross section area” / “Gross section area” for tension member design. The default value is 1.0. For the AISC 360 code, it is described in section D.3.2.
6. `SLF` is the Shear Lag Factor, as used in Section D.3.3 of the AISC 360-05 code. This factor is used to determine the effective net area by multiplying this factor with net area of the cross section. Please refer to Table D3.1 of the 360 code for a list of acceptable `SLF` values. In STAAD.Pro, the default value for `SLF` is 1.0. The effective net area is used to determine the tensile strength for tensile rupture in the net section, as per equation D.2.2.

7. To summarize, the "Gross Area" (Ag) is multiplied by `NSF` to get the "Net Area" (An) of the section. The "Net Area" (An) is again multiplied by `SLF` to get the "Effective Net Area" (Ae) of the section.
8. For the design of a single angle for flexure, the parameter `LX` should be used to specify the value of the term "L" in equations F10-4a, F10-4b, F10-5 and F10-6 of AISC 360-05 and the term "Lb" in equations F10-4, F10-5, F10-6a, and F10-6b of AISC 360-10.
9. When `BEAM` is 1.0 (default), the design is performed at 13 evenly spaced points along the length of the beam, including start and end points (i.e., 1/12th points or at ends of 12 equal length segments).

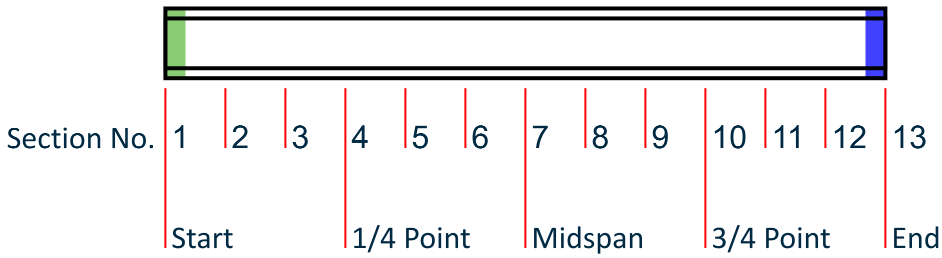

Figure 126: The default sections for design when BEAM 1.0 is used

When `BEAM` is 0.0, the start and ends along with up to three locations specified in TR.41 Section Specification (on page 2665) are designed.

10. For AISC 360-16, the material strength values are first taken from the `SGR` parameter if specified (and not zero). If `SGR` has not been specified, then the values of the `FYLD` and `FU` parameters will be used if specified. If no design parameters have been specified for material strengths, then the values in the material definition are used. If no material definition has been assigned, then the STAAD.Pro default values of Fy = 36 ksi and Fu = 58 ksi are assumed.
11. For AISC 360-16, single angle members in compression can be designed using a modified slenderness method provided a set of conditions are met for that member. It is left to the engineer to confirm that conditions E5.(1) through E5.(3) are met and to specify this for single angle member using the `E5P` parameter. Those conditions are:

    1) Members are loaded at the ends in compression through the same leg.
    2) Members are attached by welding or by connections with a minimum of two bolts.
    3) There are no intermediate transverse loads.

    If one or more of these conditions are not met, then the `E5P 1` parameter value should be assigned to those members.

    Note: Conditions E5.(4) and E5.(5) are checked by the program:

    4) Slenderness ratio, $L_c/r \leq 200$
    5) For unequal leg angles, the ratio of leg widths is < 1.7.

    The effective slenderness ratio method used for single angles also depends on if those angle members are:

    1. individual members or are web members of planar trusses (in which case, Cl. E5(a) applies - `IMM 0`)
    2. web members of box or space trusses (in which case, Cl. E5(b) applies - `IMM 1`)

    A message is issued if the `E5P` or `IMM` parameter is used with any section type other than a single angle.

Note: The `E5P` and `IMM` parameters are only applicable to standard catalog or UPT angles which also are assigned as truss members.

D1.A.7 Code Checking and Member Selection

Code Checking and Member Selection options are both available in the AISC 360 Unified Code implementation in STAAD.Pro.

For additional information on code checking, refer to:

- D1.B.1.3 Code Checking (on page 1141) for general information and
- TR.49 Code Checking Specification (on page 2677) for input command details

For addiitional information on member selection refer to:

- D1.B.1.4 Member Selection (on page 1142) for general information and
- TR.49.1 Member Selection Specification (on page 2678) for input command details

D1.A.8 Tabulated Results of Steel Design

Results of Code Checking and Member Selection are presented in the output file. The output is clearly marked for the selected specification (ASIC 360), edition used (2010 or 2005), and the design method (LRFD or ASD).

The following details are presented on Code Checking of any member:

- Result of Code Checking (Pass / Fail) for the member Number.
- Critical Condition which governed the design and the corresponding Ratio and Location.
- Loads corresponding to the Critical Condition at the Critical Location.
- Section Classification
- Slenderness check report
- Section Capacities in Axial Tension, Axial Compression, Bending, and Shear in both the directions.

  If Seismic provisions are to be checked, these follow as described in D1.A.9 Seismic Provision Checking per AISC 341 (on page 1112)

Note: An asterisk following a critical load case number indicates that this load case is a generated load combination. See TR.35 Load Combination Specification (on page 2616) for additional information.

D1.A.9 Seismic Provision Checking per AISC 341

Additional parameters may be specified for member checking or design per AISC 360-05, 360-10, or 360-16 to perform seismic provision checks per the corresponding edition of AISC 341.

The `SEISMIC` parameter is used to specify seismic provision checks for members. For those members in the AISC 360-05 or 360-10 editions, the `MTYP` (member type), `FRM` (frame type), and `BRC` (bracing type) parameters are used to specify the structure and member details. For the AISC 360-16 edition, only the `MTYP` (member type) parameter is used to specify the member details. See D1.A.6 Design Parameters (on page 1100) for details on the values used for these parameters.

Provisions Checked

The following checks are performed with the `SEISMIC 1` parameter for the AISC 341-05/10 specifications:

- seismic classification of the member - the “worst case” classification is considered among all elements for the member. For
  - For members in an ordinary moment frame (OMF) or intermediate moment frame (IMF), the general section classification of AISC 360-05/10 is used.
  - For members in a special moment frame (SMF), the classification per table I-8-1 of AISC 341-05 or table D1.1 of AISC 341-10, respectively, are used.
- required flexural strength of the member -
  - OMF - $M_r = M_z$ (moment about major axis), per Sec. 11.8 of AISC 341-05 or Sec. E.1.4 of AISC 341-10
  - IMF - $M_r = M_u = R_y Z F_y$ (LRFD) or $= R_y Z F_y / 1.5$ (ASD) per Sec. 10.8 of AISC 341-05 or Sec. D.1.2a of AISC 341-10
  - SMF - $M_r = M_u = R_y Z F_y$ (LRFD) or $= R_y Z F_y / 1.5$ (ASD) per Sec. 9.8 of AISC 341-05 or Sec. D.1.2b of AISC 341-10
- required bracing strength
  - Relative bracing for beams - $P_{br} = 0.008 M_r C_d / h_0$ per eq. A-6-5 of AISC 360 05/10
  - Nodal bracing for beams - $P_{br} = 0.02 M_r C_d / h_0$ per eq. A-6-7 of AISC 360 05/10
  - Relative bracing for columns - $P_{br} = 0.004 P_r$ per eq. A-6-1 of AISC 360 05/10
  - Nodal bracing for columns - $P_{br} = 0.01 P_r$ per eq. A-6-3 of AISC 360 05/10
- required bracing stiffness: each of the following are multiplied by $1/\phi$ for LRFD or by Ω for ASD:
  - Relative bracing for beams - $\beta_{br} = 4 M_r C_d / (L_b h_0)$ per eq. A-6-6 of AISC 360 05/10
  - Nodal bracing for beams - $\beta_{br} = 10 M_r C_d / (L_b h_0)$ per eq. A-6-8 of AISC 360 05/10
  - Relative bracing for columns - $\beta_{br} = 2 P_r / L_b$ per eq. A-6-2 of AISC 360 05/10
  - Nodal bracing for columns - $\beta_{br} = 8 P_r / L_b$ per eq. A-6-4 of AISC 360 05/10
- required bracing spacing
  - OMF - no requirement
  - IMF - $L_b = 0.17 r_y E / F_y$ per Sec 10.8 of AISC 341-05 or Sec. D.1.2a of AISC 341-10
  - SMF - $L_b = 0.086 r_y E / F_y$ per Sec 9.8 of AISC 341-05 or Sec. D.1.2b of AISC 341-10

Provisions Checked for AISC 341-16

The following checks are performed with the `SEISMIC 1` parameter for the AISC 341-16 specification:

- Section seismic classification against ductility – the section is evaluated to be seismically compact or seismically non-compact for either highly or moderately ductile members (specified using the `DUCT` parameter)
- Required flexural strength of member checked per D1-1
- Stability bracings of beam
  - Maximum allowed spacing of bracings checked per D1-2
  - Required strength of lateral beam bracing at panel type flange lateral bracing (A-6-5 of AISC 360-16), point type flange lateral bracing (A-6-7 of AISC 360-16), and special flange lateral bracing at plastic hinge locations (D1-4)
  - Required strength of torsional bream bracing at point torsional bracing (A-6-9 of AISC 360-16), continuous torsional bracing, and special torsional bracing at plastic hinge locations (D1-5)

  - Required stiffness of beam bracing at panel type flange lateral bracing and point type flange lateral bracing (A-6-6 of AISC 360-16)
  - Required stiffness of torsional bracing at point torsional bracing (A-6-10 and A-6-11 of AISC 360-16) and continuous torsional bracing (A-6-13 of AISC 360-16)
  - Special bracing at plastic hinge locations (D1-6)
- Stability bracings of column
  - Required strength of column bracing at panel type bracing (A-6-1 of AISC 360-16) and point lateral bracing (A-6-3 of AISC 360-16)
  - Required stiffness of column bracing at panel type bracing and point lateral bracing (A-6-2 of AISC 360-16)
- Stability bracing of beam-column
  - Required strength of lateral beam bracing at panel type flange lateral bracing and point type flange lateral bracing (A-6-4 of AISC 360-16)
  - Combination of lateral and torsional bracing

Output

The output for the AISC 341-05/10/16 checks follow the checks for AISC 360-05/10/16 for a member. No seismic provision checks are printed for `TRACK 0` output. For `TRACK 1` output, the seismic classification and the requirements are given. `TRACK 2` adds the details of the classification limits.

Track 1 example for AISC 341-10:

D1.A.10 AISC 360-16 Design

The checking or selection of members is performed per the following sections of AISC 360-16 and AISC 341-16:

- Section Classification: Chapter B
- Tension Chapter D
- Compression: Chapter E
- Flexure: Chapter F
- Shear: Chapter G
- Torsion (Including checks as per DG-9 for certain profile shapes – see below): Chapter H & Design Guide 9 for Torsion design
- Combined actions – Chapter H for:
  - Axial and/or
  - Flexure and/or
  - Shear and/or
  - Torsion
- Checks for Seismic suitability – AISC 341-16

The following section profile shapes are allowed for design:

- Rolled Shapes
  - I-Shape
  - Channel
  - Single angle
  - Solid Circular bar
  - Solid Rectangular bar
  - Tee
  - HSS rectangular
  - HSS round

- Built Up Shapes
  - Built Up Channel
  - Built Up I
  - Double Channels – back to back
  - Double Channels – face to face
  - Double Angles
  - Built Up Box
  - I With Cover Plates (Top and/or bottom)
- Tapered Shapes
  - I with web tapered
  - Square hollow shape with wall tapered
  - Circular hollow shape diameter tapered

Note: Certain checks (e.g., DG-9 torsion checks) will only be performed for certain profile shapes (non-HSS shapes).

Seismic Design per AISC 341-16

Refer to Provisions Checked for AISC 341-16 (on page 1113) for additional details.

D1.A.10.1 Tension

Design of the members subject to axial tension is performed per chapter D of AISC 360-16.

All the cross-section profiles described in section 1A.10 are considered for tension checks.

Eye bars and pin-connected members are *not* checked per clauses D5 and D6.

Limit States

The tensile strength is calculated with due consideration to both tensile yielding and tensile rupture effects as per D.2 of the code.

The F_y and F_u values would be chosen based on the grade of steel associated with the member, specified by `SGR` parameter. Note that the implementation also provides a means to create custom steel grades. If `SGR` is set to `0` ("custom steel"), then the values assigned for `FYLD` and `FU` is used respectively.

Slenderness Limits

The code does not mandate the maximum slenderness limit for members in tension. However, the program will check against a maximum slenderness ratio (L/r) which is specified using `TMAIN` parameter. The length considered to calculate the tension slenderness will be the full member length.

Effective Net Area

The gross area, A_g , and net area, A_n , of tension members shall be determined in accordance with the provisions of Section B4.3 of AISC 360-16.

The effective net area is the net area multiplied by the parameter `SLF` (shear lag factor).

The net area is the gross area multiplied by the parameter `NSF` (net section factor).

D1.A.10.2 Compression

Design of the members subject to compression is performed per chapter E of AISC 360-16.

All the cross-section profiles described in section 1A.10 are considered for compression.

The design compressive strength is calculated based on the applicable limit states of flexural buckling, torsional buckling, and flexural-torsional buckling modes as per Cl.E.1.

The nominal compressive strength, P_n , shall be the lowest value obtained based on the applicable limit states of flexural buckling, torsional buckling, and flexural-torsional buckling. In general, Table.E1.1 is followed for the choice of applicable sections/clauses for the various cross section shapes.

Limit States

Following limit states are checked for flexure per Equations E3-1, E3-2, and E3-3 for without slender elements:

- Flexural buckling about X axis
- Flexural buckling about Y axis
- Flexural buckling about U axis (for unsymmetrical shapes only)
- Flexural buckling about V axis (for unsymmetrical shapes only)
- Flexural-torsional buckling

Flexural-torsional buckling is checked per Equations E4-1, E4-2, and E4-3, E4-4, E4-7. Note the following:

- Check no performed for solid rect or circ bars, thin-walled rect or circ hollow sections, double-channel face-to-face (only when channels are connected by full weld or tension bolts), or single angles with compact long legs.

The gross area is used for members with non-slender elements whereas the effective area, Ae, is used for slender elements. The effective width of a slender element of any section other than round HSS is calculated for each limit state of compression as per eq. E7-2 or eq. E7-3 depending on the condition mentioned in the specification. The effective area (A_e) for a slender HSS round section is calculated as per cl. E7.2.

Parameters

The design parameters that affect compression are:

- `LEG`
- `LZ`
- `LY`
- `LX`
- `KZ`
- `KY`
- `KZ`
- `SNU`
- `CSP`

Slenderness Limits

The code does not mandate the maximum slenderness limit for members in compression. However, the program will check against a maximum slenderness ratio (L/r) which is specified using `MAIN` parameter whose default value is 180. The length considered to calculate the compression slenderness will be the full member length.

D1.A.10.3 Flexure

Design strength in flexure is calculated as per clause F1. The

Limit States

The nominal flexural strength is calculated for different limit states as per sections F2 through F13.

The following limit states are checked for flexure:

- Flexural Yielding about X and Y axis
- Flexural Yielding about U and V axis (for single angle only)
- Lateral-torsional Buckling about X and Y axis
- Lateral-torsional Buckling about U axis (for single angle only)
- Flange Local Buckling
- Web Local Buckling
- Wall Local Buckling (for HSS Round only)
- Compression Flange Yielding
- Tension Flange Yielding

Parameters

The design parameters that affect flexure are:

- `UNT`
- `UNB`
- `UNL`
- `UNR`
- `FLX`
- `SNU`
- `CB`

D1.A.10.4 Shear

Design of the members subject to shear is performed per chapter G of AISC 360-16.

All the cross-section profiles described in section 1A.10 are considered for shear.

An option to consider tension field action is available. Also, the option to consider the shear capacity of I sections or channel shapes with transverse web stiffeners.

The program does not consider any specific checks for web openings in clause G7.

The design of transverse web stiffeners is not performed.

Limit States

The design shear strength is calculated per G1.

The nominal shear strength is calculated for the following sections:

- I-Shapes and Channels G2
- Single Angles and Tees G3
- Rect HSS, Box Sections, and other Doubly Symmetric Members G4
- Round HSS G5
- Shear capacity along weak axis in Doubly Symmetric and Singly Symmetric Shapes G6

D1.A.10.5 Combined Forces and Torsion

The effects of combined actions of axial force with major and minor axis moments are accounted for the following:

Doubly and Singly symmetric members subject to flexure and compression - H1.1

- Rolled I
- Rolled Channel
- Solid circular bar
- Solid rectangular bar
- Tee
- HSS Rectangle
- HSS Round
- Built Up Channel
- Built Up I
- Double Channels – back to back
- Double Angles
- Built Up Box
- I Profile With Cover Plates (Top and/or bottom)

Doubly and Singly symmetric members subject to flexure and tension - H1.2

- Rolled I
- Rolled Channel
- Solid circular bar
- Solid rectangular bar
- Tee
- HSS Rectangle
- HSS Round
- Built Up Channel
- Built Up I
- Double Channels – back to back
- Double Angles
- Built Up Box
- I Profile With Cover Plates (Top and/or bottom)

Doubly symmetric rolled compact members subject to single axis flexure and compression – H1.3

If you prefer to use only cl. H1.1 even when cl. H1.3 is applicable, this may be done with the `INT` parameter.

Unsymmetrical and other members subject to Flexure and Axial Force - H2

This section is used to check single angles.

Members Subject to Torsion and combined Torsion, Flexure, Shear, and Axial Force - H3

Checks for members subject to pure torsion or subject to torsion combined with other effects such as flexure or axial loads will be performed based on the profile shape of the member. Only the following section profiles are considered when performing torsion checks:

- Closed profiles
    - HSS Rectangle

- HSS Round
- Solid Circular bar
- Solid Rectangular bar
- Open profiles
  - Rolled I
  - Rolled Channel
  - Tee
  - Single angle
  - Built-up I
  - Built-up Channel (Only if symmetric about X-X)
  - I Profile With Cover Plates (Top and/or bottom)

The implementation will perform the AISC 360-16 code checks as per clauses H.3.1 and H.3.2 for circular & rectangular hollow shapes. For all other shapes listed above, the component will follow the design methods as per AISC *Design Guide -9: Torsional Analysis of Structural Steel Members* (DG-9).

For non-HSS members subject to torsion and combined stress, the program cannot detect the load-end restraint condition automatically from the model. You can specify this through TND parameter. Also, for some cases the distance where the torque is applied must be provided through the ALH parameter.

D1.A.10.6 Updates to AISC 360-16

This section highlights the changes implemented from AISC 360-16 from AISC 360-10.

Section Classification

The width to thickness ratio limits for members in flexure have been updated for the following element types as per AISC 360-16:

- Stems of tees (14) are considered slender when $d / t > 1.52\sqrt{\frac{E}{F_y}}$
- Flanges of box sections (21) are considered slender when $b / t > 1.49\sqrt{\frac{E}{F_y}}$

CHAPTER E Compression Checks: Torsional & Flexural-Torsional Buckling Calculations

Design for the following profile shapes/conditions have been updated to use the corresponding clauses/ equations from AISC 360-16:

<u>2.a Cl. E4: Non-Slender Double Angles & Tee Shapes</u>

- Calculation of Fez and Fey to use (E4-9) and (E4-8).
- Calculation of Fe to use (E4-3).
- Calculation of Fcr to use (E3-2) or (E3-3).
- Calculation of Pn to use (E4-1).

<u>2.b Cl. E5: Single-Angle Compression Members</u>

- ·Flexural torsional buckling limit for single angles changed to $b / t \leq 0.71\sqrt{\frac{E}{F_y}}$.

2.c Cl. E7: Compression Members with Slender Elements

- Calculation of nominal compressive strength and critical stress F_{cr} updated to follow the updated criteria from Clause E7.

CHAPTER F Flexure Checks

Design for Flexural members has been updated to use the following:
3.a Cl.F4 : Non-Standard(other) I Shaped Members

Lateral Torsional Buckling:

The calculation of effective radius of gyration, r_t , updated to use the AISC 360-16 equation F4-11 for I-shapes with a rectangular compression flange:

$$r_t = \frac{b_{fc}}{\sqrt{12\left(1 + \frac{1}{6}a_w\right)}} \tag{F4-11}$$

3.b Cl.4 : Tension Flange Yielding

The tension flange yielding checks have been updated to use the updated web plastification factor calculations as per equations F4-16a to F4-17.

1. When $I_{yc}/I_y > 0.23$
   i. When $\frac{h_c}{t_w} \le \lambda_{pw}$

   $$R_{pt} = \frac{M_p}{M_{yt}} \tag{F4-16a}$$

   ii. When $\frac{h_c}{t_w} > \lambda_{pw}$

   $$R_{pt} = \left[\frac{M_p}{M_{yt}} - \left(\frac{M_p}{M_{yt}} - 1\right)\left(\frac{\lambda - \lambda_{pw}}{\lambda_{rw} - \lambda_{pw}}\right)\right] \le \frac{M_p}{M_{yt}} \tag{F4-16b}$$

2. When $I_{yc}/I_y \le 0.23$

   $$R_{pt} = 1.0 \tag{F4-17}$$

3.c Cl.F7 : Flexural checks for Square and Rectangular HSS & Box Sections

- Cl.F7.2: Flange local buckling checks updated to use F7-4 & F7-5 of AISC 360-16 to calculate the effective width of slender elements.
  - For HSS

  $$b_e = 1.92t_f\sqrt{\frac{E}{F_y}}\left(1 - \frac{0.38}{b/t_f}\sqrt{\frac{E}{F_y}}\right) \le b \tag{F7-4}$$

  - For box sections

  $$b_e = 1.92t_f\sqrt{\frac{E}{F_y}}\left(1 - \frac{0.34}{b/t_f}\sqrt{\frac{E}{F_y}}\right) \le b \tag{F7-5}$$

- Cl.F7.3: Web local buckling checks updated to use F7-6 through to F7-9 of AISC 360-16.
  - For sections with noncompact webs

$$M_n = M_p - (M_p - F_y S)\left(0.305\frac{h}{t_w}\sqrt{\frac{F_y}{E}} - 0.738\right) \le M_p \quad \text{(F7-6)}$$

where

h = depth of web, as defined in Section B4.1b, in. (mm)

- For sections with slender webs
  - compression flange yielding

    $$M_n = R_{pg} F_y S \quad \text{(F7-7)}$$

  - compression flange local buckling

    $$M_n = R_{pg} F_{cr} S_{xc} \quad \text{(F7-8)}$$

    and

    $$F_{cr} = \frac{0.9 E k_c}{\left(\frac{b}{t_f}\right)^2} \quad \text{(F7-9)}$$

    where

    R_{pg} = defined by Equation F5-6 with $a_w = 2ht_w/(bt_f)$
    k_c = 4.0
- Cl.F7.4: Lateral torsional buckling checks updated to use F7-6 through to F7-13 of AISC 360-16.

<u>3.d Cl.F9 : Flexural checks for Tees and Double Angles</u>

- Yielding checks for Tee sections updated to use Eqn F9-4 of AISC 360-16.
- Yielding checks for Double Angle sections updated to use Eqn F9-5 of AISC 360-16.

  $$M_p = 1.5 M_y \quad \text{(F9-5)}$$
- Lateral torsional buckling checks updated to use Eqns F9-6 through to F9-13 of AISC 360-16
- Flange Local Buckling calculations of Tees and double angle legs updated to include criteria as per CL. F9.3 (b) of AISC 360-16
- Web local buckling checks for Stem of Tee sections updated to use Cl F9.4 - Eqns F9-17 through to F9-19 of AISC 360-16.
- Web local buckling checks for legs of double angle sections updated to use Cl F9.4 (b) of AISC 360-16.

<u>3.e Cl.F10 : Flexural checks for Single Angles</u>

- Lateral Torsional Buckling checks updated to use Eqns F10-4 through to F10-5b of AISC 360-16.

CHAPTER G Shear Checks

4.a Cl.G2: I Shapes and Channels

- Calculation of Shear strength coefficient Cv updated to use Eqns G2-2 to G2-4 of AISC 360-16
- Calculation of Shear buckling coefficient kv updated to use Eqns from section G2 of AISC 360-16.
- Criteria for consideration of Tension field action updated as per Section G2.2 of AISC 360-16.
- Shear strength calculations for cases with tension field action updated to use Eqns G2-6 through to G2-11 of AISC 360-16

D1.A.10.7 Output

Preceding the member output will be a series of design statements regarding axis conventions, nomenclature, notes, and abbreviations.

TRACK 0 Output

This format reports the design summary for a member indicating the pass/fail status, the critical design ratio, the most critical load case ID, and the code clause that produced the critical design ratio.

TRACK 2 Output

This format expands on the `TRACK 1` format and will provide the final capacities along with the primary intermediate values that were considered during the design for each effect considered. This will also provide the section properties and design criteria that were used for the design process.

D1.B. American Codes - Steel Design per AISC 9th Edition

D1.B.1 Working Stress Design

D1.B.1.1 Allowables per AISC Code

For steel design, STAAD compares the actual stresses with the allowable stresses as defined by the American Institute of Steel Construction (AISC) Code. The ninth edition of the AISC Code, as published in 1989, is used as the basis of this design (except for tension stress). Because of the size and complexity of the AISC codes, it would not be practical to describe every aspect of the steel design in this manual. Instead, a brief description of some of the major allowable stresses are described herein.

D1.B.1.1.1 Tension Stress

Allowable tensile stress on the net section is calculated as;

$$F_t = 0.60\ F_y$$

D1.B.1.1.2 Shear Stress

Allowable shear stress on the gross section,

$$F_v = 0.4\ F_y$$

D1.B.1.1.3 Stress Due To Compression

Allowable compressive stress on the gross section of axially loaded compression members is calculated based on the formula E-1 in the AISC Code, when the largest effective slenderness ratio (Kl/r) is less than C_c . If Kl/r exceeds C_c , allowable compressive stress is decreased as per formula 1E2-2 of the Code.

$$C_c = \sqrt{\frac{2\pi^2 E}{F_y}}$$

D1.B.1.1.4 Bending Stress

Allowable bending stress for tension and compression for a symmetrical member loaded in the plane of its minor axis, as given in Section 1.5.1.4 is:

$$F_b = 0.66F_y$$

If meeting the requirements of this section of:

a. $b_f/2t_f \le 65/\surd(F_y)$
b. $b_f/t_f \le 190/\surd(F_y)$
c. $d/t \le 640(1 - 3.74\ (f_a/F_y))/\surd(F_y)$ when $(f_a/F_y) < 0.16$, or than $257/\surd(F_y)$ if $(f_a/F_y) > 0.16$
d. The laterally unsupported length shall not exceed $76.0\ b_f/F_y$ (except for pipes or tubes), nor $20{,}000/(d\ F_y/A_f)$
e. The diameter:thickness ratio of pipes shall not exceed $3{,}300/\surd(F_y)$

If for these symmetrical members, $b_f/2t_f$ exceeds $65/\surd(F_y)$, but is less than $95/\surd(F_y)$, $F_b = F_v(0.79 - 0.002(b_f/2t_f)\surd(F_y)$

For other symmetrical members which do not meet the above, Fb is calculated as the larger value computed as per AISC formulas F1-6 or F1-7 and F1-8 as applicable, but not more than 0.60Fy. An unstiffened member subject to axial compression or compression due to bending is considered fully effective when the width-thickness ratio is not greater than the following:

- $76.0/\surd(F_y)$, for single angles or double angles with separators
- $95.0/\surd(F_y)$, for double angles in contact
- $127.0/\surd(F_y)$, for stems of tees

When the actual width-thickness ratio exceeds these values, the allowable stress is governed by B5 of the AISC code.

Tension and compression for the double symmetric (I & H) sections with $b_f/2t_f$ less than $65/\surd(F_y)$ and bent about their minor axis, $F_b = 0.75\ F_y$. If $b_f/2t_f$ exceeds $65/\surd(F_y)$, but is less than $95/\surd(F_y)$, $F_b = F_y(1.075 - 0.005(b_f/2t_f)\surd(F_y)$.

For tubes, meeting the subparagraphs b and c of this Section, bent about the minor axis, $F_b = 0.66F_y$; failing the subparagraphs B and C but with a width:thickness ration less than $238/\surd(F_y)$, $F_b = 0.6F_y$.

D1.B.1.1.5 Combined Compression and Bending

Members subjected to both axial compression and bending stresses are proportioned to satisfy AISC formula H1-1 and H1-2 when fa/Fa is greater than 0.15, otherwise formula H1-3 is used. It should be noted that during code checking or member selection, if fa/Fa exceeds unity, the program does not compute the second and third part of the formula H1-1, because this would result in a misleadingly liberal ratio. The value of the coefficient Cm is taken as 0.85 for sidesway and $0.6 - 0.4\ (M1/M2)$, but not less than 0.4 for no sidesway.

D1.B.1.1.6 Singly Symmetric Sections

For double angles and Tees which have only one axis of symmetry, the KL/r ratio about the local Y-Y axis is determined using the clauses specified on page 3-53 of the AISC ASD 9th ed. Manual.

D1.B.1.1.7 Torsion per Publication T114

The AISC 89 code of specifications for steel design currently does not have any provisions specifically meant for design of sections for Torsion. However, AISC has published a separate document called *Torsional Analysis of Steel Members* which provides guidelines on transforming torsional moments into normal stresses and shear stresses which can then be incorporated into the interaction equations explained in Chapter H of the AISC 89 code. The guidelines of the publication have now been incorporated into the AISC-89 steel design modules of STAAD.

To consider stresses due to torsion in the code checking or member selection procedure, specify the parameter `TORSION` with a value of 1.0. See D1.B.1.2 Design Parameters (on page 1134) for more details.

Methodology

If the user were to request design for torsion, the torsional properties required for calculating the warping normal stresses, warping shear stresses and pure shear stresses are first determined. These depend of the "boundary" conditions that prevail at the ends of the member. These boundary conditions are defined as "Free", "Pinned" or "Fixed". They are explained below:

Free represents the boundary condition such as that which exists at the free end of a cantilever beam. It means that there is no other member connected to the beam at that point.

Pinned represents the condition that corresponds to either a pinned support defined at the joint through the Support command or a release of any of the moments at the joint through a Member Release Specification.

Fixed represents the condition where a fixed support exists at the joint. In the absence of a support at that joint, it represents a condition where a rigid frame connection exists between the given member and at least one other member connected to that joint. Also, no member releases should be present at that joint on the given member.

After the boundary conditions are determined, the normal and shear stresses are determined. The guidelines specified in the publication T114 for concentrated torsional moments acting at the ends of the member are used to determine these stresses.

The warping normal stresses are added to the axial stresses caused by axial load. These are then substituted into the interaction equations in Chapter H of the AISC 89 code for determining the ratio. The plane shear and warping shear stresses are added to the shear stresses causes by actual shear forces and compared against the allowable shear stresses on the cross section.

Torsional boundary conditions at a joint where a FIXED BUT type of support is specified

If the end of a the member is declared a `FIXED BUT` type of support, the torsional boundary conditions at that end are determined in the following manner.

If the member framing into that support does not have any "member releases" specified at that node, then,

a. If all of the 3 translational degrees of freedom at that support are either free to displace, or have a spring, then, that end of the member is considered torsionally `FREE`.

Example:

```
45 FIXED BUT MX MY MZ KFX 75 KFY 115
```

In this example, at joint 45, a spring has been specified along KFX and KFY, and, no restraint is provided for translation along global Z. So, the member which has joint 45 as one of its nodes is considered torsionally free at joint 45.

b. If any of the 3 translational degrees of freedom at that support are restrained, and, any of the moment degrees of freedom are unrestrained or have a spring, then, that end of the member is considered torsionally PINNED.

Examples:

```
78 FIXED BUT FX MZ
```

In this example, joint 78 is prevented from translation along global Y and Z, and free to rotate about global Z. So, the member which has joint 78 as one of its nodes is considered torsionally PINNED at joint 78.

```
17 FIXED BUT MX MY
```

In this example, joint 17 is prevented from translation along global X, Y and Z, and free to rotate about global X and Y. So, the member which has joint 17 as one of its nodes is considered torsionally PINNED at joint 17.

```
85 FIXED BUT FZ MZ KFY 1.0E8 KMX 1.6E6
```

In this example, the joint is prevented from translation along global X, has a rotational spring for resisting moments about global X and is free to rotate about global Z. So, the member which has joint 85 as one of its nodes is considered torsionally PINNED at joint 85.

Restrictions

This facility is currently available for Wide Flange shapes (W, M & S), Channels, Tee shapes, Pipes and Tubes. It is not available for Single Angles, Double Angles, members with the `PRISMATIC` property specification, Composite sections (Wide Flanges with concrete slabs or plates on top), or Double Channels. Also, the stresses are calculated based on the rules for concentrated torsional moments acting at the ends of the member.

D1.B.1.1.8 Design of Web Tapered Sections

Appendix F of AISC-89 provides specifications for design of Web-Tapered members. These specifications have been incorporated into STAAD to perform code checking on web tapered wide flange shapes. Please note that member selection cannot be performed on web-tapered members.
D1.B.1.1.9 Slender Compression Elements
For cross sections with elements which fall in the category of slender as per Table B5.1 of the AISC ASD code (the others being compact and non-compact), the rules of Appendix B of the code have been implemented. For stiffened compression elements, the effective cross section properties are calculated and used. For unstiffened compression elements, the allowable stresses are reduced per the Appendix.

D1.B.1.2 Design Parameters

The program contains a large number of parameter names which are needed to perform designing and code checking. These parameter names, with their default values, are listed in the following table. These parameters communicate design decisions from the engineer to the program.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements of an analysis, some or all of these parameter values may have to be changed to exactly model the physical structure. For example, by default the `KZ` (k value in local z-axis) value of a member is set to 1.0, while in the real structure it may be 1.5. In that case, the KZ value in the program can be changed to 1.5, as shown in the input instructions. Similarly, the `TRACK` value of a member is set to 0.0, which means no allowable stresses of the member will be printed. If the allowable stresses are to be printed, the `TRACK` value must be set to 1.0.

The parameters `PROFILE`, `DMAX`, and `DMIN` are only used for member selection.

Table 79: AISC (9th Ed.) Design Parameters

Parameter Name	Default Value	Description
AXIS	1	Select axis about which single angles are design 1) Design single angles for bending about their principle axis. 2) Design single angles for bending about their geometric axis.
BEAM	1.0	Used to specify the number of sections at which the member design is evaluated. 0.0 = design at start and end nodes and those locations specified by the `SECTION` command. 1.0 = design at 13 evenly spaced points (i.e., 1/12th points) along member length, including start and end nodes. **Note:** See D1.A.6 Design Parameters (on page 1100).
BMAX	83.3333 ft	Maximum allowable width of the flange. Used in the design of tapered sections.

Parameter Name	Default Value	Description
CAN	0	Specifies the method used for deflection checks 0) deflection check based on the principle that maximum deflection occurs within the span between DJ1 and DJ2. 1) deflection check based on the principle that maximum deflection is of the cantilever type (see note 1)
CB	1.0	Cb value as used in Section 1.5 of AISC. Use 0.0 to direct the program to calculated Cb. Any other value be used in lieu of the program calculated value.
CDIA	0.0	The diameter of circular openings. If a member has more than one circular opening, they can have different diameters.
CHOLE	NONE	Section locations of circular openings along the length of the member. Maximum three locations can be specified for each member when there is no rectangular opening.
CMP	0	Composite action with connectors 0) design as non-composite beam 1) design as a composite beam if the slab is in bending compression throughout the span, design as a non-composite beam if the slab is in tension anywhere along the span 2) design as a composite beam only. Ignore moments which cause tension in the slab.
CMZ	0.85 for sidesway and calculated for no sidesway	Cm value in local y and z axes, respectively.
CYC	500,000	Cycles of maximum stress to which the shear connectors are subject.
DFF	none (mandatory for deflection check)	"Deflection Length" / Maximum allowable local deflection
DIA	0.625 in.	Diameter of the shear connectors
DINC	1 in	Incremental depth value used in the design of tapered sections.
DJ1	Start Joint of member	Joint No. denoting starting point for calculation of "Deflection Length" (see note 1)
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length" (see note 1)

Parameter Name	Default Value	Description
DMAX	1000 in.	Maximum allowable section depth.
DMIN	0.0 in.	Minimum allowable section depth.
DR1	0.4	Ratio of moment due to dead load applied before concrete hardens to total moment.
DR2	0.4	Ratio of moment due to dead load applied after concrete hardens to total moment.
ELECTRODE	1	Weld material to be used for reinforced opening. 0) E60XX 1) E70XX 2) E80XX 3) E90XX 4) E100XX 5) E110XX
FBINC	0	Incremental bottom flange width used in the design of tapered sections. In this case, the top flange width will remain unchanged.
FLX	1	Single angle member bracing 1) Single angle member is *not* fully braced against lateral torsional buckling. 2) Single angle member is fully braced against lateral torsional buckling. 3) Single angle member is braced against lateral torsional buckling at the point of maximum moment.
FPC	3.0 ksi	Compressive strength of concrete at 28 days
FSS	1	Is the full section to be used for shear design? 0) No (False) 1) Yes (True)
FTBINC	0	Incremental flange width (top and bottom) used in the design of tapered sections.
FTINC	0	Incremental top flange width used in the design of tapered sections. In this case, the bottom flange width will remain unchanged.

Parameter Name	Default Value	Description
FU	Depends on FYLD	Ultimate tensile strength of steel in current units. If FYLD < 40 KSI, then FU = 58 KSI If 40 KSI ≤ FYLD ≤ 50 KSI, then FU = 60 KSI If FYLD > 50 KSI, then FU = 65 KSI
FYLD	36 KSI	Yield strength of steel in current units.
HECC	0.0	Eccentricity of opening with respect to the centerline of the member.
KX	1.0	K value used in computing KL/r for flexural torsional buckling for tees and double angles.
KY	1.0	Effective length factor to calculate slenderness ratio for buckling about local y-axis. Usually this is the minor axis.
KZ	1.0	Effective length factor to calculate slenderness ratio for buckling about local z-axis. Usually this is the major axis.
LX	Member Length	Length value used in computing KL/r for flexural torsional buckling for tees and double angles.
LY	Member Length	Length used to calculate slenderness ratio for buckling about the local y-axis.
LZ	Member Length	Same as LY, but in the local z-axis.
MAIN	0.0	Toggles the slenderness check 0.0) check for slenderness 1.0) suppress slenderness check Any value greater than 1 = Allowable KL/r in compression.
NSF	1.0	Net section factor for tension members.
OVR	1.0	Overstress factor. All the allowable stress are multiplied by this number. It may be assigned any value greater than 0.0. It is used to communicate increases in allowable stress for loads like wind and earthquake.
PLTHICK	0.0	Thickness of cover plate welded to the bottom flange of the composite beam.
PLWIDTH	0.0	Width of cover plate welded to the bottom flange of the composite beam.

Parameter Name	Default Value	Description
PROFILE		Used in member selection. Refer to TR.48.1 Parameter Specifications (on page 2676) for details.
RATIO	1.0	Permissible ratio of actual to allowable stress.
RDIM	0.0	Dimensions of rectangular openings (at each section, `RDIM` has a length term and a depth term – see syntax below). If a member has more than one rectangular opening they can have different dimensions.
RHOLE	None	Section locations of rectangular openings along the length of the member. Maximum three locations can be specified for each member when there is no circular opening.
RBHEIGHT	0.0	Height of ribs in the form steel deck.
RBWIDTH	2.5 in.	Width of ribs in the form steel deck.
SHE	0	Option for calculating actual shear stress. 0) Compute the shear stress using VO/Ib 1) Computer the shear stress based on the area of the section element.
SHR	0	Indicates use of temporary shoring during construction. 0) Without shoring 1) With shoring
SSY	0.0	Sidesway 0.0) Sidesway in local y-axis. 1.0) No sidesway
SSZ	0.0	Same as SSY, but in local z-axis.
STIFF	Member Length or depth of beam, whichever is greater	Spacing of stiffeners for plate girder design.
STP	1	Section type as defined in ASD Manual table. 1) Rolled 2) Welded

Parameter Name	Default Value	Description
TAPER	1.0	Design basis for tapered members 0.0) Design tapered I-section based on rules of Chapter F and Appendix B of AISC only. Due not use the rules in Appendix F of AISC-89. 1.0) Design tapered I-sections based on the rules of Appendix F of AISC-89.
THK	4.0 in.	Thickness of concrete slab or the thickness of concrete slab above the form steel deck.
TMAIN	300	Any value greater than 1 = Allowable KL/r in tension.
TORSION	0.0	Toggles the check for torsion 0.0) No torsion check is performed 1.0) Perform torsion check based on rules of AISC T114.
TRACK	0.0	Controls the level of detail to which results are reported: 0) minimum detail 1) intermediate detail 2) maximum detail (see Figure 2.1)
UNB	Member Length	Unsupported length of the bottom* flange for calculating allowable bending compressive stress. Will be used only if flexural compression is on the bottom flange
UNT	Member Length	Unsupported length of the top* flange for calculating allowable bending compressive stress. Will be used only if flexural compression is on the top flange.
WELD	1 for closed sections, 2 for open sections	Weld type as described in D1.B.1.10 Weld Design (on page 1145): 1) welding is on one side only except for wide-flange or tee sections, where the web is always assumed to be welded on both sides. 2) welding on both sides. For closed sections like a pipe or tube, the welding will be on one side only.
WIDTH	0.25 times the member length	Effective width of the concrete slab.
WMAX		Maximum welding thickness.
WMIN		Minimum welding thickness.

Parameter Name	Default Value	Description
WSTR	0.4 × FYLD	Allowable weld stress. Refer to D1.B.1.10 Weld Design (on page 1145) for how WELD, WMAX, WMIN, and WSTR parameters are used in weld design.

*Top and Bottom represent the positive and negative side of the local Y axis (local Z axis if `SET Z UP` is used).

Notes

1. When performing the deflection check, you can choose between two methods. The first method, defined by a value `0` for the `CAN` parameter, is based on the local displacement. See TR.44 Printing Section Displacements for Members (on page 2672) for details on local displacement.

   If the `CAN` parameter is set to 1, the check will be based on cantilever style deflection. Let (DX1, DY1,DZ1) represent the nodal displacements (in global axes) at the node defined by `DJ1` (or in the absence of `DJ1`, the start node of the member). Similarly, (DX2, DY2, DZ2) represent the deflection values at `DJ2` or the end node of the member.

   Compute Delta = $\sqrt{(DX2 - DX1)^2 + (DY2 - DY1)^2 + (DZ2 - DZ1)^2}$

   Compute Length = distance between `DJ1` and `DJ2` or, between start node and end node, as the case may be.

   Then, if `CAN` is specified a value 1, dff = L/Delta

   Ratio due to deflection = `DFF`/dff
2. If `CAN = 0`, deflection length is defined as the length that is used for calculation of local deflections within a member. It may be noted that for most cases the “Deflection Length” will be equal to the length of the member. However, in some situations, the “Deflection Length” may be different.

   For example, refer to the figure below where a beam has been modeled using four joints and three members. The “Deflection Length” for all three members will be equal to the total length of the beam in this case. The parameters `DJ1` and `DJ2` should be used to model this situation. Also the straight line joining `DJ1` and `DJ2` is used as the reference line from which local deflections are measured. Thus, for all three members here, `DJ1` should be "1" and `DJ2` should be "4".

   
   D is equal to the maximum local deflection for members 1, 2, and 3.

   ```
   PARAMETERS
   DFF 300. ALL
   DJ1 1 ALL
   DJ2 4 ALL
   ```
3. If `DJ1` and `DJ2` are not used, “Deflection Length” will default to the member length and local deflections will be measured from original member line.
4. It is important to note that unless a `DFF` value is specified, STAAD.Pro will not perform a deflection check. This is in accordance with the fact that there is no default value for `DFF`.

5. A critical difference exists between the parameters UNT/UNB and the parameters LY and LZ. Parameters UNT and UNB represent the laterally unsupported length of the compression flange. It is defined in Chapter F, page 5-47 of the specifications in the AISC 1989 ASD manual as the distance between cross sections braced against twist or lateral displacement of the compression flange. These parameters are used to calculate the allowable compressive stress (FCZ and FCY) for behavior as a beam. Parameters LY and LZ are the unbraced lengths for behavior as a column and are used to calculate the KL/r ratios and the allowable axial compressive stress FA.
6. Parameters SSY and CMY are based upon two values defined in page 5-55, Chapter H of the AISC 9th ed. manual. SSY is a variable which allows you to define whether or not the member is subject to sidesway in the local Y direction. CMY is a variable used for defining the expression called Cm in the AISC manual. When SSY is set to 0 (which is the default value), it means that the member is subject to sidesway in the local Y direction. When SSY is set to 1.0, it means that the member is not subject to sidesway in the local Y direction. The only effect that SSY has is that it causes the program to calculate the appropriate value of CMY. If SSY is set to 0 and CMY is not provided, STAAD.Pro will assume CMY as 0.85. If SSY is set to 1 and CMY is not provided, STAAD.Pro will calculate CMY from the equation on page 5-55. However, if you provide CMY, the program will use that value and not calculate CMY at all, regardless of what you defines SSY to be.

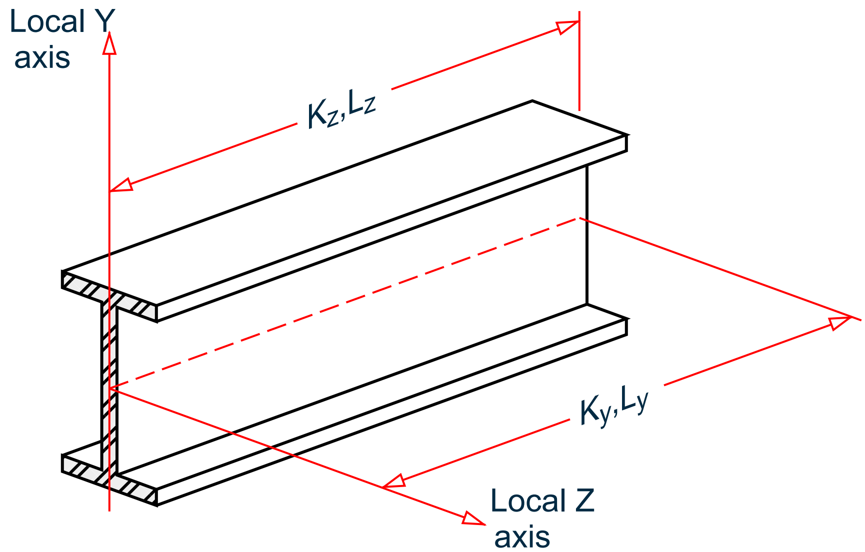

Figure 127: Terms used in calculating slenderness ratios KL/r for local Y and Z axes

7. For a T shape which is cut from a parent I, W, S, M or H shapes, the PROFILE parameter should be assigned a value corresponding to the parent shape. For example, if the T desired is an American WT6, specify W12 for the PROFILE parameter.

D1.B.1.3 Code Checking

The purpose of code checking is to check whether the provided section properties of the members are adequate. The adequacy is checked as per AISC-89. Code checking is done using the forces and moments at specified sections of the members. If no sections are specified, the program uses the start and end forces for code checking.

When code checking is selected, the program calculates and prints whether the members have passed the code or have failed; the critical condition of the AISC code (like any of the AISC specifications or compression, tension, shear, etc.); the value of the ratio of the critical condition (overstressed for a value more than 1.0 or any other specified RATIO value); the governing load case, and the location (distance from the start of the member) of forces in the member where the critical condition occurs.

Code checking can be done with any type of steel section listed in D1.A.4 Built-in Steel Section Library (on page 1088) of this manual.

- *TR.49 Code Checking Specification* (on page 2677)
- *TR.49.1 Member Selection Specification* (on page 2678)
- *TR.49.2 Member Selection by Optimization* (on page 2679)

D1.B.1.4 Member Selection

STAAD.Pro is capable of performing design operations on specified members. Once an analysis has been performed, the program can select the most economical section (i.e., the lightest section) which fulfills the code requirements for the specified member.

The section selected will be of the same type section as originally designated for the member being designed. A wide flange will be selected to replace a wide flange, etc. Several parameters are available to guide this selection. If the `PROFILE` parameter is provided, the search for the lightest section is restricted to that profile. Up to three (3) profiles may be provided for any member with a section being selected from each one. Member selection can also be constrained by the parameters `DMAX` and `DMIN` which limit the maximum and minimum depth of the members. If the `PROFILE` parameter is provided for specified members, `DMAX` or `DMIN` parameters will be ignored by the program in selecting these members.

Member selection can be performed with all the types of steel sections listed in D1.A.4 Built-in Steel Section Library (on page 1088). Note that for beams with cover plates, the sizes of the cover plate are kept constant while the beam section is iterated.

Selection of members, whose properties are originally input from a user created table, will be limited to sections in that table.

Member selection *cannot* be performed on members whose section properties are input as prismatic.

D1.B.1.4.1 Member Selection by Optimization

Steel table properties of an entire structure can be optimized by STAAD.Pro. This optimization method involves the following steps.

1. `CHECK CODE ALL`
2. Modify the ratios
3. `SELECT ALL`
4. `PERFORM ANALYSIS`
5. `SELECT ALL`

An additional step of grouping may be performed if the `FIXED GROUP` and `GROUP` commands are provided (See TR.50 Group Specification (on page 2680)). After the last step, a re-analysis is not automatically performed, so users must ensure that they specify the analysis command following the `SELECT OPTIMIZE` command.

D1.B.1.4.2 Deflection Check With Steel Design

This facility allows the user to consider deflection as a criteria in the `CODE CHECK` and `MEMBER SELECTION` processes. The deflection check may be controlled using the three parameters `DJ1`, `DJ2`, and `DFF` which are described in D1.B.1.2 Design Parameters (on page 1134). Deflection is used in addition to other strength and stability related criteria. The local deflection calculation is based on the latest analysis results.

Related Links

- *TR.49.1 Member Selection Specification* (on page 2678)

D1.B.1.5 Truss Members

As described in G.8.1 Truss and Tension- or Compression-Only Members (on page 2121), a truss member is capable of carrying only axial forces. So during the design phase, no calculation time (or, matrix bandwidth) is wasted determining the allowable bending or shear stresses. Therefore, if there is any truss member in an analysis (such as a bracing or a strut, etc.), it is advisable to declare it as a truss member rather than as a regular frame member with both ends pinned.

D1.B.1.6 Unsymmetric Sections

For unsymmetric sections like single angles, STAAD.Pro considers the smaller section modulus for calculating bending stresses.

For single angles, the "specification for allowable stress design of single-angle members," explained in pages 5-309 to 5-314 of the AISC-ASD 9th edition manual has been incorporated.

D1.B.1.7 Composite Beam Design as per AISC-ASD

In G.6.7 Composite Beams and Composite Decks (on page 2119) of this manual, two methods of specifying the properties of a beam as a composite section (I-shaped beam with concrete slab on top) are described. Those members can be designed as composite beams in accordance with the AISC ASD code provisions. If the properties are assigned using the explicit method as defined in Section 1.7.7, the design parameters must be separately assigned. The `CMP` parameter in particular must be set a value of `1` or `2`. If the properties are derived from the composite decks, the design parameters are automatically generated during the deck creation phase, and hence no separate parameters need to be assigned.

Other parameters used in the design of composite members are: `DIA`, `DR1`, `DR2`, `FPC`, `HGT`, `PLTHICK`, `PLWIDTH`, `RBHEIGHT`, `RBWWIDTH`, `SHR`, `THK`, and `WIDTH`. Refer to D1.B.1.2 Design Parameters (on page 1134) for details on design parameters.

Example

```
UNIT INCH
PARAMETER
CODE AISC
BEAM 1 ALL
TRACK 2 ALL
DR1 0.3135 ALL
WID 69.525 ALL
FPC 3.0 ALL
THK 4.0 ALL
CMP 1 ALL
CHECK CODE ALL
SELECT ALL
```

D1.B.1.8 Plate Girders

The requirements of Chapter G – pages 5-51 through 5-53 of the AISC ASD 9th edition manual – are not implemented. Therefore, if the web slenderness ratio h/t_w of a section exceeds $\frac{970}{\sqrt{F_y}}$, STAAD will *not* perform a design for that member.

D1.B.1.9 Tabulated Results of Steel Design

For code checking or member selection, the program produces the results in a tabulated fashion. The items in the output table are explained as follows:

a. `MEMBER` refers to the member number for which the design is performed.
b. `TABLE` refers to the AISC steel section name which has been checked against the steel code or has been selected.
c. `RESULT` prints whether the member has `PASS`ed or `FAIL`ed. If the `RESULT` is `FAIL`, there will be an asterisk (*) mark in front of the member number.
d. `CRITICAL COND` refers to the section of the AISC code which governed the design.
e. `RATIO` prints the ratio of the actual stresses to allowable stresses for the critical condition. Normally a value of 1.0 or less will mean the member has passed.
f. `LOADING` provides the load case number which governed the design.
g. `FX`, `MY`, and `MZ` provide the axial force, moment in local y-axis and moment in local z-axis respectively. Although STAAD does consider all the member forces and moments to perform design, only FX MY and MZ are printed since they are the ones which are of interest, in most cases.
h. `LOCATION` specifies the actual distance from the start of the member to the section where design forces govern.
i. If the parameter `TRACK` is set to 1.0, the program will block out part of the table and will print the allowable bending stresses in compression (FCY & FCZ) and tension (FTY & FTZ), allowable axial stress in compression (FA), and allowable shear stress (FV), all in kips per square inch. In addition, member length, area, section moduli, governing KL/r ratio and CB are also printed.
j. In the output for `TRACK 2.0`, the items Fey and Fez are as follows:

$$F_{ey} = 12\pi^2 E/[23\cdot(K_y L_y/r_y)^2$$

$$F_{ez} = 12\pi^2 E/[23\cdot(K_z L_z/r_z)^2$$

Example Output

D1.B.1.10 Weld Design

Selected provisions of the AISC specifications for the Design, Fabrication and Erection of Steel for Buildings, 1999, and the American Welding Society D1.1 Structural Welding Code – Steel, 1998, have been implemented.

STAAD.Pro is able to select weld thickness for connections and tabulate the various stresses. The weld design is limited to the members having properties from wide flange, tee, single angle, single channel, pipe and tube section tables only. The parameters `WELD`, `WMAX`, `WMIN`, and `WSTR` (as explained in D1.B.1.2 Design Parameters (on page 1134)) govern the weld design.

Since the thickness of a weld is very small in comparison to its length, the properties of the weld can be calculated as line member. Therefore, the cross-sectional area (AZ) of the weld will actually be the length of the weld. Similarly, the units for the section moduli (SY and SZ) will be length-squared and for the polar moments of inertia (JW) will be length-cubed. The following table shows the different available weld lines, their type and their coordinate axes.

Table 80: WELD Parameter Values

Weld Type	Angle	Wide Flange	Tee	Channel	Pipe	Tube
1						2					n/a	n/a

Actual stresses, calculated from the member forces, can be specified by three names, based on their directions.

Horizontal Stress as produced by the local z-shear force and torsional moment.

$$F_h = \frac{VZ}{AX} + \frac{CH \times MX}{JW}$$

where

VZ	=	Shear in local z-axis
MX	=	Torsional moment
CH	=	Distance of the extreme fiber for horizontal (local z) forces
AX	=	Area of the weld as the line member
JW	=	Polar moment of inertia

Vertical Stress as produced by the axial y-shear force and torsional moment.

$$F_v = \frac{VY}{AX} + \frac{CV \times MX}{JW}$$

where

VY	=	Shear in local y-axis
MX	=	Torsional moment
CY	=	Distance of the extreme fiber for vertical (local y) forces
AX	=	Area of the weld as the line member
JW	=	Polar moment of inertia

Direct Stress as produced by the axial force and bending moments in the local y and z directions.

$$F_d = \frac{FX}{AX} + \frac{|MZ|}{SZ} + \frac{|MY|}{SY}$$

where

FX	=	Axial force
MY	=	Bending in local y-axis
MZ	=	Bending in local z-axis
CH	=	Distance of the extreme fiber for horizontal (local z) forces
AX	=	Area of the weld as the line member

SY	=	= Section modulus around local y-axis
SZ	=	= Section modulus around local z-axis

Note: The moments MY and MZ are taken as absolute values, which may result in some conservative results for asymmetrical sections like angle, tee and channel.

Combined Stress calculated by the square root of the summation of the squares of the above three principal stresses.

$$F_{comb} = \sqrt{F_h^2 + F_v^2 + F_d^2}$$

The weld thickness required is then calculated by:

$$t_w = \frac{F_{comb}}{F_W}$$

where

F_W = Allowable weld stress, defined by the `WSTR` parameter.

The default value is $0.4 \times F_y$ (where F_y = `FYLD` parameter value).

The thickness, t_w, is rounded up to the nearest 1/16th of an inch and all the stresses are recalculated. The tabulated output prints the latter stresses. If the parameter `TRACK` is set to 1.0, the output will include the weld properties. The program does not calculate the minimum weld thickness as needed by some codes, but checks only against the minimum thickness as provided by the user (or 1/16th inch if not provided).

When the `TRUSS` qualifier is used with `SELECT WELD` command, the program will design the welds required for truss angle and double angle members that are attached to gusset plates. The program reports the number of welds (two for single angles, four for double angles), and the length required for each weld. The thickness of the weld is taken as 1/4 inch (6 mm) for members up to 1/4 inch (6 mm) thick, and 1/16 inch (1.5 mm) less than the angle thickness for members greater than 1/4 inch (6 mm) thick. The minimum weld length is taken as four times the weld thickness.

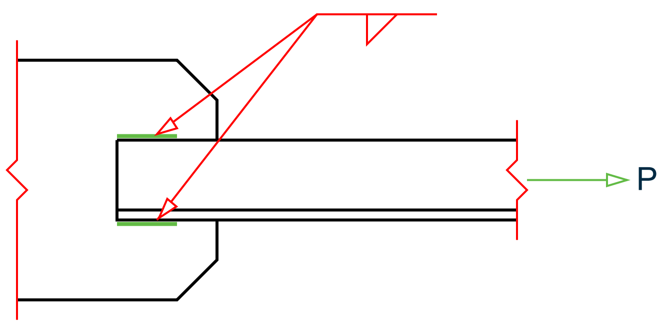

Figure 128: Weld design for `SELECT WELD TRUSS`

D1.B.2 Castellated Beams

STAAD.Pro comes with the non-composite castellated beam tables.

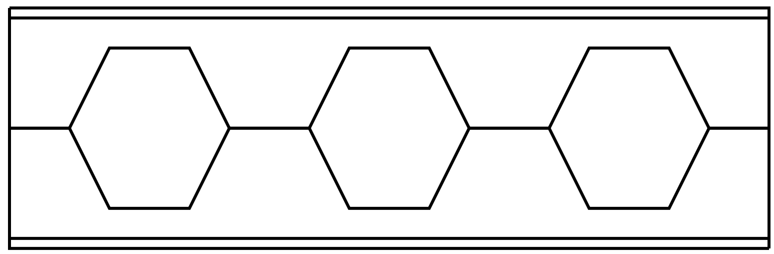

Figure 129: Castellated beam elevation

According to the manufacturer, castellated beams are manufactured by cutting a wide flange along the web in a "zig-zag" pattern, offsetting the two halves, and welding the two halves together, as shown in the next figure. As a result, the underlying steel section is a wide flange (W shapes) in the AISC table or a B shape. STAAD currently supports only the ones derived from W shapes.

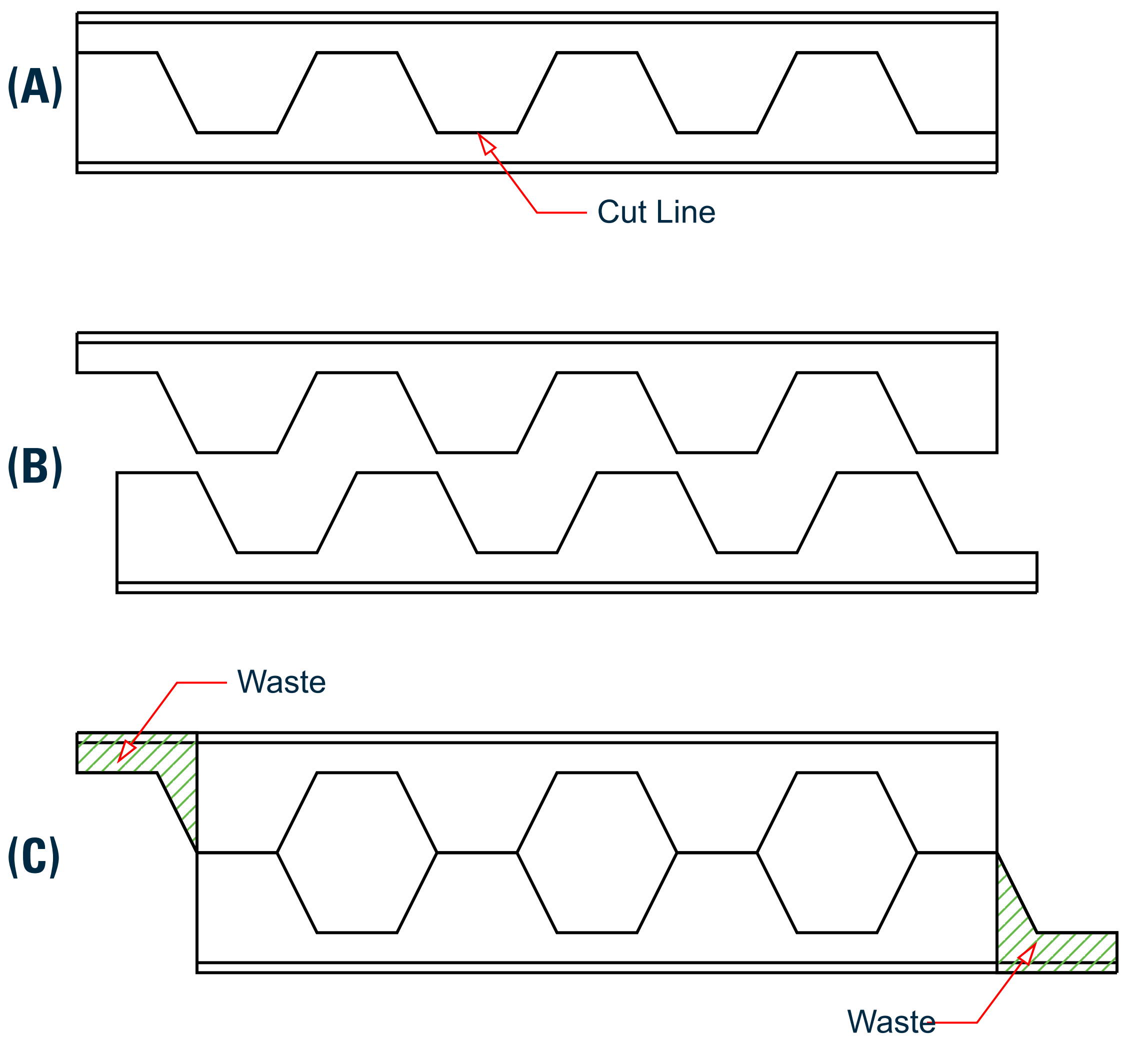

Figure 130: Manufacturing process for castellated beams: A) Cut hexagonal line, B) Stagger top and bottom sections, and C) discard waste at ends

D1.B.2.1 Analysis and Design Criteria

The local axis system (local X, local Y and local Z) of a castellated beam is identical to that for a wide flange, and is shown in G.4.2 Local Coordinate System (on page 2088).

It is important recognize that there are two basic issues to be understood with regard to these members a) analysis b) steel design

First, the design issues because only then will their relationship with the analysis issues become apparent. Design of a castellated beam is done only for FY (shear along the web) and MZ (moment about the major axis which is the Z axis). If at the start of the design process, the program detects that the beam has axial force (FX), shear along local-Z (FZ), torsion (MX) or moment about the minor axis (MY), design of that member will be terminated.

Next is how these design limitations have a bearing on the analysis issues. If you intend to design these members, as a result of the above restrictions, he/she must model it in such a way that none of the 4 unacceptable degrees of freedom end up with a non-zero value anywhere along the length of the member. That means, if the member ends are defined as supports, the support conditions must be defined with the above in mind. Similarly, if the castellated member is attached to other members, its end conditions (`MEMBER RELEASES`) must be modeled taking the above facts into consideration.

The design limitations also have a bearing on the type of loads that are applied to the member. Loads which cause any of the above-mentioned four degrees of freedom to end up with a non-zero value will cause the member design to be terminated.

However, if you wish to only analyze the structure, and are not interested in performing a steel design, the above described restrictions for supports, member end conditions or loading are not applicable.

The design method is the allowable stress method, using mainly the rules stated in the AISC ASD 9th edition code. Only code checking is currently available for castellated beams. Member selection is not.

Note: STAAD.Pro does not multiply the analysis moment by 1.7 for ASD method. It is up to you to multiply the dead and live loads by 1.7 in load combination and using this load case in design. The reason is that if program internally multiplies the analysis moment by 1.7 for ASD method (it is 1.2 for dead and 1.6 for live loads for LRFD method) then you must ensure that the analysis moment is the unfactored moment. If by mistake the 1.7 factor is used during load combination and the I-beam with web opening is designed with this load, the program will further increase the load by 1.7. Hence, it has been intentionally left to your engineering judgment to use whatever load factor you see fit before designing I-beam with opening with that factored load case.

D1.B.2.2 Design Parameters

The following table contains a list of parameters and their default values.

Table 81: American Castellated Beam Design Parameters

Parameter Name	Default Value	Description
CB	1.0	Cb value used for computing allowable bending stress per Chapter F of the AISC specifications.

Parameter Name	Default Value	Description
CMZ	0.85	Cm value in local z-axis. Used in the interaction equations in Chapter H of the AISC specifications.
EOPEN	1.5e + b	Distance from the ecenter of the last hole to the end of the member. 1.5e + b is the minimum allowable value. Any value greater than or equal to this minimum will be used by the program. See Figure 2.13 for the definition of e and b.
FYLD	36 ksi	Yield stress of steel.
RATIO	1.0	Permissible maximum ratio of actual load to section capacity. Any input value will be used to change the right hand side of the governing interaction equations in Chapter H and elsewhere in the AISC specifications.
SOPEN	1.5e + b	Distance from the start of the member to the center of the first hole. 1.5e + b is the minimum allowable value. Any value greater than or equal to this minimum will be used by the program. See Figure 2.13 for the definition of e and b.
TRACK	0	Used to control the level of description of design output. 0 = Detailed output suppressed 1 = Detail output included
UNL	Member Length	Unsupported length of compression flange for calculating allowable bending stress.

D1.B.2.3 Design Procedure

Cross-Section Checks

The first check that is carried out is a verification whether the member properties satisfy certain basic requirements. If the member fails these checks, the remainder of the checks are not performed.

The cross section checks are the following:

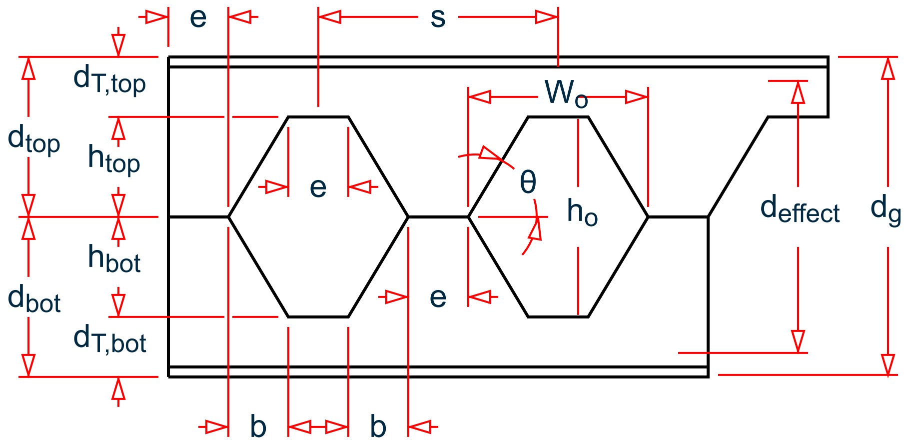

Figure 131: Castellated beam nomenclature

1. Web Post Width (e) should be at least 3.0 inches
2. Tee Depth (d_T-top and d_T-bot) should be greater than the thickness of flange plus one inch.
3. Angle θ should be between 45 and 70 degrees.
4. In order for the program to determine the number of holes which are admissible for the beam, the parameters SOPEN and EOPEN need to be assigned. In the figure above, there is a term shown as S. This value is part of the section tables supplied with STAAD.Pro, so it retrieves that value from there. It then computes the number of holes, and the remainder of the terms shown in the above diagram.
5. SOPEN and EOPEN (see the parameter table shown earlier) have to be at least 1.5e + b, with “e” and “b” as shown in the earlier figure. If you inputs a value less than these minima, the minimum values are used.

References

Design of castellated beams in STAAD.Pro is based on the information gathered from the following sources:

1. *Design of Welded Structures*, Omer W. Blodget, published by The James Lincoln Arc Welding Foundation, pages 4.7-8 and 4.7-9
2. AISC 9th edition manual – Allowable stress design
3. ASCE *Journal of Structural Engineering* 124:10, October 1998, “Castellated Beam Web Buckling in Shear,” R.G. Redwood and S. Demirdjian

Checking the member for adequacy in carrying the applied loading

This consists of five different checks:

1. Global Bending
2. Vierendeel Bending
3. Horizontal Shear
4. Vertical Shear
5. Web Post Buckling

Table 82: Cross section considered for limit states

Design For	Section Considered in the Design (shown with the vertical dotted lines)
Vierendeel Bending	Global Bending Vertical Shear Horizontal Shear Web Post Buckling	
1. Global Bending:

   Global bending check is done at the web post section. This is the region of the member where the full cross section is active, without interference of the holes.

   The actual bending stress is computed at the middle of the web post location and is obtained by dividing the moment by the section modulus of the full section.

   For computing the allowable bending stress, the compactness of the section is first determined in accordance with Table B5.1 in the Chapter B of the AISC 9th edition specifications. The rules applicable to I-shaped sections are used for this. Following this, the allowable bending stress is computed per chapter F of the same.

   The ratio is computed by dividing the actual stress by the allowable stress.
2. Vierendeel Bending:

   This is checked at the middle of the hole locations. The effective cross section at these locations is a Tee. The overall moment (Mz) at the span point corresponding to the middle of the hole is converted to an axial force and a moment on the Tee.

   The actual stress is computed at the top and bottom of each Tee section.

   $$f_a = M / (d_{effect} \times A_t)$$

   where

   A_t = area of the Tee section

   $$f_b = V \times e \times a / (2 \times S)$$

   where

α = the area factor. For the top Tee section, α = Area of Top Tee / (Area of Top Tee + Area of Bottom Tee)

Allowable Stresses for vierendeel bending:

- Axial Stress: The allowable axial stress is computed as per the Chapter E of the AISC specifications. The unsupported length for column buckling is equal to *e*.
- Bending Stress: The allowable bending stress is computed for the top and bottom Tee section as per the Chapter F of the AISC manual.

The axial stress plus bending stress is computed at the top and bottom of each tee section. If it is compressive then it is checked against equations H1-1 and H1-2 of Chapter H of the AISC manual. If it is tensile then it is checked against equation H2-1

3. Horizontal Shear

   Allowable Shear stress is computed as $0.4\ Fy$.

   Actual Stress: Please refer to pages 4.7-8 and 4.7-9 of reference #1.

4. Vertical Shear

   Allowable Shear stress is computed as $0.4\ Fy$.

   The actual shear stress is computed at the middle of the web post location.

5. Web Post buckling

   Refer to pages 1202-1207 of reference #3.

D1.B.2.4 General Format

The command syntax in the STAAD input file for assigning castellated beams is:

```
MEMBER PROPERTY AMERICAN
```

```
Member-list TABLE ST section-name
```

Example

```
MEMBER PROPERTY AMERICAN
2 TABLE ST CB12X28
```

Assigning Design parameters

Under the PARAMETERS block on input, the code name must be specified as:

```
CODE AISC CASTELLATED
```

Example

```
PARAMETER
CODE AISC CASTELLATED
UNL 0.01 MEMB 25 31
FYLD 50 MEMB 25 31
SOPEN 11.124 MEMB 25 31
…
CHECK CODE MEMB 25 31
```

D1.B.2.5 Steel Design Output

The following is a typical `TRACK 2` level output page from a STAAD output file.

```
                       STAAD.PRO CODE CHECKING - (AISC CASTELLATED)   v1.0

Viewing the design results in the GUI

1. After the analysis and design is completed, double click on the castellated member in the STAAD.Pro View window.
   The **Beam** dialog box.
2. Select the **Castellated Beam Design** tab.

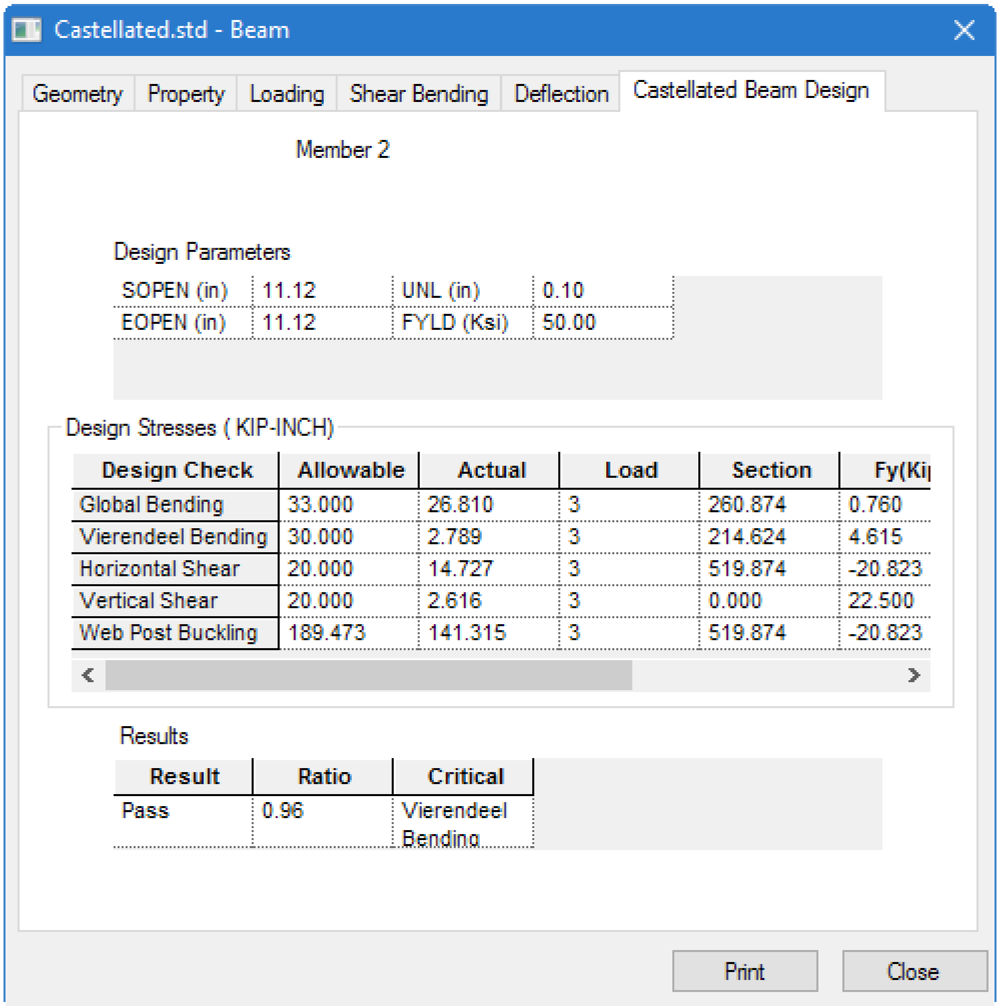

*Figure 132: **Beam** dialog box Castellated Beam Design tab*

3. (Optional) Click **Print** to create a hard copy of the Castellated Beam data for this beam.
4. Click **Close**.
   The dialog closes.

D1.B.2.6 Example

The following is an example STAAD Input for a portal frame with a castellated beam.

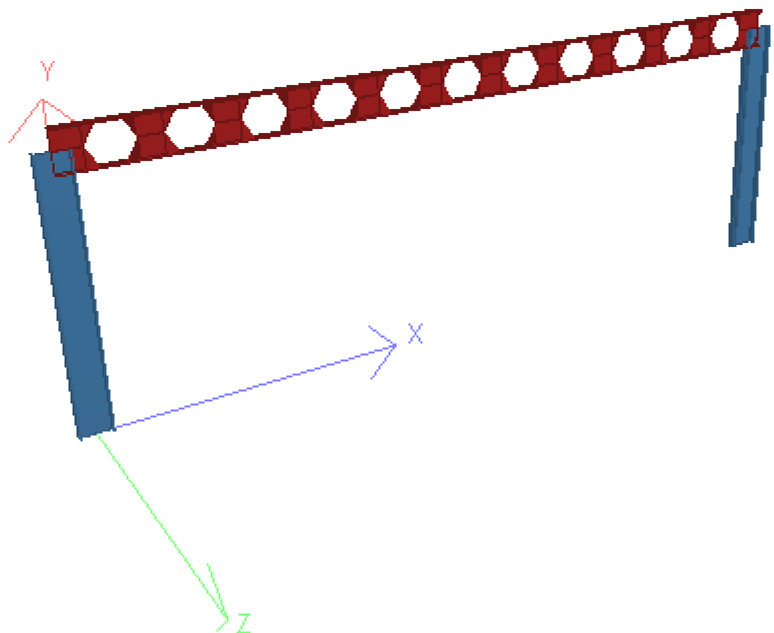

Figure 133: 3D Rendering of the example structure

Tip: You can copy the input code below and paste into the STAAD Editor or into a plain text editor program and save as an `.STD` file for use in STAAD.Pro.

D1.B.3 Design of Beams with Web Openings

Design of steel members with web openings per AISC Steel Design Guide 2 - ASD specifications may be performed in STAAD for members whose yield strength is 65 ksi or less.

Note: The web openings are given consideration only during the design phase. The reduction in section properties caused by the presence of the openings is not considered automatically during the analysis phase. Hence, the analysis is performed as if the full section properties are effective for such members.

During the design process, the program first determines the utilization ratio (U.R.) at the location of the opening as though it is an unreinforced opening. If the U.R. is less than 1.0, the member is presumed to have passed the requirements at that location. If the U.R. exceeds 1.0, then it determines the U.R. as though it is a reinforced opening. If it fails this too, the cause of the failure along with the associated numerical values is reported.

Related Links

- *V. AISC ASD - Design of Steel Beam with Web Opening* (on page 5747)
- *V. AISC ASD - Deflection Check for a Steel Beam with Web Opening* (on page 5754)

D1.B.3.1 Description

The following are the salient points of the design process.

A. Only a code check operation is permitted on members with web openings. The `MEMBER SELECTION` process will not be performed if a web opening is specified for the member.

B. The `CODE CHECK` operation is performed at the following locations along the member span:

   a. The 13 equally spaced points along the member span customary with the `BEAM 1` parameter

   or

   The section locations specified using the `SECTION` command, if the `BEAM` parameter is set to 0.0

   or

   The 2 member ends if `BEAM` parameter is set to 0, and the `SECTION` command is not specified.

   b. At the web openings locations defined using the `RHOLE` and `CHOLE` parameters (Refer to Table 2.18-1 below).

   If any of the locations defined under (a) above happen to coincide with those in (b), such locations are designed as places where openings are located, and not as an unperforated section location.

The utilization ratio (U.R.) is determined for all the locations in (a) above, as well as all the locations in (b) above. The highest value among these locations is deemed critical from the design standpoint.

The design output consists of the critical value obtained from checking the locations under (a), and each of the locations under (b).

The critical location among those in (b) is *not* displayed in the post-processing pages of the program such as the Beam-Unit Check page, or the Member Query-Steel Design tab.

Members declared as `TRUSS` (trusses) or `TENSION` (tension-only) are not designed for web openings.

D1.B.3.2 Design steps for Steel Beam with Web Opening

At the location of web holes, the capacity of the section is determined using the rules explained below.

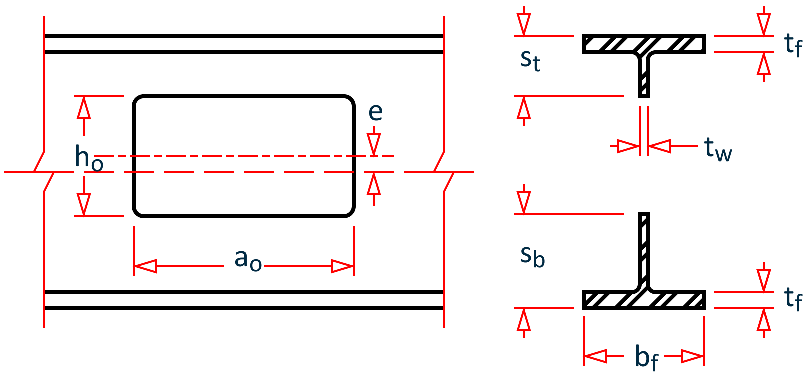

Figure 134: Opening configurations for steel beams with unreinforced opening

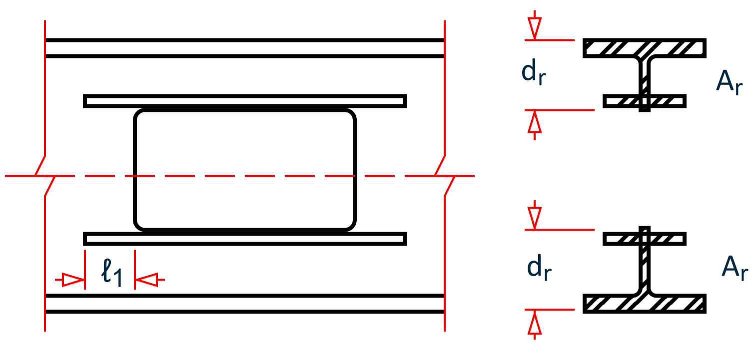

Figure 135: Opening configurations for steel beams with reinforced opening

Section Properties Required:

A_s = Cross-sectional area of steel in the unperforated member (at a section along the beam where there is no opening)
d = Depth of beam
t_w = Thickness of web
b_f = Width of flange
t_f = Thickness of flange
Z = Plastic section modulus of member without opening
J = Torsional constant of the beam

L = Length of the member
L_b = Unbraced length of compression flange

Opening Information Required:

e = Eccentricity of opening, specified using the HECC parameter (distanced from mid-depth of beam to mid-depth of the opening) = | e |
sign convention for eccentricity: upward eccentricity + e, downward eccentricity - e

Loading:

V_u = Factored shear at different opening locations
M_u = Factored bending moment at different opening locations

Calculated Parameters

Circular Opening Properties:

Unreinforced Opening Properties:

$h_o = D_o$ for bending
$h_o = 0.9\ D_o$ for shear
$a_o = 0.45\ D_o$

Reinforced Opening Properties:

$h_o = D_o$ for bending and shear
$a_o = 0.45\ D_o$

Tee Properties:

Refer to Figure 2.17(a), above

s_t = Depth of top tee = $d/2 - (h_o\ /\ 2 + e)$
s_b = Depth of bottom tee = $d/2 - (h_o\ /\ 2 - e)$

Reinforcement Properties:

A_r = Area of reinforcement on each side of the opening
t_r = Thickness of reinforcement bar
b_r = Width of reinforcement bar
D_r = Depth of reinforcement bar

D1.B.3.3 Calculation Steps

1. Check for local buckling of compression flange and reinforcement (if any)

   (AISC Design Guide 2 for Web Openings: section 3.7.a.1)

   Width to thickness ratio of compression flange, $F_1 = b_f / 2t_f$
   Width to thickness ratio of web reinforcement, $F_2 = b_r / t_r$
   Limiting width to thickness ratio, $B_1 = 65 / \sqrt{F_y}$
   F_1 and F_2 must not exceed B_1.
2. Check for web buckling

(AISC Design Guide 2 for Web Openings: section 3.7.a.2)

Width to thickness ratio of web, $W_1 = (d – 2t_f) / t_w$
W_1 must not exceed $520/\sqrt{F_y}$

3. Check for opening dimensions to prevent web buckling

(AISC Design Guide 2 for Web Openings: section 3.7.a.2 & section 3.7.b.1)

a. Limit on a_o / h_o as given below,

If W_1 is $\le 420/\sqrt{F_y}$ then web qualifies as stocky,

a_o / h_o must not exceed 3.0,

If W_1 is $> 420/\sqrt{F_y}$ but $\le 520/\sqrt{F_y}$ then

a_o / h_o must not exceed 2.2,

b. h_o / d must not exceed 0.7

c. The opening parameter, $p_o = (a_o / h_o) + (6 h_o / d)$ must not exceed 5.6

4. Check for tee dimensions

(AISC Design Guide 2 for Web Openings: section 3.7.b.1)

a. The maximum depth of the web opening is governed by the following rules:

Depth $s_t \ge 0.15d$, $s_b \ge 0.15d$

b. Aspect ratios of the tees ($v = a_0 / s$) should not be greater than 12

$a_0 / s_b \le 12$, $a_0 / s_t \le 12$

5. Check for buckling of tee-shaped compression zone

(AISC Design Guide 2 for Web Openings: section 3.7.a.3)

The tee, which is in compression, is investigated as an axially loaded column. For unreinforced members this is not done when the aspect ratio of the tee is less than or equal to four:

$$F_y t_w d/\sqrt{3} \le 4$$

For reinforced openings, this check is only done for large openings in regions of high moment.

6. Calculation for Maximum Moment Capacity, M_m

(AISC Design Guide 2 for Web Openings: section 3.5.a)

For unperforated section

$$M_p = F_y Z$$

$$\Delta A_s = h_o t_w - 2A_r$$

Unreinforced Opening:

$$M_m = M_p \left[1 - \frac{\Delta A_s \left(\frac{h_o}{4} + e \right)}{Z} \right]$$

Reinforced Opening:

a. If $t_w e < A_r$

$$M_m = M_p \left[1 - \frac{t_w \left(\frac{h_o^2}{4} + h_o e - e^2 \right) - A_r h_o}{Z} \right] \le M_p$$

b. If $t_w e \geq A_r$

$$M_m = M_p\left[1 - \frac{\Delta A_s\left(\frac{h_o}{4} + e - \frac{A_r}{2t_w}\right)}{Z}\right] \leq M_p$$

7. Calculation for Maximum Shear Capacity, V_m

(AISC Design Guide 2 for Web Openings: section 3.6.a)

V_{pb} and V_{pt} = Plastic shear capacity of the web of the tee

$$V_{pb} = F_y t_w s_b / \sqrt{3}$$

$$V_{pt} = F_y t_w s_t / \sqrt{3}$$

The values of aspect ratios ν_b and ν_t and factors μ_b and μ_t(which appear in the equations shown below) are different for reinforced and unreinforced openings.

Unreinforced Opening:

For the bottom tee, $\nu_b = a_o / s_b$ and $\mu_b = 0$
For the top tee, $\nu_t = a_o / s_t$ and $\mu_t = 0$

Reinforced Opening:

s_{t1} and s_{b1} are used to calculate for n reinforced opening.

$$s_{t1} = s_t - A_r / (2b_f)$$

$$s_{b1} = s_b - A_r / (2b_f)$$

P_r = Force in reinforcement along edge of opening = $F_y A_r \leq F_y t_w a_o / (2\sqrt{3})$
d_{rt} and d_{rb} = Distance from outside edge of flange to centroid of reinforcement.

$$d_{rt} = s_t - ½\, t_r$$

$$d_{rb} = s_b - ½\, t_r$$

For the bottom tee, $\nu_b = a_o / s_{b1}$ and $\mu_b = 2P_r d_{rb} / (V_{pb} s_b)$

For the top tee, $\nu_t = a_o / s_{t1}$ and $\mu_t = 2P_r d_{rt} / (V_{pt} s_t)$

General Equations:

Using equations given below for α_{vb} and α_{vt}

α_{vb} = Ratio of nominal shear capacity of bottom tee, V_{mb} to plastic shear capacity of the web of the tee = $(\sqrt{6} + \mu_b) / (\nu_b + \sqrt{3}) \leq 1$
α_{vt} = Ratio of nominal shear capacity of top tee, V_{mt} to plastic shear capacity of the web of the tee = $(\sqrt{6} + \mu_t) / (\nu_t + \sqrt{3}) \leq 1$

$$V_{mb} = V_{pb} a_{vb}$$

$$V_{mt} = V_{pt} a_{vt}$$

V_m = Maximum nominal shear capacity at a web opening = $V_{mb} + V_{mt}$

8. Check against Maximum Shear Capacity V_m

(AISC Design Guide 2 for Web Openings: section 3.7.a.2)

V_p = Plastic shear capacity of unperforated web = $F_y t_w d / \sqrt{3}$

If $W_1 \leq 420/\sqrt{F_y}$, V_m must not exceed 2/3 V_p
If $W_1 > 420/\sqrt{F_y}$ but $\leq 520/\sqrt{F_y}$, V_m must not exceed 0.45 V_p

9. Check against Moment Shear Interaction

AISC Design Guide 2 for Web Openings: section 3.2 & section 3.4)

$$R1 = V_u / V_m \leq 1.0$$

$$R2 = M_u / M_m \leq 1.0$$

$$R1^3 + R2^3 \leq R^3, R \leq 1.0$$

10. Corner Radii (for reinforced opening only)

(AISC Design Guide 2 for Web Openings: section 3.7.b.2)

Minimum radii = the greater of $2t_w$ or 5/8 inch

11. Calculation of length of fillet weld (for reinforced opening only)

(AISC Design Guide 2 for Web Openings: section 3.7.b.5)

For reinforcing bars on both sides / on one side of the web:

Fillet welds should be used on both sides of the reinforcement on extensions past the opening. The required strength of the weld within the length of the opening is,

$$R_{wr} = 2P_r$$

Where:

R_{wr} = Required strength of the weld

The reinforcement should be extended beyond the opening by a distance

$$L_1 = a_o / 4 \text{ or } L_1 = A_r\sqrt{3} / (2t_w)$$

whichever is greater, on each side of the opening. Within each extension, the required strength of the weld is

$$R_{wr} = F_y A_r$$

Additional requirements for reinforcing bars on one side of the web:

A_f = area of flange = $b_f \cdot t_f$

a. $A_r \leq A_f / 3$

b. $a_o / h_o \leq 2.5$

c. $V1 = s_t / t_w$ or $V2 = s_b / t_w$

$V1$ and $V2 \leq 140 / \sqrt{F_y}$

d. $M_u / (V_u d) \leq 20$

12. Calculation for spacing of openings

(AISC Design Guide 2 for Web Openings: section 3.7.b.6)

Rectangular Opening:

$$S \geq h_o$$

$$S \geq a_o (V_u / V_p) / [1 - (V_u / V_p)]$$

Circular Opening:

$$S \geq 1.5 D_o$$

$$S \geq D_o (V_u / V_p) / [1 - (V_u / V_p)]$$

13. Check for deflection

The deflection check is performed using the approximate procedure described in section 6.2 of the AISC Design Guide 2 for Web Openings.

D1.B.3.4 General Format

```
RHOLE r1 r2 r3 Memb <list>
```

```
CHOLE c1 c2 c3 Memb <list>
```

Where:

r1, *r2*, and *r3* and *c1*, *c2*, and *c3* are the section locations of three rectangular and three circular openings respectively, along the length of the member in ascending order from the start of the member (i.e., r1< r2<r3 and c1< c2<c3)

Notes

The maximum number of openings allowed for each member is three. Thus there can be three rectangular openings, three circular openings, or a combination of three rectangular and circular openings for each member.

```
RDIM [l1 d1] [l2 d2] [l3 d3] Memb <list>
```

Where l1, l2, and l3 are the three different lengths and d1, d2 and d3 are the three different depths of the rectangular openings.

```
CDIA d1 d2 d3 Memb <list>
```

Where *d1*, *d2*, and *d3* are the three different diameters of the circular openings.

```
HECC e1 e2 e3 Memb <list>
```

If the eccentricity of the opening is in the negative local Y-axis of the member the sign should be negative.

```
ELECTRODE f Memb <list>
```

Where *f* is the weld material used to calculate size and length of fillet weld required to connect reinforcing bars on beam web at opening.

Example

```
UNIT INCH PARAMETER RHOLE 0.4 0.6 MEMB 5
RDIM 10.0 5.0 20.0 10.0 MEMB 5 CHOLE 0.8 MEMB 5 CDIA 10.0 MEMB 5 ELECTRODE 3
MEMB 5
```

The above example shows that member 5 contains two rectangular openings at sections 0.4 and 0.6 whereas one circular opening is located at section 0.8 of the member. The dimensions of rectangular openings are 10.0 × 5.0 and 20.0 × 10.0 inch respectively whereas diameter of circular opening is 10.0 inch.

D1.C. American Codes - Steel Design per AISC LRFD Specification

The 2nd and 3rd editions of the American AISC LRFD code have been implemented. The commands to access those respective codes are:

For the 3rd edition code:

```
PARAMETER
```

```
CODE LRFD
```

or

```
PARAMETER
```

```
CODE LRFD3
```

For the 2nd Edition:

```
PARAMETER
```

```
CODE LRFD2
```

D1.C.1 General Comments

The design philosophy embodied in the Load and Resistance Factor Design (LRFD) Specification is built around the concept of limit state design, the current state-of-the-art in structural engineering. Structures are designed and proportioned taking into consideration the limit states at which they would become unfit for their intended use. Two major categories of limit-state are recognized--ultimate and serviceability. The primary considerations in ultimate limit state design are strength and stability, while that in serviceability is deflection. Appropriate load and resistance factors are used so that a uniform reliability is achieved for all steel structures under various loading conditions and at the same time the chances of limits being surpassed are acceptably remote.

In the STAAD implementation of LRFD, members are proportioned to resist the design loads without exceeding the limit states of strength, stability and serviceability. Accordingly, the most economic section is selected on the basis of the least weight criteria as augmented by the designer in specification of allowable member depths, desired section type, or other such parameters. The code checking portion of the program checks that code requirements for each selected section are met and identifies the governing criteria.

The following sections describe the salient features of the LRFD specifications as implemented in STAAD steel design. A detailed description of the design process along with its underlying concepts and assumptions is available in the LRFD manual. However, since the design philosophy is drastically different from the conventional Allowable Stress Design (ASD), a brief description of the fundamental concepts is presented here to initiate the user into the design process.

D1.C.2 LRFD Fundamentals

The primary objective of the LRFD Specification is to provide a uniform reliability for all steel structures under various loading conditions. This uniformity can not be obtained with the allowable stress design (ASD) format.

The ASD method can be represented by the inequality

$$\Sigma Q_i < R_n/F.S.$$

The left side is the required strength, which is the summation of the load effects, Q_i (forces and moments). The right side, the design strength, is the nominal strength or resistance, R_n, divided by a factor of safety. When divided by the appropriate section property (area or section modulus), the two sides of the inequality become the actual stress and allowable stress respectively. ASD, then, is characterized by the use of unfactored "working" loads in conjunction with a single factor of safety applied to the resistance. Because of the greater variability and, hence, unpredictability of the live load and other loads in comparison with the dead load, a uniform reliability is not possible.

LRFD, as its name implies, uses separate factors for each load and resistance. Because the different factors reflect the degree of uncertainty of different loads and combinations of loads and of the accuracy of predicted strength, a more uniform reliability is possible. The LRFD method may be summarized by the inequality

$$y_i Q_i < R_n Ø$$

On the left side of the inequality, the required strength is the summation of the various load effects, Q_i, multiplied by their respective load factors, y_i. The design strength, on the right side, is the nominal strength or resistance, R_n, multiplied by a resistance factor, Ø.

In the STAAD implementation of LRFD, it is assumed that the user will use appropriate load factors and create the load combinations necessary for analysis. The design portion of the program will take into consideration the load effects (forces and moments) obtained from analysis. In calculation of resistances of various elements (beams, columns etc.), resistance (nominal strength) and applicable resistance factor will be automatically considered.

D1.C.3 Analysis Requirements

The types of construction recognized by AISC specification have not changed, except that both “simple framing” (formerly Type 2) and “semi-rigid framing” (formerly Type 3) have been combined into the same category, Type PR (partially restrained). “Rigid Framing” (formerly Type 1) is now Type FR (fully restrained). Type FR construction is permitted unconditionally. Type PR construction may necessitate some inelastic, but self-limiting, deformation of a structural steel element. Thus, when specifying Type PR construction, the designer should take into consideration the effects of partial restraint on the stability of the structure, lateral deflections and second order bending moments. As stated in Sect. C1 of the LRFD specification, an analysis of second order effects is required. Thus, when using LRFD code for steel design, the user must use the P-Delta analysis feature of STAAD.

D1.C.4 Section Classification

The LRFD specification allows inelastic deformation of section elements. Thus local buckling becomes an important criterion. Steel sections are classified as compact, noncompact or slender element sections depending upon their local buckling characteristics. This classification is a function of the geometric properties of the section. The design procedures are different depending on the section class. STAAD is capable of determining the section classification for the standard shapes and user specified shapes and design accordingly.

D1.C.5 Limit States

D1.C.5.1 Axial Tension

The criteria governing the capacity of tension members is based on two limit states. The limit state of yielding in the gross section is intended to prevent excessive elongation of the member. The second limit state involves fracture at the section with the minimum effective net area. The net section area may be specified by the user through the use of the parameter `NSF` (see D1.C.6 Design Parameters (on page 1167)). STAAD calculates the tension capacity of a given member based on these two limit states and proceeds with member selection or code check accordingly.

D1.C.5.2 Axial Compression

The column strength equations have been revised in LRFD to take into account inelastic deformation and other recent research in column behavior. Two equations governing column strength are available, one for inelastic buckling and the other for elastic or Euler buckling. Both equations include the effects of residual stresses and initial out-of-straightness. Compression strength for a particular member is calculated by STAAD according to the procedure outlined in Chapter E of the LRFD specifications. For slender elements, the procedure described in Appendix B5.3 is used.

Singly symmetric and unsymmetric compression members are designed on the basis of the limit states of flexural-torsional and torsional buckling. The procedure of Appendix E3 is implemented for the determination of design strength for these limit states.

Effective length for calculation of compression resistance may be provided through the use of the parameters KY, KZ and/or LY, LZ. If not provided, the entire member length will be taken into consideration.

In addition to the compression resistance criterion, compression members are required to satisfy slenderness limitations which are a function of the nature of use of the member (main load resisting component, bracing member, etc.). In both the member selection and code checking process, STAAD immediately does a slenderness check on appropriate members before continuing with other procedures for determining the adequacy of a given member.

D1.C.5.3 Flexural Design Strength

In LRFD, the flexural design strength of a member is determined by the limit state of lateral torsional buckling. Inelastic bending is allowed and the basic measure of flexural capacity is the plastic moment capacity of the section.

The flexural resistance is a function of plastic moment capacity, actual laterally unbraced length, limiting laterally unbraced length, buckling moment and the bending coefficient. The limiting laterally unbraced length L_r and buckling moment M_r are functions of the section geometry and are calculated as per the procedure of Chapter F.

The purpose of bending coefficient C_b is to account for the influence of the moment gradient on lateral-torsional buckling. This coefficient can be specified by the user through the use of parameter CB (see D1.C.6 Design Parameters (on page 1167)) or may be calculated by the program (if CB is specified as 0.0). In the absence of the parameter CB, a default value of 1.0 will be used.

The procedure for calculation of design strength for flexure also accounts for the presence of residual stresses of rolling.

To specify laterally unsupported length, either or both of the parameters UNB and UNT (see D1.C.6 Design Parameters (on page 1167)) can be used.

D1.C.5.4 Combined Axial Force and Bending

The interaction of flexure and axial forces in singly and doubly symmetric shapes is governed by formulas H1-1a and H1-1b. These interaction formulas cover the general case of biaxial bending combined with axial force. They are also valid for uniaxial bending and axial force.

D1.C.5.5 Design for Shear

The procedure of Sect. F2 of the LRFD Specification is used in STAAD to design for shear forces in members. Shear strength as calculated in LRFD is governed by the following limit states: Eq. F2-1a by yielding of the web; Eq. F2-2a by inelastic buckling of the web; Eq. F2-3a by elastic buckling of the web. Shear in wide flanges and channel sections is resisted by the area of the web, which is taken as the overall depth times the web thickness.

D1.C.6 Design Parameters

Design per LRFD specifications is requested by using the CODE parameter. Other applicable parameters are summarized in Table 2-4. These parameters communicate design decisions from the engineer to the program and thus allow the engineer to control the design process to suit an application's specific needs.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements, some or all of these parameter values may be changed to exactly model the physical structure.

The parameters DMAX and DMIN are applicable for member selection only.

Table 83: AISC LRFD (2nd and 3rd Ed.) Design Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified LRFD or LRFD3 for 3rd Edition. Must be specified LRFD2 for 2nd Edition.

Parameter Name	Default Value	Description
AXIS	1	1 = Design single angles for bending about their principle axis. 2 = Design single angles for bending about their geometric axis.
BEAM	1.0	0.0 = design at start and end nodes and those locations specified by the `SECTION` command. 1.0 = design at 13 evenly spaced points (i.e., 1/12th points) along member length, including start and end nodes. **Note:** See D1.A.6 Design Parameters (on page 1100).
CAN	0	0 = deflection check based on the principle that maximum deflection occurs within the span between DJ1 and DJ2. 1 = deflection check based on the principle that maximum deflection is of the cantilever type (see D1.B.1.2 Design Parameters (on page 1134))
CB**	1.0	Coefficient Cb per Chapter F of AISC LRFD. If Cb is set to 0.0, it will be calculated by the program. Any of value will be used directly in design.
DFF	None (Mandatory for deflection check)	"Deflection Length" / Maximum allowable local deflection
DJ1	Start Joint of Member	Joint No. denoting starting point for calculation of "Deflection Length" (see D1.B.1.2 Design Parameters (on page 1134))
DJ2	End Joint of Member	Joint No. denoting end point for calculation of "Deflection Length" (see D1.B.1.2 Design Parameters (on page 1134))

Parameter Name	Default Value	Description
DMAX	45.0 in.	Maximum allowable section depth.
DMIN	0.0 in.	Minimum allowable section depth
FLX	1	1 = Single angle member is *not* fully braced against lateral torsional buckling. 2 = Single angle member is fully braced against lateral torsional buckling. 3 = Single angle member is braced against lateral torsional buckling at the point of maximum moment.
FYLD	36.0 ksi	Yield strength of steel.
FU	60.0 ksi	Ultimate tensile strength of steel.
KX	1.0	K value for flexural-torsional buckling.
KY	1.0	Effective length factor to calculate slenderness ratio for buckling about local y-axis. Usually this is the minor axis.
KZ	1.0	Effective length factor to calculate slenderness ratio for buckling about local z-axis. Usually this is the major axis.
LX	Member Length	Length used for flexural-torsional buckling.
LY	Member Length	Length to calculate the slenderness ratio for buckling about the local y-axis.
LZ	Member Length	Length to calculate the slenderness ratio for buckling about the local z-axis.
MAIN	0.0	0.0 = check for slenderness 1.0 = suppress slenderness check Any value greater than 1 = Allowable KL/r in compression.

Parameter Name	Default Value	Description
NSF	1.0	Net section factor for tension members.
PROFILE		Used in member selection. Refer to TR.48.1 Parameter Specifications (on page 2676) for details.
RATIO	1.0	Permissible ratio of actual load effect to design strength.
STIFF	Member Length or depth, whichever is greater	Spacing of stiffeners for beams for shear design.
STP	1	Section type to determine F_r (compressive residual stress in flange) per 3rd Ed. LRFD spec., p 16.1-97. 1 = Rolled section (F_r = 10 ksi) 2 = Welded section (F_r = 16.5 ksi)
TMAIN	300	Any value greater than 1 = Allowable KL/r in tension.
TRACK	0.0	Specified the level of detail included in the output. 0.0 = Suppress all design strengths 1.0 = Print all design strengths 2.0 = Print expanded design output
UNB	Member Length	Unsupported length (L_h) of the bottom* flange for calculating flexural strength. Will be used only if flexural compression is on the bottom flange.
UNT	Member Length	Unsupported length (L_h) of the top* flange for calculating flexural strength. Will be used only if flexural compression is on the top flange.

*Top and Bottom represent the positive and negative side of the local Y axis (local Z axis if `SET Z UP` is used).

Note: For a description of the deflection check parameters DFF, DJ1, DJ2, and CAN, see the D1.B.1.2 Design Parameters (on page 1134) of this manual.

The STIFF parameter represents the term "a" as defined in Section F2, page 6-113 of the LRFD 2nd edition manual.

** Non-default values of CB must be re-entered before every subsequent CHECK CODE or SELECT command.

D1.C.7 Code Checking and Member Selection

Both code checking and member selection options are available in STAAD LRFD implementation. See D1.B.1.3 Code Checking (on page 1141) and D1.B.1.4 Member Selection (on page 1142) for general information on these options.

Example for the LRFD-2001 code

```
UNIT KIP INCH
PARAMETER
CODE LRFD
FYLD 50 ALL
UNT 72 MEMBER 1 TO 10
UNB 72 MEMB 1 TO 10
MAIN 1.0 MEMB 17 20
SELECT MEMB 30 TO 40
CHECK CODE MEMB 1 TO 30
```

Example for the LRFD-1994 code

```
UNIT KIP INCH
PARAMETER
CODE LRFD2
FYLD 50 ALL
UNT 72 MEMBER 1 TO 10
UNB 72 MEMB 1 TO 10
MAIN 1.0 MEMB 17 20
SELECT MEMB 30 TO 40
CHECK CODE MEMB 1 TO 30
```

D1.C.8 Tabulated Results of Steel Design

Results of code checking and member selection are presented in a tabular format. A detailed discussion of the format is provided in D1.B.1.9 Tabulated Results of Steel Design (on page 1144). Following exceptions may be noted: CRITICAL COND refers to the section of the LRFD specifications which governed the design.

If the TRACK is set to 1.0, member design strengths will be printed out.

D1.C.9 Composite Beam Design per the AISC LRFD 3rd edition code

The design of composite beams per the 3rd edition of the American LRFD code has been implemented. The salient points of this feature are as follows:

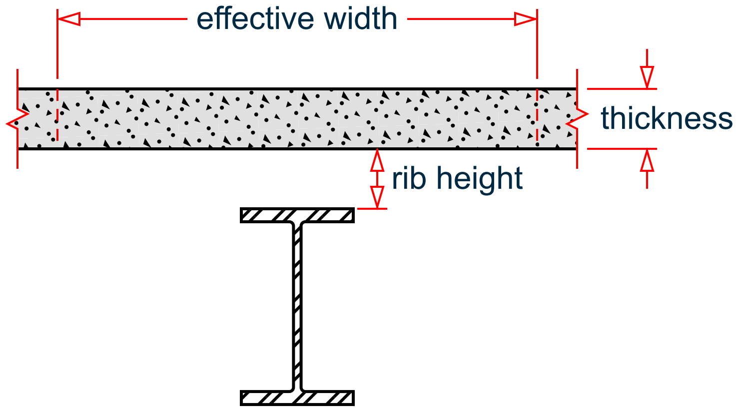

Figure 136: Nomenclature of composite beams

where

t	=	thickness of slab
A_s	=	area of steel beam
f_c	=	ultimate compressive strength of concrete
b	=	effective slab width
h_r	=	rib height

Table 84: Composite Beam Design Parameters for AISC-LRFD

Parameter Name	Default Value	Description
RBH	0.0 in.	Rib height for steel form deck.
EFFW	Value used in analysis	Effective width of the slab.
FPC	Value used in analysis	Ultimate compressive strength of the concrete slab.

Theoretical Basis

1. Find the maximum compressive force carried by concrete as:

   $0.85\ f_c \cdot b \cdot t$
2. Find the maximum tensile force carried by the steel beam as:

   $A_s\ .\ f_y$

   Tensile strength of concrete is ignored.
3. If step 1 produces a higher value than step 2, plastic neutral axis (PNA) is in the slab. Else, it is in the steel beam.

Location of the Plastic Neutral Axis (PNA) defines the moment capacity:

- Case 1: PNA in the slab

  Find the depth of the PNA below the top of the slab as:

  $$0.85f_c \cdot b \cdot a = A_s \cdot f_y$$

  Rearranging terms:

  $$a = A_s \cdot f_y/(0.85f_c \cdot b)$$

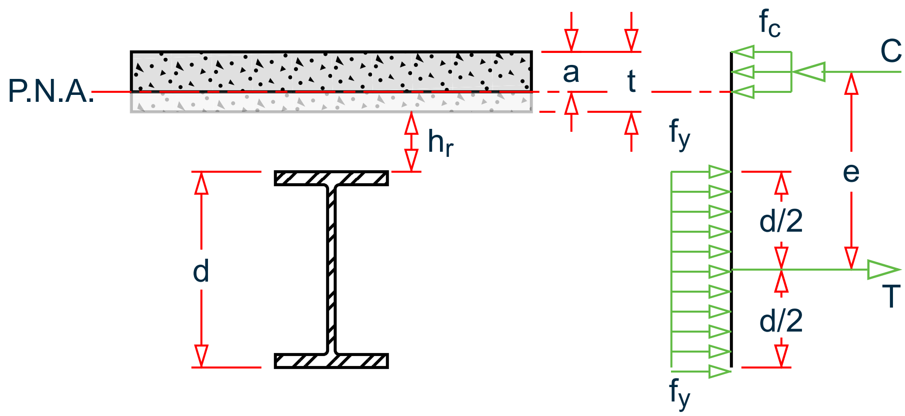

Figure 137: Plastic neutral axis in the concrete slab

  Lever arm

  $$e = d/2 + h_r + t - a/2$$

  Moment Capacity

  $$\phi_b(A_s \cdot f_y)e$$

- Case 2: PNA in Steel Beam

  $$C_s + C_b = T_b$$

  where

C_s	=	compressive force in slab = $0.85f_c \cdot b \cdot t$
C_b	=	compressive force in steel beam
T_b	=	tensile force in steel beam

  Since the magnitude of $C_b + |T_b| = A_s \cdot f_y$

  Substituting for $T_b = (A_s \cdot f_y - C_b)$ gives:

  $$C_s + C_b = A_s \cdot f_y - C_b$$

  Rearranging terms:

  $$C_b = (A_s \cdot f_y - C_s)/2$$

  Determine whether the PNA is within the top flange of the steel beam or inside the web:

  where

C_f	=	maximum compressive force carried by the flange = $A_f \cdot f_y$
A_f	=	area of the flange

  If $C_f \geq C_b$, the PNA lies within the flange (Case 2A)

  If $C_f < C_b$, the PNA lies within the web (Case 2B)

- Case 2A: PNA in Flange of Steel Beam

  Calculate:

  $$y = C_f/(b_f \cdot f_y)$$

  where

  b_f = width of the flange

  The point of action of the tensile force is the centroid of the steel are below the PNA. After find that point, e_1 and e_2 can be calculated.

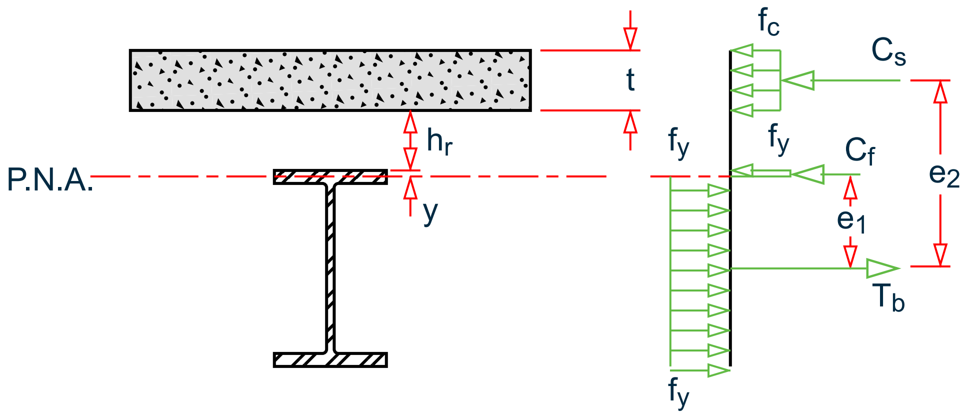

Figure 138: Plastic neutral axis falls within the top flange

  Moment Capacity

  $$\phi_b(C_f \cdot e_1 + C_s \cdot e_2)$$

- Case 2B: PNA in Web of Steel Beam

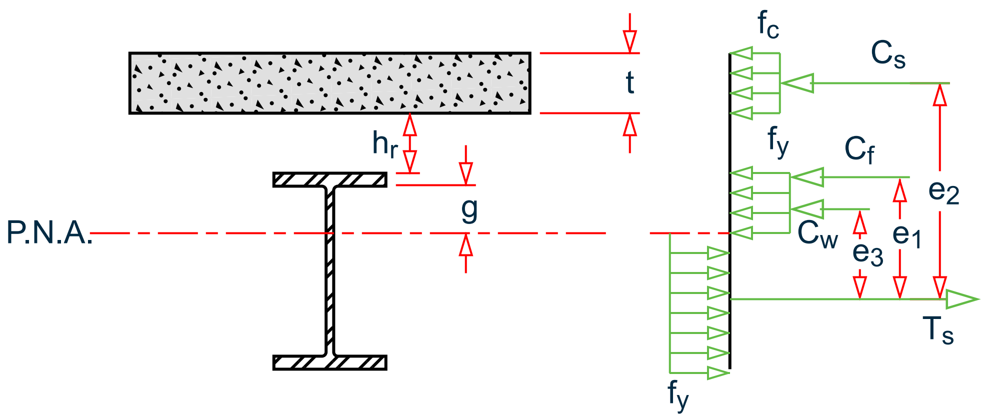

Figure 139: Plastic neutral axis falls within the web

  where

  C_w = compressive force in the web = C_b - C_f

  g = $C_w/(t_w \cdot f_y)$

  t_w = thickness of the web

The point of action of the tensile force is the centroid of the steel area below the PNA. After finding that point, e_1, e_2, and e_3 can be calculated.

Moment Capacity

$$\phi_b(C_s \cdot e_2 + C_f \cdot e_1 + C_w \cdot e_3)$$

Utilization Ratio = Applied Moment / Moment Capacity

Notes

1. Rib Height is the distance from top of flange of steel beam to lower surface of concrete.
2. If the slab is flush on top of the steel beam, set the Rib Height to zero.

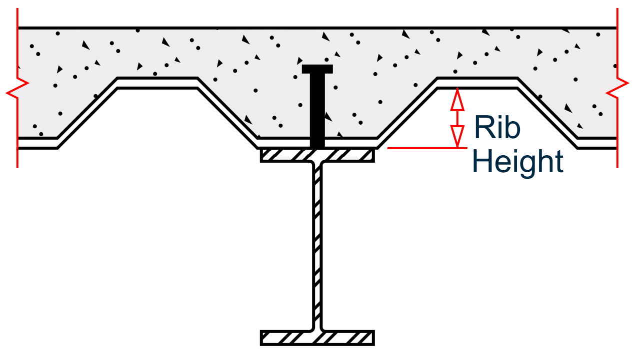

Figure 140: Steel deck form ribs

3. For moments which cause tension in the slab (called positive moments in STAAD.Pro convention), design of the beam is presently not carried out.
4. Shear connectors are presently not designed.
5. Member selection is presently not carried out.
6. In order to design a member as a composite beam, the member property specification during the analysis phase of the data must contain the `CM` attribute. See TR.20.1 Assigning Properties from Steel Tables (on page 2257) for details.

```

D1.D.1 AASHTO (ASD)

The design of structural steel members in accordance with the AASHTO *Standard Specifications for Highway Bridges*, 17th edition has been implemented.

Related Links

- *V. AASHTO 17th Ed ASD - Design Frame* (on page 4547)

D1.D.1.1 General

The section of the above code implemented in STAAD is Chapter 10, Part C – Service Load design Method, Allowable Stress design. Sections 10.32.1.A and 10.36 are implemented. As per the AASHTO committee, this is the last edition for this code (the ASD approach) and only technical errors will be fixed in the future for this code.

In general, the concepts followed in `MEMBER SELECTION` and `CODE CHECKING` procedures are similar to that of the AISC based design. It is assumed that you are familiar with the basic concepts of steel design facilities available in STAAD. Please refer to D. Steel Design (on page 969) for detailed information on this topic. This section specifically addresses the implementation of steel design based on the AASHTO specifications.

Design is available for all standard sections listed in the AISC ASD 9th edition manual, namely, Wide Flanges, S, M, HP, Tees, Channels, Single Angles, Double Angles, Tubes and Pipes. The design of HSS sections (those listed in the 3rd edition AISC LRFD manual) and Composite beams (I shapes with concrete slab on top) are not supported.

D1.D.1.2 Allowable Stresses

The member design and code checking in STAAD.Pro is based upon the allowable stress design method. It is a method for proportioning structural members using design loads and forces, allowable stresses, and design limitations for the appropriate material under service conditions. It is beyond the scope of this manual to describe every aspect of structural steel design per AASHTO specifications because of practical reasons. This section will discuss the salient features of the allowable stresses specified by the AASHTO code. Table 10.32.1A of the AASHTO code specifies the allowable stresses.

Axial Stress

Allowable tension stress, as calculated in AASHTO is based on the net section. This tends to produce a slightly conservative result. Allowable tension stress on the net section is given by,

$$F_t = 0.55 \cdot F_y$$

Allowable compressive stress on the gross section of axially loaded compression members is calculated based on the following formula:

$$F_a = F_y/FS \cdot [1-(Kl/r)^2 F_y]/(4\pi^2 E)$$

when $(Kl/r) \leq Cc$

$$Fa = \pi^2 E/[FS \cdot (Kl/r)^2]$$

when $(Kl/r) > Cc$

Where:

$$C_c = (2\pi^2 E/F_y)^{1/2}$$

It should be noted that AASHTO does not have a provision for increase in allowable stresses for a secondary member and when 1/r exceeds a certain value.

Bending Stress

Allowable stress in bending compression for rolled shape girders and built-up sections whose compression flanges are supported laterally through their full length by embedment in concrete is given by:

$$F_b = 0.55 \cdot F_y$$

For similar members with unsupported or partially supported flange lengths, the allowable bending compressive stress is given by

$$Fb = 0.55 \cdot F_y[1 - (1/r)^2 F_y/(4\pi^2 E)]$$

Where:

$$r^2 = b^2/12$$

Due to inadequate information in the AASHTO Code, the allowable tensile stresses due to bending for both axes are set to be the same as the corresponding allowable bending compressive stresses.

Shear Stress

Allowable shear stress on the gross section is given by:

$$F_v = 0.33\ F_y$$

For shear on the web, the gross section is defined as the product of the total depth and the web thickness. The AASHTO code does not specify any allowable stress for shear on flanges. The program assumes the same allowable for shear stress (0.33Fy) for both shear on the web and shear on the flanges. For shear on the flanges, the gross section is taken as 2/3 times the total flange area.

Bending-Axial Stress Interaction

Members subjected to both axial and bending stresses are proportioned according to section 10.36 of the AASHTO steel code. All members subject to bending and axial compression are required to satisfy the following formula:

$$f_a/F_a + C_{mx} \cdot f_{bx}/[(1 - f_a/F_{ex}) \cdot F_{bx}] + C_{my} \cdot f_{by}/[(1 - f_a/F_{ey}) \cdot F_{by}] < 1.0$$

at intermediate points, and

$$f_a/(0.472 \cdot F_y) + f_{bx}/F_{bx} + f_{by}/F_{by} < 1.0$$

at the ends of the member.

The start and end nodes of a member are treated as support points.

For members subject to axial tension and bending, the following equations are checked:

$$f_a/F_a + f_{bx}/F_{bx} + f_{by}/F_{by} < 1.0$$

at intermediate points, and

$$f_a/(0.472 \cdot F_y) + f_{bx}/F_{bx} + f_{by}/F_{by} < 1.0$$

at the ends of the member.

D1.D.1.3 AASHTO (ASD) Design Parameters

The following table outlines the parameters that can be used with the AASHTO (ASD) code along with the default values used if not explicitly specified.

Table 85: AASHTO (ASD) Design Parameters

Parameter Name	Default Value	Description
BEAM	1.0	0.0 = Design at ends and those locations specified by the SECTION command. 1.0 = Design at ends and every 1/12th point along the member length.
CB	1.0	Cb value as used in the calculation of Fb 0.0 = Cb value to be calculated Any other value will be used in the calculations.
CMY CMZ	0.85 for sideswayand calculatedfor no sidesway	Cm value in local y & z axes
DFF	None.(Mandatory for a deflection check)	“Deflection length” / Maximum allowable local axis deflection.
DJ1	Start joint of member	Joint No. denoting starting point for calculating “Deflection Length”.
DJ2	End joint of member	Joint No. denoting ending point for calculating “Deflection Length”.
DMAX	1000.0	Maximum allowed section depth (in current length units) for a section to be selected with the SELECT command.

Parameter Name	Default Value	Description
DMIN	0.0	Minimum allowed section depth (in current length units) for a section to be selected with the SELECT command.
FYLD	36 KSI	Yield strength of steel in current units.
KY	1.0	Effective length factor to calculate slenderness ratio for buckling about local y-axis. Usually this is the minor axis.
KZ	1.0	Effective length factor to calculate slenderness ratio for buckling about local z-axis. Usually this is the major axis.
LY	Member Length	Length to calculate slenderness ratio for buckling about local Y axis.
LZ	Member Length	Same as above except in local z-axis.
MAIN	0.0	0.0 =check for slenderness 1.0 =suppress slenderness check
NSF	1.0	Ratio of "Net cross section area" / 'Gross section area' for tension member design.
PROFILE	None	Used in member selection. Refer to TR.48.1 Parameter Specifications (on page 2676) for details.
PUNCH		1.0 = K-Overlap 2.0 = K-Gap 3.0 = T and Y 4.0 = Cross with diaphragms 5.0 = Cross without diaphragms
RATIO	1.0	Permissible ratio of the actual to allowable stresses.

Parameter Name	Default Value	Description
SSY	0.0	0.0 =Sidesway in local y-axis. 1.0 =No sidesway in local y-axis
SSZ	0.0	0.0 =Sidesway in local z-axis. 1.0 =No sidesway in local z-axis.
STIFF	Greater of member length or depth of beam.	Spacing of stiffeners for plate girder design in current length units.
TRACK	0	Level of detail in Output File: 0 = Print the design output at the minimum detail level. 1 = Print the design output at the intermediate detail level. 2 = Print the design output at maximum detail level.
UNF	1.0	Unsupported length provided as a fraction of actual member length used for lateral-torsional buckling calculation. **Note:** If both UNF and UNL parameters are specified, the effective length used is UNF×UNL.
UNL	Member Length	Unsupported length for calculating allowable bending stress. Used for the lateral-torsional buckling calculation. Value should be in the current units of length.
WSTR	0.4 x FYLD	Allowable welding stress

D1.D.2 AASHTO (LRFD)

The following outlines the implementation of the AASHTO *Standard Specifications for Highway Bridges* (LRFD, 1998) which has been implemented in STAAD.Pro.

Related Links

- *V. AASHTO 2nd Ed LRFD - Design Beam* (on page 4559)

D1.D.2.1 General

The design philosophy embodied in the Load and Resistance Factor Design (LRFD) Specification is built around the concept of limit state design, the current state-of-the-art in structural engineering. Structures are designed and proportioned taking into consideration the limit states at which they would become unfit for their intended use. Two major categories of limit-state are recognized ultimate and serviceability. The primary considerations in ultimate limit state design are strength and stability, while that in serviceability is deflection. Appropriate load and resistance factors are used so that a uniform reliability is achieved for all steel structures under various loading conditions and at the same time the chances of limits being surpassed are acceptably remote.

In the STAAD implementation of AASTHO-LRFD, members are proportioned to resist the design loads without exceeding the limit states of strength, stability and serviceability. Accordingly, the most economic section is selected on the basis of the least weight criteria as augmented by the designer in specification of allowable member depths, desired section type, or other such parameters. The code checking portion of the program checks that code requirements for each selected section are met and identifies the governing criteria.

The following sections describe the salient features of the AASTHO-LRFD specifications as implemented in STAAD steel design.

D1.D.2.2 Capacities per AASHTO (LRFD) Code

Axial Strength

The criteria governing the capacity of tension members is based on two limit states. The limit state of yielding in the gross section is intended to prevent excessive elongation of the member. The second limit state involves fracture at the section with the minimum effective net area. The net section area may be specified through the use of the parameter NSF. STAAD calculates the tension capacity of a given member based on these two limit states and proceeds with member selection or code check accordingly

$$P_r = \varphi_y P_{ny} = \varphi_y F_y A_g$$

$$P_r = \varphi_u P_{nu} = \varphi_u F_u A_n U$$

where

P_{ny}	=	Nominal tensile resistance for yielding in gross section (kip)
F_y	=	Yield strength (ksi)
A_g	=	Gross cross-sectional area of the member (in^2)
P_{nu}	=	Nominal tensile resistance foe the fracture in the net section (kip)
F_u	=	Tensile strength (ksi)
A_n	=	Net area of the member
U	=	reduction factor to account for shear lag
φ_y	=	resistance factor for yielding of tension member
φ_u	=	resistance factor for fracture of tension members

Allowable compressive stress on the gross section of axially loaded compression members is calculated based on the following formula:

$$\lambda = \left(\frac{Kl}{r_z \pi}\right)^2 \frac{F_y}{E}$$

if λ ≤ 2.25

Nominal compressive resistance,

$$P_n = 0.66^{\lambda} F_y A_s$$

if λ > 2.25

Nominal compressive resistance

$$P_n = 0.88 F_y A_s / \lambda$$

where

A_s	=	Gross sectional area

The Factored resistance

$$P_r = \varphi_c \, Pn$$

Bending Strength

The flow to calculate the allowable bending strength for rolled shape girders and built-up sections is given by the flowing flow chart.

Clause 6.10.4.2.5

Shear Strength

The nominal shear resistance of un-stiffened webs of homogeneous girders shall be calculated as.

If $D/t_w \le 2.46\sqrt{(E/F_y)}$, then

$$V_n = V_p = 0.58 F_{yw} D t_w$$

If $2.46\sqrt{(E/F_y)} < D/t_w \le 3.07\sqrt{(E/F_y)}$, then

$$V_n = 1.48 \cdot t_w^{\ 2} \sqrt{(E \cdot F_y)}$$

If $D/t_w > 3.07\sqrt{(E/F_y)}$, then

$$V_n = 4.55 \cdot t_w^{\ 3} \cdot E/D$$

Bending-Axial Interaction

Members subjected to both axial forces and bending moments are proportioned according to section 6.9.2.2 of the AASHTO steel code. All members subject to bending and axial compression or axial tension are required to satisfy the following formula:

If $P_u/P_r < 0.2$, then

$$\frac{P_u}{2.0 P_r} + \left(\frac{M_{ux}}{M_{rx}} + \frac{M_{uy}}{M_{ry}} \right) \le 1.0$$

If $P_u/P_r \ge 0.2$, then

$$\frac{P_u}{P_r} + \frac{8}{9}\left(\frac{M_{ux}}{M_{rx}} + \frac{M_{uy}}{M_{ry}} \right) \le 1.0$$

D1.D.2.3 AASHTO (LRFD) Design Parameters

The following table outlines the parameters that can be used with the AASHTO (LRFD) code along with the default values used if not explicitly specified.

Table 86: AASHTO (LRFD) Design Parameters

Parameter Name	Default Value	Description
BEAM	1.0	Identify where beam checks are performed: 0 = Perform design at ends and those locations specified in the SECTION command. 1 = Perform design at ends and 1/12th section locations along member length.
DMAX	1000	Maximum allowed section depth (in current length units) for a section to be selected with the SELECT command.

Parameter Name	Default Value	Description
DMIN	0	Minimum allowed section depth (in current length units) for a section to be selected with the SELECT command.
DFF	0	"Deflection Length"/Max allowable local deflection If set to 0, (default) then no deflection check is performed.
DJ1	Start joint of member	Joint No. denoting starting point for calculating "Deflection Length".
DJ2	End joint of member	Joint No. denoting ending point for calculating "Deflection Length".
GRADE	1	Grade of Steel: 1: Grade 36 2: Grade 50 3 Grade 50W 4: Grade 70W 5: Grade 100/100W Refer to AASHTO LRFD, Table 6.4.1-1
KY	1.0	Effective length factor to calculate slenderness ratio for buckling about local y-axis. Usually this is the minor axis.
KZ	1.0	Effective length factor to calculate slenderness ratio for buckling about local z-axis. Usually this is the major axis.
LY	Member Length	Length to calculate slenderness ratio for buckling about the local Y axis.
LZ	Member Length	Same as above except in local z-axis.

Parameter Name	Default Value	Description
MAIN	0.0	Flag for checking slenderness limit: 0.0 =check for slenderness 1.0 =suppress slenderness check
NSF	1.0	Net Section Factor. Ratio of (Net Area)/(Gross Area)
NSF	1.0	Net section factor for tension members.
TRACK	0	Level of detail in Output File: 0 = Print the design output at the minimum detail level. 1 = Print the design output at the intermediate detail level. 2 = Print the design output at maximum detail level..
UNB	Member Length	Unsupported length of bottom flange. Used for calculating the moment of resistance when the bottom of beam is in compression.
UNT	Member Length	Unsupported length of top flange. Used for calculating the moment of resistance when top of beam is in compression.

D1.E. American Codes - Steel Design per AISI Cold Formed Steel Code

Provisions of the AISI S100 *North American Specification for the Design of Cold-Formed Steel Structural Members*, 2016 Edition have been implemented. The program allows design of single (non-composite) members in tension, compression, bending, shear, as well as their combinations using the LRFD Method. For flexural members, the Nominal Section Strength is calculated on the basis of initiation of yielding in the effective section (Procedure I).

Note: Design per the AISC 1996 code has been deprecated.

D1.E.1 Cross-Sectional Properties

You specify the geometry of the cross-section by choosing one of the section shape designations from the STAAD.Pro Steel Tables for cold-formed sections, which mirror the Gross Section Property Tables published in AISI S100-16.

The following section profiles are supported in this implementation:

- Standard cold-formed sections from the section database:
  - angle (with or without lips)
  - channel (with or without lips) or eave strut
  - double-channels, arranged back-to-back or toe-to-toe

    Note: All double channels are treated as being directly welded together. Spacing is not considered for back-to-back or toe-to-toe arrangements.
  - zee or zee purlin (with or without lips)
  - hat
  - tube (SHS and RHS)
  - pipe and CHS
- The following UPT sections are supported:
  - angle
  - channel
  - tube
  - pipe

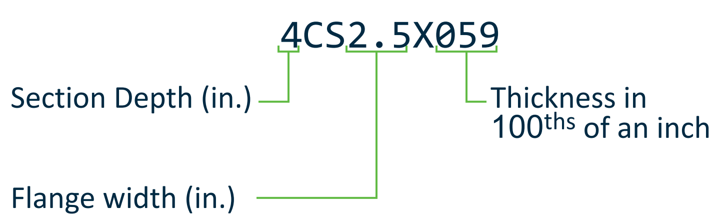
Shape selection may be done using the member property pages of the graphical user interface or by specifying the section designation symbol in the input file.

Standard hot-rolled sections, prismatic sections, and UPT sections other than those listed above are not supported.

D1.E.2 The AISI Steel Section Library

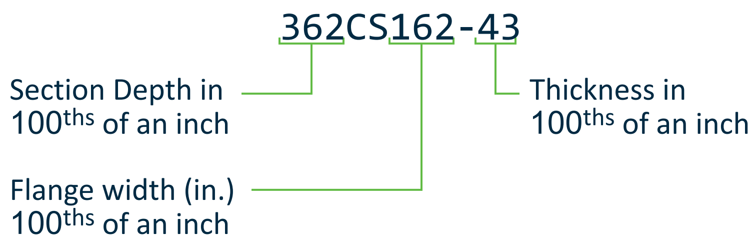
The command-line syntax for assigning steel sections from the AISI library is as explained below.

C-Section with Lips



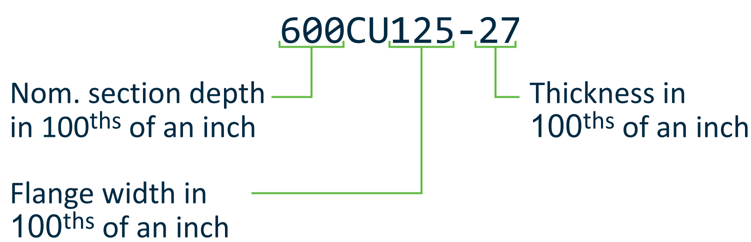
```
20 TO 30 TABLE ST 14CS3.75X135
33 36 TABLE ST 12CS1.625X102
42 43 TABLE ST 4CS4X060
```

Additionally, SSMA stud sections from the AISI tables are included in STAAD.Pro using a similar nomenclature, where CS is used instead of the AISI "S" designation.



```
44 TO 47 TABLE ST 362CS162-43
```

C-Section without Lips

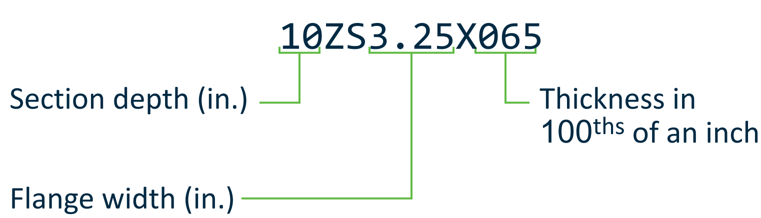


SSMA track sections from the AISI tables are included in STAAD.Pro using a similar nomenclature, where CU is used instead of the AISI "T" designation.

```
50 TO 60 TABLE ST 600CU125-27
32 33 TABLE ST 162CU125-18
21 28 TABLE ST 1000CU125-68
```

Note: The C-Sections without lips in the format of 3CU1.25X057 can be found in the **US/AISI Coldformed Legacy Profiles** database.

Z-Section with Lips



```
1 3 4 TABLE ST 12ZS3.25X105

D1.E.3 Design Procedure

Design Methodology

The AISI S100-16 follows a capacity-based design procedure. LRFD and ASD are two methods specified in the specification.

Structural members are designed to have strength such that the available strength (factored resistance) Ra, equals or exceeds the required strength (effect due to factored loads), R. Use the `METHOD` parameter to indicate which design method the program should use (the default method is LRFD).

- Allowable Strength Design (ASD): $R \leq R_a\ ,\ \ R_a = \ R_n\ /\ \Omega$
- Load and Resistance Factor Design (LRFD): $R_u \leq R_a\ ,\ \ R_a = \ \phi R_n$

Table 87: Saftey and Resistance factors in AISI 2016

Force	LRFD: ϕ Factor	ASD: Ω Value
Tension	0.90	1.67
Compression	0.85	1.80
Flexure	0.95 for box sections 0.90 for other sections	1.67
Shear	0.95	1.60

Tension Resistance

Design of the members subject to axial tension is performed as per Chapter D of AISI S100-16. The tensile strength is calculated with due consideration to both tensile yielding and tensile rupture effects. The design tensile strength, $\phi_t T_n$,(LRFD) and the allowable tensile strength, T_n/Ω_t, (ASD) will be calculated as per Chapter D2 and D3 of the code. The nominal tensile strength, T_n shall be the lower value obtained per the limit states of tensile yielding in the gross section and tensile rupture in the net section.

You can control the net area used to calculate the tensile rupture strength by assigning the `NSF` parameter.

Compression Resistance

Design of the members subject to axial compression is performed as per chapter E of AISI S100-16. The nominal compressive strength is calculated considering compression yielding, global (flexural, flexural-torsional, and torsional) buckling, local buckling, and distortional buckling. The minimum of these three criteria will be used to calculate the compression capacity or strength. The design compressive strength, $\phi_c P_n$, (LRFD) and the allowable compressive strength, P_n / Ω_c, (ASD) will be calculated as per chapter E2, E3 and E4 of the specification.

For the calculation of global compression capacities, section E2.1 is applicable for double channels front-to-front. Since this is *not* a pure box (but like a box), the program does not use E2.1.1. Rather, this built-up shape is treated like a typical section that is not subject to FTB and uses Cl. E2.1-1.

Torsional and flexural torsional buckling are *not* considered in the determination of compression capacity for L sections (with and without lips) designed about geometric axes. Rather, it is assumed that these members have restraints against torsional and flexural torsional buckling, which is typical in practice.

Flexure Resistance

Design of the members subject to bending about principal axes is performed as per Chapter F of AISI S100-16. The specification applies for bending about one principal axis only.

Note: For Z-shapes (zee and zee with lips), bending is checked about centroidal axes, axes passing through or perpendicular to the web

It is assumed that the member is loaded in a plane parallel to the axis that passes through the shear center or is restrained against twisting.

The nominal flexure resistance is calculated considering flexural yielding, global (lateral-torsional) buckling, local buckling, and distortional buckling. The smallest of these criteria will be used to calculate the flexural capacity or strength. The design flexural strength, $\phi_b M_n$, (LRFD) and the allowable flexural strength, M_n / Ω_b, (ASD) will be calculated as per chapter F2, F3 and F4 of the specification.

For calculation of yielding and global (lateral-torsional) buckling, Cl. F2.1.4 is used for double channel front-to-front section.

Shear Resistance

Design of the members subject to shear is dealt with by the module as per chapter G of AISI S100-16. The nominal shear strength, V_n, is calculated for flexural members without transverse stiffeners. The shear buckling force, V_{cr}, is calculated for for the web of members with transverse stiffeners.

The spacing of transverse stiffeners, if present, is given using the `STIFF` parameter.

The program ignores any spacing values specified for closed sections such as double channel front-to-front.

Interaction Checks

The program checks members subject to axial force and flexure about one or both axes as well as flexure and shear.

Excluded Checks

The following check are *not* made as part of the AISI S100-16 design:

- connection design

- design for torsion
- design for stability, ponding, fatigue, or corrosion effects
- web crippling checks
- combined checks for bending and web crippling
- combined checks for bending and torsion
- design for serviceability

D1.E.4 Code Checking and Member Selection

The following two design modes are available:

Code Checking

The program compares the resistance of members with the applied load effects, in accordance with the LRFD and ASD methods of the AISI code. Code checking is carried out for specified locations via the `SECTION` command or the `BEAM` parameter. The results are presented in a form of a PASS/FAIL identifier and a ratio of load effect to resistance for each member checked compared to the `RATIO` parameter. You may choose the degree of detail in the output data by setting the `TRACK` parameter.

Member Selection

You may request that the program search the cold formed steel shapes database (AISI standard sections) for alternative members that pass the code check and meet the least weight criterion. In addition, a minimum and/or maximum acceptable depth of the member may be specified. The program will then evaluate all database sections of the type initially specified (i.e., channel, angle, etc.) and, if a suitable replacement is found, present design results for that section. If no section satisfying the depth restrictions or lighter than the initial one can be found, the program leaves the member unchanged, regardless of whether it passes the code check or not.

D1.E.5 Design Parameters

The following table contains the input parameters for specifying values of design variables and selection of design options.

Tip: When using the STAAD.Pro Editor, you can right-click and select **Insert Snippet** from the pop-up menu and then select **AISI 2016 Design** from the snippets list. This will insert the Parameter block with the commonly used parameters set to their defaults for all members. Refer to I. To insert a code snippet (on page 2051) for details on using snippets.

Table 88: AISI S100-16 Cold Formed Steel Design Parameters

Parameter Name	Default Value	Description

CODE	-	Must be specified as one of the following to invoke design per AISI S100-16.
		`AISI`
		`AISI 2016`
		`AISI S100 2016`
		Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).

AXIS	0	This flag allows you to perform the design of members about the local axes otherwise the design will be performed for the principal axes. 0) design considering principal axes 1) design considering local axes
BEAM	1.0	0.0 = design at start and end nodes and those locations specified by the `SECTION` command. 1.0 = design at 13 evenly spaced points (i.e., 1/12th points) along member length, including start and end nodes. **Note:** See D1.A.6 Design Parameters (on page 1100).
CAN	0	0) deflection check based on the principle that maximum deflection occurs within the span between DJ1 and DJ2. 1) deflection check based on the principle that maximum deflection is of the cantilever type (see Note 9 in D1.A.6 Design Parameters (on page 1100))

Parameter Name	Default Value	Description
DFF	none (mandatory for deflection check)	"Deflection Length" / Maximum allowable local deflection. See TR.40 Load Envelope (on page 2663) for deflection checks using serviceability load envelopes.
DJ1	Start Joint of member	Joint No. denoting starting point for calculation of "Deflection Length" (see D1.B.1.2 Design Parameters (on page 1134))
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length" (see D1.B.1.2 Design Parameters (on page 1134))
FLX	0	Parameter for specifying the lateral-torsional restraint condition for a single angle. 0) Restraint not provided 1) Restraint provided
FU	58 ksi	Ultimate tensile strength of steel in current units.
FYLD	36 ksi	Yield strength of steel in current units.
KT	1.0	K value for flexural-torsional buckling.
KY	1.0	Effective length factor for overall column buckling about the local y-axis; used to compute the KL/r ratio for determining the capacity in axial compression. Values can range from 0.01 (for a column completely restrained against buckling) to any large value.

Parameter Name	Default Value	Description
KZ	1.0	Effective length factor for overall column buckling about the local z-axis; used to compute the KL/r ratio for determining the capacity in axial compression. Values can range from 0.01 (for a column completely restrained against buckling) to any large value.
LT	Member Length	Unbraced length used in computing KL/r for twisting, in current units of length.
LY	Member Length	Maximum distance between the lateral restrained points in Local Y axis. Length used to calculate slenderness ratio for buckling about the local y-axis.
LZ	Member Length	Maximum distance between the lateral restrained points in Local Z axis. Same as LY, but in the local z-axis.
METHOD	LRFD	Used to specify LRFD or ASD design methods. The various design factors considered are summarized in Table 31 for LRFD and in Table 32 for ASD method.
NSF	1.0	NSF is the Net Section Factor as used in most of the steel design codes in STAAD.Pro. It is defined as the Ratio of “Net cross section area” / “Gross section area” for tension member design.
RATIO	1.0	Permissible ratio of the actual to allowable capacities.
SSY	0	0) Sway or Unbraced along local Y axis 1) Braced along local Y axis
SSZ	0	0) Sway or Unbraced along local Z axis 1) Braced along local Z axis

Parameter Name	Default Value	Description
STIFF	Member Length	Spacing of transverse stiffeners **Note:** This will be used for shear capacity calculation and combine shear and bending interaction. Only used if TSA is set to 1.
TRACK	0	Specifies the amount of detail included in design output. 0) Suppress all member capacities. 1) Print all member capacities. 2) Print full member design details.
TSA	0	Specifies whether the bearing and intermediate transverse stiffeners are present. If set to 1, the program uses more liberal and set of interaction equations found in AISI S100 2016 i.e. Eq.H 2-1. 0) Beams with unreinforced webs 1) Beams with transverse web stiffeners The program uses the distance given in the STIFF parameter.
UNB	Member Length	Unsupported length of the bottom flange for calculating flexural strength. Will be used only if compression is in the bottom flange. See Note 2 below.
UNT	Member Length	Unsupported length of the top flange for calculating flexural strength. Will be used only if compression is in the top flange. See Note 2 below.

Notes

1. When BEAM is 1.0 (default), the design is performed at 13 evenly spaced points along the length of the beam, including start and end points (i.e., 1/12th points or at ends of 12 equal length segments).

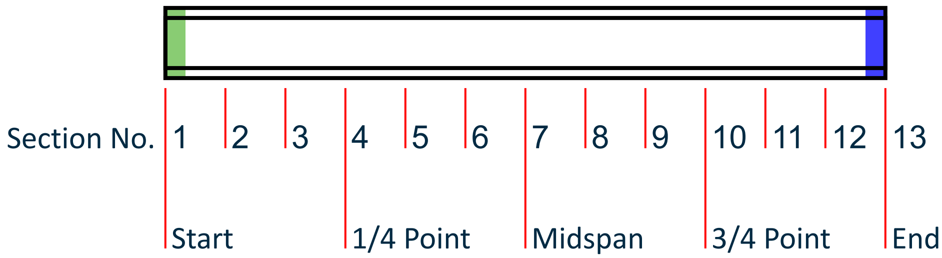

Figure 142: The default sections for design when BEAM 1.0 is used

When `BEAM` is 0.0, the start and ends along with up to three locations specified in TR.41 Section Specification (on page 2665) are designed.

2. Top and Bottom represent the positive and negative side of the local Y axis (local Z axis if `SET Z UP` is used).
3. For description of the deflection check parameters `DFF`, `DJ1`, and `DJ2`, refer to the Notes section of D1.B.1.2 Design Parameters (on page 1134).
4. The program will calculate the distortional capacities if that is applicable for assigned section type.
5. The Cb value will be calculated based on full span of an analytical member irrespective of unrestrained length specified by the user.
6. When performing the deflection check, you can choose between two methods. The first method, defined by a value `0` for the `CAN` parameter, is based on the local displacement. See TR.44 Printing Section Displacements for Members (on page 2672) for details on local displacement.

   If the `CAN` parameter is set to 1, the check will be based on cantilever style deflection. Let (DX1, DY1,DZ1) represent the nodal displacements (in global axes) at the node defined by `DJ1` (or in the absence of `DJ1`, the start node of the member). Similarly, (DX2, DY2, DZ2) represent the deflection values at `DJ2` or the end node of the member.

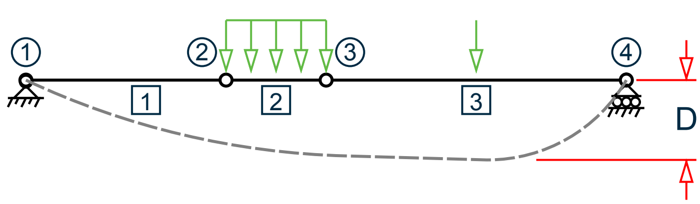
   Compute Delta = $\sqrt{(DX2 - DX1)^2 + (DY2 - DY1)^2 + (DZ2 - DZ1)^2}$

   Compute Length = distance between `DJ1` and `DJ2` or, between start node and end node, as the case may be.

   Then, if `CAN` is specified a value 1, dff = L/Delta

   Ratio due to deflection = `DFF`/dff
7. If `CAN = 0`, deflection length is defined as the length that is used for calculation of local deflections within a member. It may be noted that for most cases the “Deflection Length” will be equal to the length of the member. However, in some situations, the “Deflection Length” may be different.

   For example, refer to the figure below where a beam has been modeled using four joints and three members. The “Deflection Length” for all three members will be equal to the total length of the beam in this case. The parameters `DJ1` and `DJ2` should be used to model this situation. Also the straight line joining `DJ1` and `DJ2` is used as the reference line from which local deflections are measured. Thus, for all three members here, `DJ1` should be "1" and `DJ2` should be "4".



D is equal to the maximum local deflection for members 1, 2, and 3.

DFF 300. ALL
DJ1 1 ALL
DJ2 4 ALL
```

D1.F. American Codes - Concrete Design per ACI 318

Concrete member and floor design per ACI 318-14, ACI 318-11, ACI 318-08, ACI 318-05 ACI 318-02 and ACI 318-99 *Building Code Requirements for Structural Concrete* is available in STAAD.Pro.

Note: To use the ACI 318 design code for a specific publication year, refer to Design Operations.

D1.F.1 Design Operations

STAAD.Pro has the capabilities for performing concrete design. It will calculate the reinforcement needed for the specified concrete section. All the concrete design calculations are based on the current edition of ACI 318 (unless a previous version is specified).

The design requirements need to be contained within a concrete design block, include the code reference, any modifications to design parameters and instructions as to which objects are to be designed.

```
START CONCRETE DESIGN
CODE code_ref
parameters values
design_instructions
END CONCRETE DESIGN
```

The versions of the ACI 318 code implemented can be referred to as follows:

Code Edition	*code_ref*	Design Beams	Design Columns	Design Slabs
2014	ACI ACI 2014	Yes	Yes	
2011	ACI 2011	Yes	Yes	
2008	ACI 2008	Yes	Yes	Yes
2005	ACI 2005	Yes	Yes	Yes
2002	ACI 2002	Yes	Yes	Yes
1999	ACI 1999	Yes	Yes	Yes

For a list of the *parameters* that can be used for design, see D1.F.3 Design Parameters (on page 1201).

Note: Not all parameters apply to all versions of the ACI 318 design code.

design_instructions:

```
DESIGN BEAM { member_list | ALL }
```

```
DESIGN COLUMN { member_list | ALL }
```

```
DESIGN PLATE { element_list | ALL }
```

See also TR.53 Concrete Design Specifications (on page 2684).

Example

FYMAIN 58 ALL
MAXMAIN 10 ALL
CLB 2.5 ALL
DESIGN BEAM 1 7 10
END CONCRETE DESIGN
```

D1.F.2 Section Types for Concrete Design

The current version of ACI 318 in STAAD.Pro supports the design of beams and columns defined as follows.

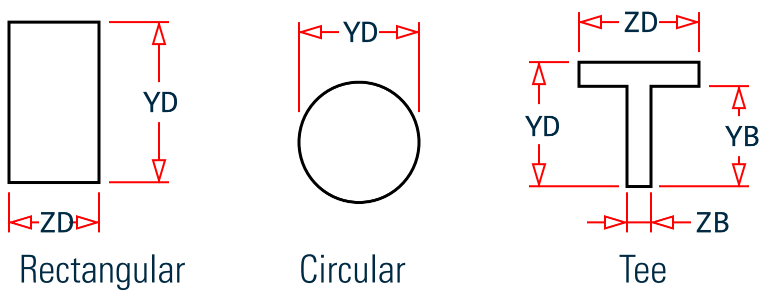

Figure 143: Section types for concrete design

Beam Design – uses a 2D beam element if specified with the following properties:

1. Rectangular
   a. Defined as a Prismatic section with YD (depth) and ZD (width)
   b. Defined in a User Table, type: prismatic
2. Tee Section
   a. Defined as a Prismatic section with YD (overall depth), YB (depth of stem), ZD (width of flange), and ZB (width of stem)

Column Design – uses a 2D beam element if specified with the following properties:

1. Rectangular
   a. Defined as a Prismatic section with YD (depth) and ZD (width)
   b. Defined in a User Table, type: prismatic
2. Tee Section

   a. Defined as a Prismatic section with YD (overall depth), YB (depth of stem), ZD (width of flange), and ZB (width of stem)

3. Circular

   a. Defined as Prismatic section with YD (circumference)

Related Links

- *TR.20.2 Prismatic Property Specification* (on page 2263)

D1.F.2.1 Section Types Supported for ACI 318-99 – ACI 318-11

Design using ACI 318-11, ACI 318-08, ACI 318-05, ACI 318-02, or ACI 318-99 in STAAD.Pro supports the design of beams, columns, or slabs defined as follows.

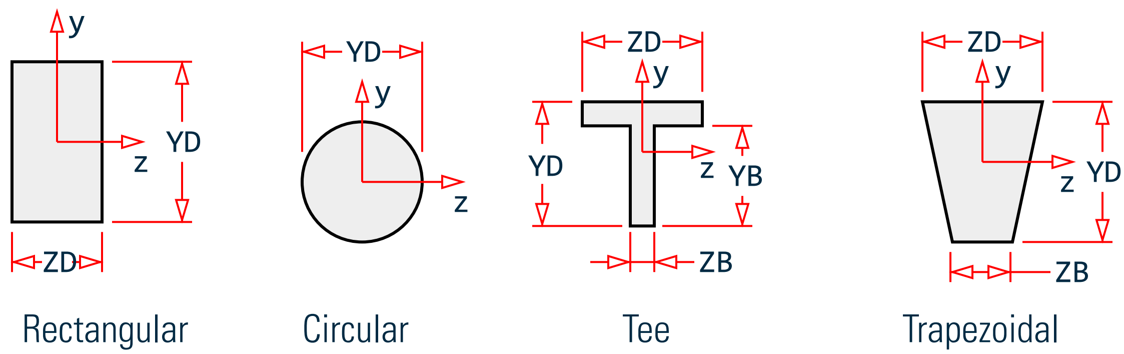

Figure 145: Section types for concrete design

Beam Design – uses a 2D beam element if specified with the following properties:

1. Rectangular

   a. Defined as a Prismatic section with YD (depth) and ZD (width)
   b. Defined in a User Table, type: prismatic

2. Tee Section

   a. Defined as a Prismatic section with YD (overall depth), YB (depth of stem), ZD (width of flange), and ZB (width of stem)

3. Trapezoidal

   a. Defined as Prismatic section with YD (depth), ZD (width at top), and ZB (width at bottom).

Column Design – uses a 2D beam element if specified with the following properties:

1. Rectangular

   a. Defined as a Prismatic section with YD (depth) and ZD (width)
   b. Defined in a User Table, type: prismatic

2. Circular

   a. Defined as Prismatic section with YD (circumference)

Floor Slab Design - uses a 2D plate element

1. 3-noded plate with thickness of element is equal to the thickness of the slab

2. 4-noded plate with thickness of element is equal to the thickness of the slab. All four nodes should be co-planar.

D1.F.3 Design Parameters

The following outlines the parameters that are available to control the design of members as beams or columns per the ACI 318-14 code. The commands that initiate the design of these is outlined in TR.53.3 Concrete Design Command (on page 2685). If any parameter is not specified and its value is required in the design, then it will use that specified as the default value in the tables below.

Note: Not all the parameters are used in all versions of the ACI 318 code. Ensure that all the necessary parameters for the version of the code are properly specified. Where practical, parameters used in earlier versions of the code will be supported in the newer versions. Some old parameters are not supported in newer versions of the code and new parameters have been added in newer versions of the code that provide greater flexibility in the design.

Table 89: ACI 318 Design Parameters

Parameter Name	Default Value	Description
BDY	1.0	Column stiffness reduction factor for bending about the local Y axis. **Note:** Not used if parameter `MMAG` > 0 **Note:** Only used with ACI 318-11 and ACI 318-14.
BDZ	1.0	Column stiffness reduction factor for bending about the local Z axis. **Note:** Not used if parameter `MMAG` > 0 **Note:** Only used with ACI 318-11 and ACI 318-14.
BRDO	0	Bottom Rebar Detail Options 0) Increase number of bars, then increase bar size, then add layers 1) Increase the bar size, then increase the number of bars, then add layers **Note:** Only used with ACI 318-14.
CLB	1.5 in. (38 mm) for members*	Minimum cover from the base of the section to the bottom longitudinal reinforcement.
CLS	1.5 in. (38 mm)*	Minimum cover from the sides of the section to the side longitudinal reinforcement. See Note a (on page 1205) and Note c (on page 1206) below.

Parameter Name	Default Value	Description
CLT	1.5 in. (38 mm) for members*	Minimum cover from the top of the section to the top longitudinal reinforcement.
CRDO	0	Design options for main reinforcement in columns 0) Increase the number of bars and the bar size 1) Increase the bar size and then the number of bars **Note:** Only used with ACI 318-14.
FC	4,000 psi (28 N/ mm^2)*	Compressive strength of concrete.
FYMAIN	60,000 psi (420 N/mm^2)*	Yield stress for main longitudinal reinforcing steel.
FYSEC	60,000 psi (420 N/mm^2)*	Yield stress for transverse reinforcing steel.
LATR	0 (No)	Is this member subject to lateral loading? 0) No 1) Yes This will be used in determining the development length requirements, in ACI 318-14 clause 9.7.3.8. This parameter is only applicable for beams. **Note:** Only used with ACI 318-14.
LWF	0	Specifies the aggregate composition of the concrete. 0) Normal weight 1) Sand light weight 2) All light weight
MAXMAIN	#18 (Imperial), 57M (Metric)	Maximum size of reinforcing bar to be used for longitudinal reinforcement. **Note:** When using ACI 318-14, the maximum size used in specific positions can be individually set. See detailing parameters below.
MIMB	#4 (Imperial), 13M (Metric)	Minimum main rebar number (size) at the bottom face **Note:** Only used with ACI 318-14.

Parameter Name	Default Value	Description
MIMS	#4 (Imperial), 13M(Metric)	Minimum main rebar number (size) at for skin (side) bars **Note:** Only used with ACI 318-14.
MIMT	#4 (Imperial), 13M (Metric)	Minimum main rebar number (size) at the top face **Note:** Only used with ACI 318-14.
MINMAIN	#4 (Imperial), 13M (Metric)	Minimum size of reinforcing bar to be used for longitudinal reinforcement. **Note:** When using ACI 318-14, the minimum size used in specific positions can be individually set. See detailing parameters below.
MINSEC	#4 (Imperial), 13M (Metric)	Minimum size of reinforcing bar to be used for transverse reinforcement.
MMAG	1.0	Factor to magnify the analysis moments used for column design. **Note:** For ACI 318-14, if this is set to 0, then the moments for the local Y and Z axis will be calculated independently using the parameters BDY and BDZ.
MXMB	#18 (Imperial), 57M (Metric)	Maximum main rebar number (size) at the bottom face **Note:** Only used with ACI 318-14.
MXMS	#18 (Imperial), 57M (Metric)	Maximum main rebar number (size) for skin (side faces) bars **Note:** Only used with ACI 318-14.
MXMT	#18 (Imperial), 57M (Metric)	Maximum main rebar number (size) at the top face **Note:** Only used with ACI 318-14.
RCOAT	0	Rebar coating type: 0) No coating 1) Epoxy coating 2) Galvanized **Note:** Only used with ACI 318-14.
REINF	0	Column transverse reinforcement type. 0) links (tied column) 1) spiral reinforcement

Parameter Name	Default Value	Description
RHOMIN	0.01	Minimum reinforcement required in a concrete column. Enter a value between 0.0 and 0.08, where 0.08 = 8% reinforcement; the maximum allowed by the ACI code. **Note:** This parameter is not used with ACI 318-14.
SKY	1.0	Effective length factor for moment magnification procedure calculations for columns, in the local Y direction. When the SWY parameter is 0 (i.e., not braced), then $SKY \geq 1.0$. When SWY is 1 (i.e., braced), then $0.5 \leq SKY \leq 1.0$. **Note:** Only used with ACI 318-11 and ACI 318-14.
SKZ	1.0	Effective length factor for moment magnification procedure calculations for columns, in the local Z direction. When the SWY parameter is 0 (i.e., not braced), then $SKZ \geq 1.0$. When SWY is 1 (i.e., braced), then $0.5 \leq SKZ \leq 1.0$. **Note:** Only used with ACI 318-11 and ACI 318-14.
SLY	n/a	Number of the load case that applies sidesway load in the local Y axis for column design. The moments from this case are used to magnify the local Y axis moments for all design load cases as per the sway or non sway requirements. Calculations are dependent on the SWY parameter setting. **Note:** This parameter is not used if MMAG has been specified. **Note:** Only used with ACI 318-11 and ACI 318-14.
SLZ	n/a	Number of the load case that applies sidesway load in the local z axis for column design. The moments from this case are used to magnify the local Z axis moments for all design load cases as per the sway or non sway requirements. Calculations are dependent on the SWY parameter setting. **Note:** This parameter is not used if MMAG has been specified. **Note:** Only used with ACI 318-11 and ACI 318-14.

Parameter Name	Default Value	Description
SQY	0.2	Stability index, Q, in the local Y axis as defined in ACI 318 section 6.6.4.3(b). **Note:** Only used with ACI 318-11 and ACI 318-14.
SQZ	0.2	Stability index, Q, in the local Z axis as defined in ACI 318 section 6.6.4.3(b). **Note:** Only used with ACI 318-11 and ACI 318-14.
SWY	0	Braced against sidesway: 0) Not braced 1) Braced **Note:** Use only when `MMAG` parameter is equal 0. **Note:** Only used with ACI 318-11 and ACI 318-14.
TRACK	0.0	Output detail 0) Design and report only the steel area requirements 1) Perform detailed design and report bar layouts 2) Perform detailed design and report all details
TRDO	0	Top Rebar Detail Options 0) Increase number of bars, then increase the bar size, then add layers 1) Increase the bar size, then increase the number of bars, then add layers
TRN	0	Specifies whether a member is subject to transverse loads between supports. This parameter influences the moment magnification calculations per CL 6.6.4.5.3. 0) True 1) False

Notes

a. The value used when specifying the `CLS` parameter for column design is taken to be the clear cover for the longitudinal bars in a column. It is not taken as the clear cover for the tie bars. Therefore, the distance from the edge of the column to the centerline of the first row of longitudinal bars is `CLS` plus half the diameter of the main bar.

b. The following parameters are *not* applicable to the ACI 318-14 (only to ACI 318-11 and earlier):

DEPTH
EFACE
RHOMAIN
SFACE
WIDTH
NSECTION

Note: In ACI 318-14, members are always designed with five sections. The parameter `NSECTION` used with older editions of the code has no effect.

c. `MAXMAIN` and `MINMAIN` are now supplemented by new set of parameters like `MXMB`, `MIMC` etc. You can assign values either in the old parameters (like `MAXMAIN`) or in the new parameters (like `MXMT`, `MXMB`, `MXMC`). If you choose to use older parameters like `MAXMAIN` and `MINMAIN`, the program will store this input into newer parameters like `MXMB`, `MIMC` etc. internally. However, if you use both older and newer parameters, only the newer parameter values are accepted by the program.

D1.F.3.1 ACI 318-2011 Design Parameters

The following outlines the parameters that are available to control the design of members as beams or columns per the ACI 318-11 code. The commands that initiate the design of these is outlined in TR.53.3 Concrete Design Command (on page 2685). If any parameter is not specified and its value is required in the design, then it will use that specified as the default value in the tables below.

Note: Not all the parameters are used in all versions of the ACI 318 code. Ensure that all the necessary parameters for the version of the code are properly specified. Where practical, parameters used in earlier versions of the code will be supported in the newer versions. Some old parameters are not supported in newer versions of the code and new parameters have been added in newer versions of the code that provide greater flexibility in the design.

Table 90: ACI 318 2011 Design Parameters

Parameter Name	Default Value	Description
ALPHA	1.5 for rectangular sections, 2.0 for square sections	Exponent for Bresler Load Contour Method for Bixaial Interaction. **Note:** The value should in theory be specified differently for each load case. This can be done by performing multiple designs with different load cases and choosing a value that is appropriate for all those cases.

Parameter Name	Default Value	Description
BDY	1.0	Column stiffness reduction factor for bending about the local Y axis. **Note:** Not used if parameter MMAG > 0 **Note:** Only used with ACI 318-11 and ACI 318-14.
BDZ	1.0	Column stiffness reduction factor for bending about the local Z axis. **Note:** Not used if parameter MMAG > 0 **Note:** Only used with ACI 318-11 and ACI 318-14.
CLB	1.5 in. (38 mm) for beams* 0.75 in. (19 mm) for plate elements*	Minimum cover from the base of the section to the bottom longitudinal reinforcement. See Note c (on page 1211) below.
CLS	1.5 in. (38 mm)*	Minimum cover from the sides of the section to the side longitudinal reinforcement. See Note a (on page 1205) and Note c (on page 1211) below.
CLT	1.5 in. (38 mm) for beams* 0.75 in. (19 mm) for plate elements*	Minimum cover from the top of the section to the top longitudinal reinforcement. See Note c (on page 1211) below.
DEPTH	YD*	Depth of the member measured in the local Y axis. **Note:** This parameter is not used with ACI 318-14.
EFACE	0.0*	Face of support location at end of beam. If specified, the shear force at end is computed at a distance of EFACE + d from the end joint of the member. **Note:** See D1.F.4.3 Shear and Torsion Design (on page 1217) for additional information. **Note:** This parameter is not used with ACI 318-14.
FC	4,000 psi (28 N/mm^2)*	Compressive strength of concrete.
FYMAIN	60,000 psi (420 N/mm^2)*	Yield stress for main longitudinal reinforcing steel.

Parameter Name	Default Value	Description
FYSEC	60,000 psi (420 N/mm^2)*	Yield stress for transverse reinforcing steel.
LWF	1.0	Modification factor, λ, for lightweight concrete as specified in ACI i318-08, cl. 8.6.1. Valid entries are between 0.75 and 1.0, inclusive. Used as a reduction factor for the mechanical properties of lightweight concrete. **Note:** This parameter is used in ACI 318-2008, 2001, and 2014 only.
MAXMAIN	#18 bar (57 mm)	Maximum size of reinforcing bar to be used for longitudinal reinforcement. **Note:** When using ACI 318-14, the maximum size used in specific positions can be individually set. See detailing parameters below. **Note:** See Note b (on page 1211) below.
MINMAIN	#4 bar (13 mm)	Minimum size of reinforcing bar to be used for longitudinal reinforcement. **Note:** When using ACI 318-14, the minimum size used in specific positions can be individually set. See detailing parameters below. **Note:** See Note b (on page 1211) below.
MINSEC	#4 bar (13 mm)	Minimum size of reinforcing bar to be used for transverse reinforcement. **Note:** When using ACI 318-14, the minimum size used in specific positions can be individually set. See detailing parameters below. **Note:** See Note b (on page 1211) below.
MMAG	1.0	Factor to magnify the analysis moments used for column design. **Note:** For ACI 318-14, if this is set to 0, then the moments for the local Y and Z axis will be calculated independently using the parameters BDY and BDZ.

Parameter Name	Default Value	Description
NSECTION	12	Number of equally spaced sections to be considered in finding critical moments for beam design. The valid range is from 12 to 20. This parameter applies to the design process rather than individual members and thus should not have any assigned member list. If more than one `NSECTION` parameter is defined, then highest value will be used.
REINF	0	Column transverse reinforcement type. 0) links (tied column) 1) spiral reinforcement
RHOMIN	0.01	Minimum reinforcement required in a concrete column. Enter a value between 0.0 and 0.08, where 0.08 = 8% reinforcement; the maximum allowed by the ACI code. **Note:** This parameter is not used with ACI 318-14.
SFACE	0.0*	Face of support location at start of beam. If specified, the shear force at start is computed at a distance of SFACE + d from the start joint of the member. **Note:** See D1.F.4.3 Shear and Torsion Design (on page 1217) for additional information. **Note:** This parameter is not used with ACI 318-14.
SKY	1.0	Effective length factor for moment magnification procedure calculations for columns, in the local Y direction. When the `SWY` parameter is 0 (i.e., not braced), then $SKY \geq 1.0$. When `SWY` is 1 (i.e., braced), then $0.5 \leq SKY \leq 1.0$. **Note:** Only used with ACI 318-11 and ACI 318-14.
SKZ	1.0	Effective length factor for moment magnification procedure calculations for columns, in the local Z direction. When the `SWY` parameter is 0 (i.e., not braced), then $SKZ \geq 1.0$. When `SWY` is 1 (i.e., braced), then $0.5 \leq SKZ \leq 1.0$. **Note:** Only used with ACI 318-11 and ACI 318-14.

Parameter Name	Default Value	Description
SLY	n/a	Number of the load case that applies sidesway load in the local Y axis for column design. The moments from this case are used to magnify the local Y axis moments for all design load cases as per the sway or non sway requirements. Calculations are dependent on the `SWY` parameter setting. **Note:** This parameter is not used if `MMAG` has been specified. **Note:** Only used with ACI 318-11 and ACI 318-14.
SLZ	n/a	Number of the load case that applies sidesway load in the local z axis for column design. The moments from this case are used to magnify the local Z axis moments for all design load cases as per the sway or non sway requirements. Calculations are dependent on the `SWY` parameter setting. **Note:** This parameter is not used if `MMAG` has been specified. **Note:** Only used with ACI 318-11 and ACI 318-14.
SQY	0.2	Stability index, Q, in the local Y axis as defined in ACI 318 section 6.6.4.3(b). **Note:** Only used with ACI 318-11 and ACI 318-14.
SQZ	0.2	Stability index, Q, in the local Z axis as defined in ACI 318 section 6.6.4.3(b). **Note:** Only used with ACI 318-11 and ACI 318-14.
SWY	0	Braced against sidesway: 0) Not braced 1) Braced **Note:** Use only when `MMAG` parameter is equal 0. **Note:** Only used with ACI 318-11 and ACI 318-14.

Parameter Name	Default Value	Description
TRACK	0.0	Output detail • Beam Design: 0) Critical moment will not be printed out with beam design report. 1) Critical moment will be printed out with beam design report 2) Print out required steel areas for all intermediate sections specified by `NSECTION`. • Column Design: 0) Prints out detailed design reports 1) Prints out column interaction analysis results in addition to TRACK 0.0 output. 2) Prints out a schematic interaction diagram and intermediate interaction values in addition to TRACK 2.0 results.
TRN	0	Transverse loads between supports 0 - False 1 - True **Note:** Only used with ACI 318-14.
WIDTH	ZD*	Width of the member measured in the local Z axis. **Note:** This parameter is not used with ACI 318-14.

Note: * These values must be provided in the current unit system being used.

Notes

a. The value used when specifying the `CLS` parameter for column design is taken to be the clear cover for the longitudinal bars in a column. It is not taken as the clear cover for the tie bars. Therefore, the distance from the edge of the column to the centerline of the first row of longitudinal bars is `CLS` plus half the diameter of the main bar.

b. When using metric units for ACI design, provide values for these parameters in actual 'mm' units instead of the bar number. The following metric bar sizes are available: 6 mm, 8 mm, 10 mm, 12 mm, 16 mm, 20 mm, 25 mm, 32 mm, 40 mm, 50 mm, and 60 mm.

c. Clear cover values are set for the concrete Not exposed to weather or in contact with ground. Plates or slabs are assumed to be reinforced with bar number 11(in imperial units) or smaller.

d. Required for bar detailing in a physical member which might contain intermediate members along with cantilevers.

For internal members both `STRS` and `EDSP` should be set to 0.

e. In ACI 318-14, members are always designed with 5 sections. The parameter `NSECTION` used with older editions of the code has no effect.

D1.F.3.2 Pre ACI 318-2011 Design Parameters

The following outlines the parameters that are available to control the design of members as beams or columns per the ACI 318-99 through ACI 318-2008 codes. The commands that initiate the design of these is outlined in TR.53.3 Concrete Design Command (on page 2685). If any parameter is not specified and its value is required in the design, then it will use that specified as the default value in the tables below.

Note: Not all the parameters are used in all versions of the ACI 318 code. Ensure that all the necessary parameters for the version of the code are properly specified. Where practical, parameters used in earlier versions of the code will be supported in the newer versions. Some old parameters are not supported in newer versions of the code and new parameters have been added in newer versions of the code that provide greater flexibility in the design.

Table 92: ACI 318 2008, 2005, 2002, and 1999 Design Parameters

Parameter Name	Default Value	Description
ALPHA	1.5 for rectangular sections, 2.0 for square sections	Exponent for Bresler Load Contour Method for Bixaial Interaction. **Note:** The value should in theory be specified differently for each load case. This can be done by performing multiple designs with different load cases and choosing a value that is appropriate for all those cases. **Note:** This parameter is not used with ACI 318-1999.
CLB	1.5 in. (38 mm) for beams* 0.75 in. (19 mm) for plate elements*	Minimum cover from the base of the section to the bottom longitudinal reinforcement. See Note c (on page 1215) below.
CLS	1.5 in. (38 mm)*	Minimum cover from the sides of the section to the side longitudinal reinforcement. See Note a (on page 1205) and Note c (on page 1215) below.
CLT	1.5 in. (38 mm) for beams* 0.75 in. (19 mm) for plate elements*	Minimum cover from the top of the section to the top longitudinal reinforcement. See Note c (on page 1215) below.
DEPTH	YD*	Depth of the member measured in the local Y axis. **Note:** This parameter is not used with ACI 318-14.

Parameter Name	Default Value	Description
EFACE	0.0*	Face of support location at end of beam. If specified, the shear force at end is computed at a distance of EFACE + d from the end joint of the member. **Note:** See D1.F.4.3 Shear and Torsion Design (on page 1217) for additional information. **Note:** This parameter is not used with ACI 318-14.
FC	4,000 psi (28 N/ mm^2)*	Compressive strength of concrete.
FYMAIN	60,000 psi (420 N/mm^2)*	Yield stress for main longitudinal reinforcing steel.
FYSEC	60,000 psi (420 N/mm^2)*	Yield stress for transverse reinforcing steel.
LWF	1.0	Modification factor, λ, for lightweight concrete as specified in ACI i318-08, cl. 8.6.1. Valid entries are between 0.75 and 1.0, inclusive. Used as a reduction factor for the mechanical properties of lightweight concrete. **Note:** This parameter is used in ACI 318-2008, 2001, and 2014 only.
MAXMAIN	#18 bar (57 mm)	Maximum size of reinforcing bar to be used for longitudinal reinforcement. **Note:** See Note b (on page 1215) below.
MINMAIN	#4 bar (13 mm)	Minimum size of reinforcing bar to be used for longitudinal reinforcement. **Note:** When using ACI 318-14, the minimum size used in specific positions can be individually set. See detailing parameters below. **Note:** See Note b (on page 1215) below.
MINSEC	#4 bar (13 mm)	Minimum size of reinforcing bar to be used for transverse reinforcement. **Note:** When using ACI 318-14, the minimum size used in specific positions can be individually set. See detailing parameters below. **Note:** See Note b (on page 1215) below.

Parameter Name	Default Value	Description
MMAG	1.0	Factor to magnify the analysis moments used for column design. **Note:** For ACI 318-14, if this is set to 0, then the moments for the local Y and Z axis will be calculated independently using the parameters BDY and BDZ.
NSECTION	12	Number of equally spaced sections to be considered in finding critical moments for beam design. The valid range is from 12 to 20. This parameter applies to the design process rather than individual members and thus should not have any assigned member list. If more than one NSECTION parameter is defined, then highest value will be used.
REINF	0	Column transverse reinforcement type. 0) links (tied column) 1) spiral reinforcement
RHOMIN	0.01	Minimum reinforcement required in a concrete column. Enter a value between 0.0 and 0.08, where 0.08 = 8% reinforcement; the maximum allowed by the ACI code. **Note:** This parameter is not used with ACI 318-14.
SFACE	0.0*	Face of support location at start of beam. If specified, the shear force at start is computed at a distance of SFACE + d from the start joint of the member. **Note:** See D1.F.4.3 Shear and Torsion Design (on page 1217) for additional information. **Note:** This parameter is not used with ACI 318-14.

Parameter Name	Default Value	Description
TRACK	0.0	Output detail • Beam Design: 0) Critical moment will not be printed out with beam design report. 1) Critical moment will be printed out with beam design report 2) Print out required steel areas for all intermediate sections specified by NSECTION. • Column Design: 0) Prints out detailed design reports 1) Prints out column interaction analysis results in addition to TRACK 0.0 output. 2) Prints out a schematic interaction diagram and intermediate interaction values in addition to TRACK 2.0 results.
WIDTH	ZD*	Width of the member measured in the local Z axis. **Note:** This parameter is not used with ACI 318-14.

Notes

a. The value used when specifying the CLS parameter for column design is taken to be the clear cover for the longitudinal bars in a column. It is not taken as the clear cover for the tie bars. Therefore, the distance from the edge of the column to the centerline of the first row of longitudinal bars is CLS plus half the diameter of the main bar.

b. When using metric units for ACI design, provide values for these parameters in actual 'mm' units instead of the bar number. The following metric bar sizes are available: 6 mm, 8 mm, 10 mm, 12 mm, 16 mm, 20 mm, 25 mm, 32 mm, 40 mm, 50 mm, and 60 mm.

c. Clear cover values are set for the concrete Not exposed to weather or in contact with ground. Plates or slabs are assumed to be reinforced with bar number 11(in imperial units) or smaller.

d. Required for bar detailing in a physical member which might contain intermediate members along with cantilevers.

For internal members both STRS and EDSP should be set to 0.

D1.F.4 Beam Design

Beams are designed at a series of locations along their length for the moment about the local Z axis (MZ), shear force in the local Y and Z axes (FY and FZ), torsional moment (MX), and axial force (FX) for an envelope of the forces from a specified collection of load cases and combinations.

The envelope is created at each design section from a collection of the max/min forces in all degrees of freedom for all the load cases and/or combinations that have been included in the design. As there are 6 degrees of freedom (Fx, Fy, Fz, Mx, My, Mz) and to capture the maximum and minimum effects, a total of 12 sets of loads are designed for. Each set will include the maximum or minimum of one force such as Max FX along with all the other associated forces in the load case/combination.

For each member that is designed as a beam, the forces from the current `LOAD LIST` (see TR.39 Load List Specification (on page 2662)) will be used to create an envelope of forces.

This envelope of forces is then used to determine a required area of longitudinal rebar at each of the key section locations. Five sections are defined on each member: the start, quarter point, mid-point, three-quarter point, and end point. This required area is then used determine an optimized bar arrangement that meets the code requirements, including detailing rules. Once the longitudinal bars have been designed and detailed, the program then designs the transverse steel based on the code provisions. Note that in case of torsion loads, the effect of the applied torsion will be catered for while designing the longitudinal steel as well as the transverse steel.

The required area of reinforcements at every cross section is first calculated. In order to then arrive at an optimized detailed bar layout, the program starts with the bar size defined in the `MINMAIN` parameter (or `MIMT` parameter for top bars and `MIMB` parameter for bottom bars, if specified)

The program will then iterate though increasing the number of bars or the size of bars dependent on the values of the `BRDO` and `TRDO` parameters.

If additional skin bars (i.e., side face bars) are needed for spacing requirements, these will be added.

Any detailing rules such as development lengths etc will be considered and the final design output would indicate whether a given set of bars are not be anchored or not.

Assumed Values Used

Most of the values are determined from the beam data, however, some values of note include:

- Young's modulus of rebar (E_s) is taken as 29,000 ksi
- Young's modulus of concrete is calculated from the given value of F'_c . But if $F'_c > 10{,}000$, then E_c is limited to 3,605 psi.
- Density of concrete is taken as 145 pcf (0.083912 kip-in^3)

Scope

Note that deep beams –where the span < 4× the beam depth– are not designed. A warning is reported in the output.

D1.F.4.1 Strength and Ductility Design

The strength design is performed in two steps considering the longitudinal reinforcement design for axial-bending in an initial step, and the shear and torsion design including the longitudinal reinforcement for torsion tension in a latter pass together with the transverse design.

The member resistance is calculated based on strain compatibility and interaction surface calculations.

The following conditions should be checked (9.5.1.1)

$$\phi Mn \geq Mu$$
$$\phi Vn \geq Vu$$

$\phi Tn \geq Tu$
$\phi Pn \geq Pu$

ϕ is determined according to 21.2

The ratio of neutral axis depth to the depth of the furthest rebar in tension is limited such that the section strain at the location of the maximum rebar depth is a minimum of 0.004.

Application of the ductility checks are limited to cross sections with net axial load (compression) less than $0.10f´c\ Ag$, in accordance with section 9.3.3.1.

The maximum strain in the tension reinforcement is calculated and compared with the Code limit. In order to reduce the time involved in the axial-bending calculations, the approximation may currently have a maximum difference with the more precise values of 12% mostly in biaxial cases, the approximation will be much better for other cases.

D1.F.4.2 Minimum Flexural Reinforcement

The code specifies to dispose a minimum area of flexural reinforcement where tension reinforcement is required.

As a minimum bound, the condition that is given in 9.6.2.1is used. Although it is intended only for prestressed beams, it may be used also in reinforced concrete beams and control in odd circumstances such as where the specified cover is extremely large. The bending strength of the section is designed to be at least $1.2\ Mcr$, where the cracking moment is assumed to be applied to each axis separately as uniaxial bending. No simultaneous biaxial moments are considered. The cracking moments about each axis are calculated to cause the stress in the extreme tension fiber to reach fr. In order to account for a possible varying of elastic modulus (Ec) values, the following formula is used ignoring the effect of the inertia product (Ixy):

$$M_{cr(region)} = \frac{\sigma_{cr(region)} E_c I_c}{E_{c(region)} c_{(region)}}$$

where

$\sigma_{cr(region)}$	=	the flexural tension strength for a region
$E_{c(region)}$	=	the modulus of elasticity for a specific region
$c_{(region)}$	=	the distance from the neutral axis to the extreme fiber of a region
$E_c I_c$	=	the integrated product of the inertia and elastic modulus for the entire section
fr	=	the modulus of rupture calculated in accordance with Clause 19.2.3.1
λ	=	calculated according to Clause 19.2.4.2

The cracking moment is individually calculated for each axis and only considers a particular axis if there is a considerable bending moment about that axis. The sign of the acting moment is also considered.

This minimum bound is considered only when the 9.6.1.2 or 9.6.1.3 is also applied

D1.F.4.3 Shear and Torsion Design

In the absence of torsion, the required shear bar density at cross section at each cross section will initially be calculated for shear along both the local Z and Y axes. Based on these required shear densities, the program will divide the member into one or more shear zones such that each zone (between the start and end cross sections) will require the same shear density. Once the shear zones have been identified, transverse bar links will be provided based on the bar size specified using the `MINSEC` parameter. In order to meet the required density demand, the program will start with the minimum number of legs and calculate the most optimum spacing for the transverse links. If the minimum / maximum spacing criteria cannot be met during this process, additional legs will be added and the spacings adjusted to optimize the design. Note that the program will use the same bar size for links to cater for shear along both the X a nd Z directions to maintain a practical design.

Note that the program will use the same bar size for all transverse bars to cater for shear requirements in both axes to maintain a practical design .

If the beam is also subject to torsional forces (MX), both the longitudinal steel as well the transverse steel will be designed to cater for the applied torsion, in addition to any longitudinal or transverse steel that would have been required for the bending/ shear effects. The torsion force increases the demand in the transverse due to pure shear and longitudinal direction due to warping effects.

See section F.7 for the clauses considered for shear and torsion design.

D1.F.4.4 Definition of Bar Positions

Both input parameters and design output refer to the positions of bars in beam sections as follows.

Note: The bars shown in these figures are representational only; they do not correspond to any examples in this section.

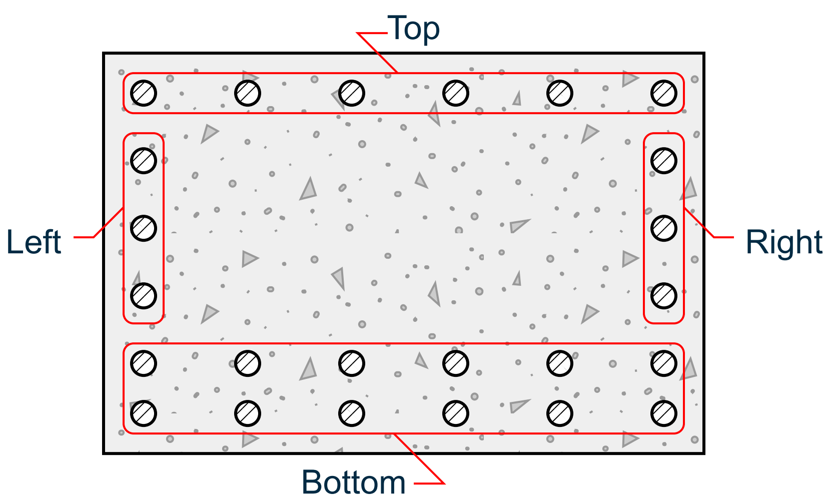

Figure 146: ACI 318-14 rectangular beam bar positions

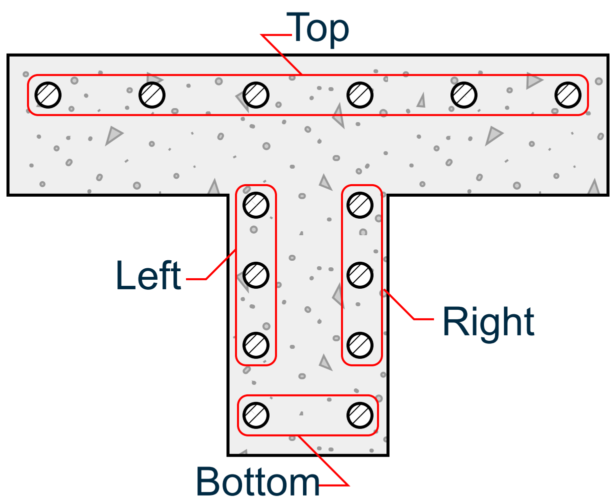

Figure 147: ACI 318-14 Tee beam bar positions

D1.F.4.5 Beam Design Output

The following report options are provided for the output for a beam design.

TRACK 0 Output

Setting the option `TRACK 0` will cause the program to produce the required area of longitudinal as well as transverse steel at 5 equally spaced locations –including member ends– along the member length.

Note: This option is meant to be considered for quick area of steel (As) requirement analysis and should *not* be considered as a safe, acceptable design.

Sample `TRACK 0` output:

Member	member number
Type	Beam
Shape	Either rectangular or Tee
As	the area of longitudinal steel required at each cross section
Asv/sv	the transverse steel density required at each cross section

```
                              STAAD.PRO CONCRETE DESIGN - (ACI-318-14)   v2.0
                              ***********************************************

Units: Kip and Inch (Unless Noted Otherwise)
   |-----------------------------------------------------------|

 |-----------------------------------------------------------|
```

TRACK 1 Output

Setting the program to output the beam design with a `TRACK 1` option will perform full design and detailing operations and will report a summary of the design. A `TRACK 1` report will include the following sections:

Design Summary — This section provides a summary of the design including the design status (i.e., PASS/FAIL), member type, length, the critical ratio, the critical criteria, and relevant clauses.

Cross section details — This section provides shape type and dimensions of the cross section profile.

Longitudinal Bar Layout — The position and extent of the longitudinal bars will be reported along with an indication if additional anchorage is required at the start or the end of the bars. A value of “yes” in the Anchor column indicates that the bar or set of bars will need to be anchored beyond the given section distances. This can be done using hooks/bends or physical anchors as deemed fit. A value of “no” indicates that no additional extension to the bar is needed beyond the given dimension. The value given in “Distance from face”is the measurement from the face defined by the position, to the center line of the bar, measured perpendicular to the face.

Transverse Bar Layout — The transverse bar table reports the details of various shear zones (see D1.F.4.3 Shear and Torsion Design (on page 1217)) within the span for both the local Y & Z axes.

Each zone is identified by the unique start and end location reported as the distances “From” and “To.”

This provides shear densities as minimum required and as provided by the given bar details.

The value “Nums” is the number of transverse groups in the zone (this equates to the zone length/spacing +1), the center to center spacing between adjacent transverse groups along the local X axis, the size of the bar used in the transverse group, and the leg count for the bars in a transverse group. A transverse group is the collection of transverse bars at a given cross section.

Note: This output will *not* report any warnings or errors from the design and member analysis. These are only reported in the `TRACK 2` output.

Sample beam design `TRACK 1` output:

TRACK 2 Output

`TRACK 2` will produce the results of `TRACK 1` along with the details of the bars and their distribution at each cross section. This option will also report any of the relevant detailed design messages. The longitudinal bar details at each cross section will have information on the setting out of each bar at the specific cross section. This should serve as a useful tool to inspect the design in detail. A `TRACK 2` output would contain:

Design Summary	This section provides a summary of the design including the design status, i.e. PASS/FAIL, member type and length, the critical ratio, the critical criteria and relevant clauses.
Cross Section Details	This section provides the shape type and dimension(s) of the cross-section
Design Inputs	This section reports the material data for the steel and concrete including the yield strength for steel (FY), compressive strength of concrete (FC) and modulus of elasticity for both (Es and Ec) This section additionally includes details of the cover to the longitudinal bars from the top, bottom and side faces.
Critical Strength Results	This section reports the demand determined from the design envelope as described in D1.F.4 Beam Design (on page 1215), along with the capacity for forces applied in positive and negative directions. The ratio is then the value of the demand divided by the appropriate capacity.

Longitudinal Bar Details at Cross Sections

For each of the design cross sections, the longitudinal bars are reported for each face where they are required, top bottom and skin. Area of steel is reported as the optimum required from the design and that provided after additionally meeting the detailing requirements.

The total quantity of bars on the given face are reported as “No(s) bars,” the size of longitudinal bars and quantity of layers that the bars are to be distributed on. For example, if the number of bars reported is 10 and in 2 layers, then there will be 5 bars in each layer.

Longitudinal Bar Layout

The position and extent of the longitudinal bars will be reported along with an indication if additional anchorage is required at the start or the end of the bars. A value of “yes” in the Anchor column indicates that the bar or set of bars will need to be anchored beyond the given section distances. This can be done using hooks/bends or physical anchors as deemed fit. A value of “no” indicates that no additional extension to the bar is needed beyond the given dimension. The value given in “Distance from face”is the measurement from the face defined by the position, to the center line of the bar, measured perpendicular to the face.

Transverse Bar Layout

The transverse bar table reports the details of various shear zones (see D1.F.4.3 Shear and Torsion Design (on page 1217)) within the span for both the local Y & Z axes.

Each zone is identified by the unique start and end location reported as the distances “From” and “To.”

This provides shear densities as minimum required and as provided by the given bar details.

The value “Nums” is the number of transverse groups in the zone (this equates to the zone length/spacing +1), the center to center spacing between adjacent transverse groups along the local X axis, the size of the bar used in the transverse group, and the leg count for the bars in a transverse group. A transverse group is the collection of transverse bars at a given cross section.

Note: This output will additionally report any warnings or errors from the design and member analysis.

Sample beam design TRACK 2 output:

D1.F.4.6 Beam Design per ACI 318-11 and Earlier

Beams are designed for flexure, shear and torsion. For all these forces, all active beam loadings are prescanned to locate the possible critical sections. The total number of sections considered is 12 (twelve) unless this number is redefined with an NSECTION parameter. All of these equally spaced sections are scanned to determine moment and shear envelopes.

D1.F.4.6.1 Cracked Moment of Inertia - ACI Beam Design

When beam design is done per ACI 318, STAAD will report the moment of inertia of the cracked section at the location where the design is performed. The cracked section properties are calculated in accordance with the equations shown below.

Rectangular Sections

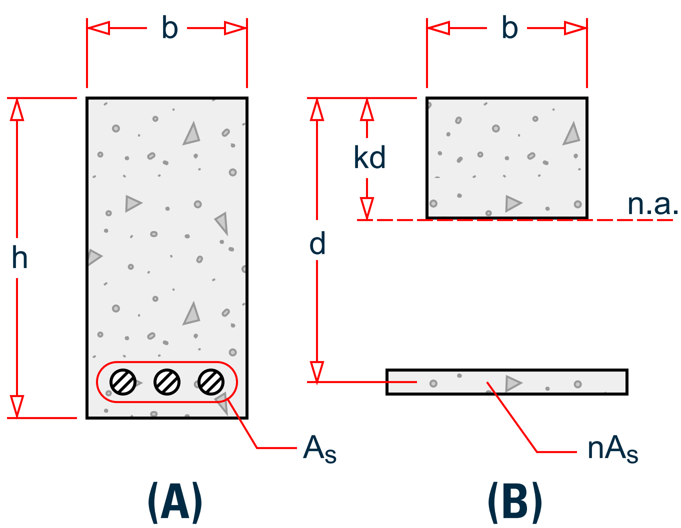

Figure 148: Gross section (A) and cracked transform section (B) for rectangular shapes

Without compression steel

$$n = E_s/E_c$$

$$B = \frac{b}{nA_I}$$

$$I_g = \frac{b \times h^3}{12}$$

$$kd = \frac{\sqrt{2d \times B + 1} - 1}{B}$$

$$I_{cr} = \frac{b(kd)^3}{3} + nA_s(d - kd)^2$$

Tee Shaped Sections

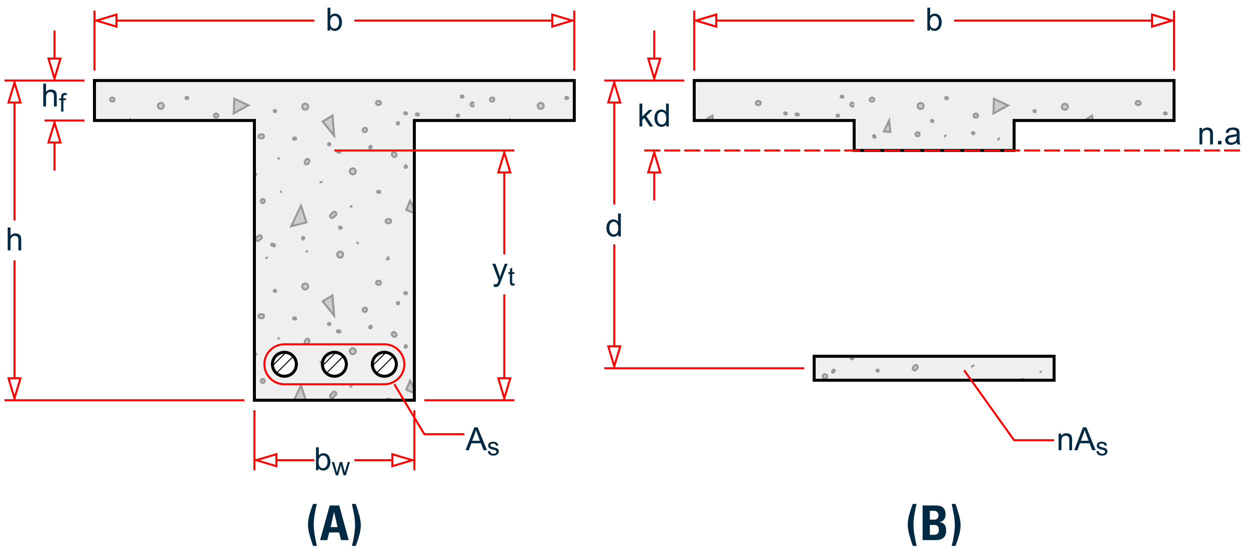

Figure 149: Gross and cracked transform sections for tee shapes without compression steel

Without compression steel

$$C = \frac{b_w}{nA_s}$$

$$f = \frac{h_f\left(b - b_w\right)}{nA_s}$$

$$y = h - \frac{1}{2}\frac{\left(b - b_w\right) \times h_f^2 + b_w \times h^2}{\left(b - b_w\right) \times h_f + b_w \times h}$$

$$kd = \frac{\sqrt{C\left(2d + h_f \times f\right) + (1 + f)^2} - \left(1 + f\right)}{C}$$

$$I_{cr} = \frac{\left(b - b_w\right) \times h_f^3}{12} + \frac{b_w(kd)^3}{3} + \left(b - b_w\right) \times h_f \times \left(kd - \frac{h_f}{2}\right)^2 + nA_s \times (d - kd)^2$$

See D1.F.4.5 Beam Design Output (on page 1219) for an example of output including the calculated cracked moment of inertia.

D1.F.4.6.2 Design of I-shaped beams per ACI-318

I-shaped sections can be designed as beams per the ACI 318 code. The property for these sections must be defined through a user table, I-section, or using the tapered specification. Information on assigning properties in this manner is available in TR.19 User Steel Table Specification (on page 2241) (I-section type) and TR.20.3 Tapered Member Specification (on page 2266) (Tapered I shape) of the Technical Reference manual.

From the standpoint of the analysis – determining member forces, nodal displacements and support reactions – the same set of facilities and rules which are applicable for any normal reinforced concrete frames or other structures can be used when I-sections or tapered concrete members are specified. In other words, there isn't anything unique or special to account for in the analysis model simply because I-shaped concrete beams are part of it.

From the standpoint of design, the following rules are applicable:

1. The member can be designed as a beam using the general principles explained in D1.F.4 Beam Design (on page 1215). It currently cannot be designed as a column. Design as a beam is done for flexure (MZ), shear (FY) and torsion (MX) just like that for rectangular, tee or trapezoidal beams. Axial forces (FX) are used during the capacity computations in shear and torsion. At each section along the length that the member is designed at, the depth at that section location is used for effective depth computation.
2. The program performs the following tests on the section dimensions before starting the design:
   - If the thickness of the web is the same as the width of the top and bottom flanges, the member is designed as a rectangular section.
   - If the thickness of the web is the same as the width of one of the flanges but not the other, the member is designed as a T-section or a rectangular section, depending on which side the compression due to bending is at.
   - If the web thickness does not match the width of either flange, design is done using the rules applicable for T-beams – one flange is in compression, the other in tension, and tensile capacity of concrete on the tensile side of the neutral axis is ignored.
   - The program is also able to design the beam as a doubly reinforced section if it is unable to design it as a single-reinforced section.
3. The parameters for designing these members are as shown in D1.F.3 Design Parameters (on page 1201) of this manual. Detailed output on design at individual section locations along the member length may be obtained by setting the TRACK parameter to 3.0.

An example for I-beam design is shown below.

D1.F.4.6.3 ACI 318-11 and Earlier Beam Design Output

The following annotations apply to the output:

LEVEL	Serial number of bar level which may contain one or more bar group
HEIGHT	Height of bar level from the bottom of beam
BAR INFO	Reinforcement bar information specifying number of bars and bar size
FROM	Distance from the start of the beam to the start of the reinforcement bar
TO	Distance from the start of the beam to the end of the reinforcement bar
ANCHOR(STA/END)	States whether anchorage, either a hook or continuation, is needed at start (STA) or at the end
ROW	Actually required flexural reinforcement (As/bd) where b = width of cross section (ZD for rectangular and square section) and d = effective depth of cross section (YD - distance from extreme tension fiber to the c.g. of main reinforcement).
ROWMN	Minimum required flexural reinforcement (Amin/bd)
ROWMX	Maximum allowable flexural reinforcement (Amax/bd)
SPACING	Distance between centers of adjacent bars of main reinforcement
Vu	Factored shear force at section
Vc	Nominal shear strength provided by concrete
Vs	Nominal shear strength provided by shear reinforcement
Tu	Factored torsional moment at section
Tc	Nominal torsional moment strength provided by concrete
Ts	Nominal torsional moment strength provided by torsion reinforcement

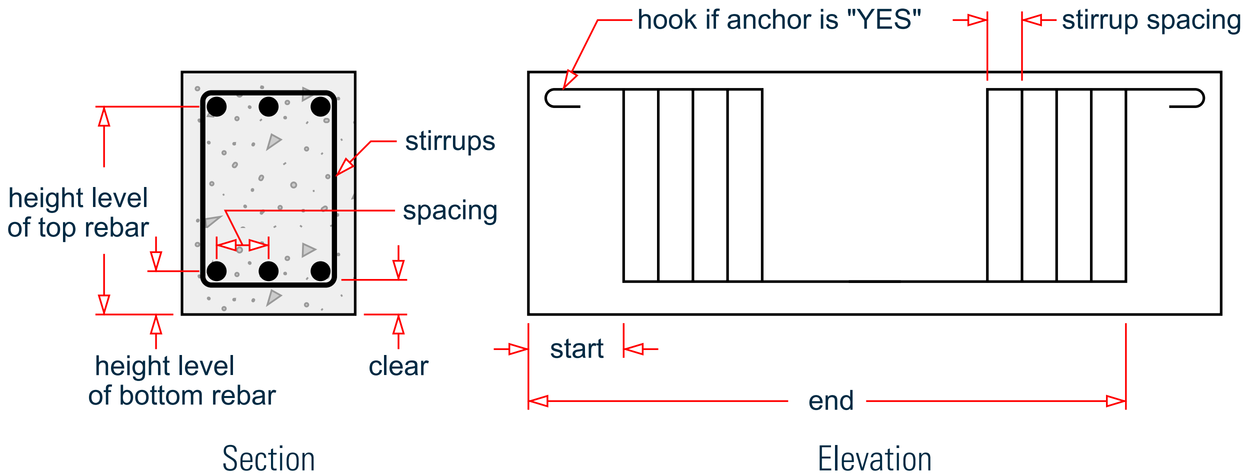

Figure 150: Nomenclature used in output

The following is a sample `TRACK 1.0` output from concrete beam design per ACI (from the file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US.8. Concrete Design for a Space Frame.std`):

D1.F.5 Column Design

Columns design as per ACI 318-14 is based on a full 3D interaction surface for a given cross section. Columns will be designed for the combined effects of axial loads and bi-axial bending moments. Other effects such as torsion and shear will also be accounted for in the design. The program then provides a final detailed design followed by a cross section wise analysis to ensure that the design is satisfactory. During the analysis stage the strengths of the cross section for each of these effects will also be calculated. The design process works on the basis of being able to find a point on or very close to the interaction surface so as to ensure the most efficient design.

As with beam design, an envelope is created at each design section from a collection of the max/min forces in all degrees of freedom for all the load cases and combinations that have been included in the design. As there are six degrees of freedom (Fx, Fy, Fz, Mx, My, Mz) and to capture the maximum and minimum effects, a total of 12 sets of loads are designed for. Each set will include the maximum or minimum of one force such as Max FX along with all the other associated forces in the load case/combination.

The following section shapes will be considered for column design with ACI 318-14:

1. square
2. rectangular
3. circular
4. tee-shaped

All column designs will be based on a uniform distribution of reinforcement around the column perimeter. The design options to control a column design will be based on the CRDO parameter setting.

D1.F.5.1 Strength Design

All column designs will be based on a uniform distribution of reinforcement around the column perimeter. The design options to control a column design will be based on the CRDO parameter setting.

Column resistance is calculated based on strain compatibility and interaction surface calculations.

The following conditions should be checked (10.5.1.1)

$$\phi Pn \geq Pu$$
$$\phi Mn \geq Mu$$
$$\phi Vn \geq Vu$$
$$\phi Tn \geq Tu$$

$\phi P_n \geq P_u$

$\phi M_n \geq M_u$

$\phi V_n \geq V_u$

$\phi\ T_n \geq T_u$

Where the nominal axial compressive strength, P_n , shall not exceed $P_{n,max}$ in accordance with Table 22.4.2.:

$P_{n,max} = 0.80\ P_o$ for ties
$P_{n,max} = 0.85\ P_o$ for spirals
$P_o = 0.85\ f'_c\ (A_g - A_{st}) + f_y A_{st}$

where

A_{st}	=	the total area (of nonprestressed) longitudinal reinforcement
Ag	=	the gross area of the concrete section
f'_c	=	the specified compressive strength of concrete
f_y	=	the specified yield strength of passive reinforcement
M_n	=	the nominal flexural strength
V_n	=	the nominal shear strength
T_n	=	the nominal torsional moment

The design is performed in two steps considering the longitudinal reinforcement design for axial-bending in an initial step, and the shear and torsion design including the longitudinal reinforcement for torsion tension in a latter pass together with the transverse design.

The minimum area of longitudinal reinforcement is taken as $0.01Ag$ and the maximum as $0.08Ag$. In agreement with the commentary a warning is triggered when the reinforcement ratio is over 4 percent due to possible lap splices zones.

D1.F.5.2 Slenderness Effects and Analysis Considerations

Slenderness effects are extremely important in designing compression members. The ACI 318-14 code specifies two options by which the slenderness effect can be accounted for. One option is to perform an exact analysis which will take into account the influence of axial loads and variable moment of inertia on member stiffness and fixed-end moments, the effect of deflections on moments and forces, and the effect of the duration of loads. Another option is to approximately magnify design moments.

STAAD.Pro uses both these options. To perform the first type of analysis, use the command `PDELTA ANALYSIS` instead of `PERFORM ANALYSIS`. This analysis method will accommodate the requirements as specified in Section 6.7 of the ACI 318-14Code (Section 10.10 in previous editions), except for the effects of the duration of the loads. It is felt that this effect may be safely ignored because experts believe that the effects of the duration of loads are negligible in a normal structural configuration. If it is desired, STAAD.Pro can also accommodate any arbitrary moment magnification factor (second option) as an input, in order to provide some safety due to the effects of the duration of loads.

Although ignoring load duration effects is somewhat of an approximation, it must be realized that the approximate evaluation of slenderness effects is also an approximate method. In this method, moment-magnification is based on empirical formula and assumptions on sidesway.

Considering all this information, it is our belief that a `PDELTA ANALYSIS`, as performed by STAAD.Pro , is most appropriate for the design of concrete members. However, you should note that to take advantage of this analysis, all combinations of loadings must be provided as repeat load cases and not as load combinations. This is due to the fact that load combinations are just algebraic combinations of forces and moments, whereas a repeat load case consists of one or more primary load case which are revised during the PDelta analysis based on the deflections. Also note that the you must provide the proper factored loads (e.g., 1.4 for DL etc.). STAAD.Pro does *not* factor the loads automatically.

D1.F.5.3 Moment Magnification

If the moment magnification method is used in lieu of an exact analysis, columns designed per ACI 318-14 in STAAD.Pro can consider sway using the moment magnification procedure. The second order effects are approximated by magnified moments for slender columns (as determined by clause 6.2.5/6.6.4.6) in sway and non-sway frames.

The following parameters apply to these calculations:

For sway frames, moments should be amplified twice, once for the member end sway (P-Δ effect) provided in clause 6.6.4.6 and using those amplified moments, again amplify them for member curvature along the length effects (P-δ effect) based on clause 6.6.4.5.

For non-sway frames moments need only be amplified once for the member curvature along the length effects (P-δ effect) based on clause 6.6.4.5

STAAD Parameters Required to Perform the Design and Their Functionality

SWY	Is member braced against side-sway: This parameter checks whether the column being designed is braced structurally against side sway for lateral loads. It will affect the slenderness limit of the structure. This parameter is based on clause 6.2.5
BDY / BSZ	β_{dns} factor required for Eq. 6.6.4.4.4(a) for stiffness reduction in case of non-sway case.
SQY / SQZ	Stability index value which is required for two main purpose; one is for checking whether the moments need to be magnified for sway or non-sway case, Clause 6.6.4.3(b), and for the calculation of δ_s give in Eq. 6.6.4.6.2(a) for moment amplification of a sway case.

SKY / SKZ Effective length factor which is based on Fig. R6.2.5 to be used to calculate member slenderness in Eq. 6.2.5(a)/(b)

SLY / SLZ The external load case number for the sway case which is used to extract moments M_{1s} and M_{2s} in equation 6.6.4.6.1(a)/(b). Incase this parameter is 0, it indicates to the program you do not want to include a load case which based on their judgement will not produce side-sway and hence needs to be amplified.

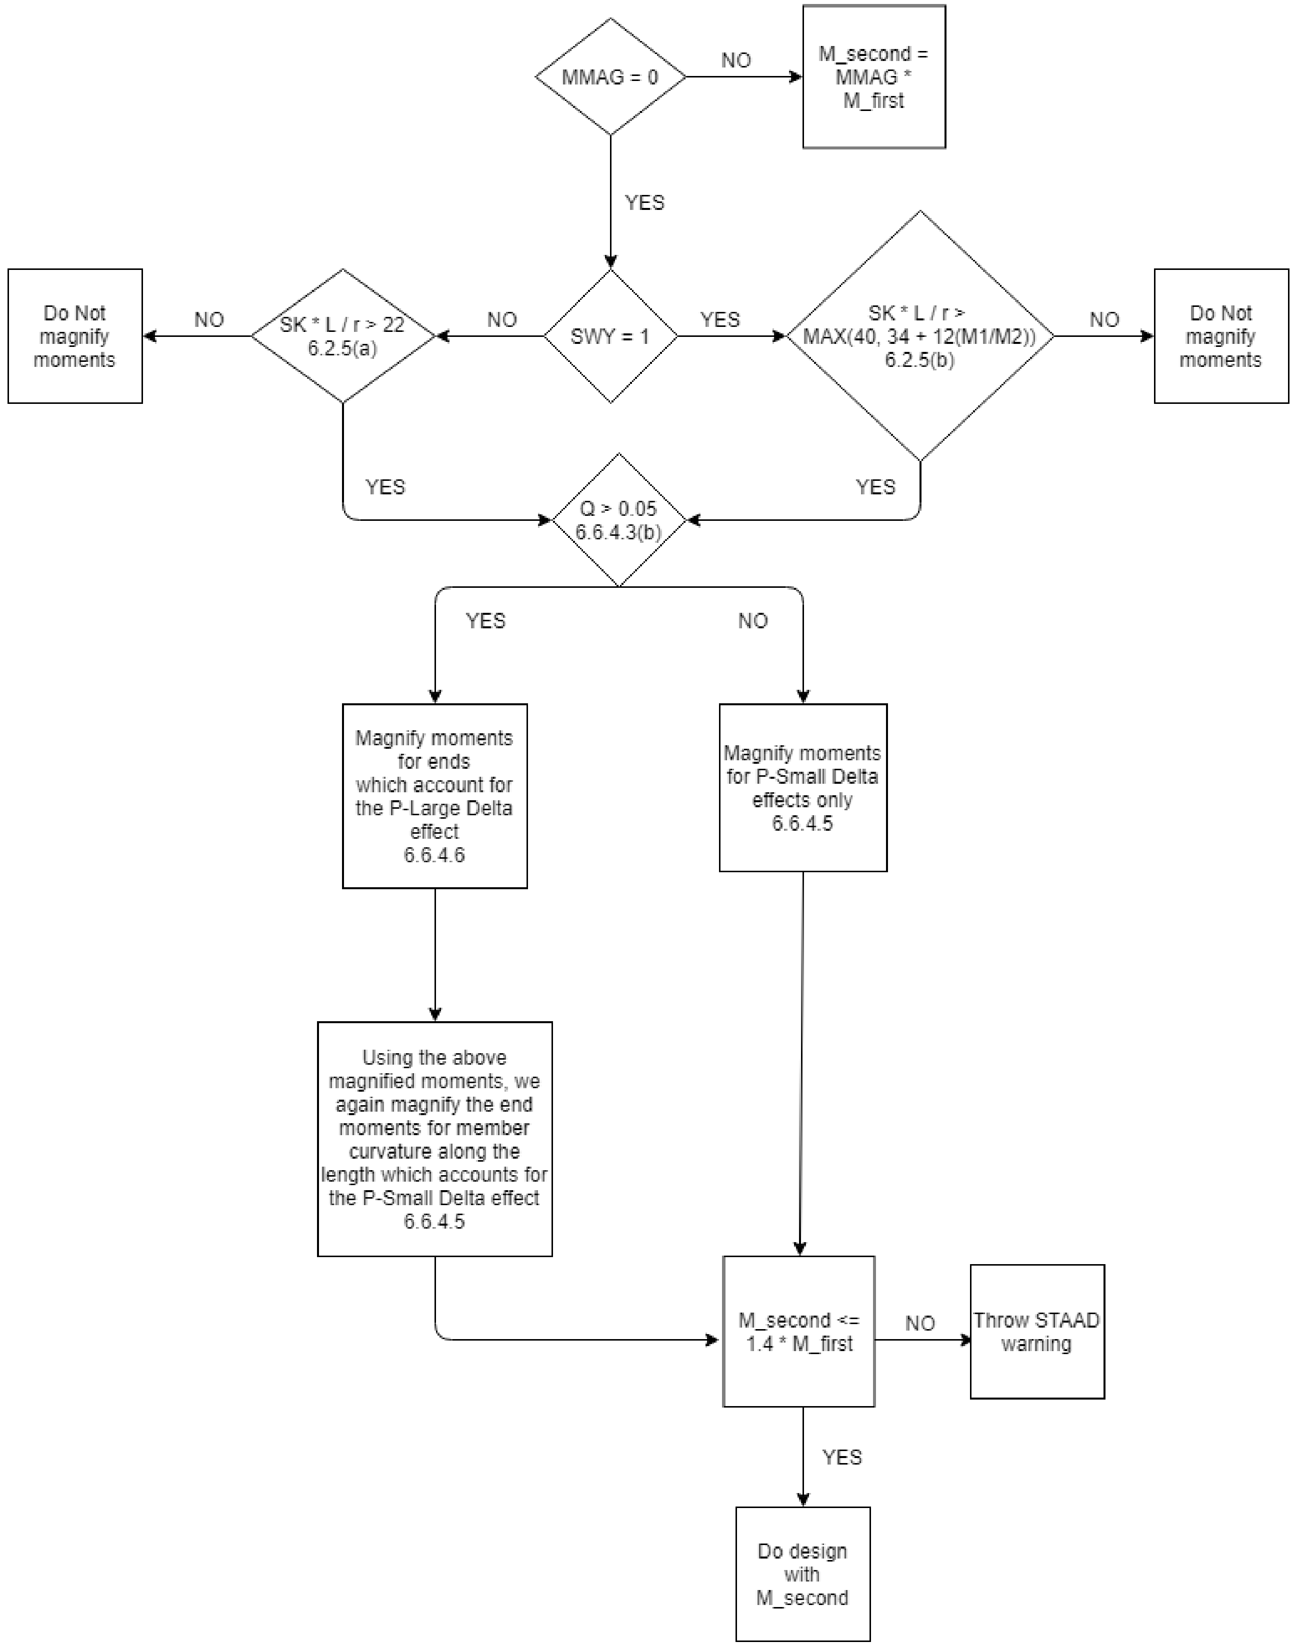
TRN This parameter asks from the user whether there are in transverse loads in the column between its two ends. It affects the calculation on Cm based on Eq. 6.6.4.5.3(a)/(b) which is required for amplification of moments for non-sway case.

MMAG This is the starting point parameter for the program. A non-zero value represents that the program will ignore all the moment amplification algorithm and just amplify the moments by multiplying this MMAG user-defined factor.

Note: The program will only go through with the moment magnification algorithm if and only if `MMAG` is specified as 0.

Flowchart

Given below is a flowchart of the moment amplification algorithm which is being incorporated in STAAD.Pro.



MMAG = 0
NO
M_second = MMAG * M_first
YES
Do Not magnify moments
NO
SK * L / r > 22 6.2.5(a)
NO
SWY = 1
YES
SK * L / r > MAX(40, 34 + 12(M1/M2)) 6.2.5(b)
NO
Do Not magnify moments
YES
Q > 0.05 6.6.4.3(b)
YES
YES
NO
Magnify moments for ends which account for the P-Large Delta effect 6.6.4.6
Magnify moments for P-Small Delta effects only 6.6.4.5
Using the above magnified moments, we again magnify the end moments for member curvature along the length which accounts for the P-Small Delta effect 6.6.4.5
M_second <= 1.4 * M_first
NO
Throw STAAD warning
YES
Do design with M_second

D1.F.5.4 Definition of Bar Positions

Both input parameters and design output refer to the positions of bars in column sections as follows.

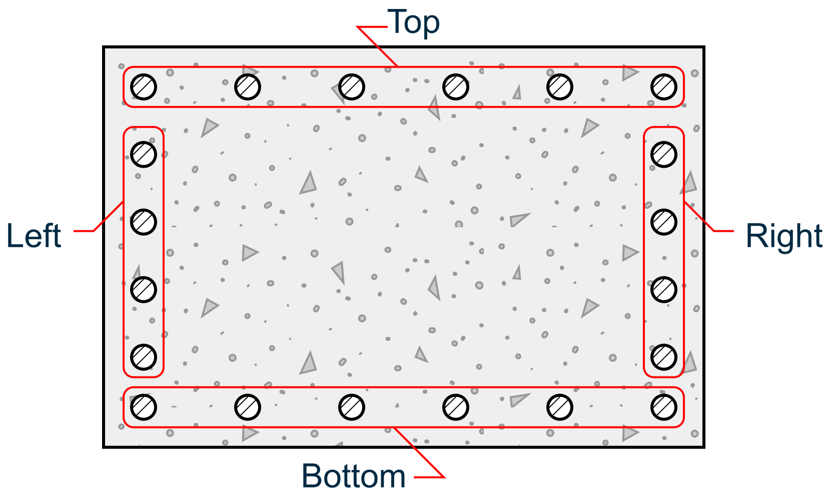


Figure 151: ACI 318-14 Rectangular column bar positions

Bars are evenly distributed around circumference

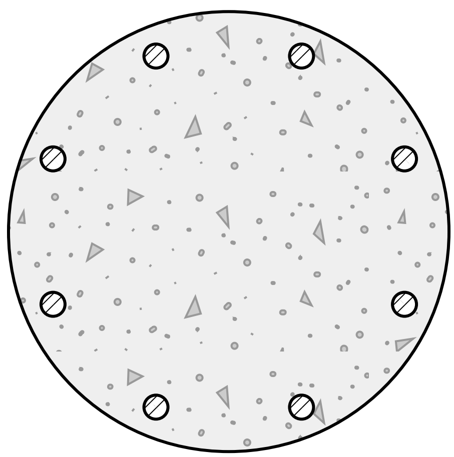

Figure 152: ACI 318-14 Circular column bar positions

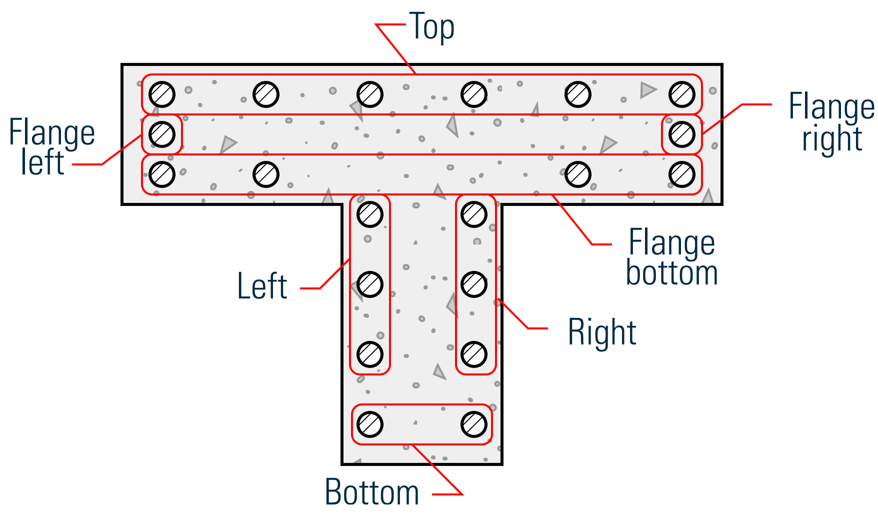

Figure 153: ACI 318-14 Tee column bar positions

D1.F.5.5 Column Design Output

The following report options are provided for the output for a column design.

TRACK 0 Output

Setting the option `TRACK 0` will cause the program to produce the required area of longitudinal as well as transverse steel at 5 equally spaced locations –including member ends– along the member length.

Note: This option is meant to be considered for quick area of steel (As) requirement analysis and should *not* be considered as a safe, acceptable design.

Sample `TRACK 0` output:

Member	member number
Type	Column
Shape	Either rectangular, Tee, or circular
As	the area of longitudinal steel required at each cross section
Asv/sv	the transverse steel density required at each cross section

```
                     STAAD.PRO CONCRETE DESIGN - (ACI-318-14)   v2.0
                     ***********************************************

Units: Kip and Inch (Unless Noted Otherwise)
  |---------------------------------------------------------|
  |  Member :      8                                        |
  |  Type   : Column           Shape  : Rectangular         |
  |---------------------------------------------------------|
  |  AREA OF STEEL REQUIRED                                 |
  |---------------------------------------------------------|
  |  Section -        |   1   |   2   |   3   |   4   |   5   |
  |---------------------------------------------------------|
  |  Location         |  0.00 | 36.00 | 72.00 |108.00 |144.00 |
  |  As(Longitudinal)|  3.29 |  1.44 |  1.44 |  1.73 |  5.45 |
  |  As/sv(Trans Y)   |  0.03 |  0.03 |  0.03 |  0.03 |  0.03 |
```

```
  |  As/sv(Trans Z)  |  0.03 |  0.03 |  0.03 |  0.03 |  0.03 |
  |----------------------------------------------------------|
```

TRACK 1 Output

Setting the program to output the beam design with a `TRACK 1` option will perform full design and detailing operations and will report a summary of the design. A `TRACK 1` report will include the following sections:

Design Summary	This section provides a summary of the design including the design status (i.e., PASS/FAIL), member type, length, the critical ratio, the critical criteria, and relevant clauses.
Cross section details	This section provides shape type and dimensions of the cross section profile.
Longitudinal Bar Layout	The position and extent of the longitudinal bars will be reported along with an indication if additional anchorage is required at the start or the end of the bars. A value of "yes" in the Anchor column indicates that the bar or set of bars will need to be anchored beyond the given section distances. This can be done using hooks/bends or physical anchors as deemed fit. A value of "no" indicates that no additional extension to the bar is needed beyond the given dimension. The value given in "Distance from face"is the measurement from the face defined by the position, to the center line of the bar, measured perpendicular to the face.
Transverse Bar Layout	The transverse bar table reports the details of various shear zones (see D1.F.4.3 Shear and Torsion Design (on page 1217)) within the span for both the local Y & Z axes. Each zone is identified by the unique start and end location reported as the distances "From" and "To." This provides shear densities as minimum required and as provided by the given bar details. The value "Nums" is the number of transverse groups in the zone (this equates to the zone length/spacing +1), the center to center spacing between adjacent transverse groups along the local X axis, the size of the bar used in the transverse group, and the leg count for the bars in a transverse group. A transverse group is the collection of transverse bars at a given cross section.

Note: This output will *not* report any warnings or errors from the design and member analysis. These are only reported in the `TRACK 2` output.
