-CFR CFL CFT MR
BPR BPL BPT
```

Note: There is a leading dash on the first line of section property specifications when composite slab properties are specified and again at the beginning of the composite slab properties when bottom cover plate dimensions are specified.

AX	Cross section area
D	Depth of the section
TW	Thickness of web
WF	Width of the top flange (or both flanges when `WF1` is not specified)
TF	Thickness of top flange (or both flanges when `WF1` is not specified)
IZ	Moment of inertia about local z-axis (usually strong axis)

IY Moment of inertia about local y-axis

IX Torsional constant

AY Shear area in local y-axis. If zero, shear deformation is ignored in the analysis.

AZ Shear area in local z-axis. If zero, shear deformation is ignored in the analysis.

WF1 (Optional) Width of the bottom flange. The width of the top flange will be used if this value is not specified.

TF1 (Optional) Thickness of bottom flange. The thickness of the top flange will be used if this value is not specified.

The following option parameters are used to include a composite concrete slab. If included, these must be on a separate line following a dash, -, on the line containing the required section parameters.

CFR Width of the composite slab to the right of the web center line

CFL Width of the composite slab to the left of the web center line

CFT Thickness of the composite slab

MR Modular ratio of the concrete in the composite slab

The following option parameters are used to include a bottom flange cover plate.

Tip: Bottom cover plates can only be added in association with a composite slab.

BPR Width of the additional bottom flange plate to the left of the web center line

BPL Width of the additional bottom flange plate to the right of the web center line

BPT Thickness of the additional bottom flange plate

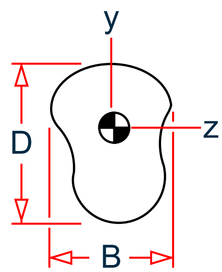
TR.19.8 General

The following cross-sectional properties should be used for this section-type. This facility allows you to specify a built-up or unconventional steel section. Provide both the Y and Z parameters for design or code checking.

Note: STAAD.Pro can perform some code checks on a General section where as a Prismatic section (TR.20.2 Prismatic Property Specification (on page 2263)) is for analysis only.



```
property-spec = AX D TD B TB IZ IY IX SZ SY AY AZ PZ PY HSS DEE
```

AX Cross section area

D Depth of the section

TD Thickness associated with section element parallel to depth (usually web). To be used to check depth/ thickness ratio

B Width of the section

TB Thickness associated with section element parallel to flange. To be used to check width/thickness ratio

IZ Moment of inertia about local z-axis (usually strong axis)

IY Moment of inertia about local y-axis

IX Torsional constant

SZ Section modulus about local z-axis

SY Section modulus about local y-axis

AY Shear area in local y-axis.

AZ Shear area in local z-axis.

PZ Plastic modulus about local z-axis

PY Plastic modulus about local y-axis

HSS Warping constant for lateral torsional buckling calculations

DEE Depth of web. For rolled sections, distance between fillets should be provided

Note: Properties PZ, PY, HSS, and DEE must be provided for code checking or member selection per plastic and limit state based codes (AISC LRFD, British, French, German and Scandinavian codes). For codes based on allowable stress design (AISC-ASD, AASHTO, Indian codes), zero values may be provided for these properties.

You can also specify points to define a general section. Refer to TR.19 User Steel Table Specification (on page 2241) for details. When this method is used, the section property-spec values can be calculated automatically by the graphical interface.

TR.19.9 I Section

This section type may be used to specify a generalized I-shaped section. The cross-sectional properties required are listed below. This section can be used to specify tapered I-shapes.

```
ISECTION
```

```
section-name
```

```
-DWW TWW DWW1 BFF TFF BFF1 TFF1 AYF AZF XIF
```

```
CFL -
```

```
CFR CFT MR
```

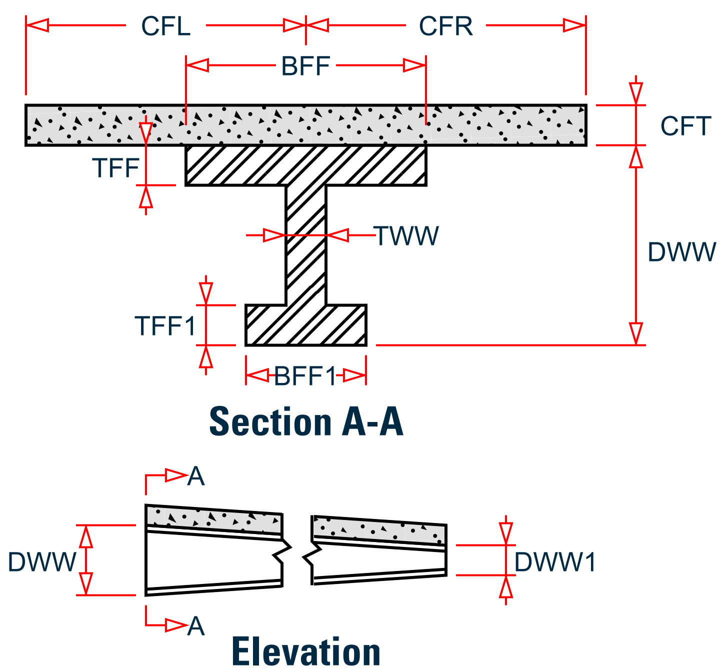


Figure 283: I section and tapered web

DWW	Depth of section at start node
TWW	Thickness of web
DWW1	Depth of section at end node (see note #1)
BFF	Width of top flange

TFF	Thickness of top flange
BFF1	Width of bottom flange
TFF1	Thickness of bottom flange
AYF	Shear area for shear parallel to Y-axis (see note #2)
AZF	Shear area for shear parallel to Z-axis (see note #2)
XIF	Torsional constant (IX or J) (see note #2)

The following option parameters are used to include a composite concrete slab. If included, these must be on a separate line following a dash, **-**, on the line containing the required section parameters.

CFR	Width of the composite slab to the right of the web center line
CFL	Width of the composite slab to the left of the web center line
CFT	Thickness of the composite slab
MR	Modular ratio of the concrete in the composite slab

Notes

1. `DWW` should never be less than `DWW1`. Therefore, you must provide the member incidences accordingly.
2. You are allowed the following options for the values `AYF`, `AZF`, and `XIF`:
   - If positive values are provided, they are used directly by the program.
   - If zero is provided, the program calculates the properties using the following formulae:

     $$AYF = D \times TWW$$

     $$AZF = 0.66\ ((BFF \times TFF) + (BFF1 \times TFF1))$$

     $$XIF = 1/3\ ((BFF \times TFF^3) + (DEE \times TWW^3) + (BFF1 \times TFF1^3))$$

     where

D	=	Depth at section under consideration
DEE	=	Depth of web of section

   - If negative values are provided, they are applied as factors on the corresponding value(s) calculated by the program using the above formula. The factor applied is always the absolute of the value provided. For example, if you specify a value of XIF as `-1.3`, then the program will multiply the value of XIF, calculated by the above formula, by a factor of 1.3.

TR.19.10 Prismatic

The property-spec for the `PRISMATIC` section-type is as follows:

AX	Cross-section area
IZ	Moment of inertia about the local z-axis
IY	Moment of inertia about the local y-axis
IX	Torsional constant

AY Shear area for shear parallel to local y-axis.

AZ Shear area for shear parallel to local z-axis.

YD Depth of the section in the direction of the local y-axis.

ZD Depth of the section in the direction of the local z-axis

Note: When listing multiple shapes, those section names must be provided in ascending order by weight since the member-selection process uses these tables and the iteration starts from the top.

Example

```
START USER TABLE
TABLE  1
UNIT . . .
WIDE FLANGE

TR.19.11 Using Reference Table Files

The User-Provided Steel Tables may be created and maintained as separate files. The same files may be used for all models using sections from these tables. These files should reside in the same directory where the input file is located.

```
START USER TABLE
TABLE  1 TFILE1
TABLE  2 TFILE2
END
```

Where `TFILE1` and `TFILE2` are names of files which must be created prior to running STAAD, and where the file `TFILE1` contains the following:

On each file the first table should contain a `UNITS` command.

```
UNIT  . . .
WIDE FLANGE
W14X30
```

```
8.85  13.84  .27  6.73  .385  291.  19.6  .38  0  0
W21X50
14.7  20.83  .38  6.53  .535  984  24.9  1.14  7.92  0
W14X109
32.  14.32  0.525  14.605  .86  1240  447  7.12  7.52  0
```

and the file *TFILE2* contains:

```
UNIT  . . .
ANGLES
L25255
2.5  2.5  .3125  .489  0  0
L40404
4.  4.  .25  .795  0  0
```

TR.20 Member Property Specification

This set of commands may be used for specification of section properties for frame members.

The options for assigning properties come under two broad categories:

1. Those which are specified from built-in property tables supplied with the program, such as for steel, aluminum and timber.
2. Those which are *not* assigned from built-in tables, but instead are specified on a project-specific basis, such as for concrete beams and columns, or custom-made sections for industrial structures.

Properties which are specified from built-in property tables

1. General format for standard steel (hot rolled):

```
MEMBER PROPERTIES { AMERICAN | APLAPOLLOTUBE | AUSTRALIAN | BRAZILIAN | BRITISH |
CANADIAN | CHINESE | DUTCH | EUROPEAN | FRENCH | GERMAN | INDIAN | JAPANESE |
JINDAL | KOREAN | MEXICAN | RUSSIAN | SAFRICAN | SPANISH | STOASCHM | TATASTRUCTURA
| VENEZUELAN }
```

```
member-list  { TABLE type-spec section-name-in-table (additional-spec) | ASSIGN
profile-spec }
```

AMERICAN, BRITISH, EUROPEAN (etc.) option will instruct the program to read properties from the appropriate steel table. The default depends on the country of distribution.

- Refer to TR.20.1 Assigning Properties from Steel Tables (on page 2257) for type-specs and additional-specs.
- Refer to TR.20.5 Assign Profile Specification (on page 2268) for ASSIGN profile-spec.
- contain information on the section types which can be assigned for the various countries named in the above list.
- Refer to TR.20.6 Examples of Member Property Specification (on page 2270) for examples.

The MEMBER PROPERTY command may be extended to multiple lines by ending all lines but the last with a space and hyphen (-).

2. General format for cold formed steel:

```
MEMBER PROPERTIES { BUTLER | COLD AMERICAN | COLD AUSTRAILIAN | COLD BRITISH | COLD
EUROPEAN | COLD INDIAN | COLD JAPANESE | COLD RUSSIAN | KINGSPAN | LYSAGHT }
```

```
member-list TABLE ST section-name-in-table
```

Refer to D. Design Codes (on page 1086) information on the section types which can be assigned for the various countries/organizations named in the above list.

3. General format for steel joist:

```
MEMBER PROPERTIES SJIJOIST
```

```
member-list TABLE ST section-name-in-table
```

US Steel Joist Sections (on page 2261) contains information on the joist types which can be assigned from the Steel Joist Institute's tables.

4. General format for Aluminum:

```
MEMBER PROPERTIES ALUMINUM
```

```
member-list TABLE ST section-name-in-table
```

D1.H. American Codes - Aluminum Design per 1994 ADM (on page 1264) contains contains information on the section types which can be assigned for the aluminum table in the above list.

5. General format for Timber:

```
MEMBER PROPERTIES { AITC | TIMBER CANADIAN }
```

```
member-list TABLE ST section-name-in-table
```

D1.H. American Codes - Aluminum Design per 1994 ADM (on page 1264) contains information on the section types which can be assigned for the above list.

Properties that are *not* specified from built-in property tables

```
MEMBER PROPERTIES
```

```
member-list { PRISMATIC property-spec | TAPERED argument-list | UPTABLE i1section-
name }
```

- Refer to TR.20.2 Prismatic Property Specification (on page 2263) for specification of PRISMATIC properties.
- Refer to TR.20.3 Tapered Member Specification (on page 2266) for specification of TAPERED members.
- Refer to TR.20.4 Property Specification from User Provided Table (on page 2267) for specification from UPTABLES.
- Refer to TR.20.6 Examples of Member Property Specification (on page 2270) for examples.

The MEMBER PROPERTY command may be extended to multiple lines by ending all lines but the last with a space and hyphen (-).

TR.20.1 Assigning Properties from Steel Tables

The following commands are used for specifying section properties from built-in steel table(s). The section type specification is followed by additional specifications as needed.

General Format

```
member-list TABLE type-spec  table-name additional-spec
```

Where:

member-list A list of member numbers.

type-spec `= { ST | RA | D | LD | SD | T | CM | TC | BC | TB | FR }`

Table 234: Type-specs for various profile types

type-spec	**Description**	**Diagram**
ST	standard, single section from the built-in tables	RA	single reverse angle (reverse Y-Z axes, refer to G. 4.2 Local Coordinate System (on page 2088))	
type-spec	**Description**	**Diagram**
D	double profile. In the case of channels, back-to-back The spacing between shapes is provided using the SP additional specification.	LD	double angle with long legs back-to-back	SD	double angle with short legs back-to-back	T	tee section cut from I shaped section	CM	composite section, available for I shaped sections	
type-spec	**Description**	**Diagram**
TC	section with top cover plate	BC	section with bottom cover plate	TB	section with both top and bottom cover plate top plate dimensions are described using `WP` and `TH` parameter values and bottom plate dimensions are described using `BW` and `BT` parameter values	FR	front-to-front (i.e., toe-to-toe) channels. **Note:** Spacing between the channels must be provided using the SP option mentioned in the additional spec specification described below.	SA	double angle in a star arrangement (heel to heel)	
table-name Table section name like W8X18, C15X33 etc.

The documentation on steel design per individual country codes contains information regarding their steel section specification also. For details on specifying sections from the American steel tables, refer to D1.A.4 Built-in Steel Section Library (on page 1088).

additional-spec

```
= * {SP f1 | WP f2 | TH f3 | WT f4 | DT f5 | OD f6 | ID f7 | CT f8 |
FC f9 | CW f10 | CD f11 | BW f12 | BT f13 }
```

Table 235: Additional specifications for steel sections

Variable	Description
SP *f1*	Either: • Spacing between double angles, double channels, or double wide-flange sections (i.e., D, LD, SD, or FR). The default spacing is 0.0. • Rib height for composite sections
WP *f2*	Width of top cover plate for I shaped sections with cover plate.
TH *f3*	Thickness of plates (top plate for I shaped sections) or wall thickness for a parametric tube section.
WT *f4*	Width of a parametric tube section.
DT *f5*	Depth of a parametric tube section.
OD *f6*	Outer diameter of a parametric pipe section.
ID *f7*	Inside diameter of a parametric pipe section.
CT *f8*	Concrete thickness of the concrete for composite sections.
FC *f9*	Compressive strength of concrete for composite sections.
CW *f10*	Concrete width for composite sections.
CD *f11*	Concrete density for composite sections (default is 150 pounds per cubic ft.)
BW *f12*	With of bottom cover plate for I shaped sections with cover plates

Variable	Description
BT *f13*	Thickness of cover plates for I shaped sections with cover

Refer to G.6.2 Built-In Steel Section Libraries (on page 2116) for more information.

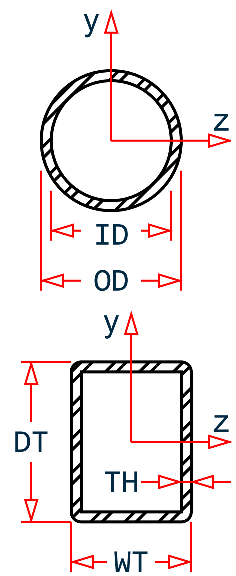
Parametric Pipe and Tube Sections

In lieu of specifying a table shape, you can specify pipe and tube sections parametrically. Only the standard (ST) single sections are used for pipes and tubes for table sections. So the input format for a pipe section is:

```
member-list TABLE ST PIPE OD f6 ID f7
```

The input format for a tube section is:

```
member-list TABLE ST TUBE DT f5 WT f4 TH f3
```



US Steel Joist Sections

Several tables of US steel joists and joist girders are available for use. Member properties can be assigned by specifying a joist designation contained in tables supplied with the program. The following joists and joist girder types have been implemented:

Open web steel joists – K series and KCS joists
Longspan steel joists – LH series
Deep Longspan steel joists – DLH series
Joist Girders – G series

The format for specifying steel joists is

```
MEMBER PROPERTIES SJIJOIST
```

```
member-list TABLE ST section-name-in-table
```

The STAAD.Pro joists database includes the weight per length of the joists. Thus, the weight of the joist is automatically considered for selfweight computations in the model.

The designation for most joists (K, KCS, LH, and DLH series) are similar to those given in the SJI publication (e.g., 16K2, 22KCS4, 24LH05, 60DLH13).

The designation for the G series Joist Girders is as shown in the Steel Joist Institute publication. STAAD.Pro incorporates the span length also in the name, as shown in the next figure.

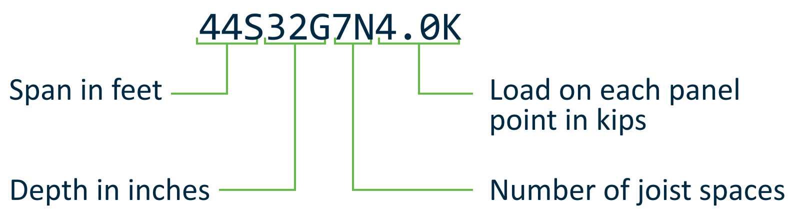


Figure 284: STAAD.Pro nomenclature for SJI joist girders

Examples

```
UNIT  …
MEMBER PROPERTIES
1  TO  5  TABLE  ST  W8X31
9  10  TABLE  LD  L40304  SP  0.25
12  TO  15  PRISMATIC  AX  10.0  IZ  1520.0
17  18  TA  ST  PIPE  OD  2.5  ID  1.75
20  TO  25  TA  ST  TUBE  DT  12.  WT  8.  TH  0.5
27  29  32  TO  40  42  PR  AX  5.  IZ  400.  IY  33. -
IX  0.2  YD  9.  ZD  3.
43  TO  47  UPT  1  W10X49
50  51  UPT  2  L40404
52  TO  55  ASSIGN  COLUMN
56 TA TC W12X26 WP 4.0 TH 0.3
57 TA CM W14X34 CT 5.0 FC 3.0
```

See TR.20.6 Examples of Member Property Specification (on page 2270) for additional details on this example.

Notes

All values *f1* - *f9* must be supplied in current units.

Some important points to note in the case of the composite section are:

1. The CM parameter can be assigned to I-shaped sections only. A CM (composite) section is one obtained by considering a portion of a concrete slab to act in unison with the I shaped steel section. FC is the strength or grade of concrete used in the slab. In the USA, F_C is called the specified compressive strength of concrete. Typical values of F_C range between 2.0 and 5.0 ksi, and 20 to 50 Mpa.
2. The width of the concrete slab (CW) (if not entered) is assumed to be the width of the top flange of the steel section + 16 times the thickness of the slab.
3. In order to calculate the section properties of the cross-section, the modular ratio is calculated assuming that:

   E_s = Modulus of elasticity of steel = 29,000 ksi.
   E_c = Modulus of elasticity of concrete = $1{,}802.5\sqrt{(F_c)}$ ksi

Where F_c (in ksi) is defined earlier.

Some other general notes on this subject of member property designations are:

1. The T parameter stands for a T-shaped section obtained by cutting an I-shaped section at exactly its mid height level along the web. Hence, the area of a T shape is exactly half the area of the corresponding I shape. The depth of a T shape is half the depth of the I shape it was cut from.

   What we refer to as I shaped sections are sections which look like the English alphabet I. The American Wide Flange, the British UB and UC sections, Japanese H sections, etc., all fall under this category. Consequently, the 'T' shape cut from a Japanese H shape is one obtained by cutting the H shape at exactly its mid-height level of the web.

   Not all I shaped sections have a corresponding T. This may be inferred by going through the section libraries of individual countries and organizations. In such cases, if a user were to specify such a T section, the program will terminate with the message that the section does not exist.
2. Steel Cover plates also can be added only to I shaped sections. Thus, the TC, BC, and TB are not applicable to any shape other than an I shape.

TR.20.2 Prismatic Property Specification

The following commands are used to specify section properties for prismatic cross-sections.

General Format

For the PRISMATIC specification, properties are provided directly (End each line but last with a hyphen "-") as follows:

```
property-spec  = * { AX f1 | IX f2 | IY f3 | IZ f4 | AY f5 | AZ f6 | YD f7 | ZD f8 |
YB f9 | ZB f10 }
```

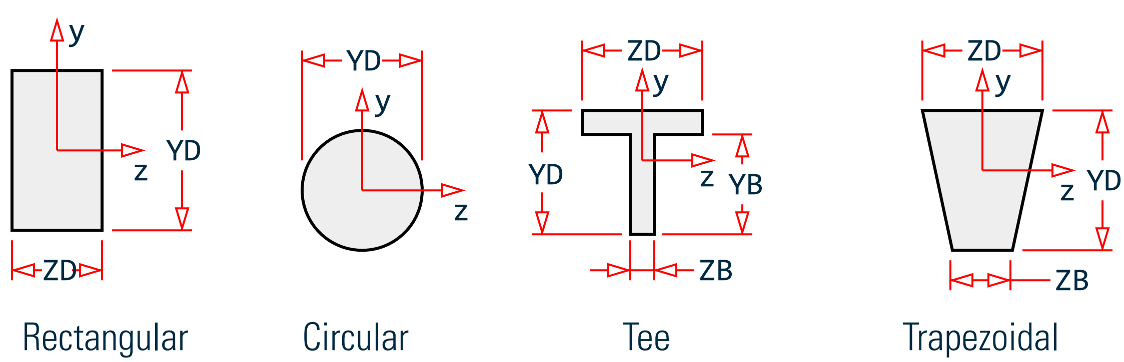

Figure 285: Prismatic property nomenclature for a Tee and Trapezoidal section

Where:

`AX` *f1* = Cross sectional area of the member. Set to zero for TEE, Rectangular, Trapezoid, or circular.
`IX` *f2* = Torsional constant.
`IY` *f3* = Moment of inertia about local y-axis.
`IZ` *f4* = Moment of inertia about local z-axis (usually major).
`AY` *f5* = Effective shear area in local y-axis.
`AZ` *f6* = Effective shear area in local z-axis.

If any of the previous six parameters are omitted, it will be calculated from the YD, ZD, YB, and/or ZB dimensions.

`YD` *f7* = Depth of the member in local y direction. Used as the diameter of section for circular members.
`ZD` *f8* = Depth of the member in local z direction. If ZD is not provided and YD is provided, the section will be assumed to be circular.
`YB` *f9* = Depth of stem for T-section.
`ZB` *f10* = Width of stem for T-section or bottom width for TRAPEZOIDAL section.

The values that STAAD calculates for the omitted terms can be obtained by specifying the command `PRINT MEMBER PROPERTIES`.

The values of many of the derived properties like shear areas (AY, AZ), section modulii (SY, SZ), etc. will be shown in the output file.

This command can be used regardless of the manner in which the properties are specified (e.g., PRISMATIC, user table, built-in table).

TR.20.2.1 Prismatic Tapered Tube Property Specification

The following commands are used to specify section properties for prismatic tapered tube cross-sections. For the property types shown below, additional information can be obtained from Table 2.1 of the ASCE 72 document, 2nd edition.

General Format

```
property-spec  = { ROUND | HEXDECAGONAL | DODECAGONAL | OCTAGONAL | HEXAGONAL |
SQUARE } START D1 END D2 THICK t
```

Where:

START *D1*	Depth of section at start of member.

END *D2*	Depth of section at end of member.
THICK *t*	Thickness of section (constant throughout the member length).

Figure 286: Prismatic tapered tube shapes

 Square	 Hexagonal (6 sides)
 Octagonal (8 sides)	 Dodecagonal (12 sides)
 Hexdecagonal (16 sides)	 Round

Notes

a. Section properties are calculated using the rules applicable for thin-walled sections.

b. Shear deformation is not considered for tapered I-Beams and tapered poles. This means that the `SET SHEAR` command has no effect on the deformation computed for members with these cross sections.

Example

```
UNIT …
MEMBER PROPERTY
1 PRIS ROUND STA 10 END  8  THI 0.375
```

```
2 PRIS HDC STA 15 END 10 THI 0.375
3 PRIS DOD STA 12 END 12 THI 0.375
```

See `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\US\Square_tapered.std` and `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\US\Round_tapered.std` for additional examples of designing members with prismatic tapered tube sections.

TR.20.3 Tapered Member Specification

The following commands are used to specify section properties for tapered I-shapes.

General Format

```
argument-list  = f1 f2 f3 f4 f5 (f6 f7)
```

Where:

f1 Depth of section at start node. Must be greater than *f3*.

f2 Thickness of web.

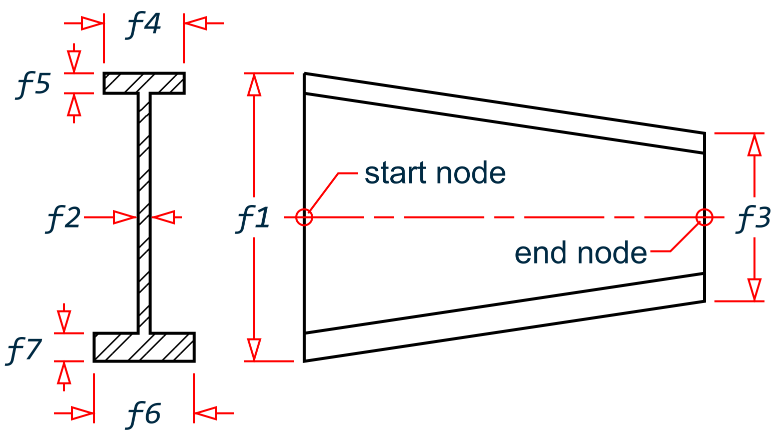
f3 Depth of section at end node.

f4 Width of top flange.

f5 Thickness of top flange.

f6 Width of bottom flange. Defaults to *f4* if left out.

f7 Thickness of bottom flange. Defaults to *f5* left out



Example

```
MEMBER PROPERTY
1 TO 5 TAPERED 15.98 0.285 11.98 6.745 .455 6.745 .455
```

See `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\US\Doubly_Symm-I_tapered.std` for an additional example of designing a member with a tapered I section.

Notes

a. All dimensions (*f1*, *f2*, ... *f7*) should be in current units.

b. *f1* (Depth of section at start node) should always be greater than *f3* (Depth of section at end node). You must provide the member incidences accordingly.

c. Shear deformation is not considered for tapered I-Beams and tapered poles. This means that the `SET SHEAR` command has no effect on the deformation computed for members with these cross sections.

TR.20.4 Property Specification from User Provided Table

The following commands are used to specify section properties from a previously created `USER-PROVIDED STEEL TABLE`.

General Format

```
member-list UPTABLE i1section-name
```

Where:

`UPTABLE` stands for User-Provided TABLE
i_1 = table number as specified previously (1 to 20)
section-name = section name as specified in the table.

See TR.20.6 Examples of Member Property Specification (on page 2270) for an example.

Related Links

- *G.6.3 User-Provided Steel Table* (on page 2117)
- *M. To create a general section* (on page 743)
- *G.6.3 User-Provided Steel Table* (on page 2117)

TR.20.5 Assign Profile Specification

The ASSIGN command may be used to instruct the program to assign a suitable steel section to a frame member based on the profile-spec shown below. The current country of the member properties is used to search for a suitable size based on the profile spec provided, if a such a shape is included in that country table.

General Format

```
profile-spec  = { BEAM | COLUMN | CHANNEL | ANGLE (DOUBLE) }
```

See TR.20.6 Examples of Member Property Specification (on page 2270) for an example.

Note: Sections are always chosen from the relevant built-in steel table. To find out the details of the sections that are chosen, the command PRINT MEMBER PROPERTIES should be provided after specification of all member properties. These commands may not work with certain tables such as cold-formed steel, Timber, Aluminum, and even some of the standard steel tables.

Sections Provided based on Country

The following table is a list of the actual section that is applied for each database and ASSIGN type.

Country	Beam	Column	Channel	Angle
0 US	W18X40	W14X43	C10X20	L40406

TR.20.6 Examples of Member Property Specification

This section illustrates the various options available for `MEMBER PROPERTY` specification.

```
UNIT  …
MEMBER PROPERTIES
1  TO  5  TABLE  ST  W8X31
9  10  TABLE  LD  L40304  SP  0.25
12  TO  15  PRISMATIC  AX  10.0  IZ  1520.0
17  18  TA  ST  PIPE  OD  2.5  ID  1.75
20  TO  25  TA  ST  TUBE  DT  12.  WT  8.  TH  0.5
27  29  32  TO  40  42  PR  AX  5.  IZ  400.  IY  33. -
IX  0.2  YD  9.  ZD  3.
43  TO  47  UPT  1  W10X49
50  51  UPT  2  L40404
52  TO  55  ASSIGN  COLUMN
56 TA TC W12X26 WP 4.0 TH 0.3
57 TA CM W14X34 CT 5.0 FC 3.0
```

This example shows each type of member property input. Members 1 to 5 are wide flanges selected from the AISC tables; 9 and 10 are double angles selected from the AISC tables; 12 to 15 are prismatic members with no shear deformation; 17 and 18 are pipe sections; 20 to 25 are tube sections; 27, 29, 32 to 40, and 42 are prismatic members with shear deformation; 43 to 47 are wide flanges selected from the user input table number 1; 50 and 51 are single angles from the user input table number 2; 52 through 55 are designated as COLUMN members using the ASSIGN specification. The program will assign a suitable I-section from the steel table for each member.

Member 56 is a wide flange W12X26 with a 4.0 unit wide cover plate of 0.3 units of thickness at the top. Member 57 is a composite section with a concrete slab of 5.0 units of thickness at the top of a wide flange W14X34. The compressive strength of the concrete in the slab is 3.0 force/length^2.

TR.20.7 Composite Decks

A composite deck generation facility is available in the program.

General Format

The command syntax for defining the deck within the STAAD input file is as shown below.

```
START DECK DEFINITION
_DECK deck-name
PERIPHERY member-list
DIRECTION d1 d2 d3
COMPOSITE member-list
OUTER member-list
VENDOR name
FC f1
CT f2
CD f3
RBH f4
RBW f5
PLT f6
PLW f7
DIA f8
HGT f9
DR1 f10
SHR f11
CMP f12
CW f13 MEMB cw-member-list
END DECK DEFINITION
```

Where:

_DECK *deck-name*	an alphanumeric name you specify to identify the deck. The *deck-name* line must start with '_DEC' or '_DECK'. The *deck-name* is the second word and is limited to 23 characters. This name must not be the same as any group name.
member-list	the list of members belonging to the deck. TO, BY, ALL, and BEAM are permitted. ALL means all members in structure; BEAM means all beams.
DIRECTION *d1 d2 d3*	the x, y, and z components of the direction of the deck, respectively

The following parameters may be in any order or omitted. They only apply to the composite members listed above. Do not enter a member list for these parameters.

FC *f1*	compressive strength of the concrete for all composite members listed above for this composite deck.

CT ***f2***	concrete thickness
CD ***f3***	concrete density
RBH ***f4***	height of rib of form steel deck. This is the distance from the top of the I beam to the bottom of the concrete deck.
RBW ***f5***	width of rib of form steel deck
PLT ***f6***	thickness of cover plate welded to bottom flange of composite beam
PLW ***f7***	width of cover plate welded to bottom flange of composite beam
DIA ***f8***	diameter of shear connectors
HGT ***f9***	height of shear connectors after welding
DR1 ***f10***	ratio of moment due to dead load applied before concrete hardens to the total moment
SHR [0 | 1]	temporary shoring during construction. 0 = no shoring 1 = with shoring
CMP [0 | 1 | 2]	composite action with connectors. 0 = no composite action in design 1 = composite action 2 = ignore positive moments during design
CW ***f11*** **MEMB** ***cw-member-list***	*f11* is the concrete width for each composite member listed. *cw-member-list* is the list of composite members in this deck that have this width. Enter as many CW lines as necessary to define the width of all composite members of this deck.

This Deck definition data should be entered after the member properties have been entered.

Notes

1. The DECK definition must start with the START DECK DEFINITION command and end with the END command.
2. More than one DECK may be specified between the START and END.
3. The same member number may be included in up to 4 deck/groups. Multiple definitions are useful for output but can be ambiguous for input data such as constants, section property, release, etc.
4. If two or more consecutively entered decks have the same name, then they will be merged. If not consecutive, the second entry of the same name will be ignored.
5. The _deck-name must be unique within the Deck definitions and the Group definitions.
6. PER, DIR, OUT are data created by the GUI. Do not edit this data.
7. This Deck definition data should be entered after the member properties have been entered.

Example

```
START DECK DEFINITION
_DECK DEC-1
PERIPHERY 4 1640 18 38 56 50 49
DIRECTION 0.0000000.000000 -1.000000
COMPOSITE 41 74 38
OUTER 7 8 3130
VENDOR USSTEEL
DIA 0.700
HGT 2.75
CT 11.0
FC 3.1
RBW 2.6
RBH 0.1
CMP 1.0
SHR 1
CD 0.0000870
CW 123.000000 MEMB41
CW 123.000000 MEMB7
CW 61.500000 MEMB4
CW 61.500000 MEMB38
END DECK DEFINITION
```

TR.20.8 Curved Member Specification

The following commands are used to specify that a member is curved. The curve must be a segment of a circle and the internal angle subtended by the arc must be less than 180 degrees. Any non-tapered cross-section is permitted.

General Format

```
MEMBER CURVED
```

```
member-list RADIUS r GAMMA g PRESS p
```

Where:

RADIUS *r* = radius in length units

GAMMA *g* = The angle in degrees used to define the plane of the circle. The angle is defined using the same set of rules used to define the orientation (beta angle) of a straight member connected between the two nodes. See Gamma Angle (on page 2275).

PRESS *p* = Pressure/Flexibility parameter for pipe bends. See Pressure/Flexibility Parameter (on page 2274).

Notes

1. The radius should be in current units.
2. Certain attributes like releases, `TENSION/COMPRESSION` flags, and several member load types are currently not available. Section forces too are currently not available.
3. The design of curved members is not supported.

Pressure/Flexibility Parameter

This applies only to pipe bend (elbow) members (OD and ID entered). These members will flex more due to ovalization depending on internal pressure. The ASME Boiler and Pressure Vessel Code, Section III, NB-3687.2, 1971, for Class I components is used to calculate the flexibility reduction factor.

- Set p = 0 or omit for this flexibility increase calculation to occur with internal pressure equal to zero.
- Set p > 0 to specify internal pressure to use in this flexibility calculation. Pressure reduces the flexibility increase.
- Set p = -9999 to ignore this additional flexibility calculation and use only beam theory.
- Set p = flexibility reduction factor (-FLEXF below); which must be a negative number less than –1.0 .

ASME Pipe Elbow flexibility factors theory [ASME Section NB-3687.3]

This section only applies if *(Bend Radius/Mean Radius)* $\geq$ *1.70* or if *(Arclength)* > *(2x Mean Radius)*

Flexibility Factor, FLEXF = (1.65x (Mean Radius)^2)/[t·(Bend Radius)] x 1/[1 + (Press)(Mean Radius)(FACT.)]

where

FACT.	=	$6\cdot(MR/t)^{4/3}\cdot(BR/MR)^{1/2}/(Et)$
MR	=	Mean Radius of elbow wall
BR	=	Bend Radius
Press	=	Internal Pressure
t	=	elbow wall thickness
E	=	Modulus of Elasticity

If the Flexibility Factor computed is less than 1.0, then STAAD.Pro will use 1.0 . The Flexibility Factor directly multiplies or contributes to most non-shear terms in the elbow flexibility matrix.

Notes

1. The input for defining the curved member involves 2 steps. The first is the member incidence, which is the same as that for a straight line member. The second is the command described above, which indicates that the segment between the 2 nodes of the member is curved, and not a straight line.
2. Any non-tapered cross section property currently available in STAAD can be assigned to these members.
3. Currently, two load types are permitted on curved members. One is the `SELFWEIGHT` load type, described in TR.32.9 Selfweight (on page 2496). The other is the uniformly (`UNI`) distributed load type of the `MEMBER LOAD` options explained in TR.32.2 Member Load Specification (on page 2464). The uniformly distributed load has to be applied over the full span of the member. Other member loads such as `LINEAR`, `TRAP`, `CONCENTRATED` force or moment, `UNIFORM` moment, etc. are not supported.
4. Some of the other member load types such as `PRESTRESS`, `TEMPERATURE`, `STRAIN` loads, etc. are also not currently supported. These options too are expected to become available in future versions of the program.
5. The results of the analysis currently consist of the nodal displacements of the ends of the curved member, and the member end forces. The nodal displacements are in the global coordinate system. The member end forces are in the local coordinate system, with each end of the member having its own unique local axis

system. Results at intermediate sections, such as sectional displacements, and sectional forces will be available in future versions of the program.

Gamma Angle

The plane of the circle defines the plane formed by the straight line joining the two ends of the arc, and the local Y axis of an imaginary straight member between those two points. The positive value of the GAMMA angle is obtained using the same sense as the positive value of the beta angle of that imaginary straight line member whose local Y axis points towards the vertex of the arc.

Several diagrams intended to show the GAMMA angle for various segments lying in the three global planes are shown.

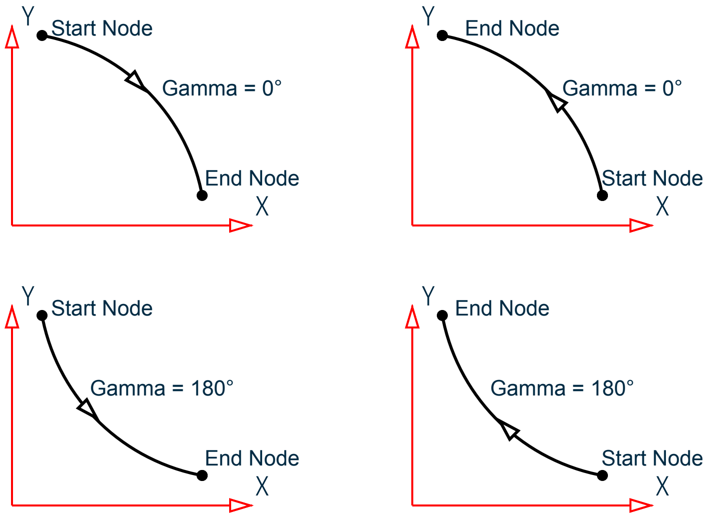

Figure 287: Gamma angle for various configurations of the circular arc lying in the global XY plane

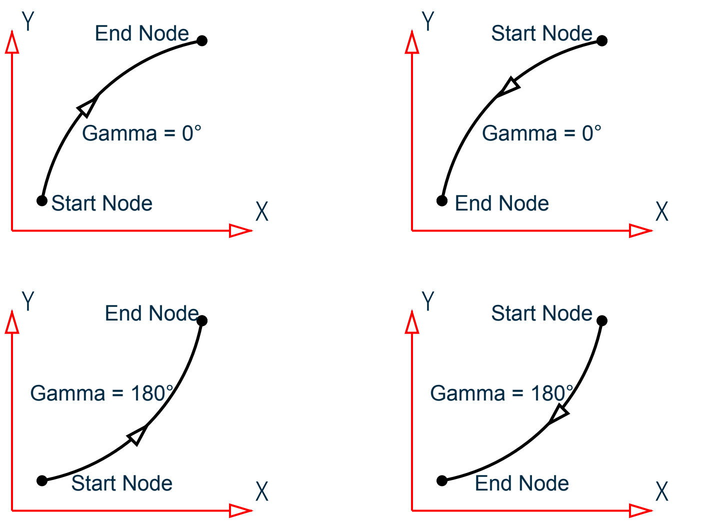

Figure 288: Gamma angle for various configurations of the circular arc lying in the global XY plane

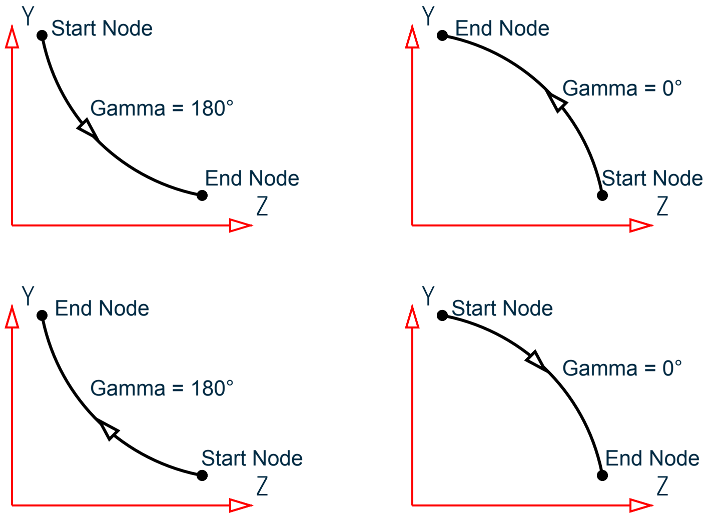

Figure 289: Gamma angle for various configurations of the circular arc lying in the global YZ plane

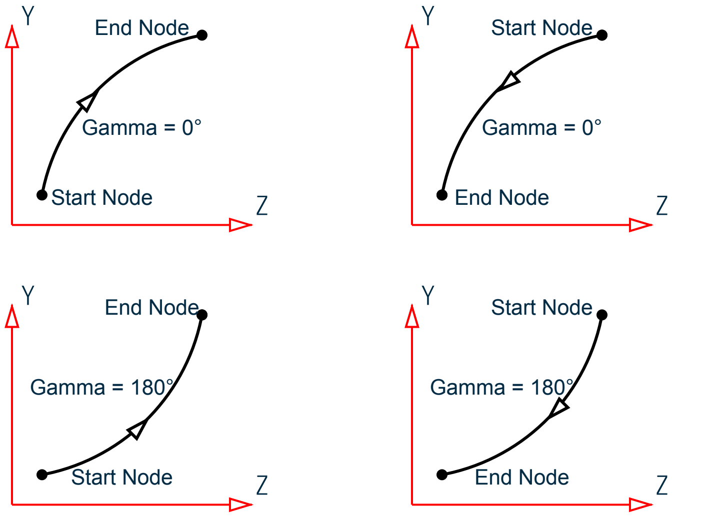

Figure 290: Gamma angle for various configurations of the circular arc lying in the global YZ plane

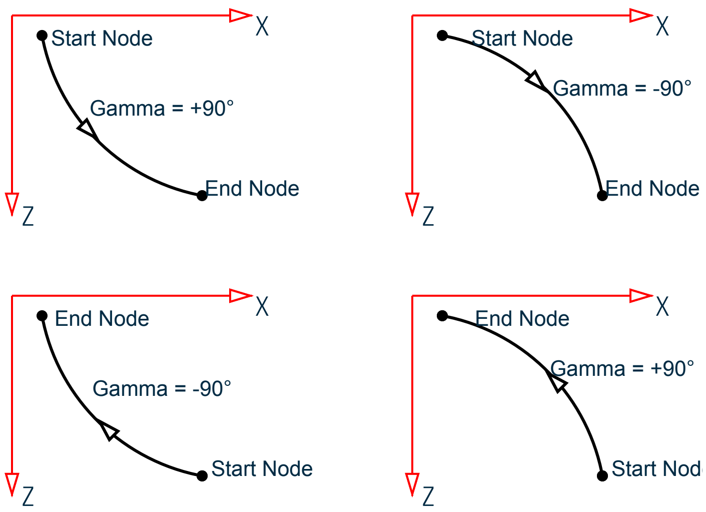

Figure 291: Gamma angle for various configurations of the circular arc lying in the global XZ plane

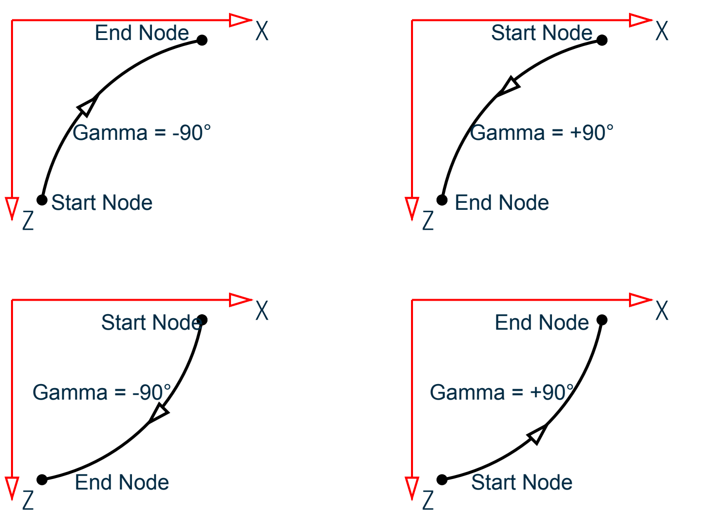

Figure 292: Gamma angle for various configurations of the circular arc lying in the global XZ plane

Member local axis system

The local axis directions for curved members are dependent on the point of interest along the curve. The general rules for local axis, as laid out in G.4.2 Local Coordinate System (on page 2088) are applicable. The figure shown later for member end forces indicates the directions of axes at the start and end nodes.

Rotation of local axis

There is a limited facility available to change the orientation of a curved member cross section. The cross-section may be at the default position where the strong axis (local y) is normal to the plane of the curve and the weak axis is in that plane.

The BETA ANGLE and REFERENCE POINT options, explained in G.4.3 Relationship Between Global and Local Coordinates (on page 2092) and TR.26.2 Specifying Constants for Members and Elements (on page 2305), are *not* available for curved members.

Sign conventions

The displacements of the nodes of the curved member are along the global axis system just as in the case of straight members.

The member end forces for curved members are quite similar to that for straight members. The only distinguishing item is that they are normal and tangential to the local axis at the corresponding ends. For example, FX at the start is tangential to the curve at the start node, and FX at the end is tangential to the curve at the end node. Similarly, FZ is along the radial direction at the two ends.

Member releases, offsets, tension/compression, truss and cable may not be specified for curved beams.

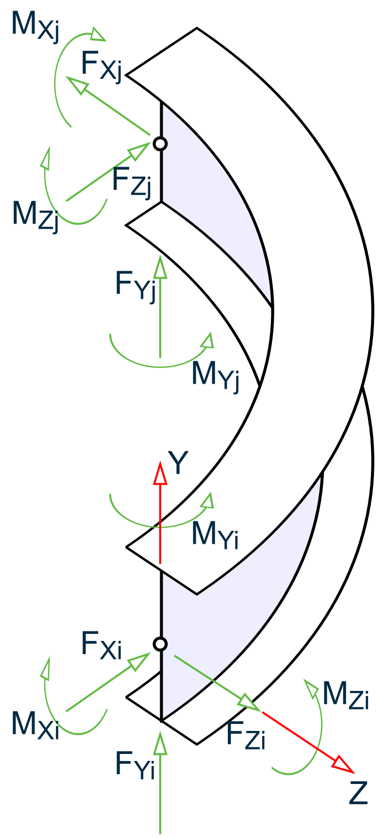

Figure 293: Sign conventions for member end actions; Global Y is vertical

TR.20.9 Applying Fireproofing on members

STAAD.Pro includes a method to automatically consider the weight of fireproofing material applied to structural steel.

General Format

```
MEMBER FIREPROOFING
```

```
member-list FIRE { BFP | CFP } THICKNESS f1 DENSITY f2
```

Where:

THICKNESS *f1*	thickness (T in the figures below) in length units

DENSITY *f2*	density of fireproofing material in (force / length^3) units

In the actual load case itself, nothing besides the `SELFWEIGHT` command is necessary to instruct the program to include the weight of the fireproofing material in the selfweight calculation.

Two types of fireproofing configurations are currently supported. They are:

block fireproofing
contour fireproofing

Block Fireproofing (BFP)

The following figure shows this configuration. The fire-protection material forms a rectangular block around the steel section.

The area of fireproofing material (A_{fp}) at any section along the member length is calculated in the following manner.

For Wide Flanges (I-shaped sections), Channels and Tees,

$$A_{fp} = [(B_f + 2T)*(D+2T)] - A_{steel}$$

For single angles,

$$A_{fp}= [(B_f + 2T)*(D+2T)] - A_{steel}$$

where

B_f	=	the flange width
D	=	the overall depth of the steel section
T	=	the thickness of the fireproofing material beyond the outer edges of the cross section as dimensioned in the next figure
A_{steel}	=	area of the steel section

Where:

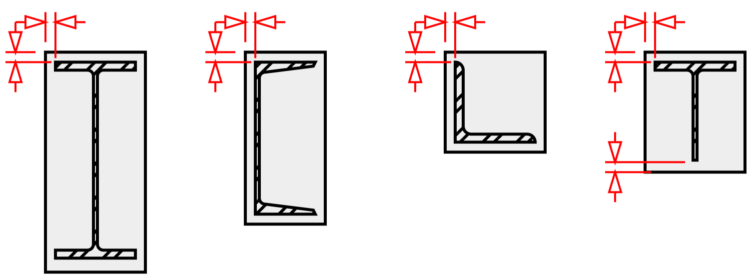

Figure 294: Block fireproofing (BFP) on various shapes

Contour Fireproofing (CFP)

In this configuration, the fire-protection material forms a coating around the steel section as shown in the next figure. The area of fireproofing material (A_{fp}) for this case is calculated in the following manner.

For Wide Flanges (I-shaped sections)

$$A_{fp} = [(B_f + 2T)*(T_f+2T)]*2 + [(D-2T-2T_f)*(T_w+2T)] - A_{steel}$$

For single angles,

$$A_{fp} = [(L_1+2T)*(2T+T_a) + (L_2-T_a)*(2T+T_a)] - A_{steel}$$

For Tees,

$$A_{fp} = [(B_f + 2T)*(T_f+2T)] + [(D-T_f)*(T_w+2T)] - A_{steel}$$

where

B_f	=	the flange width
D	=	the overall depth of the steel section
T	=	the thickness of the fireproofing material beyond the outer edges of the cross section as dimensioned in the next figure
T_f	=	the thickness of the flange for the I shape and Tee
T_a	=	the thickness of the leg of the angle
T_w	=	the thickness of the web for the I shape and Tee
A_{steel}	=	area of the steel section

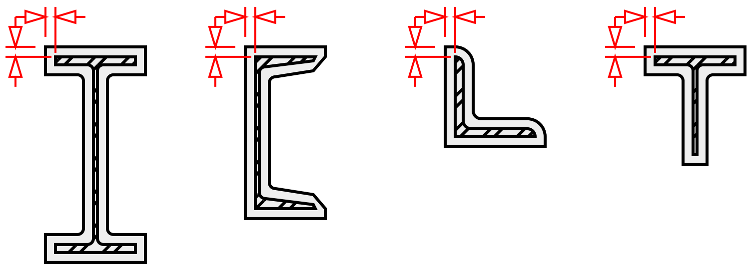

Figure 295: Contour fireproofing (CFP) on various shapes

The number of input items required to apply this attribute is:

a. the type of fireproofing
b. the thickness T shown in the above figures
c. the density of the fireproofing material
d. the members on which it is to be applied

For each such member, A_{fp} is calculated and multiplied by the density of the fireproofing material to obtain the weight per unit length of the member. This is added to the weight per unit length of the steel section itself and the total is used in calculating selfweight. Hence, `SELFWEIGHT` must be one of the load components of load cases if the weight of the fireproofing material should be considered as part of those load cases.

Notes

1. STAAD calculates the fire proofing weight only for the following sections:

   For block fireproofing - I-shaped sections like those from the built-in tables (American W,S,M,HP, British UC and UB, etc.), tapered I shaped sections, single channels, angles and Tees.

   For CFP-contour fireproofing - the sections are I-beam straight or tapered, angle, Tee.

   I-shaped sections like those from the built-in tables (American W,S,M,HP, British UC and UB, etc.), tapered I shaped sections, angles and Tees..
2. Fire proofing weight is not calculated for the following section types: Pipe, tube, composite I beams with slab on top, double channel, double angle, HSS, I-beam with cover plates, prismatic, solid circle or rectangle, castellated, cold formed sections, wood, aluminum, tapered poles, etc.

TR.20.10 Member Property Reduction Factors

Concrete design specifications recommend the use of cracked section properties for the analysis and design of concrete sections. The methodology to handle cracked section properties is nonlinear in nature (i.e., the section capacities should be checked and modified depending upon the section forces the section is handling). The model should then be re-analyzed with modified reduced section properties and redesigned. This iteration should be continued until the forces in all sections designed are below the allowable limit of ultimate strength.

In STAAD.Pro, you can specify a set of reduction factors to be applied on the calculated section properties such as area, moments of inertia, and torsional constant. If you want to adopt this approach to account for cracking of concrete sections, refer to Section 10.11.1 of ACI 318 for a set of values to use for these reduction factors depending upon the nature of forces and moments the member is subjected to.

Note: The specifications in the AISC 13th edition manual suggest reducing the stiffness of the steel member during the analysis. In place of the `MEMBER CRACKED` command, the `REDUCEDEI` parameter may be used when the PERFORM DIRECT ANALYSIS command is used. See TR.37.5 Direct Analysis (on page 2630) for additional information.

General Format

The format of the command is:

```
MEMBER CRACKED (CODE IS1893 2016)
```

```
{ member-list | group-list } REDUCTION *{ RAX f1 | RIX f2 | RIY f3 | RIZ f4 }
```

Each reduction factor value, *f1* through *f4*, should be a fraction of unity.

RAX *f1* Reduction factor in the axial area.

RAX is *not* applicable for reduction factors for the IS1893 2016 code.

RIX *f2* Reduction factor of the torsion constant (about the local x-axis).

RIY *f3* Reduction factor in the moment of inertia about the local major axis (y-axis).

RIZ *f4* Reduction factor in the moment of inertia about the local minor axis (z-axis).

This is a multiplication factor on the property value. It does not signify the amount by which the property is reduced, but, it is simply a value by which the unreduced property is multiplied. Thus, the calculated (or the user-specified value) of the property will be multiplied by the reduction factor to arrive at the value used in the analysis.

For example, a factor of 0.45 defined for RAX will mean that if the cross sectional area of the gross section is 0.8 ft^2, the value used in the analysis will be $0.8 \times 0.45 = 0.36\ ft^2$.

Multiple factors can be assigned on the same line.

The reduction factor is considered only for analysis but not for design.

Code-Specific Reduction Factors

IS1893 2016 Clause 6.4.3 calls for a reduction of moment of inertia values by 0.35 for beams and 0.7 for columns of concrete members only while analyzing the structure for static seismic and response spectrum/linear dynamic analysis.

Note: Automated stiffness reduction requires a STAAD.Pro Advanced license.

Code-specific reduction factors will not affect non-concrete members. A separate stiffness matrix is generated for the use of IS1893 2016 static seismic and response spectra loads. For all other load cases, the analysis is performed using the unreduced stiffness matrix.

Tip: For a STAAD.Pro model containing multiple analysis commands, a different set of code-specific reduction factors may be used for each analysis command.

The CHANGE command has no affect or code-specific reduction factors.

Example

```
MEMBER CRACKED
1 REDUCTION RAX 0.35 RIX 0.40 RIY 0.45 RIZ 0.45
```

IS1893 2016 Example

```
START GROUP DEFINITION
MEMBER
_BEAM 1 4
_COLUMN 2 3 5 6
END GROUP DEFINITION
…
MEMBER CRACKED CODE IS1893 2016
_COLUMN REDUCTION RIY 0.700 RIZ 0.700
_BEAM REDUCTION RIY 0.350 RIZ 0.350
```

TR.21 Element/Surface Property Specification

Individual plate elements, and the Surface element need to have their thickness specified before the analysis can be performed. The commands for specifying this information are explained in this section. No similar properties are required for solid elements. However, constants such as modulus of elasticity, Poisson's Ratio, etc. are required.

Related Links

- *G.5 Finite Element Information* (on page 2099)
- *G.5.1 Plate and Shell Elements* (on page 2099)
- *G.5.2 Solid Elements* (on page 2110)
- *G.5.3 Surface Elements (Deprecated)* (on page 2113)

TR.21.1 Element Property Specification

This set of commands may be used to specify properties of plate finite elements. Elements of uniform or linearly varying thickness may be modeled using this command. The value of the thickness must be provided in current units.

Unlike members and plate/shell elements, no properties are required for solid elements. However, constants such as modulus of elasticity and Poisson's ratio are to be specified.

General Format

```
ELEMENT PROPERTY
```

```
element-list   THICKNESS f1  (f2 f3 f4)
```

Where:

THICKNESS *f1*	thickness of the element
f2 … f4	thicknesses at other nodes of the element if different from *f1*

Example

```
UNIT …
ELEMENT PROPERTY
1 TO 8 14 16 THI 0.25
```

Related Links

- *G.5.1 Plate and Shell Elements* (on page 2099)
- *M. To specify plate thickness* (on page 811)
- *G.5 Finite Element Information* (on page 2099)
- *G.5.1 Plate and Shell Elements* (on page 2099)
- *G.5.2 Solid Elements* (on page 2110)
- *G.5.3 Surface Elements (Deprecated)* (on page 2113)

TR.21.2 Surface Property Specification

This set of commands may be used to specify properties of surface entities.

Note: Surface elements have been deprecated in STAAD.Pro CONNECT Edition. The analysis and design engine will allow them but their use is not recommended.

General Format

```
SURFACE PROPERTY
```

```
surface-list THICKNESS t
```

Where:

t = Thickness of the surface element, in current units.

Example

```
SURFACE PROPERTY
1 TO 3 THI 18
```

TR.22 Member and Element Releases

STAAD.Pro allows specification of releases of degrees of freedom for frame members and plate elements.

Related Links

- *G.7 Member and Element Release* (on page 2120)

TR.22.1 Member Release Specification

This set of commands may be used to fully release specific degrees of freedom at the ends of frame members. They may also be used to describe a mode of attachment where the member end is connected to the joint for specific degrees of freedom through the means of springs.

General Format

```
MEMBER RELEASES
```

```
member-list  {START | END | BOTH } { *{ FX | FY | FZ | MX | MY | MZ } | *{KFX f1 | KFY
f2 | KFZ f3 | KMX f4 | KMY f5 | KMZ f6 } | {MP f7 | *{     MPX f8 | MPY f9 | MPZ
f10 }} }
```

Where:

FX ... MZ	represent force-x through moment-z degrees of freedom in the member local axes
KFX *f1* ... KMZ *f6*	spring constants for these degrees of freedom, in current units
MP *f7*	partial moment release factor for all three moments
MPX *f8*, MPY *f9*, MPZ *f10*	partial moment release factors for each moment separately. The moment related stiffness coefficient will be multiplied by a factor of (1 - *fn*) at the specified end. Release factors must be in the range of 0.001 through 0.999.

Note: If FX through MZ is used, it signifies a full release for that degree of freedom and if KFX through KMZ is used, it signifies a spring attachment.

Notes

a. Member releases are a means for describing a type of end condition for members when the default condition, namely, fully moment and force resistant, is not applicable. Examples are bolted or riveted connections. Partial moment releases are a way of specifying bending and torsional moment capacity of connections as being a fraction of the full bending and torsional strength.

b. It is important to note that the factor f_1 indicates a reduction in the stiffness corresponding to the rotational degrees of freedom MX, MY, and MZ. In other words, you should not expect the moment on the member to reduce by a factor of f_1 . It may be necessary to perform a few trials in order to arrive at the right value of f_1 that results in the desired reduction in moment.

c. The START and END are based on the MEMBER INCIDENCE specification. The BOTH specification will apply the releases at both ends.

d. At any end of the member—for any particular DOF—full, partial, and spring release cannot be applied simultaneously. Only one out of the three is permitted.

e. If MY (or MZ) is fully released at both ends, then VZ (or VY) cannot be transmitted through the member. The final shears in the member will be entirely due to loads applied directly to the member.

Example

```
MEMBER RELEASE
1 3 TO 9 11 12 START KFX 1000.0 MY MZ
1 10 11 13 TO 18 END MZ KMX 200.0
```

In this example, for members 1, 3 to 9, 11 and 12, the moments about the local Y and Z axes are released at their start joints (as specified in `MEMBER INCIDENCES`). Further, these members are attached to their START joint along their local x axis through a spring whose stiffness is 1000.0 units of force/length. For members 1, 10, 11 and 13 to 18, the moment about the local Z axis is released at their end joint. Also, the members are attached to their END joint about their local x axis through a moment-spring whose stiffness is 200.0 units of force-length/Degree. Members 1 and 11 are released at both start and end joints, though not necessarily in the same degrees of freedom.

Partial Moment Release

Moments at the end of a member may be released partially using the MP option (to provide the same partial release in all . This facility may be used to model partial fixity of connections. The following format may be used to provide a partial moment release. This facility is provided under the `MEMBER RELEASE` option and is in addition to the existing `RELEASE` capabilities.

Example

```
MEMBER RELEASE
15 TO 25 START MP 0.25
```

The above `RELEASE` command will apply a factor of 0.75 on the moment related stiffness coefficients at start node of members 15 to 25.

Related Links

- *G.7 Member and Element Release* (on page 2120)
- *M. To assign member end release* (on page 804)
- *M. To assign specifications to physical members* (on page 810)

TR.22.2 Element Release Specification

This set of commands may be used to release specified degrees of freedoms at the corners of plate finite elements.

General Format

```
ELEMENT RELEASE
```

```
element-list  { J1 | J2 | J3 | J4 } *{ FX | FY | FZ | MX | MY | MZ }
```

Where:

J1, J2, J3 and J4 = signify joints in the order of the specification of the element incidence. For example, if the incidences of the element were defined as 35 42 76 63, J1 represents 35, J2 represents 42, J3 represents 76, and J4 represents 63.
FX through MZ = represents forces/moments to be released per local axis system.

Note: Element releases at multiple joints cannot be specified in a single line. Those must be specified separately as shown below.

Examples

Example of Correct Usage

```
ELEMENT RELEASE
10 TO 50 J1 MX MY
10 TO 50 J2 MX MY
10 TO 50 J3 MY
10 TO 50 J4 MY
```

Example of Incorrect Usage

```
ELEMENT RELEASE
10 TO 50 J1 J2 MX MY
10 TO 50 J3 J4 MY
```

Notes

a. All releases are in the local axis system. See G.5.1 Plate and Shell Elements (on page 2099) for the various degrees of freedom. Fx and Fy have the same sense as Sx and Sy in G.5.1 Plate and Shell Elements (on page 2099). Fz has the same sense as SQx or SQy. Generally, do not over release. The element must still behave as a plate after the releases.

b. Selfweight is applied at each of the nodes as if there were no releases.

c. Thermal stresses will include the fixed-end thermal pre-stress as if there were no release.

d. May not be used with the Element Plane Stress or Element Ignore Inplane Rotation commands on the same element.

e. Note that the usual definitions of local Mx and My are reversed here. See G.5.1 Plate and Shell Elements (on page 2099) for the definitions of Mx and My. Releasing Fz, Mx, My will release all bending capability. Releasing Fx, Fy, Mz will release all in-plane stiffness.

Related Links

TR.22.3 Element Ignore Stiffness

Structural units like glass panels or corrugated sheet roofs are subjected to loads like wind pressures or snow loads. While these units are designed to carry those loads and transmit those loads to the rest of the structure, they are not designed to provide any additional stiffness to the structure. One way to handle the situation is to not input the unit as part of the structural model, and apply the load using load generation techniques like `AREA LOAD` or `FLOOR LOAD`.

STAAD provides another way of handling such units. This is through the help of the `ELEMENT IGNORE STIFFNESS` command. To use this feature, the glass panel or roof unit must be defined using plate elements. The `IGNORE STIFFNESS` command enables one to consider the unit just for the purpose of application of `ELEMENT LOAD` commands, while its stiffness will not be considered during the assembly of the stiffness matrix. In other words, it is like an `INACTIVE` member which is active for `ELEMENT LOAD` command application but `INACTIVE` for stiffness. Like the `INACTIVE` command, the plates listed here will become active at the next `CHANGE` command. To keep them inactive, re-enter this data after each `CHANGE`.

The `SELFWEIGHT`, `ELEMENT WEIGHT`, `TEMPERATURE`, and mass of the plates listed here will still be ignored.

General Format

```
IGNORE STIFFNESS {ELEMENT} element-list
```

Example

```
IGNORE STIFFNESS ELEMENT 78 TO 80
```

Related Links

- *G.5.1 Plate and Shell Elements* (on page 2099)
- *M. To ignore plate stiffness* (on page 816)

TR.23 Axial Member Specifications

A member can have only *one* of the following specifications:

Truss
Tension-only
Compression-only
Cable

If multiple specifications are applied to the same member, only the last entered will be used (Warnings will be printed).

Note: `MEMBER TRUSS`, `MEMBER TENSION`, `MEMBER COMPRESSION`, and `MEMBER CABLE` are axial-only for stiffness. `MEMBER CABLE` are special truss members that may also be specified as tension-only.

TR.23.1 Member Truss Specification

This command may be used to model a specified set of members as TRUSS members.

This specification may be used to specify truss type members in a PLANE, SPACE, or FLOOR structure. The truss members are capable of carrying only axial forces. For example, bracing members in 2D (i.e., PLANE or FLOOR) or 3D (i.e., SPACE) frames will often be truss type members.

Tip: This command is unnecessary when a TR.2 Problem Initiation and Model Title (on page 2202) has already been specified using the command `STAAD TRUSS`.

General Format

```
MEMBER TRUSS
```

```
member-list (TENSION f1)
```

Where:

TENSION *f1* optional initial tension in the truss member, in current units

Note: The `TENSION` parameter is ignored except in Nonlinear Cable Analysis. For that analysis type, a truss with pretension is considered to be nonlinear (large displacement). Also for that analysis type, trusses without preload are assumed to be linear members that carry both tension and compression regardless of this command.

Example

```
MEMB TRUSS
1  TO  8  10  12  14  15
```

Notes

a. The `TRUSS` member has only one degree of freedom-the axial deformation.
b. Member Releases are not allowed for TRUSS members.
c. Self-weight and transverse loads may induce shear/moment distributions in the member.
d. Member loads are lumped at each end, whereas a frame member with moment releases only retains the axial component of the applied member load.

- *G.8.2.2 Nonlinear Cable and Truss Members* (on page 2123)
- *G.17.2.7 Nonlinear Cable or Truss Analysis* (on page 2149)

TR.23.2 Member Cable Specification

This command may be used to model a specified set of members as cable members.

Cable members, in addition to elastic axial deformation, are also capable of accommodating the stiffness effect of initial tension and tension due to static loads. When used in a nonlinear cable analysis, cable members are capable of accommodating large displacements. See G.8.2 Cable Members (on page 2122) for a theoretical discussion of cable members.

General Format

```
MEMBER  CABLE
```

```
member-list cable-spec
```

```
cable-spec  = { TENSION f1 ( { START | END } )| LENGTH f2 } *{ (FWX f3) | (FWY f4) |
 (FWZ f5) }
```

Where:

TENSION *f1*	Initial tension in cable member (in current units), when the `TENSION` option is specified.
LENGTH *f2*	Unstressed cable length (in current units), when the initial `LENGTH` option is specified.
FWX *f3*, FWY *f4*, FWZ *f5*	Multiplying factors on self weight components applied in the global X, Y, and Z directions, respectively.
START, END	The initial tension is measured at the cable start node or cable end node, respectively. This is used for advanced cable analysis (refer to Note 5 in Nodes for use with Advanced Cable Analysis).

Notes for use with Standard Cable Analysis

1. The tension specified in the cable member is applied on the structure as an external load as well as is used to modify the stiffness of the member. The tension value must be positive to be treated as a cable otherwise it is a truss (See G.8.2 Cable Members (on page 2122)). If the `TENSION` parameter or the value is omitted, a minimum tension will be used.

   The end at which initial tension is measured is not used for standard cable analysis (i.e., START or END is ignored).
2. This is a truss member but not a tension-only member unless you also include this member in a `MEMBER TENSION` input (See TR.23.3 Member Tension/Compression Specification (on page 2292)). Note also that Member Releases are *not* allowed.
3. The tension is a preload and will not be the final tension in the cable after the deformation due to this preload.
4. The tension is used to determine the unstressed length. That length will be shorter than the distance between the joints by the distance that the tension will stretch the cable.
5. No weight (other than the assumed self weight) is used with standard cable analysis.
6. Cables should not be used in analysis involving frequency extraction or for dynamic loading conditions such as response spectrum, time history, or steady state.

Notes for use with Advanced Cable Analysis

1. A cable member is a truss member that has three translational degrees of freedom only. Note also that member releases are *not* allowed for a cable member.
2. `FWY` is used to add any additional weight that may be acting on the cable along with self weight before the application of external applied load. This additional weight will be added to cable self-weight in global Y direction. These are used to find the initial cable profile before the application of the external load.
3. If no self weight is included in the external applied load and also `FWY` parameter is not defined, the program will calculate self weight of the cable member and include it in the analysis.

   Warning message will be issued in the output file.
4. If self weight is included in the external applied load, during calculation cable self weight will not be considered in the external applied load vector. The reason is that it will be considered separately while finding the initial cable configuration under self weight and thus cannot be considered as external applied load.
5. If `START` or `END` is not specified with the initial `TENSION` parameter in the cable member, then the average tension is assumed. The average option is suitable *only for a taut cable*. This is because in a taut cable, the undeformed length is shorter than the chord length. due to this, the taut cable carries significant tension with little sag. The undeformed legth, Lu, is calculated as:

$$L_u = \frac{L_c}{(1 + T_{avg} / EA)}$$

where

L_c	=	chord length
T_{avg}	=	initial average tension in the taut cable
E	=	Young's modulus
A	=	area of the cross-section

However, for a slack cable, this does not hold true because the undeformed length is longer that the chord length and the cable member has significant sag. The catenary curve effect is required to be included. Thus, for a slack cable, initial TENSION should be defined either at the START or END node of the cable member. For a cable member which is considered to have significant sag, defining the average tension is *not* a suitable option.

6. Cables should not be used in analysis involving frequency extraction or for dynamic loading conditions such as response spectrum, time history, or steady state.

Example

A series of cable members with a tension of 15.5 specified for use with either standard or advanced cable analysis:

```
MEMB CABLE
20 TO 25 TENSION 15.5
```

A series of cable members with a tension of 15.5 at the cable start node for use with advanced cable analysis. An additional weight on the cable of 20% of the cable self weight which acts in the same direction of the cable's self weight is used.

```
MEMB CABLE
20 TO 25 TENSION 15.5 START FWY -0.2
```

TR.23.3 Member Tension/Compression Specification

This command may be used to designate certain members as Tension-only or Compression-only members.

Tension-only members are truss/cable members that are capable of carrying tensile forces only. Thus, they are automatically inactivated for load cases that create compression in them.

General Format

```
MEMBER TENSION
```

```
member-list
```

or

```
MEMBER COMPRESSION
```

```
member-list
```

or

```
MEMBER TENSION 0
```

Linear Tension/ Compression Analysis

Compression-only members are truss members that are capable of carrying compressive forces only. Thus, they are automatically inactivated for load cases that create tension in them. Member Releases are not allowed on members with this attribute.

The procedure for analysis of Tension-only or Compression-only members requires iterations for every load case and therefore may be quite involved. you may also consider using the `INACTIVE` specification (instead of Tension/Compression) if the solution time becomes unacceptably high.

If a `CHANGE` command is used (because of a change in the list of tension members, cable tension, supports, etc.), then the `SET NL` command must be used to convey to STAAD that multiple analyses and multiple structural conditions are involved.

Note: For Nonlinear cable analysis, this command is unnecessary and ignored. Cables are automatically assumed to be partially to fully tension only (except that there should always be selfweight) without this command. In this analysis type, trusses without preload are assumed to be linear members that carry both tension and compression regardless of this command.

a. Loads that have been defined on members declared as `MEMBER TENSION` or `MEMBER COMPRESSION` will be active even when the member becomes `INACTIVE` during the process of analysis. This applies to `SELFWEIGHT`, `MEMBER LOADS`, `PRESTRESS` & `POSTSTRESS LOADS`, `TEMPERATURE LOAD`, etc.

b. A member declared as a `TENSION` only member or a `COMPRESSION` only member will carry axial forces only. It will not carry moments or shear forces. In other words, it is a truss member.

c. Do not use Load Combination to combine these cases. Tension/Compression cases are Nonlinear and should not be linearly combined as in Load Combination. Use a primary load case with the Repeat Load command.

Example

```
MEMBER TENSION
12 17 19 TO 37 65
MEMBER COMPRESSION
5 13 46 TO 53 87
```

Member Tension 0

This command switches off all tension/compression only specifications for load cases which are specified subsequent to this command, usually entered after a `CHANGE` command. There is no list associated with this command. Hence, for any further primary load cases, the tension/compression only attributed is disabled for *all* members.

Example

The following is the general sequence of commands in the input file if the `MEMBER TENSION` or `MEMBER COMPRESSION` command is used. This example is for the `MEMBER TENSION` command. Similar rules are applicable for the `MEMBER COMPRESSION` command. The dots indicate other input data items.

```
STAAD …
SET NL …
UNITS …
JOINT COORDINATES
…
MEMBER INCIDENCES
…
ELEMENT INCIDENCES
…
CONSTANTS
…
MEMBER PROPERTY
…
SUPPORTS
…
MEMBER TENSION
…
LOAD 1
…
LOAD 2
…
LOAD 3
…
LOAD 4
…
LOAD 5
REPEAT LOAD
…
PERFORM ANALYSIS
CHANGE
LOAD LIST ALL
PRINT …
PRINT …
PARAMETER
…
CHECK CODE …
FINISH
```

Notes

a. See TR.5 Set Command Specification (on page 2206) for explanation of the `SET NL` command. The number that follows this command is an upper bound on the total number of primary load cases in the file.
b. STAAD performs up to 10 iterations automatically, stopping if converged. If not converged, a warning message will be in the output. Enter a `SET ITERLIM i` command (i > 10) before the first load case to increase the default number of iterations. Since convergence may not be possible using this procedure, do not set the limit too high.
c. The principle used in the analysis is the following.

- The program reads the list of members declared as MEMBER TENSION and/or COMPRESSION.
- The analysis is performed for the entire structure and the member forces are computed.
- For the members declared as MEMBER TENSION / COMPRESSION, the program checks the axial force to determine whether it is tensile or compressive. If the member cannot take that load, the member is "switched off" from the structure.
- The analysis is performed again without the switched off members.
- Up to 10 iterations of the above steps are made for each load case, unless a higher value is set using the command ITERLIM.
- This method does not always converge and may become unstable. Check the output for instability messages. Do not use results if the last iteration was unstable.

d. A revised MEMBER TENSION / COMPRESSION command and its accompanying list of members may be provided after a CHANGE command. If entered, the new MEMBER TENSION/COMPRESSION commands replace all prior such commands. If these commands are not entered after a CHANGE, then the previous commands will still be applicable.

e. The MEMBER TENSION command should not be used if the following load cases are present : Response Spectrum load case, Time History Load case, or Moving Load case. If used, the MEMBER TENSION / COMPRESSION will be ignored in all load cases.

f. If UBC Load cases are included, then follow each UBC load case with an Analysis command, then a Change command.

g. If the model requires a PDelta analysis, then only the first method as described in TR.37.2 P-Delta Analysis Options (on page 2621) (i.e., small or large delta) may be used.

TR.24 Element Plane Stress and Ignore Inplane Rotation Specification

These commands allow the user to model the following conditions on plate elements

a. PLANE STRESS condition

b. In-plane rotation stiffness reformulated to be rigid or to be zero.

General Format

```
ELEMENT { PLANE STRESS | RIG ID ( INPLANE ROTATION ) | IGNORE ( INPLANE ROTATION) }
element-list
```

The `PLANE STRESS` specification allows the user to model selected elements for PLANE STRESS action only [No bending or transverse shear stiffness].

The `RIGID INPLANE ROTATION` command causes the program to connect the corner Mz "in-plane rotation" action to the other corner Mz rotations rigidly. The STAAD plate element formulation normally produces a very soft Mz stiffness that improves the inplane shear deformation. However when the plate Mz is connected to a beam bending moment as the only load path for that moment, then the RIGID INPLANE option may be used to have that element carry the Mz moment to the other joints rigidly to avoid the instability at the beam end. Usually only the elements connected to beams in this manner would have this specification.

The `IGNORE INPLANE ROTATION` command causes the program to ignore "in-plane rotation" actions. The STAAD plate element formulation normally includes this important action automatically. However, it may be noted that some element formulations ignore this action by default. The user may utilize this option to compare STAAD results with solutions from these programs.

These options are exclusive of each other and also exclusive of element releases. No single element may have more than one of these options.

Example

```
ELEMENT PLANE STRESS
1 TO 10 15  20 25 35
ELEMENT IGNORE
30 50 TO 55
```

TR.25 Offset Specifications

The program can generate rigid links between the analytical joints and the ends of members or vertices of plate elements.

TR.25.1 Member Offset Specification

This command may be used to rigidly offset a frame member end from a joint to model the offset conditions existing at the ends of frame members.

General Format

```
MEMBER OFFSETS
```

```
member-list  { START | END } ( LOCAL ) dx dy dz
```

Where:

dx*, *dy*, and *dz	correspond to the distance, measured in localized or global coordinate system, from the joint (START or END as specified) to the centroid of the starting or ending point of the members listed.

LOCAL optional parameter, if not entered then *dx*, *dy*, *dz* are assumed to be in global. LOCAL means that the distances *dx*, *dy*, *dz* are in the same member coordinate system that would result if the member were not offset and BETA = 0.0.

Description

The `MEMBER OFFSET` command can be used for any member whose starting or ending point is not concurrent with the given incident joint. This command enables the user to account for the secondary forces, which are induced due to the eccentricity of the member. Member offsets can be specified in any direction, including the direction that may coincide with the member x-axis.

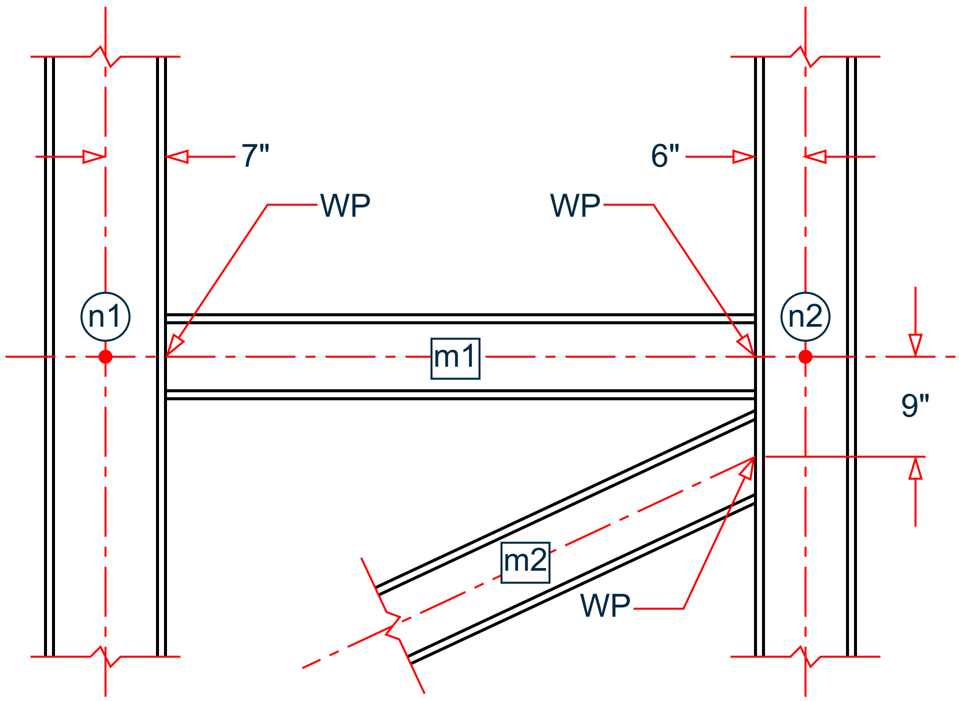

Figure 296: Example of working point (WP) represented by member end offsets

In the figure above, WP refers to the location of the centroid of the starting or ending point of the member.

Example

```
MEMBER OFFSET
1 START 7
1 END -6
2 END -6 -9
```

Notes

a. If a `MEMBER LOAD` (See TR.32.2 Member Load Specification (on page 2464)) is applied on a member for which `MEMBER OFFSETS` have been specified, the location of the load is measured not from the coordinates of the starting joint. Instead, it is measured from the offset location of the starting joint.

b. `START` and `END` is based on the user's specification of `MEMBER INCIDENCE` for the particular member.
c. Local offsets are defined in the local axes prior to rotation when a `BETA` angle is used.

- *G.11 Member and Plate Offsets* (on page 2125)

TR.25.2 Element Offset Specification

This command may be used to rigidly offset a plate element corner from a global joint to model the offset condition existing at the corners of plate elements.

General Format

The element offsets can be specified using one of two methods:

1. for individual joints in either local or global directions or
2. offsets along the local Z axis of the element.

```
element-list { JT1 | JT2 | JT3 | JT4 } ( LOCAL ) f1 f2 f3
```

or

```
element-list ZOFF { f4 | f5 f6 f7 f8 }
```

where

JT1 | JT2 | JT3 | JT4	The element joint number based on the joint incidence for the particular element. For example, JT1 is used for the first joint specified in that element's joint incidence list. Do not use JT4 for triangular plates.
f1, f2, f3	correspond to the distance, measured in local or global coordinate system, from a plate joint (JT1, JT2, JT3, or JT4 as specified) to the center plane of the associated corner point of the elements listed.

> **Note:** The joint offsets must result in offset corners which are co-planar to prevent a warped surface.

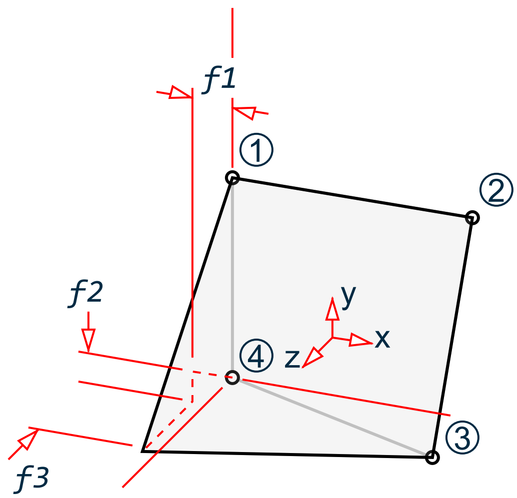

Figure 297: Local offsets given for JT4

LOCAL an option parameter that indicates the distances *ƒ1*, *ƒ2*, and *ƒ3* are in the member coordinate system with respect to the joint. If not entered, then *ƒ1*, *ƒ2*, and *ƒ3* are in the global coordinate system.

ƒ4 the Z offset distance to use for all four , measured in the local coordinate system from the joint perpendicular to the surface face in the local Z axis. This results in a constant offset of the entire element parallel to the joints.

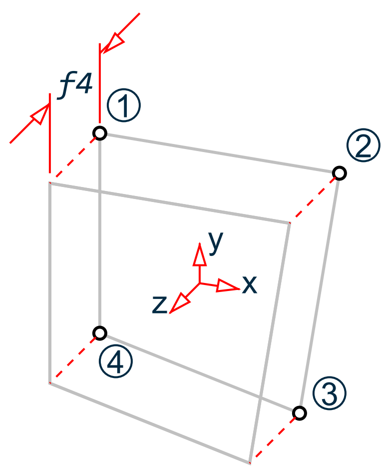

Figure 298: Constant Z offset

ƒ5*, *ƒ6*, *ƒ7*, *ƒ8 the Z offset distance to use for each of the four joints, in order. These are measured in the local coordinate system from the joint perpendicular to the surface in the local Z axis. Do not use *ƒ8* for triangular plates.

> **Note:** The joint offsets must result in offset corners which are co-planar to prevent a warped surface.

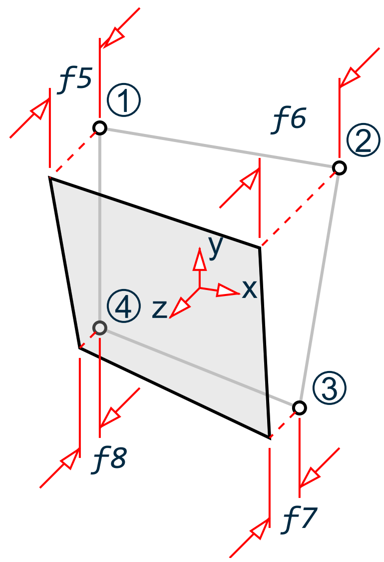

Figure 299: Z offset using different distances

Description

This command can be used for any element whose corner points are not concurrent with the given incident joint. This command enables you to account for the secondary forces which are induced due to the eccentricity of the element. Element offsets can be specified in any direction, including the direction that may coincide with the element in-plane axes.

Notes

a. If an element load (see TR.32.3 Element Load Specifications (on page 2468)) is applied on an element for which element offsets have been specified, then the location of the load is measured from the offset corner locations rather than the coordinates of the global joints.

b. Plate offsets are not applicable for steady state, geometric nonlinear, buckling, cable, or imperfection analysis types. An error message is generated if they are used with any of these analyses. Plate offsets are also not applicable for pushover analysis, as no elements (surface, plate, or solid) may be used with that analysis type.

c. The plate area, the warped element checks, and local element coordinates are based on the offset coordinates of the corner points.

d. Plate offsets are ignored static seismic loads.

e. Plate offsets are ignored for joint loads, since these are not applies to plates.

f. For floor diaphragms, use the `SET MASS 1` command to ensure that the plate offsets are considered during the center of mass calculations. Otherwise, the plate offsets will be ignored for this calculation. The mass modeling must be done using a `SET Y UP` command.

Examples

The following code example demonstrates from usage of this specification.

```
ELEMENT OFFSET
* All 4 joints of plate 1 are offset by 7 units in the local z direction.
1 ZOFF 7
```

```
* All 4 joins of plate 2 are offset by the units specified in the local z
* direction, in the order of the joint incidience.
2 ZOFF 7 7.5 7 7.5

* The first joint in the incidence of plate 3 is offset by 7 units in the
* local z direction.
3 JT1 LOCAL 0 0 7

* The second joint int he incidence of plate 4 is offset by 7.5 units in
* the global X direction.
4 JT2 7.5 0 0
```

Examples of Constant Offsets

The following offset methods all give the same results for element number 1:

Note: In practice, this model would only use *one* of these methods for element offsets.

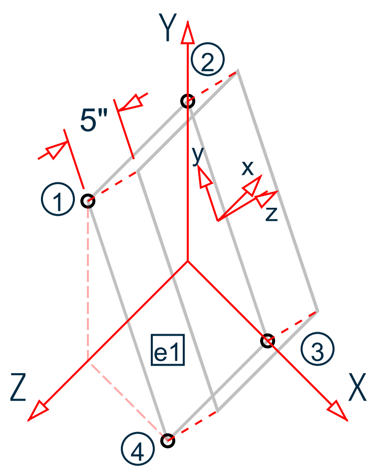

Figure 300: Example of uniform offsets for an element using different methods

```
UNIT INCH
JOINT COORDINATES
1 0 20 20
2 0 20 0
3 15 0 0
4 15 0 20
…
ELEMENT INCIDENCES
1 1 2 3 4
…
ELEMENT OFFSETS
* 1) Using global coordinates at each joint
1 JT1 3 4 0
1 JT2 3 4 0
1 JT3 3 4 0
1 JT4 3 4 0
```

```
* 2) Using local coordinates at each joint
1 JT1 LOCAL 0 0 5
1 JT2 LOCAL 0 0 5
1 JT3 LOCAL 0 0 5
1 JT4 LOCAL 0 0 5

* 3) Using a single Z offset
1 ZOFF 5

* 4) Using the same Z offset at each corner
1 ZOFF 5 5 5 5
```

Example of Physical Modeling Offset

The following example shows how element offsets can be used to model the "real world" physical properties of how concrete walls intersect with relation to the analytical model meshing centerlines. The adjoining wall on the right side has offsets from the analytical nodes of the elements (n1, n2) to the WP at the top and bottom of the wall intersection.

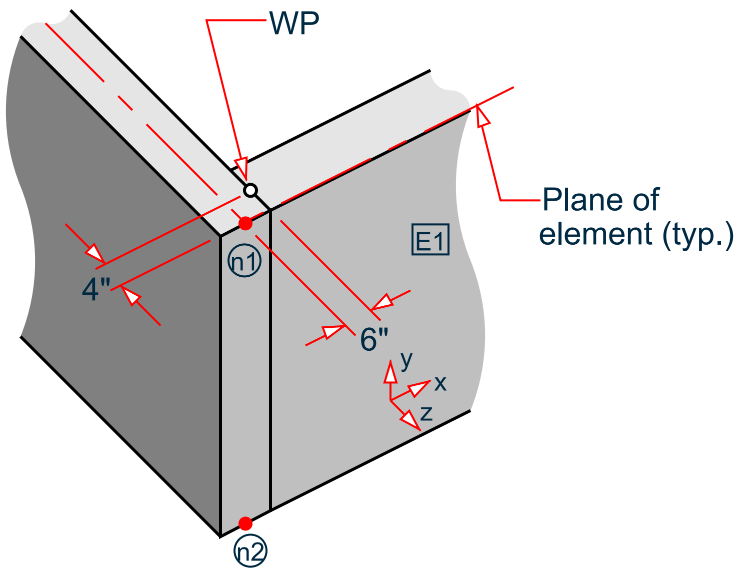

Figure 301: Example of working point (WP) represented by element offsets

```
UNIT INCH
ELEMENT OFFSETS
1 JT1 LOCAL 6 0 -4
1 JT2 LOCAL 6 0 -4
```

TR.26 Specifying and Assigning Material Constants

Material constants are attributes like Modulus of Elasticity and Density which are required for operations like generating the stiffness matrix, computing selfweight, and for steel and concrete design.

In STAAD, there are two ways in which this data may be specified :

a. A two-step process that involves:

   a. Creating the material data by defining `MATERIAL` tags specified under the heading `DEFINE MATERIAL` (See TR.26.1 Define Material (on page 2303))

   b. Assigning them to individual members, plates and solids under the heading `CONSTANTS` (See TR.26.2 Specifying Constants for Members and Elements (on page 2305))

   This will create commands as shown below:

```
Part 1DEFINE MATERIAL
... name
...
...
END MATERIAL

Part 2CONSTANTS
MATERIAL name ...
```

b. Assign material attributes explicitly by specifying the individual constants (See TR.26.2 Specifying Constants for Members and Elements (on page 2305)).

```
CONSTANTS
E ...
POISSON .
```

See TR.26.3 Surface Constants Specification (on page 2311) for an explanation for the commands required to assign material data to Surface elements.

Related Links

- *G.12 Material Properties* (on page 2126)

TR.26.1 Define Material

This command may be used to specify the material properties by material name. You will then assign the members and elements to this material name in the `CONSTANTS` command (See TR.26.2 Specifying Constants for Members and Elements (on page 2305) for details and an example).

> **Note:** `ISOTROPIC` materials can be assigned to all element types, `2DORTHOTROPIC` materials should only be assigned to plate elements.

General Format

```
DEFINE MATERIAL
```

then

```
ISOTROPIC name
E f1
G f3
POISSON f6
DENSITY f7
ALPHA f8
DAMPING  f10
```

or

```
2DORTHOTROPIC name
E f1 (f2)
G f3 (f4) (f5)
POISSON f6
DENSITY f7
ALPHA f8 (f9)
DAMPING  f10
```

Repeat `ISOTROPIC` or `2DORTHOTROPIC` name and values for as many materials as desired then:

```
END MATERIAL (DEFINITION)
```

Where:

name	material name (name of up to 36 characters)
f1*, *f2	specifies Young's Modulus (E). (*f2* in local Y for 2DOthotropic materials)
f3*, *f4*, *f5	specifies Shear Modulus (G). For plates, the following are G values in local directions: *f3* is the G for in-plane shear; *f4* is the G for transverse shear in the local Y-Z direction; *f5* is the G for transverse shear in the local Z-X direction. (Enter only for beams when the Poisson ratio is *not* in the range of 0.01 to 0.499.)
f6	specifies Poisson's Ratio. If G is not entered, then this value is used for calculating the Shear Modulus (G = 0.5xE/(1+POISSON)). This value must be in the range of 0.01 to 0.499. Poisson's ratio must be entered for orthotropic plates or when Poisson cannot be computed from G.
f7	specifies weight density
f8*, *f9	Coefficient of thermal expansion. (*f9* in local Y for 2DOthotropic materials)
f10	the damping ratio to be used in computing the modal damping by the composite damping method in a dynamic analysis when `CDAMP` has been specified. Damping must be in the range of 0.001 to 0.990.

Note:

Any material property which you do not explicitly specify is assumed to be the default value.

- *f1* defaults to 0.0 but a positive value must be entered or an error will ensue
- *f2* defaults to *f1*

- *f3* defaults to 0.5xE/(1+POISSON)
- *f4* defaults to *f3*
- *f5* defaults to *f4*.
- *f6* defaults to a sliding scale value based on E (that is: 0.30 when E is near that of steel, 0.33 when E is near that of aluminum, 0.17 when E is near that of concrete) .
- *f7* defaults to 0.0
- *f8* defaults to 0.0
- *f9* defaults to *f8*
- *f10* defaults to 0.0

Tip: If one or more of the material properties is not explicitly specified, the results may be unpredictable or even incorrect with respect to the intended behavior. Therefore, it is best practice to always specify each material property for each defined material.

TR.26.2 Specifying Constants for Members and Elements

This command may be used to specify the individual material properties (Modulus of Elasticity, Poisson's ratio, Density, Coefficient of linear expansion, and material damping) of the members and elements. In addition, this command may also be used to specify the member orientation (BETA angle or reference point/vector).

General Format

```
CONSTANTS
```

To define the orientation:

```
BETA {  f5 | ANGLE | RANGLE } MEMBER memb/elem-list
```

```
{ REF f8 f9 f10 | REFJT f11 | REFVECTOR f12 f13 f14 } MEMBER memb/elem-list
```

To define the material properties:

```
MATERIAL name { MEMBER member/element-list | (ALL) }
```

or

```
{ E f1 | G f2 | POISSON f3 | DENSITY f4 | ALPHA f6 | CDAMP f7 } { MEMBER memb/elem-
list | BEAM | PLATE | SOLID | (ALL) }
```

Where:

name = material name as specified in the `DEFINE MATERIAL` command (Refer to TR.26.1 Define Material (on page 2303)).

```
{ REF f8 f9 f10 | REFJT f11 | REFVECTOR f12 f13 f14 } MEMBER memb/elem-list
```

Where:

memb/elem-list = MEM, BEA, PLA, SOL, ALL. Only MEM may be followed by a list. If none are specified, the default is to use `ALL`, which means all members and elements; BEA means all members; PLA, all plates; SOL, all solids.

Parameter	Value	Description
E	*f1*	Specifies the modulus of elasticity, E (i.e, Young's Modulus). This value must be provided before the `POISSON` for each member/ element in the Constants list.
G	*f2*	specifies Shear Modulus (G). Enter only for beams when Poisson would not be 0.01 to 0.499.
POISSON	*f3*	specifies Poisson's Ratio, υ. This value is used for calculating the Shear Modulus ($G = 0.5xE/(1+\upsilon)$).
DENSITY	*f4*	specifies weight per unit volume, γ
ALPHA	*f6*	Coefficient of thermal expansion, a
CDAMP	*f7*	Damping ratio to be used in computing the modal damping by the composite damping method in a dynamic analysis when `CDAMP` has been specified. Damping must be in the range of 0.001 to 0.990.
BETA	*f5*	Specifies member rotation angle in degrees (Refer to G.4.3 Relationship Between Global and Local Coordinates (on page 2092)).

The following values are used in various methods to define the BETA angle based on geometry:

f8, *f9*, *f10* = Global X, Y, and Z coordinates for the reference point f11= use location of joint *f11* for the reference point, from which the BETA angle will be calculated by STAAD.Pro.

f12, *f13*, *f14* = Establishes a Reference Vector along which the local y-axis is aligned. From the start node of the member, move by a distance of *f12* along the beam's local X axis, *f13* along the local Y axis, and *f14* along the local Z axis to define the end node of the reference vector. (The BETA angle is thus the angel between the local y-axis and the reference vector)

Using BETA ANGLE and RANGLE

Single angle sections are oriented according to their principal axes by default. If it is necessary to orient them such that their legs are parallel to the global axes, the BETA specification must be used. STAAD.Pro offers the following additional specifications for this purpose:

- `BETA ANGLE`
- `BETA RANGLE`

Both of the above options will result in an orientation with the legs parallel to the global axis. The ANGLE option rotates the section counterclockwise by the angle, α (where α = angle between the principal axis system and the geometric axis system of the angle). The RANGLE option rotates the section counterclockwise by an angle equal to (180° - α). For unequal angles, the right option must be used based on the required orientation.

Table 236: Effect of BETA ANGLE and BETA RANGLE commands

BETA value =	Zero (0)	ANGLE	RANGLE
ST Angle			RA Angle			
Note: The figures in the preceding table are for a Y-UP system where the local x-axis goes into the screen. Global Y-axis is vertical. Refer to G.4.2 Local Coordinate System (on page 2088) for the orientation of angles when Z-UP is specified

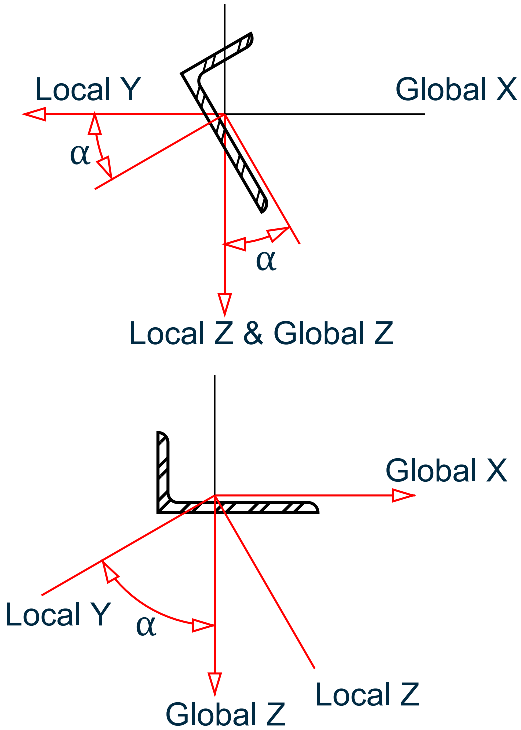

Figure 302: Orientation of an angle profile vertically aligned (i.e,. local x = Global Y) with (A) BETA = 0 (default) and (B) BETA = ANGLE

Note: The figures is for a Y-UP system where the local x-axis goes into the into the screen. Refer to G.4.2 Local Coordinate System (on page 2088) for the orientation of angles when Z-UP is specified.

Built-In Material Constants

For E, G, POISSON, DENSITY, ALPHA, and CDAMP, built-in material names can be entered instead of a value for *f1*. The built-in names are `STEEL`, `CONCRETE`, & `ALUMINUM`. Appropriate values will be automatically assigned for the built-in names.

Table 237: Constants (in Kip, inch, Fahrenheit units)

Constant	Material			Units
	Steel	Concrete	Aluminum	
E (US)	29,000	3,150	10,000	Kip/in^2
Poisson's	0.30	.17	.33	(ratio)
Density	.000283	.0000868	.000098	Kip/in^3
Alpha	6.5E-6	5.5E-6	12.8E-6	L/L/° F
CDAMP	.03	.05	.03	(ratio)

Constant	Material			Units
	Steel	Concrete	Aluminum	
E (nonUS)	29,732.736			Kip/in^2

Table 238: Constants (in MKS, Celsius units)

Constant	Material			Units
	Steel	Concrete	Aluminum	
E (US)	199, 947,960	21,718,455	68,947,573	kN/m^2
Poisson's	0.30	.17	.33	(ratio)
Density	76.819 541	23.561612	26.601820	kN/m^3
Alpha	12.0E-6	10.0E-6	23.0E-6	L/L/° C
CDAMP	.03	.05	.03	(ratio)
E (nonUS)	205, 000,000			kN/m^2

Note: E (US) is used if US codes were installed or if Member Properties American is specified for an analysis; otherwise E (nonUS) is used.

Example 1

```
DEFINE MATERIAL
ISOTROPIC CFSTEEL
E 28000.
POISSON 0.25
DENSITY 0.3E-3
ALPHA 11.7E-6
DAMP 0.075
END MATERIAL
CONSTANTS
MATERIAL  CFSTEEL MEMB 1 TO 5
CONSTANTS
E 2.1E5  ALL
BETA 45.0  MEMB  5  7  TO  18
DENSITY STEEL MEMB  14  TO  29
BETA  90  MEMB X
```

Example 2

The REFVECTOR command is used as in the following example:

```
REFVECTOR 0 2 1 MEMBER 27 TO 32
```

This command will set BETA as 90° for all members parallel to the X-axis and instructs the program to do the following procedure:

1. Establish the beam's local X,Y and Z axis corresponding to Beta = 0
2. Set the start node of the reference vector to be the same as the start node of the member.
3. From the start node of the reference vector, move by a distance of 0 along the beam's local X axis, 2 along the local Y axis, and 1 along the local Z axis. This establishes the end node of the reference vector.
4. At the end of step 3, the start node as well as the end node of the reference vector are known. That is the now the final direction of the member's local Y axis.

Since the local Y axis corresponding to Beta 0 is known, and the local-Y axis corresponding to the beam's final position has been established in step 4, Beta angle is calculated as the angle between these two vectors.

In this example, the angle is $Tan\text{-}1(1/2) = 26.5651$ degrees

Notes

a. The value for E must always be given first in the Constants list for each member/element.
b. All numerical values must be provided in the current units.
c. It is not necessary or possible to specify the units of temperature or ALPHA. You must ensure that the value provided for ALPHA is consistent in terms of units with the value provided for temperature (see TR.32.6 Temperature Load Specification for Members, Plates, and Solids (on page 2493)).
d. If G is not specified, but Poisson (υ) *is* specified, G is calculated as $E/[2\ (1+v)]$.
e. If neither G nor Poisson is specified, Poisson is assumed based on E, and G is then calculated.
f. If G and Poisson are both specified, the input value of G is used. That is, G is *not* calculated in this situation.
g. If G and Poisson are both required in the analysis, such as for the stiffness matrix of plate elements, and G is specified, but Poisson is not, then, Poisson is calculated as $[(E/2G)-1]$.
h. To obtain a report of the values of these terms used in the analysis, specify the command `PRINT MATERIAL PROPERTIES`.
i. Local offsets are defined in the local axes prior to rotation when a BETA angle is used.

TR.26.3 Surface Constants Specification

Explained below is the command syntax for specifying constants for surface entities.

Note: Surface elements have been deprecated in STAAD.Pro CONNECT Edition. The analysis and design engine will allow them but their use is not recommended.

General Format

```
SURFACE CONSTANTS
```

```
{ E f1 | G f2 | POISSON f3 | DENSITY f4 | ALPHA f5 }  { LIST surface-list | ALL }
```

Where:

E *f1*	Young's Modulus (E)
G *f2*	Modulus of Rigidity (G)
POISSON *f3*	Poisson's ratio
DENSITY *f4*	weight density
ALPHA *f5*	coefficient of thermal expansion

In lieu of numerical values, built-in material names may be used for the above specification of constants. The built-in names are STEEL, CONCRETE, and ALUMINUM. See TR.26.2 Specifying Constants for Members and Elements (on page 2305) for the values used in the built-in materials.

Example

```
SURFACE CONSTANTS
E 3150 LIST 1 TO 4
POISSON 0.17 ALL
DENSITY 8.68e-005 LIST 1 TO 4
ALPHA 5.5e-006 LIST 1 TO 4
```

Alternatively, where the material constants have been defined in a material object such as CONCRETE:

```
SURFACE CONSTANTS
MATERIAL CONCRETE LIST 1 TO 4
```

Notes

a. If G is not specified, but Poisson is specified, G is calculated from $E/\ [2\ (1 + Poisson)]$.
b. If neither G nor Poisson is specified, Poisson is assumed based on E, and G is then calculated.
c. If G and Poisson are both specified, the input value of G is used, G is not calculated in this situation.
d. If G and Poisson are both required in the analysis, such as for the stiffness matrix of plate elements, and G is specified, but Poisson is not, then, Poisson is calculated from $[(E/2G) - 1]$.
e. To obtain a report of the values of these terms used in the analysis, specify the command PRINT MATERIAL PROPERTIES.

TR.26.4 Modal Damping Information

To define unique modal damping ratios for every mode. STAAD.Pro allows you to specify modal damping either directly or by using Rayleigh damping (the algebraic combination of mass-proportional damping and stiffness-proportional damping). This will be used in a dynamic analysis when `MDAMP` has been specified.

Note: If all modes have the same damping, then you may simply enter damping within the define time history load or within the dynamic loading commands.

Damping may be entered:

- by specifying that the program `EVALUATE` each mode's damping based on the frequency of the mode and the minimum and maximum damping entered here. The formula used to evaluate the damping is given in Evaluate Damping (on page 2162).
- by specifying that the program `CALCULATE` each mode's damping based on the frequency of the mode and the mass factor, ALPHA, and the stiffness factor, BETA. The formula used to calculate the damping is given in Calculate Damping (on page 2160).
- explicitly for some or all modes (`EXPLICIT`).

The damping entered will be used in time history load cases and in response spectrum load cases that use the `CQC` or `ASCE4` methods and/or Spectra vs. Period curves versus damping.

General Format

```
DEFINE DAMPING INFORMATION
```

```
{ EVALUATE dmin (dmax) | CALCULATE ALPHA c1 BETA c2 (MAX dmax MIN dmin) | EXPLICIT d1
(d2 d3 d4 … dn ) }
```

```
END
```

Where:

dmin	the minimum damping ratio to be used in the evaluate damping formula
dmax	the optional maximum damping ratio to be used in the evaluate damping formula
ALPHA ***c1***	the mass-proportional damping coefficient, α, used in the cacluate damping formula
BETA ***c2***	the stiffness-proportional damping coefficient, β, used in the cacluate damping formula
MAX ***dmax***, **MIN** ***dmin***	optional minimum and maximum damping ratios, respectively, sed in the calculate damping formula
d1 d2 … dn	the damping ratios for each mode given in the explicit method

Note: Damping ratios must be in the range 0.0 through 1.0.

TR.26.5 Composite Damping for Springs

This command may be used to designate certain support springs as contributing to the computation of modal damping by the composite damping method. The Response Spectrum or Time History dynamic response analyses must select composite damping, `CDAMP`, for this data to have any effect on results and the material used must have suitable damping values, `DAMP`, specified.

General Format

```
SPRING DAMPING
```

```
joint-list *{ KFX f1 | KFY f2 | KFZ f3 }
```

Where:

f1, f2, f3	damping ratios (0.001 to 0.990) in the local X, Y, and Z directions, respectively

Note: At least one of KFX, KFY, or KFZ must be entered and each one entered must have a spring damp value following it.

Description

If this Spring Damping command is entered, then all springs in the structure are included in the composite damping calculation, otherwise no spring is considered in that calculation.

This input command does not create a spring. Rather, if a support spring exists at the joint in the specified direction, then it will be assigned the damping ratio.

Note: This is not a discrete damper definition.

TR.26.6 Member Imperfection Information

To define camber and drift specifications for selected members. Drift is usually for columns and camber for beams.

General Format

```
DEFINE IMPERFECTION
```

```
CAMBER { Y | Z } (f1) RESPECT (f2) *{ XR f4 f5 | YR f4 f5 | ZR f4 f5 | MEM memb-list |
 LIST memb-list | ALL }
```

```
DRIFT { Y | Z } (f3) *{ XR f4 f5 | YR f4 f5 | ZR f4 f5 | MEM memb-list | LIST memb-list |
 ALL }
```

f_1 Camber value. Default = 300

f_2 Respect value. Default = 1.6

f_3 Drift value. Default = 200.

f_4, f_5 global coordinate values to specify X, Y, or Z range for member selection.

Imperfections will be simulated by loads. These loads will be generated for the specified members if there is an Imperfection Analysis specified and if the specified members are active, in compression, and are not truss or tension/compression only members.

Notes

Camber is the maximum offset of the neutral axes in the defined direction from a vector that passes through the ends of the beam (i.e., the local X axis) defined as the ratio of member length/offset.

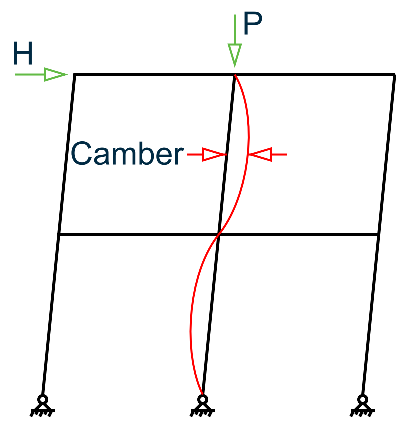

Figure 303: Camber definition

Drift is the offset of the end a member from its specified location defined as a ratio of member length/offset.

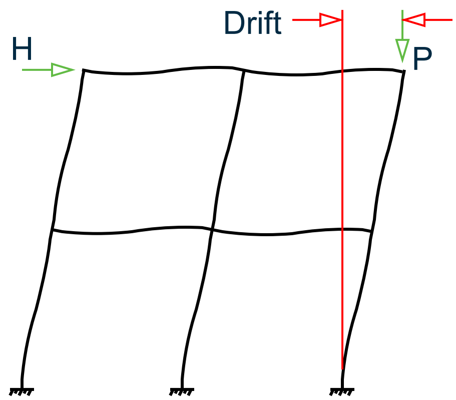

Figure 304: Drift definition

RESPECT is a non dimensional constant used to skip the camber imperfection calculation if the compressive load is small or EI is great or length is short. A combination of these terms is calculated and called EPSILON. If EPSILON is less than RESPECT, then the imperfection calculation is skipped for that local direction, for that case, for that member. The imperfection calculation is also skipped for any member that is in tension.

EPSILONy = Length * SQRT[(abs(axial load)) / EIz]

EPSILONz = Length * SQRT[(abs(axial load)) / EIy]

Example

```
SUPPORTS
1 FIXED
2 FIXED BUT FX
DEFINE IMPERFECTION
CAMBER Y 300 RESPECT 0.4 ALL
LOAD 1 GRAVITY + LATERAL
MEMBER LOAD
1 UNI GY -1
JOINT LOAD
2 FX -10
PERFORM IMPERFECTION ANALYSIS PRINT STATICS CHECK
```

TR.27 Support Specifications

STAAD support specifications may be either parallel or inclined to the global axes.

See TR.27.1 Global Support Specification (on page 2316) for specification of supports parallel to the global axes. See TR.27.2 Inclined Support Specification (on page 2318) for specification of inclined supports.

Related Links

- *G.13 Supports* (on page 2127)

TR.27.1 Global Support Specification

This set of commands may be used to specify the SUPPORT conditions for supports parallel to the global axes.

For SURFACE elements, if nodes located along a straight line are all supported identically, as in the case of the base of a wall, support generation can be performed for assigning restraints to those nodes. See the GENERATE option in the command syntax below. You only need to provide the starting and ending nodes of the range, and the type of restraint.

General Format

```
SUPPORTS
```

```
{ joint-list | ni TO nj GENERATE } { PINNED | FIXED ( BUT release-spec (spring-spec) )
| ENFORCED ( BUT release-spec) }
```

```
release-sepc = { FX | FY | FZ | MX | MY | MZ }
```

```
spring-spec = *{KFX f1 | KFY f2 | KFZ f3 | KMX f4 | KMY f5 | KMZ f6 }
```

Where:

ni, nj = Start and end node numbers, respectively, for generating supports along a SURFACE element edge.

f_1 ... f_6 = Spring constants corresponding to support spring directions X, Y, and Z and rotations about X, Y, and Z, repsectively.

Description of Pinned and Fixed

A PINNED support is a support that has translational, but no rotational restraints. In other words, the support has no moment carrying capacity. A FIXED support has both translational and rotational restraints. A FIXED BUT support can be released in the global directions as described in release-spec (FX for force-X through MZ for moment-Z). Also, a FIXED BUT support can have spring constants as described in spring-spec (translational spring in global X-axis as KFX through rotational spring in global Z-axis as KMZ). Corresponding spring constants are f1 through f6. The rotational spring constants are always per degree of rotation. All six releases may be provided as may be required when using the CHANGE command. If both release specifications and spring specifications are to be supplied for the same support joint, release specifications must come first.

1. See TR.38 Change Specification (on page 2660) for information on specification of SUPPORTS along with the CHANGE command specifications.
2. Spring constants must be provided in the current units.
3. All spring DOF must be entered after the last non-spring DOF is specified, if both are on the same line.
4. If there are two entries for the same joint, then:
   a. any direction that is pinned/fixed on either will be fixed in that direction.
   b. any direction released on one and is a spring on the other will use the spring.
   c. any direction that is pinned/fixed on one and a spring on the other will use the spring.
   d. any direction that is a spring on two or more entries will have the spring constants added.

Example 1

```
SUPPORTS
1 TO 4  7 PINNED
5  6 FIXED BUT FX MZ
8  9 FIXED BUT MZ KFX 50.0 KFY 75.
18  21 FIXED
27 FIXED BUT KFY 125.0
```

In this example, joints 1 to 4 and joint 7 are pinned. No moments are carried by those supports. Joints 5 and 6 are fixed for all DOF except in force-X and moment-Z. Joints 8 and 9 are fixed for all DOF except moment-Z and have springs in the global X and Y directions with corresponding spring constants of 50 and 75 units respectively. Joints 18 and 21 are fixed for all translational and rotational degrees of freedom. At joint 27, all the DOF are fixed except the FY DOF where it has a spring with 125 units spring constant.

Description of Enforced

Enforced Support defines which translational and rotational directions, at a joint, may have a support displacement imposed. The support displacements are defined for each load case in TR.32.8 Support Joint Displacement Specification (on page 2494). If no support displacement is entered, then zero displacement will be imposed, as if that direction was FIXED. The enforced displacement directions will be fixed for dynamic load cases.

If there are two entries for the same joint, then any direction that is enforced on either will be enforced in that direction, overriding any other support specification for that joint-direction.

Currently the support generation command can only be used in conjunction with the Surface element support specifications.

Example 2

```
SUPPORTS
3 TO 7 GENERATE PIN
```

The above command will generate pinned supports for all joints located between nodes No. 3 and 7 along a straight line. This may include joints explicitly defined by the user or joints generated by the program for internal use only (e.g., as a result of SET DIVISION and SURFACE INCIDENCES commands).

TR.27.2 Inclined Support Specification

These commands may be used to specify supports that are inclined with respect to the global axes.

General Format

```
SUPPORT
joint-list INCLINED { f1 f2 f3 | REF  f4 f5 f6 | REFJT f7 } { PINNED | FIXED ( BUT
release-spec (spring-spec) ) | ENFORCED ( BUT release-spec) }
```

Where:

f1, f2, f3	x, y, z relative distances from the joint in the global directions to the reference point
f4, f5, f6	x, y, z global coordinates of an arbitrary reference point
f7	a joint number whose x, y, z global coordinates are the reference point

A vector from the joint location to the reference point location serves to define a local coordinate system (same as member with BETA = 0). The inclined support directions are in this local "Inclined Support Axis System (on page 2318)" (see more below).

Note: The release-spec and spring-spec are the same as in the Global Supports (See TR.27.1 Global Support Specification (on page 2316)). However, FX through MZ and KFX through KMZ refer to forces/moments and spring constants in the "Inclined Support Axis System" (see below).

Inclined Support Axis System

The INCLINED support specification is based on the "Inclined Support axis system." The local x-axis of this system is defined by assuming the inclined support joint as the origin and joining it with a "reference point" with coordinates of f1, f2, and f3 (see the following figure) measured from the inclined support joint in the global coordinate system.

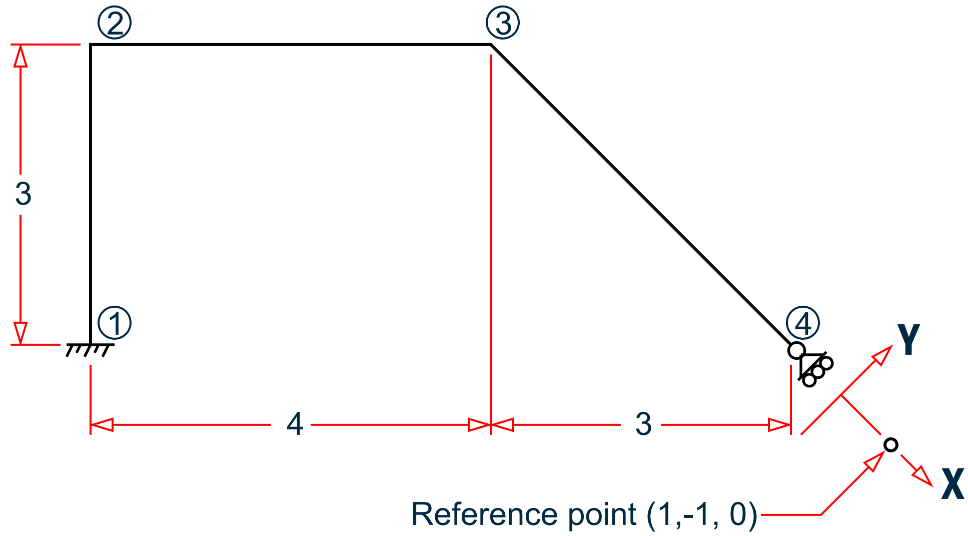

Figure 305: Reference point for defining an inclined support angle

The Y and Z axes of the inclined support axis system have the same orientation as the local Y and Z axes of an imaginary member whose BETA angle is zero and whose incidences are defined from the inclined support joint to the reference point. G.4.3 Relationship Between Global and Local Coordinates (on page 2092) for more information on these concepts.

Note: Inclined support directions are assumed to be same as global when computing some dynamic and UBC intermediate results (e.g., global participation factors). If masses and/or forces in the free directions at inclined supports are a relatively small portion of the overall forces, then the effect should be very small.

Example

```
SUPPORT
4 INCLINED 1.0 -1.0 0.0 FIXED BUT FY MX MY MZ
```

TR.27.3 Automatic Spring Support Generator for Foundations

STAAD.Pro has a facility for automatic generation of spring supports to model footings and foundation mats. This command is specified following the SUPPORT command.

General Format

```
SUPPORT
```

then either

```
{ joint-list ELASTIC FOOTING f1 (f2) | joint-list ELASTIC MAT | plate-list PLATE MAT }
DIR { X | XONLY | Y |  YONLY | Z | ZONLY } SUBGRADE f3
```

```
(PRINT) ( {COMP | MULTI } )
```

or

```
plate-list PLATE MAT DIR ALL SUBGRADE f4 (f5 f6)
```

```
(PRINT) ( {COMP | MULTI } )
```

Where:

FOOTING *f1 f2*	Length and width of the ELASTIC footing. If f_2 is not given, the footing is assumed to be a square with sides f_1.
X,Y,Z	Global direction in which soil springs are to be generated.
SUBGRADE *f3*	Soil subgrade modulus in current force/area/length units for elastic footings.
SUBGRADE *f4 f5 f6*	Soil subgrade modulus for mat foundations for use with ALL option in current force/area/length units in Y, X, Z directions respectively. f4, f5 default to f3 if omitted.

Note: For mat foundation subgrade values, the Y value is specified *first*, followed by X and then Z.

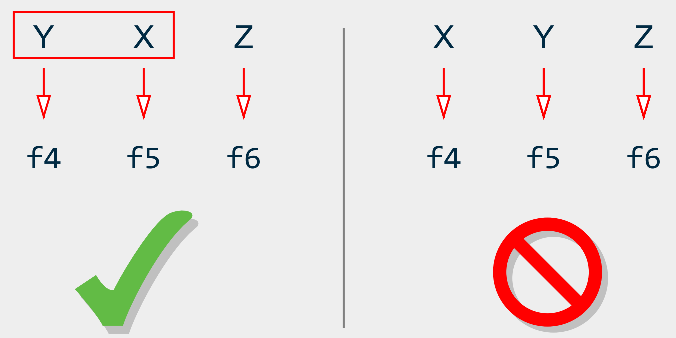

Figure 306: Correct and Incorrect order for specifying subgrade modulus values

Caution: Do not use this command with SET Z UP.

Description

If you want to specify the influence area of a joint yourself and have STAAD simply multiply the area you specified by the sub-grade modulus, use the ELASTIC FOOTING option. Situations where this may be appropriate are such as when a spread footing is located beneath a joint where you want to specify a spring support. A value for f_1 (and f_2 if its a non-square footing) is required for the FOOTING option.

If you want to have STAAD calculate the influence area for the joint (instead of you specifying an area yourself) and use that area along with the sub-grade modulus to determine the spring stiffness value, use the ELASTIC MAT option. Situations where this may be appropriate are such as when a slab is on soil and carries the weight of the structure above. You may have modeled the entire slab as finite elements and wish to generate spring supports at the nodes of the elements.

The `PLATE MAT` option is similar to the Elastic Mat except for the method used to compute the influence area for the joints. If your mat consists of plate elements and all of the influence areas are incorporated in the plate areas, then this option is preferable. Enter a list of plates or YRANGE f1 f2 at the beginning of the command, the joint influence areas are then calculated using the same principles as joint forces would be from uniform pressure on these plates. This method overcomes a major limitation of the Delaunay triangle method used in the ELASTIC MAT option, which is that the contour formed by the nodes of the mat must form a convex hull.

The `PLATE MAT DIR ALL` option is similar to the Plate Mat except that the spring supports are in 3 directions. If the compression only option is also specified, then the compression direction will be assumed to be in the Y direction. If the Y spring at a joint goes slack (lift off), then the X and Z spring stiffnesses for that joint will also be set to zero. Otherwise the X and Z springs act in both directions. The influence area for the X and Z springs is the same as used for the Y spring. Three values of subgrade reaction may be entered, the first is for the Y direction, the second for X and the third for Z.

The keyword `DIR` is followed by one of the alphabets X, Y or Z (or XONLY, YONLY, or ZONLY) which indicate the direction of resistance of the spring supports. If X or Y or Z is selected then a spring support is generated in that direction plus 3 other directions receive a fixed support, e.g., if Y is selected, then FY is supported by a spring; FX and FZ and MY are fixed supports; and MX and MZ are free. If XONLY, YONLY, or ZONLY are selected then only a spring support in that direction is generated.

The keyword `SUBGRADE` is followed by the value of the subgrade reaction. The value should be provided in the current unit system signified by the most recent `UNIT` statement prior to the `SUPPORT` command.

The `PRINT` option prints the influence area of each joint.

Use the `COMP` option generated will be compression only springs

Use the `MULTI` option to generate multilinear springs. Add the associated multilinear curve input after each `MAT` command (with the multi option) to describe the displacement-spring constant curve. See TR.27.4 Multilinear Spring Support Specification (on page 2322) for additional information on this input format. The actual spring constant used will be the subgrade modulus (f3 entered above) times the influence area (computed by STAAD) times the si values entered in the curve (so the curve stiffness values will likely be between 0.0 and 1.0).

```
SPRINGS d1 f1 d2 f2 … dn fn
```

Example

```
SUPPORTS
1 TO 126 ELASTIC MAT DIREC Y SUBG 200.
1 TO 100 PLATE MAT DIREC Y SUBG 200.
YR -.01 .01 PLA MAT DIR Y SUBG 200 MUL
SPRINGS -100 2.0 -0.51 2.0 -0.50 1.0 0.0 0.0 1000 0.0
```

The first command above instructs STAAD to internally generate supports for all nodes 1 through 126 with elastic springs. STAAD.Pro first calculates the influence area perpendicular to the global Y axis of each node and then multiplies the corresponding influence area by the soil subgrade modulus of 200.0 to calculate the spring constant to be applied to the node. In the 2nd example, the nodes of plates 1 to 100 are assigned spring supports, generated using a subgrade modulus of 200 units.

Notes

a. A closed surface is generated by the program based on the joint-list that accompanies the `ELASTIC MAT` command. The area within this closed surface is determined and the share of this area for each node in the list is then calculated.

Hence, while specifying the joint-list, one should make sure that these joints make up a closed surface. Without a proper closed surface, the area calculated for the region may be indeterminate and the spring constant values may be erroneous. Consequently, the list should have at a minimum, 3 nodes.

b. The internal angle formed by 2 adjacent segments connecting 3 consecutive nodes in the list should be less than 180 degrees. In other words, the region should have the shape of a convex polygon. The example below explains the method that may be used to get around a situation where a convex polygon is not available.

c. For the model comprised of plate elements 100 to 102 in the figure below, one wishes to generate the spring supports at nodes 1 to 8. However, a single `ELASTIC MAT` command will not suffice because the internal angle between the edges 1-8 and 8-7 at node 8 is 270 degrees, which violates the requirements of a convex polygon.

So, you should break it up into two commands:

```
1 2 3 8 ELASTIC MAT DIREC Y SUBG 200.
3 4 5 6 7 8 ELASTIC MAT DIREC Y SUBG 200.
```

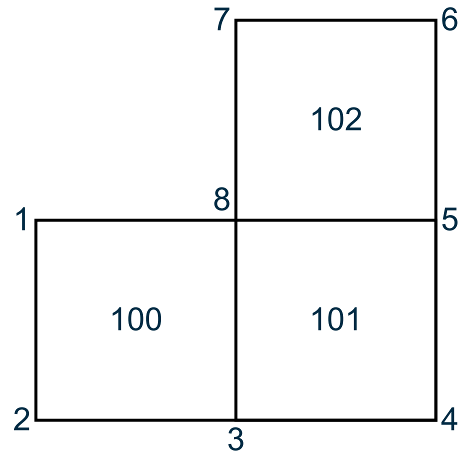

Figure 307: Example for elastic mat generation for a convex polygonal shape

Joints 3 and 8 will hence get the contribution from both of the above commands.

The command works only when the plane of the closed region is parallel to one of the global planes X-Y, Y-Z or X-Z. For regions that are inclined to one of the global planes, the spring constant will have to be evaluated manually and specified using the FIXED BUT type of spring support.

TR.27.4 Multilinear Spring Support Specification

When soil is modeled as spring supports, the varying resistance it offers to external loads can be modeled using this facility, such as when its behavior in tension differs from its behavior in compression.

General Format

```
MULTILINEAR SPRINGS
```

joint-list SPRINGS d_1 s_1 d_2 s_2 … d_n s_n

Where:

d_i s_i pairs represent displacement and spring constant pairs (s_i is zero or positive), starting from the maximum negative displacement to the maximum positive displacement.

The first pair defines the spring constant from negative infinity displacement up to the displacement defined in the second pair. The second pair define the spring constant when the support displaces in the range from the displacement defined in the second pair, up to the displacement defined in the third pair. This continues for each displacement and spring constant pair until the last pair which defines the spring constant for displacements greater than the displacement in the last pair to positive infinity.

Each load case in a multilinear analysis must be separated by a `CHANGE` command and have its own `PERFORM ANALYSIS` command. There may not be any `PDELTA`, `NONLIN`, dynamics, `CABLE`, or `TENSION/COMPRESSION` analysis included. The multilinear spring command will initiate an iterative analysis and convergence check cycle. The cycles will continue until the root mean square (RMS) of the effective spring rates used remain virtually the same for two consecutive cycles.

Example

```
UNIT …
SUPPORT
1 PINNED; 2 4 FIXED BUT KFY 40.0
MULTILINEAR SPRINGS
2 4 SPRINGS -1 40.0 -0.50 50.0 0.5 65.0
```

Load-Displacement characteristics of soil can be represented by a multilinear curve. Amplitude of this curve will represent the spring characteristic of the soil at different displacement values. A typical spring characteristic of soil may be represented as the step curve as shown in the figure below. In the above example, the multilinear spring command specifies soil spring at joints 2 and 4. (Note that the amplitude of the step curve does not change after the first point.)

Notes

a. `SUPPORT` springs must have previously been entered for each spring entered here. For the first cycle, the spring value used will be the support spring value (not the zero displacement value here). Use a realistic and stable value.

b. All directions that have been defined with an initial spring stiffness in the `SUPPORT` command will become multilinear with this one curve.

c. This command can be continued to up to 11 lines by ending all but last with a hyphen. The semi-colons and the XRANGE, YRANGE, ZRANGE list items may not be used.

d. This command needs a minimum of two displacement and spring constant pairs.

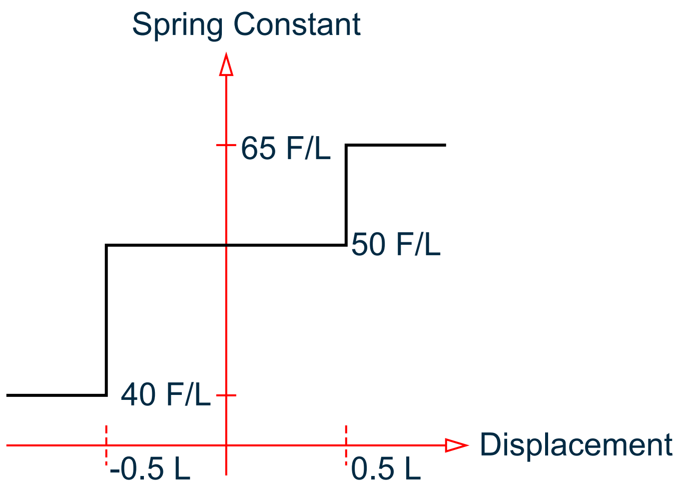

Figure 308: Spring constant is always positive or zero. F = Force Units, L = Length Units

e. Multilinear springs should *not* be used in the following conditions:

Modal dynamics
Buckling analysis
Imperfection analysis
`PDELTA` analysis
`NONLINEAR` analysis
Advanced cable analysis
Direct analysis
Models with tension/compression members and/or supports
Models with inclined supports

Related Links

- *G.17.2.5 Multilinear Analysis* (on page 2148)

TR.27.5 Spring Tension/Compression Specification

This command may be used to designate certain support springs as Tension-only or Compression-only springs.

General Format

```
SPRING TENSION
joint-list  (spring-spec )
SPRING COMPRESSION
joint-list  (spring-spec )
```

where:

```
spring-spec  = *{ KFX | KFY | KFZ | ALL }
```

Description

Tension-only springs are capable of carrying tensile forces only. Thus, they are automatically inactivated for load cases that create compression in them. Compression-only springs are capable of carrying compressive forces only. Thus, they are automatically inactivated for load cases that create tension in them.

If no spring spec is entered or ALL is entered then all translational springs at that joint will be tension (or compression) only. This input command does not create a spring, only that if a support spring exists at the joint in the specified direction then it will also be tension (or compression) only. Refer to TR.27 Support Specifications (on page 2315) to define springs.

For compression only springs the `ALL` parameter has special meaning. The compression only spring is in the Y direction; the X and Z direction springs are bi-directional. However when the Y direction spring goes slack, the X and Z springs at the same joint are made inactive as well.

Note: The procedure for analysis of Tension-only or Compression-only springs requires iterations for every load case and therefore may be quite involved.

Since this command does not specify whether the spring is in the positive or negative direction from the joint, it is assumed in STAAD.Pro to be in the negative direction. For negative displacement the spring is in compression and for positive the spring is in tension.

If a `CHANGE` command is used (because of a change in list of tension springs, supports, etc.), then the `SET NL` command must be used to convey to STAAD.Pro that multiple analyses and multiple structural conditions are involved.

1. Refer to TR.5 Set Command Specification (on page 2206) for explanation of the `SET NL` command. The number that follows this command is an upper bound on the total number of primary load cases in the file.
2. STAAD.Pro performs up to 10 iterations automatically, stopping if converged. If not converged, a warning message will be in the output. Enter a `SET ITERLIM i` command (with `i` > 10) before the first load case to increase the default number of iterations. Since convergence may not be possible using this procedure, do not set the limit too high. If not converged, a message will be in the output.
3. The principle used in the analysis is the following.
   - The program reads the list of springs declared as `SPRING TENSION` and/or `COMPRESSION`.
   - The analysis is performed for the entire structure and the spring forces are computed.
   - For the springs declared as `SPRING TENSION` / `COMPRESSION`, the program checks the axial force to determine whether it is tensile or compressive. Positive displacement is `TENSION`. If the spring cannot take that load, the spring is "switched off" from the structure.
   - The analysis is performed again without the switched off springs.
   - Up to `ITERLIM` iterations of the above steps are made for each load case.
   - This method does not always converge and may become unstable. Check the output for instability messages. Do not use results if the last iteration was unstable. You may need to include some support in each global direction that is not tension (or compression) only to be stable on every iteration.
4. A revised `SPRING TENSION` / `COMPRESSION` command and its accompanying list of joints may be provided after a `CHANGE` command. If entered, the new `SPRING` commands replace all prior `SPRING` commands. If not entered after a CHANGE, then the previous spring definitions are used.
5. The `SPRING TENSION` command should not be used if the following load cases are present: Response Spectrum load case, Time History Load case, Moving Load case. If used, the `SPRING TENSION` / `COMPRESSION` will be ignored in all load cases.
6. If the `SPRING TENSION` / `COMPRESSION` command is used in a model with UBC, IBC or other such seismic load cases, each such load case must be followed by an `ANALYSIS` and `CHANGE` command.

Notes

a. A spring declared as tension-only or compression-only will carry axial forces only. It will not carry moments.

b. The `SPRING TENSION` / `COMPRESSION` commands should not be specified if the `INACTIVE MEMBER` command is specified.

c. Do not use Load Combination to combine these cases. Tension/Compression cases are non-linear and should not be linearly combined as in Load Combination. Use a primary load case with the Repeat Load command.

Example

```
SPRING TENSION
12 17 19 TO 37 65
SPRING COMPRESSION
5 13 46 TO 53 87 KFY
```

The following is the general sequence of commands in the input file if the `SPRING TENSION` or `COMPRESSION` command is used. This example is for the `SPRING TENSION` command. Similar rules are applicable for the `SPRING COMPRESSION` command. The dots indicate other input data items.

TR.28 Rigid Diaphragm Modeling

STAAD.Pro has two methods for defining rigid floor diaphragms. Both are functionally equivalent but the Control-Dependent joint requires that an analytical node be located and specified as the control node. For most models, the simpler Floor Diaphragm option is preferred.

TR.28.1 Control/Dependent Specification

This set of commands may be used to model specialized linkages (displacement tying, rigid links) through the specification of “control” and “dependent” joints. Please read the notes for restrictions.

Note: Control / Dependent was formerly referred to as master / slave.

General Format

```
Dependent *{ XY | YZ | ZX | RIGID | FX | FY | FZ | MX | MY | MZ } CONTROL j JOINT
joint-spec
```

where:

```
joint-spec = { joint-list  | *{ XRANGE | YRANGE | ZRANGE } f1 f2 }
```

Description

The control/dependent option provided in STAAD.Pro allows you to model specialized linkages (displacement tying, rigid links) in the system. For example, `DEPENDENT FY` … connects the two joints such that the Y displacement at the dependent will be the sum of Y displacement at the control plus the rigid rotation,

$$R \sin \theta$$

Note that instead of providing a joint list for the dependent joints, a range of coordinate values (in global system) may be used. All joints whose coordinates are within the range are assumed to be dependent joints. For convenience, the coordinate range specified for dependent joints in this entry may include the control joint for this entry. However, control and dependent joints of other entries must *not* be included in the coordinate range. All 2 or 3 ranges can be entered to form a “tube” or “box” for selecting joints in the tube or box region.

Fx, Fy etc. are the directions in which they are dependent (any combination may be entered).

If two or more entries have the same control, the dependent lists will be merged. Please ensure that the same direction specs are used.

The direction specifiers (XY, YZ, ZX) are combinations of the basic directions, XY is the same as entering FX, FY, MZ; etc. Any combination of direction specifiers may be entered. An example of the use of this format is: a rigid diaphragm floor that still retains bending flexibility entered as `SLA ZX` … .

If `RIGID` or if all directions are provided, the joints are assumed to be rigidly connected as if `SLA DIA RIG` were entered, even if `DIA` is omitted.

Note: Due to the mechanisms used to include control/dependent systems, if the reactions on control nodes are not included in a statics check then an out of balance report may result. This can be avoided by adding a short stiff member from a control node to the support.

Restrictions

- Solid elements may not be connected to dependent joints.
- Control joints may not be control or dependent in another entry.
- Dependent joints may not be control or dependent in another entry.
- Dependent directions at joints may not be supported directions or have displacements imposed.
- Control and/or dependent joints may not be inclined supports.
- The control/dependent specification is only intended for linear static and dynamic analysis.
- Multilinear springs are not permitted.
- Control/dependent joints may not be specified when rigid floor diaphragms are used (refer to TR.28.2 Floor Diaphragm (on page 2328)).
- If a TR.38 Change Specification (on page 2660) is specified, then any control/dependent joints must be re-specified if they are intended to be used after the change.

The internal processing of any control/dependent command includes an automatic bandwidth reduction.

Example

Fully Rigid and Rigid Floor Diaphragm

```
DEPENDENT RIGID CONTROL 22 JOINT 10 TO 45
DEPENDENT RIGID CONTROL 70 JOINT YRANGE 25.5 27.5
DEP ZX CON 80 JOINT YR 34.5 35.5
```

TR.28.2 Floor Diaphragm

This command is used to create rigid floor diaphragms without the need to specify a control joint at each. When specified, this command directs the engine to perform the following:

a. Calculate the center of mass for each rigid diaphragm (where control joint is to be located) considering the mass model of the structure. The mass must be modeled using mass reference load. See TR.31.6 Defining Reference Load Types (on page 2453)

b. Create, internally, an analytical node at the center of mass location to be included during analysis (unless a control node is specified) if an existing analytical node exists at this point, then the existing joint is used in lieu of creating a new joint.

Tip: The center of mass of each diaphragm is included in the preprocessing output. To include the center of rigidity in the post-processing output, you must include the `PRINT DIAPHRAGM CR` command. See TR.42 Print Specifications (on page 2666)

c. Search all nodes available within a diaphragm and add them as dependent nodes; with the control node located at the center of mass for the diaphragm (or at the specified control node)

General Format

```
FLOOR DIAPHRAGM
DIAPHRAGM i1 TYPE RIGID diaphragm-spec
...
( BASE b1 )
```

After all diaphragms are defined, the following optional commands can be added:

```
( CHECK SOFT STORY soft-story-code )
( CHECK IRREGULARITIES CODE irregularities-code )
```

where:

```
diaphragm-spec = HEIGHT f1 ( CONTROL i2 ) (JOINT joint-list )
```

or

```
diaphragm-spec = YRANGE f2 f3 ( CONTROL i2 ) ( JOINT XRANGE f4 f5 ZRANGE f6 f7 )
```

or

```
diaphragm-spec = ( CONTROL i2 ) JOINT joint-list
```

DIAPHRAGM *i1*	Diaphragm identification number
BASE *b1*	base/ground floor level of the structure when not at the minimum Y coordinate defined in the model
HEIGHT *f1*	Global coordinate value, in Y direction, to specify the floor level
YRANGE *f2 f3*	Global coordinate values to specify a Y range, where *f2* is the lower bound and *f3* is the upper bound. The diaphragm is considered to be located at that floor height.
XRANGE *f4 f5*	Global coordinate values to specify an X range. The diaphragm is considered to be located between this X range. If full floor is to be considered as only one diaphragm there is no need to define X range.
ZRANGE *f6 f7*	Global coordinate values to specify Z range. The diaphragm is considered to be located between this Z range. If full floor is to be considered as only one diaphragm there is no need to define Z range.
CONTROL *i2*	User-specified control joint number at the specified floor level. If not defined, the program will automatically calculate this joint as the diaphragm center of mass.

Instead of providing height or Y-range, joint lists can be provided to indicate the number of joints present at a particular floor level which will be connected to a control joint (either specified or calculated by the program).

Note: A single diaphragm may be defined at a given level in STAAD.Pro.

Soft Story and Irregularities Checks

Refer to TR.28.2.1 Soft Story Checking (on page 2331) for details on *soft-story-code* and to TR.28.2.2 Check Irregularities (on page 2333) for details on *irregularities-code*.

Notes

a. One full diaphragm definition should be provided per line. However, if there is joint-list, the list can extend to the second line with a continuation sign ("-").

```
DIA f1 TYP RIG YR f2 f3 JOI XR f4 f5 ZR f6 f7
DIA f11 TYP RIG YR f21 f31 JOI XR f41 f51 ZR f61 f71
DIA f12 TYP RIG JOI 35 45 51 TO 57 59 TO 83 -
90 TO 110
```

where *f1*, *f11*, and *f12* are three rigid diaphragms located at floor height ranging between *f2* and *f3*, *f21* and *f31*, and the joints lying in the plane as indicated by their global Y coordinates respectively.

b. Diaphragms should be specified in ascending order (i.e., diaphragms at first floor level should be specified first before specifying that on 2nd floor level and so on).

c. If a user-defined control joint is specified in one diaphragm, then user-defined control joints should be specified for *all* diaphragms. Combination of user-defined control joint for one diaphragm and program calculated control joint for another diaphragm is not supported.

d. The mass model (in terms of reference load) must be specified before specifying floor diaphragm .

e. Floor diaphragms can be specified only once in an input file.

f. Floor diaphragm cannot be specified along with the `FLOOR HEIGHT` command (refer to TR.31.2.9.1 Identification of Floor Level (on page 2392)).

g. Floor diaphragm cannot be specified along with the `CONTROL-DEPENDENT` command (refer to TR.28.1 Control/Dependent Specification (on page 2327)).

h. Floor diaphragm cannot be specified with the `SET Z UP` command.

i. Sloped diaphragms are not supported.

j. Base level (or ground floor level or support level) is taken as the minimum of Y coordinates defined. Different base level can be specified using the `BASE` *b1* option in the command. If used, this option must be the last line of the floor diaphragm system.

k. The maximum number of diaphragms allowed by the program (default value) is 150. If more than 150 diaphragms need to be specified, then `SET RIGID DIAPHRAGM` *n* must be specified before specifying joint incidence, where n = total number of diaphragms in the structure.

TR.28.2.1 Soft Story Checking

STAAD.Pro will perform this check when the option `CHECK SOFT STORY` command is used following a floor diaphragm. If omitted, no soft story check is performed. Soft story checking is only valid for structures having vertical elements in the form of columns and shear wall (without opening). When used, the program will exclude the effect of any other forms of lateral force resisting structural elements.

General Format

Note: This command is inserted after any pre-analysis `PRINT` commands.

```
CHECK SOFT STORY { 1893 | 1893 2016 | ASCE7 }
```

Tip: Include the `PRINT STORY STIFFNESS` command in the post-analysis print commands in order to review the story stiffness values.

Description

The option check for soft story can be performed per the IS 1893:2002, IS 1893-2016, or ASCE 7-95 codes.

A soft story building is a multi-story building where one or more floors are soft due to structural design. These floors can be dangerous in earthquakes, because they cannot cope with the lateral forces caused by the swaying of the building during a quake. As a result, the soft story may fail, causing what is known as a soft story collapse.

Soft story buildings are characterized by having a story which has a lot of open space. Parking garages, for example, are often soft stories, as are large retail spaces or floors with a lot of windows. While the unobstructed space of the soft story might be aesthetically or commercially desirable, it also means that there are less opportunities to install shear walls, specialized walls which are designed to distribute lateral forces so that a building can cope with the swaying characteristic of an earthquake.

If a building has a floor which is 70% less stiff than the floor above it, it is considered a soft story building. This soft story creates a major weak point in an earthquake, and since soft stories are mostly associated with retail spaces and parking garages, they are often on the lower stories of a building, which means that when they collapse, they can take the whole building down with them, causing serious structural damage which may render the structure totally unusable.

When used, the program checks for soft stories per Clause 7.1 Table 5 i)a and i)b for IS 1893 and per Clause 12.3.3 Table 12.3-2 1a and 1b for ASCE 7-05 (used for seismic design categories D, E, and F).

Stiffness Irregularities

- **Stiffness Irregularities: Soft Story** – As per this provision of the code, a soft story is one in which the lateral stiffness is less than 70 percent of that in the story above or less than 80 percent of the average lateral stiffness of the three story above.
- **Stiffness Irregularities: Extreme Soft Story** – As per this provision of the code, a extreme soft story is one in which the lateral stiffness is less than 60 percent of that in the story above or less than 70 percent of the average lateral stiffness of the three story above.

  Thus, if any story of a building is found to be soft or extremely soft, the building is likely to suffer much damage in an earthquake than a similar type of building but has more regular vertical stiffness.

Example

```
FLOOR DIAPHRAGM

TR.28.2.2 Check Irregularities

STAAD.Pro can check irregularities per the IS 1893 2016 and ASCE 7-05/10/16 seismic codes.

For IS 1893 2016, the program can check horizontal irregularities (torsional and reentrant corners) per Table 5 and vertical irregularities (mass irregularities and irregular modes of oscillation) per Table 6.

For ASCE 7-05/10/16, the program can check horizontal irregularities (torsional and reentrant corners) and vertical irregulares (mass). Irregular modes of oscillation are not considered for this code.

General Format

Note: This command is inserted after any pre-analysis PRINT commands.

```
CHECK IRREGULARITIES CODE [ ASCE7 | IS1893 2016 ]
```

Note: Soft story checks per IS 1893 2016, Table 6(i) can also be performed by the program. Refer to TR.28.2.1 Soft Story Checking (on page 2331). For ASCE 7, soft story checking is performed per figure C12-3, Type-1.

Note: Only one code may be checked per irregularities in a single model.

Torsion Check per ASCE 7

Torsion checks per Cl. 12.3.2.1 of ASCE 7 2016 (ref. fig C12.3-1 Type 1) are preformed by applying unit loads in each orthogonal direction to the control node of the diaphragm.

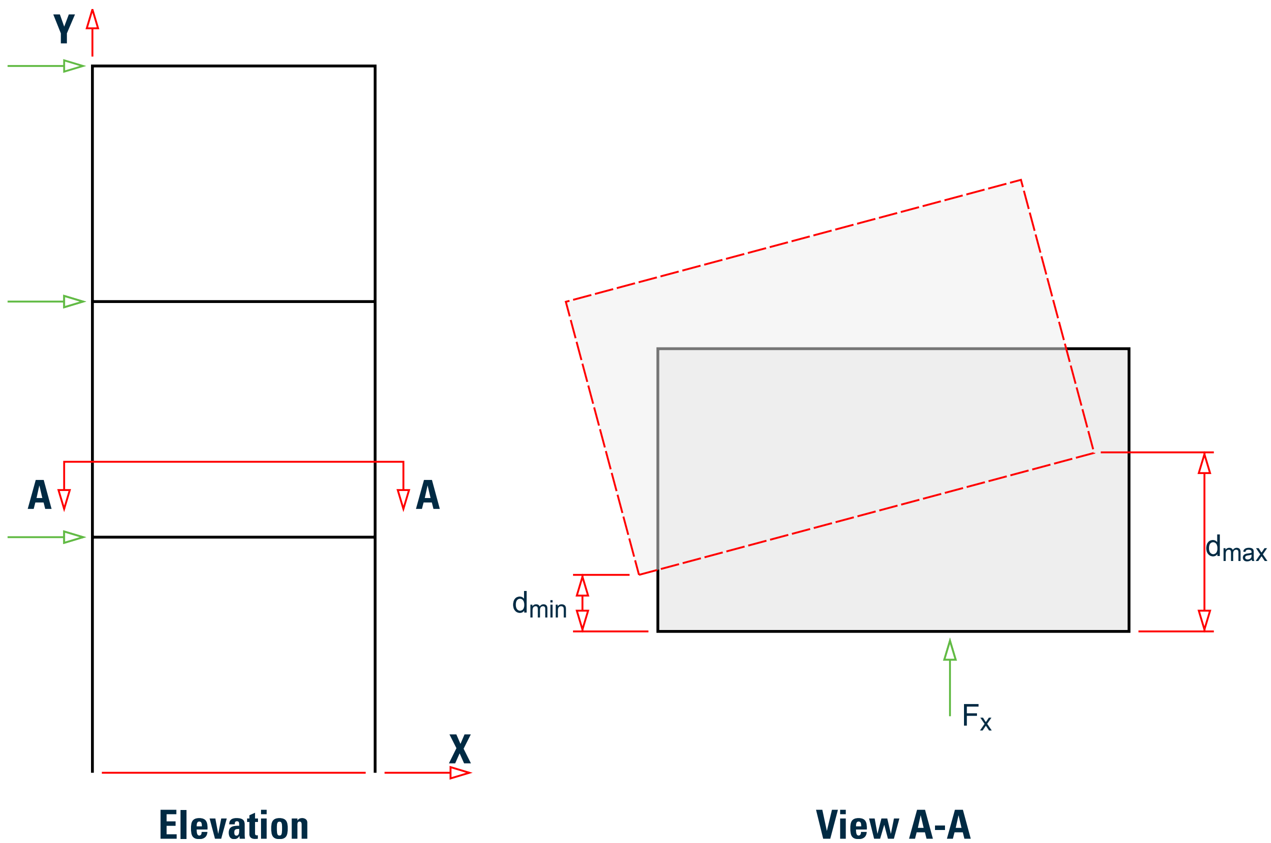

Figure 309: Example floor diaphragm torsion evaluation

The unit load, F_x, is applied at each diaphragm in the X-direction. After analysis, the program locates the extreme nodes of the diaphragm and then d_{min} and d_{max} are calculated. The ratio of d_{max}/d_{min} is evaluated and compared to the code limit of 1.5. This process is then repeated in the Z direction for this diaphragm. Then the similar process is applied to the other diaphragms in the structure.

Torsion Check per IS 1893

Torsion checks per Table 5(i)-a IS 1893 2016 are performed by applying a unit force in each orthogonal direction at two different distances (the design eccentricity, e_{di}) as per Cl. 7.8.2. This results in evaluating four different conditions for IS 1893 2016. The analysis is run and the displacements of the two extreme ends of the diaphragm are extracted from the analysis results. This ratio of these displacements is then reported with a status based on the following limits:

Ratio	Status	Description
$\Delta_{max}/\ \Delta_{avg} < 1.2$	OK	Indicates that the floor is regular and passes the irregularity checks.
$1.2 \leq \Delta_{max}/\ \Delta_{avg} \leq 1.4$	Warning	Indicates that the floor is irregular and requires a full 3D dynamic analysis in order to justify the structural configuration *or* requires a change in structural configuration as per Cl. 7.1, Table 5, Sl No. (i) sec-i.a and sec-i.b.

Ratio	Status	Description
$\Delta_{max}/\ \Delta_{avg} > 1.4$	Fails	Indicates that the floor is irregular and fails the irregularity checks. The structural arrangement must be changed as per Cl. 7.1, Table 5, Sl No. (i) sec-ii.

$$e_{di} = \begin{cases} 1.5e_{si} + 0.05b_i \\ e_{si} - 0.05b_i \end{cases} \qquad \text{(Design eccentricity per IS 1893 2016 Cl. 7.8.2)}$$

where

e_{si} = the static eccentricity at floor i, which is equal to the distance between the center of mass and the center of rigidity.

b_i = the floor plan dimension of floor i perpendicular to the direction of force

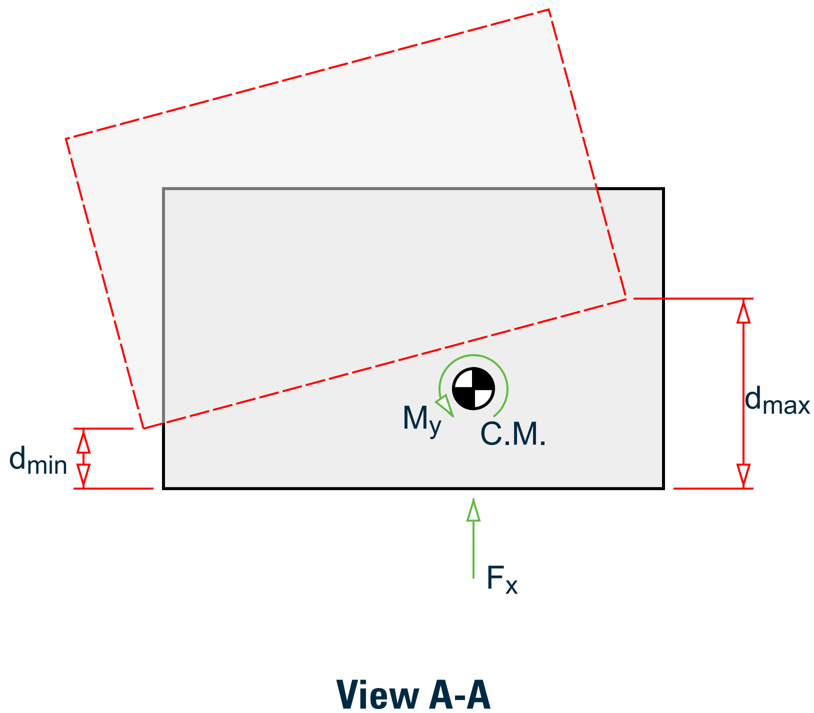

Figure 310: Example floor diaphragm torsion for IS 1893

The unit load, F_x is applied at each diaphragm in the X-direction in combination with two cases of $M_y = F_x \times (e_{di} - e_{si})$ representing the to cases for e_{di}. After analysis, the program locates the extreme nodes of the diaphragm and then Δ_{min}, Δ_{max}, and Δ_{avg} values are calculated. The ratio of $\Delta_{max}/\Delta_{avg}$ is evaluated per the table above. This process is then repeated in the Z direction for this diaphragm for a total of four cases at each diaphragm. Then the similar process is applied to the other diaphragms in the structure.

Note: Checks mandated by IS 1893 2016, Table 5(i)-b are *not* implemented as the prerequisite modelling information to determine the torsional mode is not present in STAAD.Pro.

Reentrant Corners

The program will check for reentrant corners per Table 5(ii) of IS 1893 2016 and Cl. 12.3.2.1 of ASCE 7 2016 (ref. fig C12.3-1 Type 2). The program first automatically identifies the boundary topology of the diaphragm. That is, the order in which analytical members and nodes of the boundary of the diaphragm are joined together to for a closed polygon. The program then determines the reentrant, or concave, corners of the diaphragm. The two analytical members joining the reentrant node is determined, their lengths are calculated, and then the projections of those lengths are calculated. To determine the ratios, the following are calculated:

$$L_i \times \cos(\alpha)/L_x \leq 0.15$$

$$L_i \times \cos(\alpha)/L_z \leq 0.15$$

If both members from the reentrant node are orthogonal, then for each member, only 1 ratio is calculated as L_i/L_x for members oriented along the x-direction and L_i/L_z for members oriented along the z-direction.

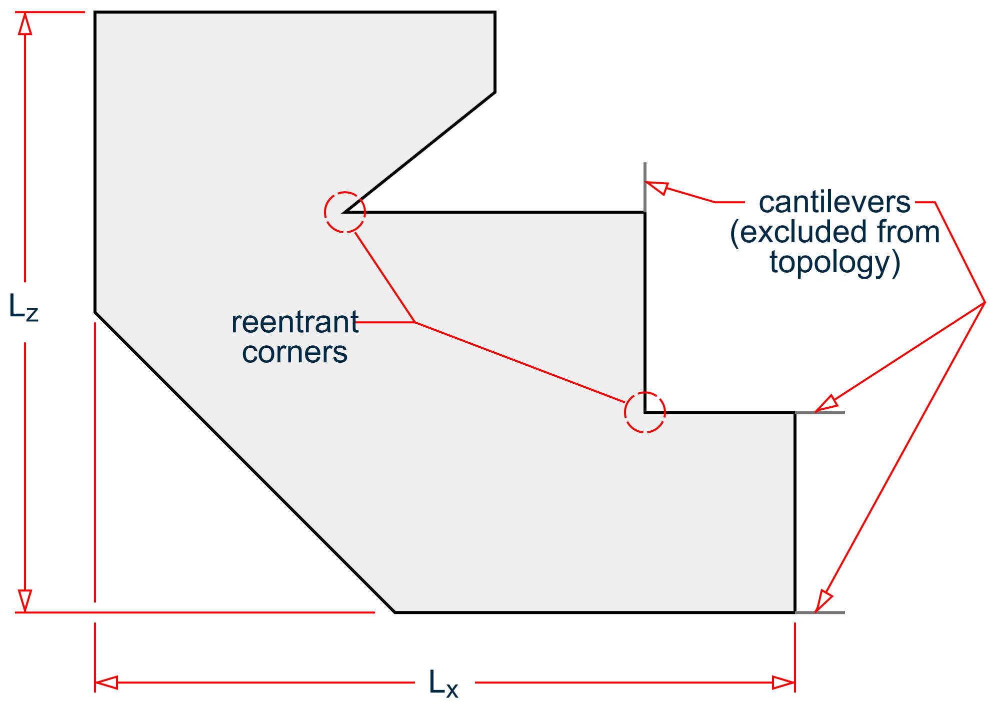

Figure 311: Example reentrant corner topology

Note: Cantilever members that do not form part a closed polygon are identified. These members are ignored by the program when evaluating reentrant corners.

All dependent nodes that form part of a diaphragm must lie within the same plane. Further, the boundary dependent nodes must form a closed polygon. Improper modeling of diaphragms may yield incorrect irregularity status results.

Note: Member offsets both in plan as well as in elevation may result in the reentrant corner check to be incorrect. You must exercise caution while using offsets and should check such joints manually.

Mass Irregularities

The program will check for mass irregularities per Table 6(ii) of IS 1893 2016 and Cl. 12.3.2.2 of ASCE 7 2016 (ref. fig C12.3-2 Type 2). The mass of each floor is calculated as the total of all floor diaphragm masses at the same level. The ratio of each floor mass to the floor above and below is calculated. These ratios are compared to the code stipulated values.

Irregular Modes of Oscillation

Note: The program will check for irregular modes of oscillation per the IS 1893 2016 code. This check is performed only if you have include the static seismic IS 1893 2016 definition using zone 4 or 5.

Per Table 6(vii)-a, the sum of the percentage of mass participation for the first 3 lateral translational modes should contribute at least 65% in each principle plan direction. This is checked in both orthogonal directions.

Per Table 6(vii)-b, the time period for the fundamental modes in one direction should differ by at least 10%.

Note: Irregular modes of oscillation are not considered the ASCE 7 codes.

IS 1893 2016 Example

An example using IS 1893 2016:

```
FLOOR DIAPHRAGM

TR.29 Definition of Member Attributes

Used to contain additional member attributes typically inserted from the STAAD.Pro User Interface.

General Format

Note: This section immediately follows `MEMBER RELEASE` data.

```
DEFINE MEMBER ATTRIBUTE
"attr-name " "attr-value " LIST member-list
...
END DEFINE
```

Note: The attribute name and attribute value are surrounded in quote mark (") characters.

Where

attr-name	The name of the attribute being used.
attr-value	The value of the current attribute. Values are specifically defined for each attribute name. Refer to the attribute types for explanations of appropriate values.
member-list	A list of member numbers.

Example

An example of some member attribute definitions in a STAAD.Pro input file:

```
DEFINE MEMBER ATTRIBUTE
"STRUCLINK" "BREAK_MEMBER_ACCROSS" LIST 6 8
"CONTAG" "START:SHEAR:SS" LIST 4
END DEFINE
```

TR.29.1 Struclink Member Attribute

Used to provide identify continuity which analytical model members in the STAAD input file should be made continuous physical members across a joint passing data through the Struclink utility.

Caution: Though it is possible to manually enter Struclink data in the STAAD input file, it is *strongly* recommended that the user interface be used to add this information.

General Format

Note: A `STRUCLINK` attribute must be inserted in the `DEFINE MEMBER ATTRIBUTE` section.

```
"STRUCLINK" "{ USE_DEFAULT | BREAK_MEMBER_ACROSS }" LIST member-list
```

Where

USE_DEFAULT	This attribute value indicates that two adjacent members which meet the requirements for merging into a physical member will do so when exported via Struclink.
BREAK_MEMBER_ACROSS	This attribute value indicates that two adjacent members will *not* be merged into a single physical member when exported via Struclink, even if they would meet the criteria to do so. This allows you to define where physical members should be broken at a joint. For example, where two identical beams frame into either side of a multi-story column.
member-list	A list of member numbers.

Example

An example of some physical member formation attributes for Struclink in a STAAD.Pro input file:

```
DEFINE MEMBER ATTRIBUTE
"STRUCLINK" "USE_DEFAULT" LIST 1 TO 5 7
"STRUCLINK" "BREAK_MEMBER_ACCROSS" LIST 6 8
END DEFINE
```

TR.29.2 Connection Tag Member Attribute

Used to assign members connection tag data from an associated Connection Tag XML file which is used for storing connection data and checking connection capacities.

Caution: Though it is possible to manually enter connection tag data in the STAAD input file, it is *strongly* recommended that the user interface be used to add this information as to ensure compatibility with the associated Connection Tags XML file. Refer to D. Connection Tags sub menu (on page 1066) for additional information on using this feature.

General Format

Note: A `CONTAG` attribute must be inserted in the `DEFINE MEMBER ATTRIBUTE` section.

The attribute value for the `CONTAG` attribute is delimited into three parts: the end of the member, the tag category, and the tag name to use for this tag assignment. The later two parts are used to look up the connection tag releases and capacities in the Connection Tag XML file.

```
"CONTAG" "{ START | END }:tag-category :tag-name " LIST member-list
```

Where:

tag-category One of the Category Names (`//Categories/Category/@CategoryName`) defined in the Connection Tag XML file.

tag-name One of the Tag Names (`//Tags/Tag/@TagName`) defined in the Connection Tag XML file.

member-list A list of member numbers.

Example

An example of a pair of connection tags in a STAAD.Pro input file:

```
DEFINE MEMBER ATTRIBUTE
"CONTAG" "START:MOMENT:EM" LIST 6
"CONTAG" "START:SHEAR:SS" LIST 4
END DEFINE
```

The corresponding Connection Tag XML file would have —as a minimum— the following data:

```
<?xml version="1.0" encoding="utf-8" ?>
<ConnectionTagFile xmlns="http://tempuri.org/XMLSchema.xsd">
 <FileVersion value="1.0" />
  <Categories>
   <Category CategoryName="MOMENT">
    <CategoryDesc>End Moment Connection</CategoryDesc>
   </Category>
   <Category CategoryName="SHEAR">
    <CategoryDesc>Single Shear Connection</CategoryDesc>
   </Category>
  </Categories>
  <Equations>
   <Equation EquationID="Eq1" Equation="Abs([MZ])/[MZ.CAP]+Abs([FX])/
[FX.CAP]" Condition="LT" Limit="1.0" />
   <Equation EquationID="Eq2" Equation="Abs([FZ])/[FZ.CAP]" Condition="LT"

TR.29.3 Member Type Attribute

Used to specify member types for connection design performed in Connection Design workflow.

General Format

```
"MEMBTYPE" "member-type" LIST member-list
```

Where:

member-type One of the following predefined member types:

- column
- primary beam
- brace
- rafter
- girt
- purlin
- eave-strut
- secondary-beam
- tertiary-beam
- chord
- branch

member-list A list of member numbers.

These member types are utilized by RAM Connection in order to identify members for connection design.

Example

```
DEFINE MEMBER ATTRIBUTE
"MEMBTYPE" "BRACE" LIST 14 15 20 21
END DEFINE
```

TR.30 Miscellaneous Settings for Dynamic Analysis

When dynamic analysis such as frequency and mode shape calculation, response spectrum analysis and time history analysis is performed, it involves eigenvalue extraction and usage of a certain number of modes during the analysis process. These operations are built around certain default values. This section explains the commands required to override those defaults.

Related Links

- *G.17.3 Dynamic Analysis* (on page 2154)
- *G.17.3 Dynamic Analysis* (on page 2154)
- *G.17.3 Dynamic Analysis* (on page 2154)
- *G.17.3.1 Solution of the Eigenproblem* (on page 2155)

TR.30.1 Cut-Off Frequency, Mode Shapes, or Time

These commands are used in conjunction with dynamic analysis. They may be used to specify the highest frequency or the number of mode shapes that need to be considered.

General Format

```
CUT (OFF) { FREQUENCY f1 | MODE SHAPE i1 ( SHIFT MODE i2 ) (FREQ f2 )  | TIME t1 }
```

Where:

FREQUENCY *f1*	Highest frequency (cycle/sec) to be considered for dynamic analysis.
MODE SHAPE *i1*	Number of mode shapes to be considered for dynamic analysis. If the cut off frequency command is not provided, the cut off frequency will default to 108 cps. If the cut off mode shape command is not provided, the first six modes will be calculated. These commands should be provided prior to the loading specifications.
SHIFT MODE *i2*	Number of eigen vectors per shift. This input may be used only when the solver fails to extract *i1* number of modes due to insufficient memory.
FREQUENCY *f2*	Frequency (in Hz) to be used as initial shift in Arnoldi/Lanczos method (i.e., it is not applicable to the basic solver). This is an optional input. If provided, the solver looks for eigenvalues close to the shift. The eigen values found may not necessarily be the smallest eigenvalues (i.e., closest to zero). If a full scale eigen solution is required, this value should not be defined. The engine default value in 0.0 (zero)
TIME *t1*	Ending time for a time history analysis. If zero (default), the time history will end when the last forcing function ends.

A maximum of *i1* mode shapes will be computed regard-less of *f1*. If during convergence testing, the 0 through *f1* frequencies are converged, then the modal calculation will be completed before *i1* mode shapes are calculated.

A maximum of *i1* mode shapes will be computed regard-less of *f1*. If the `CUT OFF FREQ` *f1* and `CUT OFF MODE` *i1* commands are both entered, the program will report only those modes that lie within *f1* frequency.

- *G.17.3 Dynamic Analysis* (on page 2154)
- *G.17.3 Dynamic Analysis* (on page 2154)

TR.30.2 Mode Selection

This command allows specification of a reduced set of active dynamic modes. All modes selected by this command remain selected until a new `MODE SELECT` is specified.

This command is used to limit the modes used in dynamic analysis to the modes listed in this command and deactivate all other modes that were calculated but not listed in this command. If this command is not entered, then all modes calculated are used in the dynamic analysis.

General Format

```
MODE SELECT mode-list
```

Example

```
CUT OFF MODES 10
MODE SELECT 1 TO 3
```

In this example, 10 modes will be calculated but only modes 1 and 3 will be used in dynamic analysis.

Notes

a. Do not enter this command within the loads data (from the first Load command in an analysis set down to the associated Analysis command).

b. The advantage of this command is that you may find the amount of structural response generated from a specific mode or a set of modes. For example, if 50 modes are extracted, but the effect of just the 40th to the 50th mode in a response spectrum analysis is to be determined, you may set the active modes to be 40 through 50. The results will then be devoid of any contribution from modes 1 through 39.

TR.31 Definition of Load Systems

This section describes the specifications necessary for defining various load systems, for automatic generation of Moving loads, UBC Seismic loads and Wind loads. In addition, this section also describes the specification of Time History load for Time History analysis.

STAAD.Pro has built-in algorithms to generate moving loads, lateral seismic loads, and wind loads on a structure. Use of the load generation facility consists of two parts:

1. Definition of the load system(s).
2. Generation of primary load cases using previously defined load system(s).

Definition of the load systems must be provided before any primary load case is specified. This section describes the specification of load systems. Information on how to generate primary load cases using the defined load systems is available in TR.32.12 Generation of Loads (on page 2596).

Note: UBC loads do not fully consider the effects of forces at inclined support directions or at dependent joint directions. Applying forces at these locations may introduce errors that are generally small.

- *G.16 Load Generator* (on page 2134)

TR.31.1 Definition of Moving Load System

This set of commands may be used to define the moving load system. Enter the DEFINE command only once with up to 100 TYPE commands.

The `MOVING LOAD` system may be defined in two possible ways: directly within the input file or using an external file.

General Format

```
DEFINE MOVING LOAD (FILE file-name)
TYPE j { LOAD f1 f2 … fn ( DISTANCE d1 d2 … dn-1 (WIDTH w) ) | load-name (f) }
( DISTANCE d1 d2 … dn-1 (WIDTH w) ) optionally as 2nd set
```

The FILE option should be used only in the second case when the data is to be read from an external file. The file name should be limited to 24 characters.

Note: Moving Loads can be generated for frame members only. They will not be generated for finite elements.

Note: All loads and distances are in current unit system.

Define Moving Load Within the Input File

Use the first TYPE specification. Input Data must be all in one line (as shown above) or two sets of lines. If two sets, then the second set must begin with DIS as shown above. If two sets, then Load and Dist lines may end each line but last of each set with a hyphen (See example).

```
TYPE j  LOAD f1 f2 … fn
DISTANCE d1 d2 … dn-1 (WIDTH w)
```

Where:

TYPE *j*	moving load system type number (integer limit of 200 types)
n	number of loads (eg, axles), 2 to 200.
LOAD *fi*	value of concentrated i^{th} load
DISTANCE *di*	distance between the $(i+1)^{th}$ load and the i^{th} load in the direction of movement
WIDTH *w*	spacing between loads perpendicular to the direction of movement (e.g., the width of vehicle). If left out, one dimensional loading is assumed. This parameter will double the total load since the f_i is applied to each wheel.

Note: For a single moving load use: `TYPE j LOAD f1 DIST 0`

Define Moving Load Using an External File

Use the second TYPE specification.

```
TYPE j load-name (f)
```

Where:

TYPE *j*	moving load system type no. (integer).
load-name	the name of the moving load system (maximum of 24 characters).
f	Optional multiplying factor to scale up or down the value of the loads. (default = 1.0)

Following is a typical file containing the data.

```
CS200
50. 80. 90. 100.
7. 7. 9.
6.5
```

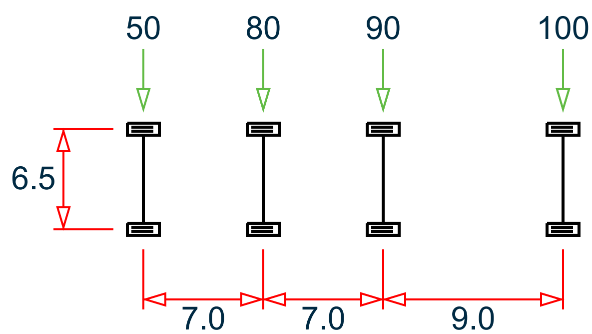

Figure 312: Graphical representation of the previous load system

Several load systems may be repeated within the same file.

The STAAD moving load generator assumes:

1. All positive loads are acting in the negative global vertical (Y or Z) direction. The user is advised to set up the structure model accordingly.
2. Resultant direction of movement is determined from the X and Z (or Y if Z is up)increments of movements as provided by the user.

Reference Load

The first specified concentrated load in the moving load system is designated as the reference load. While generating subsequent primary load cases, the initial position of the load system and the direction of movement are defined with respect to the reference load location. Also, when selecting the reference load location with a positive value of Width specified, then the following two views define the reference load location.

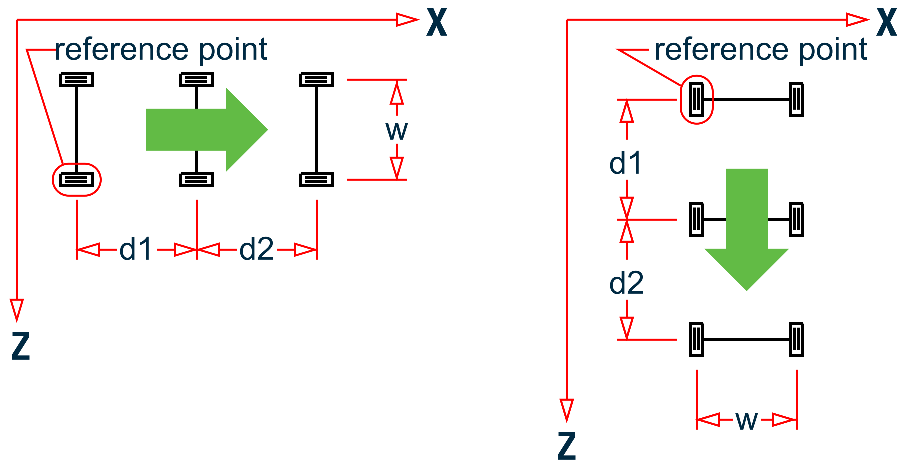

Figure 313: Movement parallel to global X axis; Movement parallel to global Z axis

Notice that in the left view, the reference point is on the positive Z wheel track side; whereas in the right view, the reference point is on the least positive X wheel track side.

Specifying Standard AASHTO Loadings

Truck loads specified in AASHTO specifications are also built in to STAAD.

```
TYPE j { HS20 | HS15 | H20 | H15 } (f) ( vs )
```

Where:

TYPE *j*	moving load system type no. (integer).
f	Optional multiplying factor to scale up or down the value of the loads. (default = 1.0)
vs	variable spacing as defined by AASHTO, for HS series trucks (default = 14 ft.)

Example 1

```
DEFINE MOVING LOAD
TYPE 1 LOAD 10.0 20.0 -
15.0 10.0
DISTANCE 5.0 7.5 -
6.5 WIDTH 6.0
TYPE 2 HS20 0.80 22.0
```

Example 2

When data is provided through an external file called `MOVLOAD`

Data in STAAD input file

```
UNIT …
DEFINE MOVING LOAD FILE MOVLOAD
TYPE 1 AXLTYP1
TYPE 2 AXLTYP2 1.25
```

Data in external file MOVLOAD

```
AXLTYP1
10 20 15
5.0 7.5
6.0
AXLTYP2
20 20
10
7.5
```

TR.31.2 Definitions for Static Force Procedures for Seismic Analysis

STAAD.Pro offers facilities for determining the lateral loads acting on structures due to seismic forces, using the rules available in several national codes and widely accepted publications. The codes and publications allow for so called equivalent static force methods to be used in place of more complex methods like response spectrum and time history analysis.

Once the lateral loads are generated, the program can then analyze the structure for those loads using the applicable rules explained in the code documents.

oneway-weight-spec See TR.32.4.2 One-way Load Specification (on page 2476) for One-way load specification.

Note: The weight definitions must be in the order specified above. That is, selfweight, joint weight, member weight, element weight, and then floor weights. If one or more is not present, it can be skipped as long as the general order is preserved.

WEIGHT *w*	The joint weight associated with list
UNI *v1 v2 v3*	Used when specifying a uniformly distributed load with a value of *v1* starting at a distance of *v2* from the start of the member and ending at a distance of *v3* from the start of the member. If *v2*and v $_3$ are omitted, the load is assumed to cover the entire length of the member.
CON *v4 v5*	Used when specifying a concentrated force with a value of *v4* applied at a distance of *v5* from the start of the member. If *v5* is omitted, the load is assumed to act at the center of the member.
PRESS *p1*	The weight per unit area for the plates selected. Assumed to be uniform over the entire plate. Element Weight is used if plate elements are part of the model, and uniform pressures on the plates are to be considered in weight calculation.
Ri1	Identification number of a previously defined reference load case. See TR.31.6 Defining Reference Load Types (on page 2453)
f11	Magnification factor (required for reference loads).

Floor Weight is used if the pressure is on a region bounded by beams, but the entity which constitutes the region, such as a slab, is not defined as part of the structural model. It is used in the same sort of situation in which you would use `FLOOR LOADS` (See TR.32.4.3 Floor Load Specification (on page 2483) for details). Similarly, you can use the Oneway Weight command to specify a load path direction for the pressure on a region.

Note: If both mass table data (`SELFWEIGHT`, `JOINT WEIGHT`, and `MEMBER WEIGHT` options) and a `REFERENCE LOAD` are specified, these will be added algebraically for a combined mass.

Wall Area Definitions

Wall width and length data for the first story of the structure must be specified in order to calcluate the natural period of the structure per TR.31.2.11 IS:1893 (Part 1) 2016 Codes - Lateral Seismic Load (on page 2393) when `ST 4` (i.e., reinforced concrete buildings with structural walls).

```
WALL AREA { X | Z }
wall-data-pairs
```

where

```
wall-data-pairs = w1, l1; w2, l2; w3, l3, …; wn, ln;
```

w1, l1; w2, l2; w3, l3, ...; wn, ln	Used to specify wall dimensions for calculating effective cross section area of wall in the first story of the building. These should specify the walls which resist seismic force along the global direction (X or Z) of the seismic load only. *w* is the width of the wall and *l* is the length of the wall.

TR.31.2.1 RPA (Algerian) Seismic Load

The purpose of this command is to define and generate static equivalent seismic loads as per RPA specifications using a static equivalent approach similar to those outlined by RPA. Depending on this definition, equivalent lateral loads will be generated in horizontal direction(s).

The seismic load generator can be used to generate lateral loads in the X & Z directions for Y up or X & Y for Z up. Y up or Z up is the vertical axis and the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)). All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.

General Format

```
DEFINE RPA (ACCIDENTAL) LOAD
```

```
 rpa-spec
```

```
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

```
rpa-spec = { A f1 Q f2 RX f3 RZ f4 STYPE f5 CT f6 CRDAMP f7 (PX f8) (PZ f9) }
```

A *f1* Seismic zone coefficient. Use a fractional value such as 0.08, 0.15, 0.2, 0.3, 0.05, etc., instead of an integer value.

Q *f2* Importance factor

RX *f3* Coefficient R for lateral load in X direction – table 4.3

RZ *f4* Coefficient R for lateral load in Z direction – table 4.3

STYPE *f5* Soil Profile Type

CT *f6* Coefficient from table 4.6 of RPA 99

CRDAMP *f7* Critical damping factor

PX *f8* Optional Period of structure (in sec) in X direction

PZ *f9* Optional Period of structure (in sec) in Z direction to be used as fundamental period of the structure instead of the value calculated by the program using Rayleigh method.

Used for Y if the `SET Z UP` command is used.

Generation of RPA Seismic Load

General format to provide RPA Seismic load in any load case:

```
LOAD i
```

```
RPA LOAD {X | Y | Z} (f10) (ACC f11)
```

Where:

LOAD *i*	the load case number
RPA LOAD {X | Y | Z} *f10*	factor to multiply horizontal seismic load.
ACC *f11*	multiplying factor for Accidental Torsion, to be used to multiply the RPA accidental torsion load (default = 1.0). May be negative (otherwise, the default sign for MY is used based on the direction of the generated lateral forces).

Note: If the `ACCIDENTAL` option is specified, the accidental torsion will be calculated per the RPA specifications. The value of the accidental torsion is based on the "center of mass" for each level. The center of mass is calculated from the `SELFWEIGHT`, `JOINT WEIGHT`s and `MEMBER WEIGHT`s you have specified.

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Methodology

The design base shear is computed in accordance with section 4.2.3 of the RPA 99 code. The primary equation, namely 4-1, as shown below, is checked.

$$V = (A\ D\ Q)W / R$$

Where:

W = total weight on the structure
A = zone coefficient
D = average dynamic amplification factor
R = lateral R factor
Q = structural quality factor

Seismic zone coefficient and parameter values are supplied by the user through the `DEFINE RPA LOAD` command.

Program calculates the natural period of building T utilizing clause 4.2.4 of RPA 99.

Design spectral coefficient (D) is calculated utilizing T as,

$$D = 2.5\eta \text{ when } 0 \leq T \leq T_2$$

$$= 2.5\eta(T_2/T)^{2/3} \text{ when } T_2 \leq T \leq 0.3 \text{ sec.}$$

$$= 2.5\eta(T_2/3)^{2/3}(3/T)^{5/3} \text{ when } T > 0.3 \text{ sec.}$$

Where:

η = factor of damping adjustment (Eq. 4.3)
T_2 = specific period (Table 4.7)

Total lateral seismic load, V is distributed by the program among different levels.

There are 2 stages of command specification for generating lateral loads. This is the first stage and is activated through the DEFINE RPA LOAD command.

Example

```
DEFINE RPA LOAD
A 0.15 Q 1.36 STYP 2 RX 3 RZ 4 CT 0.0032 -
```

```
CRDAMP 30 PX .027 PZ 0.025
JOINT WEIGHT
51 56 93 100 WEIGHT 1440
101 106 143 150 WEIGHT 1000
151 156 193 200 WEIGHT 720
LOAD 1 ( SEISMIC LOAD IN X DIRECTION )
RPA LOAD X 1.0
```

- *G.16.2 Seismic Load Generator* (on page 2135)

TR.31.2.2 Canadian Seismic Code (NRC) - 1995

This set of commands may be used to define the parameters for generation of equivalent static lateral loads for seismic analysis per National Building Code (NRC/CNRC) of Canada- 1995 edition. Depending on this definition, equivalent lateral loads will be generated in horizontal direction(s).

The seismic load generator can be used to generate lateral loads in the X & Z directions for Y up or X & Y for Z up. Y up or Z up is the vertical axis and the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)). All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.

General Format

There are two stages of command specification for generating lateral loads. This is the first stage and is activated through the `DEFINE NRC LOAD` command.

```
DEFINE NRC LOAD
```

```
nrc-spec
```

```
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

```
nrc-spec = *{ V f1 ZA f2 ZV f3 RX f4 RZ f5 I f6 F f7 (CT f8) (PX f9) (PZ f10) }
```

V ***f1***	Zonal velocity ratio per Appendix C
ZA ***f2***	Factor for acceleration related seismic zone per Appendix C
ZV ***f3***	Factor for velocity related seismic zone per Appendix C
RX ***f4***	Force modification factor along X-direction that reflects the capability of a structure to dissipate energy through inelastic behavior. Please refer Table 4.1.9.1B
RZ ***f5***	Force modification factor along Z-direction that reflects the capability of a structure to dissipate energy through inelastic behavior. Please refer Table 4.1.9.1B
I ***f6***	Seismic importance factor per sentence 10 section 4.1.9.1
F ***f7***	Foundation factor conforming to Table 4.1.9.1C and sentence 11 section 4.1.9.1
CT ***f8***	Factor to be used to calculate the fundamental period of structure .This is an optional parameter.
PX ***f9***	Period of structure (in seconds) in the X- direction. This is an optional parameter.

PZ *f10* Period of structure (in seconds) in the Z- direction. This is an optional parameter.

Used for Y if the `SET Z UP` command is used.

w joint weight associated with list

v1*, *v2*, *v3 Used when specifying a uniformly distributed load with a value of *v1* starting at a distance of *v2* from the start of the member and ending at a distance of v_3 from the start of the member. If *v2*and v_3 are omitted, the load is assumed to cover the entire length of the member.

v4*, *v5 Used when specifying a concentrated force with a value of *v4* applied at a distance of *v5* from the start of the member. If *v5* is omitted, the load is assumed to act at the center of the member.

p1 weight per unit area for the plates selected. Assumed to be uniform over the entire plate.

Element Weight is used if plate elements are part of the model, and uniform pressures on the plates are to be considered in weight calculation.

Floor Weight is used if the pressure is on a region bounded by beams, but the entity which constitutes the region, such as a slab, is not defined as part of the structural model. It is used in the same sort of situation in which one uses FLOOR LOADS (see TR.32.4 Area, One-way, and Floor Load Specifications (on page 2475) for details of the Floor Load input).

The weights have to be input in the order shown.

Generation of NRC Load

The load so defined as above is applied on the structure in the NRC loadcases. These loadcases have to be the first loadcases in the input file. Built-in algorithms will automatically distribute the base shear among appropriate levels and the roof per the relevant code specifications.

The following general format should be used to generate loads in a particular direction.

```
LOAD i
```

```
NRC LOAD { X | Y | Z } (f1)
```

Where:

LOAD *i*	load case number
NRC LOAD { X | Y | Z } *f1*	factor to be used to multiply the NRC Load (default = 1.0). May be negative.

Notes

1. By providing either PX or PZ or both, you may override the period calculated by STAAD using Rayleigh method. If you do not define PX or PZ, the period for Method 2(b) above will be calculated by the program using Rayleigh method and the stipulations of sentence 7(c) of section 4.1.9.1
2. Some of the items in the output for the NRC analysis are explained below.

   T_a = Time period calculated per sentence 7(a) or 7(b) of section 4.1.9.1
   T_c = Time period calculated per sentence 7(c) of section 4.1.9.1

   CALC / USED PERIOD

   The CALC PERIOD is the period calculated using the Rayleigh method. For NRC in the x-direction, the USED PERIOD is PX. For the NRC in the z-direction (or Y direction if SET Z UP is used), the USED PERIOD is PZ. If PX and PZ are not provided, then the used period is the same as the calculated period for that direction. The used period is the one utilized to find out the value of S.

3. In the analysis for NRC loads, all the supports of the structure have to be at the same level and have to be at the lowest elevation level of the structure.

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Methodology

The minimum lateral seismic force or base shear (V) is automatically calculated by STAAD using the appropriate equation(s); namely sentence 4, section 4.1.9.1 of NRC.

$$V = 0.6 \cdot V_e/R$$

Where:

V_e ,the equivalent lateral seismic force representing elastic response (per sentence 5,section 4.1.9.1) is given by:

$$V_e = v \cdot S \cdot I \cdot W$$

Where:

v = Zonal velocity ratio per appendix C
S = Seismic Response Factor per table 4.9.1.A
I = Seismic importance factor per sentence 10 section 4.1.9.1
F = Foundation factor conforming to Table 4.9.1.C and sentence 11 section 4.1.9.1
W = Total load lumped as weight per sentence 2 section 4.1.9.1
R = Force modification factor conforming to Table 4.9.1.B that reflects the capability of a structure to dissipate energy through inelastic behavior.

STAAD utilizes the following procedure to generate the lateral seismic loads.

1. User provides seismic zone co-efficient and desired "nrc-spec" (1995) through the DEFINE NRC LOAD command.
2. The program calculates the fundamental period(T) of the structure by
   a. finding out whether the structure being analysed is a moment resisting frame made primarily of steel or of concrete or it is a structure of any other type. Alternatively, the software uses the optional parameter CT if provided. The calculation is done per sentence 7(a) & 7(b) of section 4.1.9.1.
   b. using the Rayleigh method or using the optional parameters PX , PZ –if provided. The stipulations of sentence 7(c) of section 4.1.9.1 are also considered while calculating.
   c. taking the conservative value of T between those calculated by methods (a) and (b) above.
3. The program finds out the value of Seismic Response Factor(S) per table 4.9.1.A utilizing the values of T as calculated above and the values of ZA & ZV input by the user.
4. The program calculates V per sentence 4 section 4.1.9.1. W is obtained from the weight data (SELFWEIGHT, JOINT WEIGHT(s), etc.) provided by the user through the DEFINE NRC LOAD command. The weight data must be in the order shown.
5. The total lateral seismic load (base shear) is then distributed by the program among different levels of the structure per applicable NRC guidelines like sentence 13(a) section 4.1.9.1.

Example

```
DEFINE NRC LOAD
V 0.2 ZA 4 ZV 4 RX 4 RZ 4 I 1.3 F 1.3 CT 0.35 PX 2 PZ 2
SELFWEIGHT
JOINT WEIGHT
```

```
17 TO 48 WEIGHT 7
49 TO 64 WEIGHT 3.5
LOAD 1 EARTHQUAKE ALONG X
NRC LOAD X 1.0
PERFORM ANALYSIS PRINT LOAD DATA
CHANGE
```

- *G.16.2 Seismic Load Generator* (on page 2135)

TR.31.2.3 Canadian Seismic Code (NRC) – 2005 Volume 1

This set of commands may be used to define the parameters for generation of equivalent static lateral loads for seismic analysis per National Building Code (NRC/CNRC) of Canada- 2005 Volume 1 edition. Depending on this definition, equivalent lateral loads will be generated in horizontal direction(s).

The seismic load generator can be used to generate lateral loads in the X & Z directions for Y up or X & Y for Z up. Y up or Z up is the vertical axis and the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)). All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.

General Format

STAAD.Pro utilizes the following format to generate the lateral seismic loads.

```
DEFINE NRC 2005 (ACCIDENTAL) LOAD
```

```
nrc-spec
```

```
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

```
nrc-spec = { SA1 f1 SA2 f2 SA3 f3 SA4 f4 MVX f5 MVZ f6 JX f7 JZ f8 IE f9 RDX f10 ROX
f11 RDZ f12 ROZ f13 SCLASS f14 ( FA f15 ) ( FV f16 ) ( CT f17 ) ( PX f18 ) ( PZ f19) }
```

where:

SA1 *f1*	Seismic Data, Sa(0.2), as per Table C-2.
SA2 *f2*	Seismic Data, Sa(0.5), as per Table C-2.
SA3 *f3*	Seismic Data, Sa(1.0), as per Table C-2.
SA4 *f4*	Seismic Data, Sa(2), as per Table C-2.
MVX *f5*	The higher mode factor along the X direction. Refer NRC Table 4.1.8.11.
MVZ *f6*	The higher mode factor along the Z direction. Refer NRC Table 4.1.8.11.
JX *f7*	The numerical reduction coefficient for base overturning moment along the X direction. Refer to NRC Table 4.1.8.11.
JZ *f8*	The numerical reduction coefficient for base overturning moment along the Z direction. Refer to NRC Table 4.1.8.11.

IE *f9* The earthquake importance factor of the structure. This input is based on Importance Category and ULS / SLS. Refer to NRC Table 4.1.8.11.

RDX *f10* The ductility-related force modification factor reflecting the capability of a structure to dissipate energy through inelastic behavior as described in article 4.1.8.9. along the X direction. Refer to NRC Table 4.1.8.9.

ROX *f11* The over strength-related force modification factor accounting for the dependable portion of reserve strength in a structure designed according to the provision of the Article 4.1.8.9. along the X direction. Refer to NRC Table 4.1.8.9.

RDZ *f12* The ductility-related force modification factor reflecting the capability of a structure to dissipate energy through inelastic behavior as described in article 4.1.8.9. along the Z direction. Refer to NRC Table 4.1.8.9.

ROZ *f13* The over strength-related force modification factor accounting for the dependable portion of reserve strength in a structure designed according to the provision of the Article 4.1.8.9. along the Z direction. Refer to NRC Table 4.1.8.9.

SCLASS *f14* an integer corresponding to site classes A through E(where 1 = A and 6 = F). F_a and F_v are determined based on Site Class as per NRC Table 4.1.8.4.B and Table 4.1.8.4.C.

FA *f15* Optional Short-Period site coefficient at 0.2s. Value must be provided if `SCLASS` set to F (i.e., *f14* = 6).

FV *f16* Optional Long-Period site coefficient at 1.0s. Value must be provided if `SCLASS` set to F (i.e., *f14* = 6).

CT *f17* Optional CT value used in calculating the period of the structure based on the empirical method.

> **Note:** The CT parameter entered is used directly in the calculation of the fundamental period, Ta. Therefore, care should be taken to convert the CT value to imperial units as the program internally uses the height of the building in feet for this calculation.

PX *f18* Optional period of the structure (in sec) in the X direction, to be used as fundamental period of the structure. If not entered the value is calculated from the code.

PZ *f19* Optional period of the structure (in sec) in the Z direction, to be used as fundamental period of the structure. If not entered the value is calculated from the code.

If the `ACCIDENTAL` option is specified, the program calculates the accidental torsion per the NRC 2005 specifications. The value of the accidental torsion is based on the center of mass for each level. The center of mass is calculated from the SELFWEIGHT, JOINT WEIGHT, and MEMBER WEIGHT commands.

The `ACC` option along with accidental eccentricity factor (default 0.1 as per NRC 2005) needs to be provided in the NRC seismic primary load case (i.e., `NRC LOAD X / Z f1 ACC f3`). f3 can be negative.

To consider horizontal torsion in cases where a floor diaphragm is present in the model, the `ACCIDENTAL` option should *not* be specified. Instead, dynamic eccentricity along with accidental eccentricity should be provided in the NRC seismic primary load case (i.e., `NRC LOAD X / Z f1 DEC f2 ACC f3`). For equivalent seismic analysis, *f2* is 1 and *f3* is 0.1 as per NRC 2005 code. *f1* is always positive or zero, however *f2* can be negative. If *f2* is 0.0, only accidental torsion will be considered for this particular load case.

> **Note:** For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Methodology

The minimum lateral seismic force or base shear (V) is automatically calculated by STAAD.Pro using the appropriate equation (s).

$$V = \frac{S(T_a) M_v I_E W}{R_d R_o}$$

as per section 4.1.8.11(2) of NBC of Canada 2005, Volume 1

Except that V shall not be less than:

$$V_{\min} = \frac{S(2.0) M_v I_E W}{R_d R_o}$$

and for an R_d= 1.5, V need not be greater than:

$$V_{\max} = \frac{2}{3} \frac{S(0.2) I_E W}{R_d R_o}$$

(i.e., the upper limit of V)

Description of the terms of the equation to calculate V:

- T_a is the fundamental lateral period in the direction under consideration and is determined as:
  - **a.** For moment-resisting frames that resist 100% of the required lateral forces and where the frame is not enclosed by or adjoined by more rigid elements that would tend to prevent the frame from resisting lateral forces, and is calculated by the empirical formulae as described below provided h_n is in meter
    - **i.** $0.085(h_n)^{3/4}$ for steel moment frames,
    - **ii.** $0.075(h_n)^{3/4}$ for concrete moment frames, or
  - **b.** The period is also calculated in accordance with the Rayleigh method but could be overridden by user specified time period (PX, PZ).

    If design spectral acceleration, $S(T_a)$,calculated considering structural time period calculated based on method (b) is greater than 0.8 time the same calculated considering structural time period calculated based on method (a), the former is used for further calculation. Otherwise, the later time period is used.
  - **c.** Other established methods of mechanics using a structural model that complies with the requirements of Sentence 4.1.8.3.(8), except that
    - **i.** for moment resisting frames, Ta shall not be greater than 1.5 times that determined in Clause (a).
    - **ii.** for braced frames, Ta shall not be greater than 2.0 times that determined in Clause (b).
    - **iii.** for shear wall structures, Ta shall not be greater than 2.0 times that determined in Clause (c), and
    - **iv.** for the purpose of calculating the deflections, the period without the upper limit specified is referred from Appendix A.
- $S(T_a)$ is the design spectral acceleration and is determined as follows, using linear interpolation for intermediate values of T_a:

$$S(T_a) = F_a S_a(0.2) \text{ for } T_a \le 0.2\text{s}$$

= $F_v S_a(0.5)$ or $F_a S_a(0.2)$, whichever is smaller for T_a = 0.5s
= $F_v S_a(1.0)$ for T_a = 1.0s
= $F_v S_a(2.0)$ for T_a = 2.0s
= $F_v S_a(2.0)/2$ for $T_a \ge$ 4.0s

The above terms $S_a(0.2)$, $S_a(0.5)$, $S_a(1.0)$ and $S_a(2.0)$ are the Seismic Data and are obtained as user input from the *Table C-2.*

Based on the above values of $S_a(T_a)$, F_a and$F_{v,}$ the acceleration- and velocity based site coefficients are determined from the Tables 4.1.8.4.B and 4.1.8.4.C, using linear interpolation for intermediate values of $S_a(0.2)$ and $S_a(1.0)$. It is to be mentioned that, these are the user inputs based on the site classes from A to E and the desired $S_a(0.2)$ and $S_a(1.0)$ values as required as per the above equations.

- M_v is the factor to account for higher mode effect on base shear and the associated base overturning moment reduction factor is J which are obtained as user input from the Table 4.1.8.11. To get this higher mode factor (M_v) and numerical reduction coefficient for base overturning moment (J), you must get the ratios of $S_a(0.2)/S_a(2.0)$ as also the "Type of Lateral Resisting System."

  For values of Mv between fundamental lateral periods, Ta of 1.0 and 2.0 s, the product S(Ta). Mv shall be obtained by linear interpolation.

  Values of J between fundamental lateral periods, Ta of 0.5 and 2.0 s shall be obtained by linear interpolation.
- I_E is the earthquake importance factor of the structure and is determined from the Table 4.1.8.5. This is a user input depending on Importance Category and ULS / SLS
- W is the weight of the building and shall be calculated internally using the following formula:

$$W = \sum_{i=1}^{n} W_i$$

  Where W_i is the portion of W that is located at or assigned to level i.
- R_d is the ductility-related force modification factor reflecting the capability of a structure to dissipate energy through inelastic behavior as described in article 4.1.8.9.
- R_o is the over-strength-related force modification factor accounting for the dependable portion of reserve strength in a structure designed according to the provision of the Article 4.1.8.9.

  These R^d and R_o values are the user inputs depending on the type of SFRS

As per 4.1.8.11(6), the total lateral seismic force, V, shall be distributed such that a portion, F_t shall be concentrated at the top of the building, where,

$F_t = 0.07T_aV$

but F_t is not greater than 0.25V and $F_t = 0$ when T_a is not greater than 0.7s.

The remainder (V- F_t), shall be distributed along the height of the building, including the top level, in accordance with the following formula [as per section 4.1.8.11(6)]:

$$F_x = \frac{(V - F_t)W_x h_x}{\sum_{i=1}^{n} W_i h_i}$$

where

F_x	=	the lateral force applied to level x
F_t	=	the portion of V to be concentrated at the top of the structure
W_i, W_x	=	the portion of W that is located at or assigned to level i or x, respectively
h_i, h_x	=	the height above the base (i=0) to level i or x, respectively
i	=	is any level in the building (e.g., i = 1 for the first level above the base)
n	=	is the uppermost level in the main portion of the structure

TR.31.2.4 Canadian Seismic Code (NRC) - 2010

This set of commands may be used to define the parameters for generation of equivalent static lateral loads for seismic analysis per National Building Code (NRC/CNRC) of Canada- 2010 edition. Depending on this definition, equivalent lateral loads will be generated in horizontal direction(s).

The seismic load generator can be used to generate lateral loads in the X & Z directions for Y up or X & Y for Z up. Y up or Z up is the vertical axis and the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)). All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.

General Format

STAAD.Pro utilizes the following format to generate the lateral seismic loads.

```
DEFINE NRC 2010 (ACCIDENTAL) LOAD
```

```
nrc-spec
```

```
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

```
nrc-spec = { SA1 f1 SA2 f2 SA3 f3 SA4 f4 MVX f5 MVZ f6 I f7 RDX f8 ROX f9 RDZ f10 ROZ
f11 SCLASS f12 STX f13 STZ f14 MD f15 ( CTX f16 ) ( CTZ f17 ) ( PX f18 ) ( PZ f19 )
( FA f20 ) ( FV f21 ) }
```

where:

SA1 *f1*	Seismic Data, Sa(0.2), as per Table C-2.
SA2 *f2*	Seismic Data, Sa(0.5), as per Table C-2.
SA3 *f3*	Seismic Data, Sa(1.0), as per Table C-2.
SA4 *f4*	Seismic Data, Sa(2), as per Table C-2.

MVX *f5* The higher mode factor along the X and Z direction. Refer to NRC Table 4.1.8.11.

MVZ *f6* The higher mode factor along the Z direction. Refer to NRC Table 4.1.8.11.

I *f7* Earthquake Importance Factor, I_e, of the structure as determined from table 4.1.8.5 in the code. This dependent on the Importance Category and ULS/SLS.

RDX *f8* The ductility-related force modification factor reflecting the capability of a structure to dissipate energy through inelastic behavior as described in article 4.1.8.9. along the X direction. Refer to NRC Table 4.1.8.9.

RDZ *f10* The ductility-related force modification factor reflecting the capability of a structure to dissipate energy through inelastic behavior as described in article 4.1.8.9. along the Z direction. Refer to NRC Table 4.1.8.9.

ROX *f9* the over strength-related force modification factor accounting for the dependable portion of reserve strength in a structure designed according to the provision of the Article 4.1.8.9. along the X direction. Refer to NRC Table 4.1.8.9.

ROZ *f11* the over strength-related force modification factor accounting for the dependable portion of reserve strength in a structure designed according to the provision of the Article 4.1.8.9. along the Z direction. Refer to NRC Table 4.1.8.9.

SCLASS *f12* an integer corresponding to site classes A through E (where 1 = A and 6 = F). F_a and F_v are determined based on Site Class as per Table 4.1.8.4.B and Table 4.1.8.4.C.

STX *f13* Type of lateral resisting system along the X direction. The parameters can take values from 1 to 5:

1 = Moment Resisting Frames
2 = Coupled Walls
3 = Braced Frames
4 = Walls, wall-frame systems
5 = Other systems

STZ *f14* Type of lateral resisting system along the Z direction. The parameters can take values from 1 to 5:

1 = Moment Resisting Frames
2 = Coupled Walls
3 = Braced Frames
4 = Walls, wall-frame systems
5 = Other systems

MD *f15* Command to check if the time period calculated is for the purpose of Member Strength or Deflection as per Clause 4.1.8.11.(3).(v)

1 = Member strength
2 = Deflection

CTX *f16* Optional CT value along the X direction to calculate time period.

CTZ *f17* Optional CT value along the Z direction to calculate time period.

PX *f18* Optional Periods of structure (in sec) in the X direction to be used as fundamental period of the structure. If not entered the value is calculated from the code.

PZ *f19* Optional Periods of structure (in sec) in the Z direction to be used as fundamental period of the structure. If not entered the value is calculated from the code.

FA *f20* Optional Short-Period site coefficient at 0.2s.

> **Note:** Value must be provided if SCLASS set to F (i.e., *f12* = 6).

FV *f21* Optional Long-Period site coefficient at 1.0s.

> **Note:** Value must be provided if SCLASS set to F (i.e., *f12* = 6).

If the `ACCIDENTAL` option is specified, the program calculates the accidental torsion per the NRC 2010 specifications. The value of the accidental torsion is based on the center of mass for each level. The center of mass is calculated from the `SELFWEIGHT`, `JOINT WEIGHT`, and `MEMBER WEIGHT` commands.

The `ACCIDENTAL` option along with accidental eccentricity factor (default 0.1 as per NRC 2010) needs to be provided in the NRC seismic primary load case (i.e., NRC LOAD X / Z *f1* ACC *f3*). *f3* can be negative.

To consider horizontal torsion in cases where a floor diaphragm is present in the model, the `ACCIDENTAL` option should not be specified. Instead, dynamic eccentricity along with accidental eccentricity should be provided in the NRC seismic primary load case (i.e., `NRC LOAD X / Z f1 DEC f2 ACC f3`). For equivalent seismic analysis, *f2* is 1 and *f3* is 0.1 as per NRC 2005 code. *f1* is always positive or zero, however *f2* can be negative. If *f2* is 0.0, only accidental torsion will be considered for this particular load case.

> **Note:** For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Methodology

The equivalent static force procedure to obtain the base shear is implemented according to section 4.1.8.11, Division B of NBCC 2010.

Seismic Base Shear

The minimum lateral earthquake force is calculated according to the following equation (see 4.1.8.11.2)

$$V = \frac{S(T_a)M_v I_E W}{R_d R_o}$$

- · For walls, coupled walls and wall-frame systems, V shall not be less than

  $$S(2.0)M_v I_E W/R_d R_o)$$

  M_v must be calculated with $T \geq 4.0$
- For moment-resisting frames, braced-frames and other systems, V shall not be less than

  $$S(2.0)M_v I_E W/R_d R_o)$$

  M_v must be calculated with $T \geq 2.0$
- And for $V > 1.5$, V need not be greater than

  $$\frac{2}{3}S(0.2)I_E W / \left(R_d R_o\right)$$

Fundament Period, T_a

The fundamental period, Ta, is based on one of the following choices:

- Clause (a): Use 4.1.18.11.3a:
  i. $0.085(h_n)^{3/4}$ for steel moment frames
  ii. $0.075(h_n)^{3/4}$ for concrete moment frames
- Clause (b):

  $0.025h_n$ for braced frames
- Clause (c):

  $0.05(h_n)^{3/4}$ for shear walls and other structures

where

h_n = the height of the building in meters

In the preceding equations, clauses (a), (b) and (c) are implemented except $T_a = 0.1N$. The period is also calculated in accordance with the Rayleigh method

You may also specify the time period using parameters PX an PX. In this case the program checks the following limits:

- Clause d-i: For moment resisting frames: $T_a \leq 1.5\times$that determined in clause (a)
- Clause d-ii: For braced frames: $T_a \leq 2.0\times$that determined in clause (b)
- Clause d-iii: For shear wall structures: $T_a \leq 2.0\times$that determined in clause (c)
- Clause d-iv: For other structures: $T_a \leq$ that determined in clause (c)

However, if the load case is created for drift provisions, (i.e., calculating drift/deflections), the above limits are *not* checked but instead the following limits are enforced (see Clause d-v):

- $T_a \leq 2.0$ if it is a moment-resisting frame, braced frame, or other system
- $T_a \leq 4.0$ for all others (i.e., walls, coupled walls, and wall frame system)

Also, it is stated in code that these upper limits specified may not be checked for deflection and period calculations.

Design Spectral Response Acceleration, $S(T)$

The design spectral acceleration, $S(T)$, is determined as follows, using linear interpolation for intermediate values of T:

$$S(T) = \begin{array}{ll} F_a S_a(0.2) & \text{for} \quad T \leq 0.2s \\ F_v S_a(0.5) \text{or} F_a S_a(0.2) \text{whichever is smaller} & \text{for} \quad T = 0.5s \\ F_v S_a(1.0) & \text{for} \quad T = 1.0s \\ F_v S_a(2.0) & \text{for} \quad T = 2.0s \\ \frac{1}{2} F_v S_a(2.0) & \text{for} \quad T \geq 4.0s \end{array}$$

The above data Sa(0.2), Sa(0.5), Sa(1.0) and Sa(2) are the seismic data and are provided in the parameters SA1, SA2, SA3, and SA4, respectively, from the table C-2.

Based on the above values of Sa(Ta), Fa and Fv, the acceleration- and velocity- based site coefficients are determined from the Tables 4.1.8.4.B and 4.1.8.4.C, using linear interpolation for intermediate values of Sa(0.2) and Sa(1.0). It is to be mentioned that, these are the user inputs based on the site classes from A to E and the desired Sa(0.2) and Sa(1.0) values as required as per the above equations.

Higher Mode Factor, M_v

M_v is the factor to account for higher mode effect on base shear which is obtained from the Table 4.1.8.11 based on Lateral Resisting System, Sa(0.2), and Sa(2.0). To get this higher mode factor (M_v), you must evaluate the ratios of $Sa(0.2)/Sa(2.0)$ as also the "Type of Lateral Resisting System." You may alternatively directly specify M_v using the `MVX` and `MVZ` parameters.

Force Modification Factors, R_d and R_o

The ductility related force modification factor, R_d, reflects the capability of a structure to dissipate energy through inelastic behavior. The over-strength-related force modification factor, R_o , accounts for the dependable portion of reserve strength in a structure designed according to the provision of Article 4.1.8.9. These values are specified using the `RDX`, `ROX`, `RDZ`, and `ROZ` parameters and depend on the type of SFRS.

Seismic Weight of the Building, W

Calculated by the program as:

$$W = \sum_{i=1}^{n} W_i$$

where

W_i = the portion of W that is located at or assigned to level i

Distribution of Lateral Earthquake Force

The calculated base shear, V, is distributed over the height of the building by the following equation:

$$F_x = \frac{(V - F_t) W_x h_x}{\sum_{i=1}^{n} W_i h_i}$$

where

F_t	=	Concentrated force applied on the top of the building and it accounts for effects of higher order modes. As per Clause 4.1.8.11(6) Ft is equal to $0.07T_aV$, but F_t is not greater than 0.25V and Ft = 0 when Ta is not greater than 0.7s
W_i, W_x	=	the portion of W that is located at or assigned to level i or x respectively
h_i, h_x	=	height above the base($i=0$) to level i or x respectively
i	=	any level of the building, $i=1$ for the first floor above the base and $i=n$ for the uppermost level in the main portion of the structure

Torsional Effect

Torsional effects are accounted for according to the Clause 4.1.8.11(10):

$$T_x = F_x(e_x + 0.10\ D_{nx})$$

$$T_x = F_x(e_x - 0.10\ D_{nx})$$

where

e_x	=	natural eccentricity due to center of rigidity and center of mass being at different positions
D_{nx}	=	plan dimension normal to the direction of ground motion

Note: The overturning moment calculation as given in 4.1.8.11 is *not* evaluated by the program.

Example

This example input file demonstrates a seismic load using the equivalent force method and a seismic response spectrum analysis per NRC 2010.

TR.31.2.5 Chinese Static Seismic per GB50011-2001

This set of commands may be used to define and generate static equivalent seismic loads as per Chinese specifications GB50011-2001. This load uses a static equivalent approach, similar to that found in the UBC. Depending on this definition, equivalent lateral loads will be generated in the horizontal direction(s).

Note: As GB50011-2010 static seismic was added in CONNECT Edition V22 Update 6, in order to use the 2001 edition you must directly specify the code year. Otherwise, the program will default to the latest code edition as is typical for STAAD.Pro.

General Format

The following general format should be used to generate loads in a particular direction.

```
DEFINE GB50011 2001 (ACCIDENTAL) LOAD
```

```
INTENSITY s1 { FREQUENT | RARE } GROUP i1 SCLASS i2 (DAMP f1) GFACTOR { 0.85 | 1.0 }
(DELN f2) (SF f3) (PX f4) (PZ f5)
```

Where:

INTENSITY *s1*	the Fortification Intensity (ref. table 5.1.4-1). Acceptable values are 6, 7, 7A, 8, 8A, or 9. 7A represents 7 (0.15g), 8A represents 8 (0.30g).
FREQUENT | RARE	Frequency of seismic action, as specified by FREQUENT or RARE (ref. table 5.1.4-1).
GROUP *i1*	Design Seismic Group (ref. table 5.1.4-2). Acceptable values are 1,2, or 3.
SCLASS *i2*	Site-Class (ref. table 5.1.4-2). Acceptable values are 1, 2, 3, or 4.
DAMP *f1*	Damping ratio (default = 0.05 for 5% damping)

GFACTOR	Equivalent factor of gravity load of horizontal seismic action, as specified by 0.85 or 1.0 (ref. clause 5.2.1). The default value is 0.85.
DELN *f2*	δ_n , Additional seismic action factor at the top of the building (default as calculated from Table 5.2.1)
SF *f3*	Shear Factor, λ, Minimum seismic shear factor of the floor (default as calculated from Table 5.2.5)
PX *f4*	optional time period along the X direction
PZ *f5*	optional time period along the Z direction

Generation of GB50011 Seismic Load

To apply the load in any load case, following command would be used

```
LOAD CASE i
```

```
GB LOAD { X | Y | Z } (f6) (ACC f7)
```

Where:

LOAD *i*	load case number
GB LOAD { X | Y | Z } *f6*	An optional factor to multiply horizontal seismic load.
ACC *f7*	The multiplying factor for Accidental Torsion, to be used to multiply the accidental torsion load (default = 1.0). May be negative (otherwise, the default sign for MY is used based on the direction of the generated lateral forces).

Note: If the `ACCIDENTAL` option is specified, the accidental torsion will be calculated per the GB specifications. The value of the accidental torsion is based on the "center of mass" for each level. The "center of mass" is calculated from the SELFWEIGHT, JOINT WEIGHTs and MEMBER WEIGHTs you have specified.

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Notes:

1. When the seismic load is defined as per topic TR.32.12.2 Generation of Seismic Loads (on page 2598), then currently only the accidental torsion `ACC` is supported, `DEC` is *not* supported.
2. If the `ACCIDENTAL` option is specified, the accidental torsion will be calculated per the GB 50011-2001 specifications. The value of the accidental torsion is based on the “center of mass” for each level. The “center of mass” is calculated from the selfweight, joint weights and member weights you have specified.
3. The seismic load generator can be used to generate lateral loads in the X and Z directions for Y up and the X and Y directions for Z up; where Y up or Z up is the vertical axis parallel to the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)).
4. All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.
5. This method of seismic load generation is limited in use to buildings not taller than 40 meters, with deformations predominantly due to shear, and a rather uniform distribution of mass and stiffness in elevation. Alternately, for buildings modeled as a single-mass system, a simplified method such as this base shear method, may be used.

Gravity Loads for Design

In the computation of seismic action, the representative value of gravity load of the building shall be taken as the sum of characteristic values of the weight of the structure and members plus the combination values of variable loads on the structure. The combination coefficients for different variable loads shall be taken from the following table.

Table 240: Combinations of different load effects per GB50011-2001

Type of Variable	land Combination coefficient	
Snow load	0.5	
Dust load on roof	0.5	
Live load on roof	Not considering	
Live load on the floor, calculated according to actual state	1.0	
Live load on the floor, calculated according to equivalent uniform state	Library, archives	0.8
	Other civil buildings	0.5
Gravity for hanging object of crane	Hard hooks	0.3
	Soft hooks	Not considering

Seismic Influence Coefficient

This shall be determined for building structures according to the Intensity, Site-class, Design seismic group, and natural period and damping ratio of the structure. The maximum value of horizontal seismic influence coefficient shall be taken from Table 2.2; the characteristic period shall be taken as Table 2.3 according to Site-class and Design seismic group, that shall be increased 0.05s for rarely earthquake of Intensity 8 and 9.

Table 241: Earthquake influence per GB50011-2001

Earthquake influence	Intensity 6	Intensity 7	Intensity 8	Intensity 9
Frequent earthquake	0.04	0.08 (0.12)	0.16(0.24)	0.32
Rarely earthquake	-	0.50(0.72)	0.90(1.20)	1.40

Note: The values in parenthesis are separately used for where the design basic seismic acceleration is 0.15g and 0.30g.

Table 242: Earthquake group per GB50011-2001

Earthquake Group	Site class			
	I	II	III	IV
1	0.25	0.35	0.45	0.65
2	0.30	0.40	0.55	0.75
3	0.35	0.45	0.65	0.90

Calculation of Seismic Influence Coefficient

The design base shear is computed in accordance with the equations shown below.

The damping adjusting and forming parameters on the building seismic influence coefficient curve (Fig.2.1) shall comply with the following requirements:

1. The damping ratio of building structures shall select 0.05 except otherwise provided, the damping adjusting coefficient of the seismic influence coefficient curve shall select 1.0, and the coefficient of shape shall conform to the following provisions:
   a. Linear increase section, whose period (T) is less than 0.1 s;
   b. Horizontal section, whose period form 0. is thought to characteristic period, shall select the maximum value (α_{max});
   c. Curvilinear decrease section, whose period from characteristic period thought to 5 times of the characteristic period, the power index (γ) shall choose 0.9.
   d. Linear decrease section, whose period from 5 times characteristic period thought to 6s, the adjusting factor of slope (η_1) shall choose 0.02.

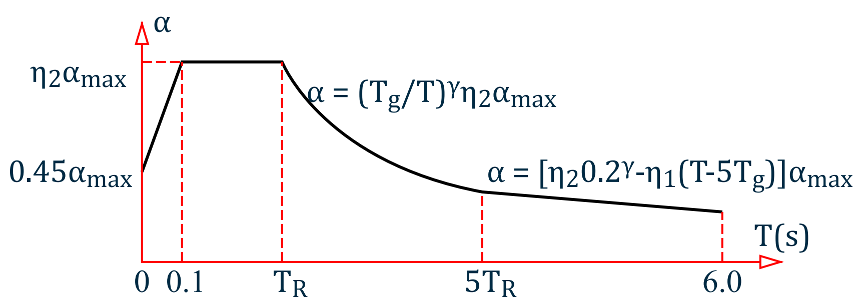

Figure 314: Seismic influence coefficient curve

2. When the damping adjusting and forming parameters on the seismic influence coefficient curve shall comply with the following requirements:
   a. The power index of the curvilinear decreased section shall be determined according to the following equation E2.1

$$\gamma = 0.9 + \frac{0.05 - \zeta}{0.5 + 5\zeta} \tag{E2.1}$$

where

γ	=	the power index of the curvilinear decrease section
ξ	=	the damping ratio

b. The adjusting factor of slope for the linear decrease section shall be determined from following equation:

$$\eta_1 = 0.02 + \frac{0.05 - \zeta}{8} \quad \text{E2.2}$$

where

η_1 = the adjusting factor of slope for the linear decrease section, when it is less than 0, shall equal 0.

c. The damping adjustment factor shall be determined according to the following equation:

$$\eta_2 = 1 + \frac{0.05 - \zeta}{0.06 + 1.7\zeta} \quad \text{E2.3}$$

where

η_2 = the damping adjustment factor, when it is smaller than 0.55 shall equal 0.55.

Calculation of Horizontal Seismic Action

Characteristic Value of Horizontal Seismic Action

When the base shear force method is used, only one degree of freedom may be considered for each story; the characteristic value of horizontal seismic action of the structure shall be determined by the following equations:

$$F_{Ek} = a_1 G_{eq} \quad \text{E2.4}$$

$$F_i = \frac{G_i H_i}{\sum_{j=1}^{n} G_j H_j} F_{Ek}(1 - \delta_n) \quad \text{E2.5}$$

$$\Delta F_n = \delta_n F_{Ek} \quad \text{E2.6}$$

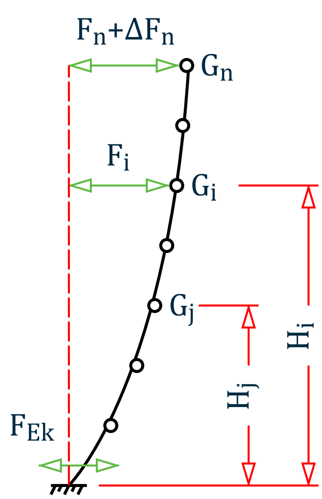

Figure 315: Calculation of horizontal seismic action

where

F_{Ek} = characteristic value of the total horizontal seismic action of the structure

a_1 = horizontal seismic influence coefficient corresponding to the fundamental period of the structure, which shall be determined by using Clause 2.3. For multistory masonry buildings and multi-story

		brick buildings with bottom-frames or inner-frames, the maximum value of horizontal seismic influence coefficient should be taken.
G_{eq}	=	equivalent total gravity load of a structure. When the structure is modeled as a single-mass system, the representative value of the total gravity load shall be used; and when the structure is modeled as a multi-mass system, the 85% of the representative value of the total gravity load may be used.
F_i	=	characteristic value of horizontal seismic action applied on mass i^{th} level.
G_i, G_j	=	representative values of gravity load concentrated at the masses of i^{th} and j^{th} respectively, which shall be determined by Clause 2.1.
H_i, H_j	=	calculated height of i^{th} and j^{th} from the base of the building respectively.
δ_n	=	additional seismic action factors at the top of the building; for multi-story reinforced concrete buildings, it may be taken using Table 2.4; for multi-story brick buildings with inner-frames, a value of 0.2 may be used; no need to consider for other buildings
ΔF_n	=	additional horizontal seismic action applied at top of the building.

Table 243: Additional seismic action factors at top of the building (Table 5.2.1 from GB50011)

T_g (s)	$T_1 > 1.4T_g$	$T_1 \le 1.4T_g$
$T_g \le 0.35$	$0.08T_1 + 0.07$	0
$0.35 < T_g \le 0.55$	$0.08T_1 + 0.01$	
$T_g > 0.55$	$0.08T_1 - 0.02$	

Note: T_1 is the fundamental period of the structure.

Horizontal Seismic Shear Force Verification

The horizontal seismic shear force at each floor level of the structure shall comply with the requirement of the following equation:

$$V_{Eki} > \lambda \sum_{j=1}^{n} G_j \quad \text{E2.7}$$

where

V_{Eki}	=	the floor i^{th} shear corresponding to horizontal seismic action characteristic value.
λ	=	Shear factor, it shall not be less than values in Table 2.5; for the weak location of vertical irregular structure, these values shall be multiplied by the amplifying factor of 1.15.
G_j	=	the representative value of gravity load in floor j^{th} of the structure.

Table 244: Minimum seismic shear factor value of the floor level per GB50011-2001

Structures	Intensity 7	Intensity 8	Intensity 9
structures with obvious torsion effect or fundamental period is less than 3.5s	0.16 (0.024)	0.032 (0.048)	0.064
Structures with fundamental period greater than 5.0s	0.012 (0.018)	0.024 (0.032)	0.040

Note:

1. The values may be selected through interpolation method for structures whose fundamental period is between 3. 5s and 5s.
2. Values in the brackets are used at the regions with basic seismic acceleration as 0.15g and 0.30g respectively.

Notes

1. Structures having the oblique direction lateral-force-resisting members and the oblique angel to major orthogonal axes is greater than 150, the horizontal seismic action along the direction of each lateral-force-resisting member shall he considered respectively. So we could consider this though the item, the action of the oblique member could be multiplied by this factor as design force.
2. Eccentricity: similar to UBC code. The eccentricity value of gravity center on each floor should be $e_i = \pm 0.05L_i$,

   where

e_i	=	Eccentricity value of gravity center on ith floor.
L_i	=	maximum width of calculated story of the building.

3. Structures having obviously asymmetric mass and stiffness distribution, the torsion effects caused by both two orthogonal horizontal direction seismic action shall be considered; and other structures, it is permitted that a simplified method, such as adjusting the seismic effects method, to consider their seismic torsion effects.

TR.31.2.6 Chinese Static Seismic per GB50011-2010

This set of commands may be used to define and generate static equivalent seismic loads as per Chinese specifications GB50011-2010 (2016 edition). This load uses a static equivalent approach, similar to that found in the UBC. Depending on this definition, equivalent lateral loads will be generated in the horizontal direction(s).

General Format

The following general format should be used to generate loads in a particular direction.

```
DEFINE GB50011 ( 2010 ) (ACCIDENTAL) LOAD
```

```
INTENSITY s1 { FREQUENT | FORTIFIED | RARE } GROUP i1 SCLASS i2 (DAMP f1) GFACTOR
{ 0.85 | 1.0 } (DELN f2) (SF f3) (PX f4) (PZ f5)
```

Where:

INTENSITY *s1*	the Fortification Intensity (ref. table 5.1.4-1). Acceptable values are 6, 7, 7A, 8, 8A, or 9. 7A represents 7 (0.15g), 8A represents 8 (0.30g).
FREQUENT | FORTIFIED | RARE	Frequency of seismic action, as specified by `FREQUENT`, `FORTIFIED`, or `RARE` (ref. table 5.1.4-1 and clause 3.10.3).
GROUP *i1*	Design Seismic Group (ref. table 5.1.4-2). Acceptable values are 1,2, or 3.
SCLASS *i2*	Site-Class (ref. table 5.1.4-2). Acceptable values are 0, 1, 2, 3, or 4. 0 represents I0, 1 represents I1, 2 represents II, 3 represents III, 4 represents IV
DAMP *f1*	Damping ratio (default = 0.05 for 5% damping)
GFACTOR	Equivalent factor of gravity load of horizontal seismic action, as specified by 0.85 or 1.0 (ref. clause 5.2.1). The default value is 0.85.
DELN *f2*	δ_n , Additional seismic action factor at the top of the building (default as calculated from Table 5.2.1)
SF *f3*	Shear Factor λ, Minimum seismic shear factor of the floor (default as calculated from Table 5.2.5)
PX *f4*	optional time period along the X direction
PZ *f5*	optional time period along the Z direction

Generation of GB50011 Seismic Load

To apply the load in any load case, following command would be used

```
LOAD CASE i
```

```
GB LOAD { X | Y | Z } (f6) (ACC f7)
```

Where:

LOAD *i*	load case number
GB LOAD { X | Y | Z } *f6*	An optional factor to multiply horizontal seismic load.
ACC *f7*	The multiplying factor for Accidental Torsion, to be used to multiply the accidental torsion load (default = 1.0). May be negative (otherwise, the default sign for MY is used based on the direction of the generated lateral forces).

Note: If the `ACCIDENTAL` option is specified, the accidental torsion will be calculated per the GB specifications. The value of the accidental torsion is based on the "center of mass" for each level. The "center of mass" is calculated from the SELFWEIGHT, JOINT WEIGHTs and MEMBER WEIGHTs you have specified.

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Notes:

1. When the seismic load is defined as per topic TR.32.12.2 Generation of Seismic Loads (on page 2598), then currently only the accidental torsion ACC is supported, DEC is *not* supported.

2. If the `ACCIDENTAL` option is specified, the accidental torsion will be calculated per the GB 50011-2001 specifications. The value of the accidental torsion is based on the "center of mass" for each level. The "center of mass" is calculated from the selfweight, joint weights and member weights you have specified.
3. The seismic load generator can be used to generate lateral loads in the X and Z directions for Y up and the X and Y directions for Z up; where Y up or Z up is the vertical axis parallel to the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)).
4. All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.
5. This method of seismic load generation is limited in use to buildings not taller than 40 meters, with deformations predominantly due to shear, and a rather uniform distribution of mass and stiffness in elevation. Alternately, for buildings modeled as a single-mass system, a simplified method such as this base shear method, may be used.

Gravity Loads for Design

In the computation of seismic action, the representative value of gravity load of the building shall be taken as the sum of characteristic values of the weight of the structure and members plus the combination values of variable loads on the structure. The combination coefficients for different variable loads shall be taken from the following table.

Table 245: Combinations of different load effects per GB50011-2010

Type of Variable	land Combination coefficient	
Snow load	0.5	
Dust load on roof	0.5	
Live load on roof	Not considering	
Live load on the floor, calculated according to actual state	1.0	
Live load on the floor, calculated according to equivalent uniform state	Library, archives	0.8
	Other civil buildings	0.5
Gravity for hanging object of crane	Hard hooks	0.3
	Soft hooks	Not considering

Seismic Influence Coefficient

This shall be determined for building structures according to the Intensity, Site-class, Design seismic group, and natural period and damping ratio of the structure. The maximum value of horizontal seismic influence coefficient shall be taken from Table 5.1.4-1; the characteristic period shall be taken from Table 5.1.4-2 according to Site-class and Design seismic group, that shall be increased 0.05s for rarely earthquake.

Table 246: Earthquake influence per GB50011-2010

Earthquake influence	Intensity 6	Intensity 7	Intensity 8	Intensity 9
Frequent earthquake	0.04	0.08 (0.12)	0.16(0.24)	0.32
Fortified earthquake (per clause 3.10.3)	0.12	0.23 (0.34)	0.45 (0.68)	0.90
Rarely earthquake	0.28	0.50(0.72)	0.90(1.20)	1.40

Note: The values in parenthesis are separately used for where the design basic seismic acceleration is 0.15g (equal to 7A in the command) and 0.30g (equal to 8A in the command).

Table 247: Characteristic Period per GB50011-2010

Earthquake Group	Site class				
	I0	I	II	III	IV
1	0.20	0.25	0.35	0.45	0.65
2	0.25	0.30	0.40	0.55	0.75
3	0.30	0.35	0.45	0.65	0.90

Calculation of Seismic Influence Coefficient

The design base shear is computed in accordance with the equations shown below.

The damping adjusting and forming parameters on the building seismic influence coefficient curve (Fig.2.1) shall comply with the following requirements:

1. The damping ratio of building structures shall select 0.05 except otherwise provided, the damping adjusting coefficient of the seismic influence coefficient curve shall select 1.0, and the coefficient of shape shall conform to the following provisions:
   a. Linear increase section, whose period (T) is less than 0.1 s;
   b. Horizontal section, whose period form 0. is thought to characteristic period, shall select the maximum value (α_{max});
   c. Curvilinear decrease section, whose period from characteristic period thought to 5 times of the characteristic period, the power index (γ) shall choose 0.9.
   d. Linear decrease section, whose period from 5 times characteristic period thought to 6s, the adjusting factor of slope (η_1) shall choose 0.02.

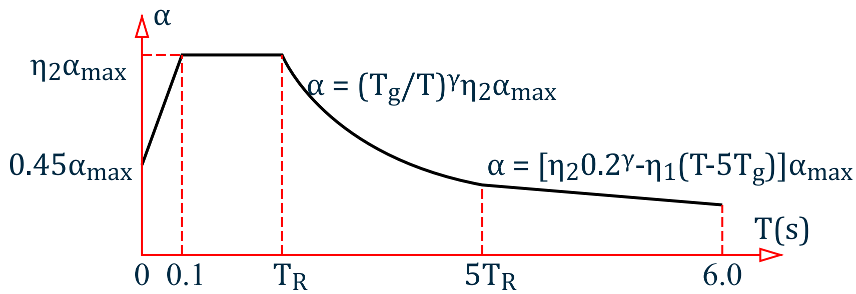

Figure 316: Seismic influence coefficient curve

2. When the damping adjusting and forming parameters on the seismic influence coefficient curve shall comply with the following requirements:

   a. The power index of the curvilinear decreased section shall be determined according to the following equation:

   $$\gamma = 0.9 + \frac{0.05 - \zeta}{0.3 + 6\zeta}$$

   where

γ	=	the power index of the curvilinear decrease section
ξ	=	the damping ratio

   b. The adjusting factor of slope for the linear decrease section shall be determined from following equation:

   $$\eta_1 = 0.02 + \frac{0.05 - \zeta}{4 + 32\zeta}$$

   where

η_1	=	the adjusting factor of slope for the linear decrease section, when it is less than 0, shall equal 0.

   c. The damping adjustment factor shall be determined according to the following equation:

   $$\eta_2 = 1 + \frac{0.05 - \zeta}{0.08 + 1.6\zeta}$$

   where

η_2	=	the damping adjustment factor, when it is smaller than 0.55 shall equal 0.55.

Calculation of Horizontal Seismic Action

<u>Characteristic Value of Horizontal Seismic Action</u>

When the base shear force method is used, only one degree of freedom may be considered for each story; the characteristic value of horizontal seismic action of the structure shall be determined by the following equations:

$$F_{Ek} = a_1 G_{eq} \qquad \text{E2.4}$$

$$F_i = \frac{G_i H_i}{\sum_{j=1}^{n} G_j H_j} F_{Ek}(1 - \delta_n) \qquad \text{E2.5}$$

$$\Delta F_n = \delta_n F_{Ek} \qquad \text{E2.6}$$

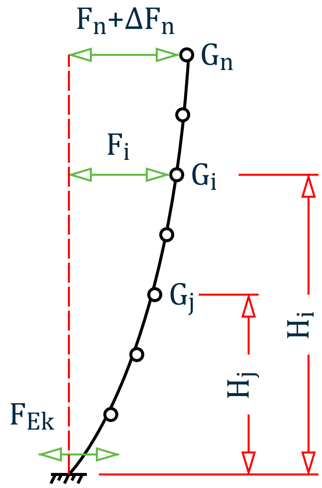

Figure 317: Calculation of horizontal seismic action

where

F_{Ek}	=	characteristic value of the total horizontal seismic action of the structure
a_1	=	horizontal seismic influence coefficient corresponding to the fundamental period of the structure, which shall be determined by using Clause 5.1.4, 5.1.5. For multistory masonry buildings and multi-story brick buildings with bottom-frames or inner-frames, the maximum value of horizontal seismic influence coefficient should be taken.
G_{eq}	=	equivalent total gravity load of a structure. When the structure is modeled as a single-mass system, the representative value of the total gravity load shall be used; and when the structure is modeled as a multi-mass system, the 85% of the representative value of the total gravity load may be used.
F_i	=	characteristic value of horizontal seismic action applied on mass i^{th} level.
G_i, G_j	=	representative values of gravity load concentrated at the masses of i^{th} and j^{th} respectively, which shall be determined by Clause 2.1.
H_i, H_j	=	calculated height of i^{th} and j^{th} from the base of the building respectively.
δ_n	=	additional seismic action factors at the top of the building; for multi-story reinforced concrete buildings, it may be taken using Table 2.4; no need to consider for other buildings
ΔF_n	=	additional horizontal seismic action applied at top of the building.

Table 248: Additional seismic action factors at top of the building (Table 5.2.1 from GB50011)

T_g (s)	$T_1 > 1.4T_g$	$T_1 \leq 1.4T_g$
$T_g \leq 0.35$	$0.08T_1 + 0.07$	0
$0.35 < T_g \leq 0.55$	$0.08T_1 + 0.01$	

$T_g > 0.55$	$0.08T_1 - 0.02$	

Note: T_1 is the fundamental period of the structure.

Horizontal Seismic Shear Force Verification

The horizontal seismic shear force at each floor level of the structure shall comply with the requirement of the following equation:

$$V_{Eki} > \lambda \sum_{j=1}^{n} G_j \qquad \text{E2.7}$$

where

V_{Eki} = the floor ith shear corresponding to horizontal seismic action characteristic value.

λ = Shear factor, it shall not be less than values in Table 2.5; for the weak location of vertical irregular structure, these values shall be multiplied by the amplifying factor of 1.15.

G_j = the representative value of gravity load in floor jth of the structure.

Table 249: Minimum seismic shear factor value of the floor level per GB50011-2001

Structures	Intensity 6	Intensity 7	Intensity 8	Intensity 9
structures with obvious torsion effect or fundamental period is less than 3.5s	0.008	0.16 (0.024)	0.032 (0.048)	0.064
Structures with fundamental period greater than 5.0s	0.006	0.012 (0.018)	0.024 (0.032)	0.040

Note:

1. The values may be selected through interpolation method for structures whose fundamental period is between 3. 5s and 5s.
2. Values in the brackets are used at the regions with basic seismic acceleration as 0.15g and 0.30g respectively.

Notes

1. Structures having the oblique direction lateral-force-resisting members and the oblique angel to major orthogonal axes is greater than 150, the horizontal seismic action along the direction of each lateral-force-resisting member shall he considered respectively. So we could consider this though the item, the action of the oblique member could be multiplied by this factor as design force.
2. Eccentricity: similar to UBC code. The eccentricity value of gravity center on each floor should be $e_i = \pm 0.05L_i$,

   where

   e_i = Eccentricity value of gravity center on ith floor.

   L_i = maximum width of calculated story of the building.
3. Structures having obviously asymmetric mass and stiffness distribution, the torsion effects caused by both two orthogonal horizontal direction seismic action shall be considered; and other structures, it is permitted

that a simplified method, such as adjusting the seismic effects method, to consider their seismic torsion effects.

- *V. GB 50011-2010 Static Seismic - Case2* (on page 3403)

TR.31.2.7 Colombian NSR-98 Seismic Load

Used to define and generate static equivalent seismic loads as the 1998 edition of the Colombian seismic code, *Reglamento Colombiano de Construcción Sismo Resistente* (NSR-98),*Normas Colombianas de Diseño y Construcción*, 1998, Asociación Colombiana de Ingeniería Sísmica.

This implementation uses a static equivalent approach similar to those outlined by UBC. Depending on this definition, equivalent lateral loads will be generated in horizontal direction(s). The load is based on

The seismic load generator can be used to generate lateral loads in the X & Z directions for Y up or X & Y for Z up. Y up or Z up is the vertical axis and the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)). All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.

General Format

```
DEFINE COLOMBIAN (ACCIDENTAL) LOAD
```

```
ZONE f1 ( I f2 S f3)
```

```
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

ZONE *f1*	Seismic Risk factor
I *f2*	Soil Site Coefficient
S *f3*	Coefficient of Importance

Generation of NSR Seismic Load

General format to provide Colombian Seismic load in any load case:

```
LOAD i
```

```
COLOMBIAN LOAD {X | Y | Z} (f4) (ACCIDENTAL f5)
```

Where:

LOAD *i*	load case number
COLUMBIAN LOAD { X | Y | Z } *f4*	factor to multiply horizontal seismic load
ACCIDENTAL *f5*	multiplying factor for Accidental Torsion, to be used to multiply the accidental torsion load (default = 1.0). May be negative (otherwise, the default sign for MY is used based on the direction of the generated lateral forces).

If the `ACCIDENTAL` option is specified, the accidental torsion will be calculated per the specifications. The value of the accidental torsion is based on the center of mass for each level. The center of mass is calculated from the `SELFWEIGHT`, `JOINT WEIGHT`, and `MEMBER WEIGHT` commands specified for this load definition.

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Example

Using NSR-98:

```
DEFINE COLOMBIAN LOAD
ZONE 0.38  1.0  S  1.5
JOINT  WEIGHT
51 56 93 100 WEIGHT 1440
101 106 143 150 WEIGHT 1000
151 156 193 200 WEIGHT 720
LOAD 1 ( SEISMIC LOAD IN X DIRECTION )
COLOMBIAN  LOAD  X
```

Methodology for NSR-98

Seismic zone coefficient and parameter values are supplied by the user through the `DEFINE COLOMBIAN LOAD` command.

The program calculates the natural period of building T utilizing clause 1628.2.2 of UBC 1994.

Design spectral coefficient, S_a, is calculated utilizing T as:

$$S_a = \begin{cases} A_a I(1.0 + 5.0T) \text{ when } 0 \le T \le 0.3 \text{ sec} \\ 2.5 A_a I \text{ when } 0.3 < T \le 0.48 \text{ sec} \\ 1.2 A_a S \frac{I}{T} \text{ when } 0.48 < T < 2.4 \text{ sec} \\ A_a I / 2 \text{ when } 2.4\text{sec} < T \end{cases}$$

where

A_a = Seismic Risk factor

S	=	Soil Site Coefficient
I	=	Coefficient of Importance

Base Shear, Vs is calculated as:

$$V_s = W \times S_a$$

where

W	=	Total weight on the structur

The total lateral seismic load, V_s, is then distributed by the program among different levels as:

$$F_x = C_{vx} \times V_s$$

where

C_{vx}	=	$\dfrac{W_x h_x^K}{\sum_{i=1}^{n} \left(W_x h_x^K\right)}$
W_x	=	Weight at the particular level
h_x	=	Height of that particular level
K	=	1.0 when $T \leq 0.5$ sec $0.75 + 0.5T$ when $0.5 < T \leq 2.5$ sec 2.0 when $T > 2.5$ sec

weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

AA *f1* A coefficient representing effective peak horizontal acceleration for design (Table A.2.4-3 NSR-10). Must be within the range of 0 to 0.5 (inclusive) or the output will indicate an error.

AV *f2* A coefficient representing the effective peak horizontal velocity for design (Table A.2.4-4 NSR-10). Must be within the range of 0 to 0.5 (inclusive) or the output will indicate an error.

FA *f3* The dimensionless amplification factor that affects the acceleration in the short periods due to the effects site (Table A.2.4-3 NSR-10). Must be within the range of 0 to 3.5 (inclusive) or the output will indicate an error.

FV *f4* The dimensionless amplification factor that affects the acceleration in the intermediate periods due to site effects (Table A.2.4-4 NSR-10). Must be within the range of 0 to 3.5 (inclusive) or the output will indicate an error.

I *f5* The importance factor (Table A.2.5-1 NSR-10). Must be within the range of 1 to 1.5 (inclusive) or the output will indicate an error.

CT *f6* Optional CT value to calculate time period. (Table A.4.2-1 NSR-10)

PX *f7* Optional Period of structure (in sec) in X-direction to be in lieu of fundamental period of the structure

PZ *f8* Optional Period of structure (in sec) in Z-direction to be in lieu of fundamental period of the structure

ALPHA *f9* Exponent used in calculating the approximate period, T_a (Table A.4.2-1 NSR-10).

Generation of NSR Seismic Load

General format to provide Colombian Seismic load in any load case:

```
LOAD i
```

```
COLOMBIAN LOAD {X | Y | Z} (f10) (ACCIDENTAL f11)
```

Where:

LOAD *i*	load case number
COLOMBIAN LOAD { X | Y | Z } *f10*	factor to multiply horizontal seismic load
ACCIDENTAL *f11*	multiplying factor for Accidental Torsion, to be used to multiply the accidental torsion load (default = 1.0). May be negative (otherwise, the default sign for MY is used based on the direction of the generated lateral forces).

If the `ACCIDENTAL` option is specified, the accidental torsion will be calculated per the specifications. The value of the accidental torsion is based on the center of mass for each level. The center of mass is calculated from the `SELFWEIGHT`, `JOINT WEIGHT`, and `MEMBER WEIGHT` commands specified for this load definition.

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Example

Using NSR-10:

```
DEFINE COLOMBIAN 2010 LOAD
AA 0.2 AV 0.15 FA 0.85 FV 1.01 I 1.12
JOINT WEIGHT
6 TO 15 21 TO 30 36 TO 45 WEIGHT 10
LOAD 1
COLOMBIAN LOAD X 1.2
```

Methodology for NSR-10

The time period, T, is determined using the Rayleigh method (see section TR.34.1 Rayleigh Frequency Calculation (on page 2614)) or specified directly in the X and Z directions with the optional parameters PX and PZ, is used to calculate spectral coefficient, S_a, as (refer to Fig. A.2.6-1 in the code):

$$S_a = \begin{cases} 2.5A_aF_aI\left(0.4 + 0.6\frac{T}{T_0}\right) \text{ when } T < T_0 \\ 2.5A_aF_aI \text{ when } T_0 \leq T < T_C \\ 1.2A_vF_v\frac{I}{T} \text{ when } T_C \leq T < T_L \\ 1.2A_vF_vT_L\frac{I}{T^2} \text{ when } T > T_L \end{cases}$$

where

T_0	=	$0.1\frac{A_vF_v}{A_aF_a}$
T_C	=	$0.48\frac{A_vF_v}{A_aF_a}$
T_L	=	$2.4F_v$
A_a	=	Seismic Risk factor
S	=	Soil Site Coefficient
I	=	Coefficient of Importance

Base Shear, Vs is calculated as

$$V_s = S_aW$$

where

W	=	Total weight on the structure

The horizontal seismic force, F_x, at any level x is calculated by the program as:

$$F_x = V_sC_{vx}$$

where

C_{vx}	=	$\frac{W_xF_x{}^k}{\Sigma\left(W_xF_x{}^k\right)}$
W_x	=	Weight at the particular level
k	=	the exponent related to the fundamental period, T, of the building;

$$k = \begin{cases} 1.0 \text{ when } T \leq 0.5\text{sec} \\ 0.75 + 0.5T \text{ when } 0.5 \leq T < 2.5\text{sec} \\ 2.0 \text{ when } 2.5\text{sec} \geq T \end{cases}$$

TR.31.2.9 IS:1893 - 1984 Code - Lateral Seismic Load

This feature enables you to generate seismic loads using a static equivalent approach per the IS:1893 - 1984 specifications, *Earthquake Resistant Design of Structures*.

General Format

```
DEFINE 1893 ( ACCIDENTAL ) LOAD
ZONE f1 K f2 I f3 B f4 PX f5 PZ f6
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

where:

ZONE *f1*	Seismic zone coefficient.
K *f2*	Performance factor.
I *f3*	Importance factor depending upon the functional use of the structures, characterized by hazardous consequences of its failure, post-earthquake functional needs, historical value, or economic importance.
B *f4*	Soil interaction factor.
PX *f5*	Optional period in the X direction.
PZ *f6*	Optional period in the Z direction.

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR.32.12.2 Generation of Seismic Loads (on page 2598).

Example

```
DEFINE 1893 LOAD
ZONE 0.36 K 2 I B 1
JOINT WEIGHT
39 60 80 WEIGHT 100
LOAD 1 LOADTYPE Seismic  TITLE SS_(+X)
1893 LOAD X 1
LOAD 2 LOADTYPE Seismic  TITLE SS_(+Z)
1893 LOAD Z 1
```

TR.31.2.10 IS:1893 (Part 1) 2002 & Part 4 (2005) Codes - Lateral Seismic Load

This feature enables one to generate seismic loads per the IS:1893 specifications using a static equivalent approach. Both Part 1 (2002) for building structures and Part 4 (2005) for industrial and stack-like structures are available.

The seismic load generator can be used to generate lateral loads in the X and Z directions only. Y is the direction of gravity loads. This facility has not been developed for cases where the Z axis is set to be the vertical direction (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)).

General Format

```
DEFINE 1893 ( ACCIDENTAL ) LOAD ( PART4 )
ZONE f1 { 1893-spec-part1  | 1893-spec-part4  }
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

```
(CHECK SOFT STORY)
```

where

```
1893-spec-part1 =    RF f2 I f3 { SS f4 | SA f11 } (ST f5) ( { DM f6 | DF f12 } ) (PX
f7) (PZ f8) ( { DT f9 | GL f10 } )
```

```
1893-spec-part4 =    RF f2 I f3 { SS f4 | SA f11 } ST f5 ( { DM f6 | DF f12 } ) (PX
f7) (PZ f8) ( { DT f9 | GL f10 } ) ( CS f13 ) ( AX f14 ) ( ES f15 ) CV f16 DV f17
```

where

ZONE *f1* Seismic zone coefficient. Refer to Table 2 of IS:1893 (Part 1)-2002.

RF *f2* Response reduction factor. Refer Table 7 of IS: 1893 (Part 1) -2002 or Table 3 of IS: 1893 (Part 4) -2005.

I *f3* Importance factor depending upon the functional use of the structures, characterized by hazardous consequences of its failure, post-earthquake functional needs, historical value, or economic importance. Refer Table 6 of IS: 1893(Part 1)-2002 or Table 2 of IS: 1893 (Part 4)-2005.

SS *f4* Rock or soil sites factor. Depending on type of soil, average response acceleration coefficient S_a/g is calculated corresponding to 5% damping. Refer Clause 6.4.5 of IS: 1893 (Part 1) -2002 or Clause 8.3.2 of IS: 1893 (Part 4) -2005.

1 = hard soil
2 = medium soil
3 = soft soil

Note: Use either SS *or*SA to specify site conditions. If both parameters are specified, SS is ignored.

ST *f5* For IS 1893 Part 1, the program will calculate natural period as per Clause 7.6 of IS:1893(Part 1)-2002.

1 = RC frame building
2 = Steel frame building
3 = All other buildings

For IS1893 Part 4, the program will calculate period as per Clause 14.1 of IS:1893(Part 4)-2005 for stack-like structures. For Category 1 Industrial Structures base shear is calculated as twice the base shear of other structures as per Clause 8.3 of IS:1893(Part 4)-2005.

1 = Category 1 industrial structure (Part 4)
3 = All other industrial structures
5 = stack-like structures

Note: This parameter is optional for Part 1, but is required for Part 4.

DM *f6* Damping ratio to obtain multiplying factor for calculating S_a/g for different damping. If no damping is specified 5% damping (default value 0.05) will be considered corresponding to which multiplying factor is 1.0. Refer Table 3 of IS:1893(Part 1)-2002.

Note: Use either `DM` *or* `DF` to specify damping. If both parameters are specified, `DM` is ignored.

This should be a value between 0 (zero) and 1.0, inclusive. For example, 7% damping should be specified as `0.07`.

PX *f7* Optional period of structure (in sec) in X direction. If this is defined this value will be used to calculate S_a/g for generation of seismic load along X direction.

Note: See Note 'b' below.

PZ *f8* Optional period of structure (in sec) in Z direction. If this is defined this value will be used to calculate Sa/g for generation of seismic load along Z direction.

Note: See Note 'b' below.

DT *f9* Depth of foundation below ground level. It should be defined in current units. If the depth of foundation is 30 m or more, the value of A_h is taken as half the value obtained. If the foundation is placed between the ground level and 30 m depth, this value is linearly interpolated between A_h and $0.5A_h$.

Note: Use either `DT` *or* `GL` to specify foundation depth. If both parameters are specified, `DT` is ignored.

GL *f10* Y coordinate of ground level. A reduced lateral force is applied to levels below this height, per Clause 6.4.4.

Used for Y if the `SET Z UP` command is used.

SA *f11* Average response spectral acceleration coefficient corresponding to site specific spectra.

DF *f12* Multiplying factor for calculating S_a/g.

CS *f13* Coefficient as given in Table 6 of IS:1893(Part 4)-2005. Valid only for stack-like structures for calculating fundamental time period per Cl. 14.1.

AX *f14* Area of cross-section at the base of stack-like structures for calculating fundamental time period per Cl. 14.1 of IS:1893(Part 4)-2005.

ES *f15* Modulus of elasticity of material of stack-like structures for calculating fundamental time period per Cl. 14.1 of IS:1893(Part 4)-2005.

CV *f16* Coefficient of shear force given in Table 6 of IS:1893(Part 4)-2005. Required for stack-like structures (`ST 5`).

DV *f17* Distribution factor for shear force given in Table 11 of IS:1893(Part 4)-2005. Required for stack-like structures (`ST 5`).

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Notes

a. If the `ACCIDENTAL` option is specified, the accidental torsion will be calculated per the IS 1893 specifications. The value of the accidental torsion is based on the center of mass for each level. The center of mass is calculated from the `SELFWEIGHT`, `JOINT WEIGHT`, and `MEMBER WEIGHT` commands you have specified.

The `ACC` option along with accidental eccentricity factor (generally 0.05 as per IS 1893 code) needs to be provided in the 1893 seismic primary load case (i.e., `1893 LOAD X / Z f1 ACC f3`). *f2* can be negative. See TR.32.12.2 Generation of Seismic Loads (on page 2598)

To consider horizontal torsion in cases where a floor diaphragm is present in the model, the `ACCIDENTAL` option should *not* be specified. Instead, dynamic eccentricity along with accidental eccentricity should be provided in the 1893 seismic primary load case (i.e., `1893 LOAD X / Z f1 DEC f2 ACC f3`). For equivalent seismic analysis, *f2* is 1.5 and *f3* is 0.05 as per IS 1893 code. *f1* is always positive or zero, however *f2* can be negative. If *f2* is 0.0, only accidental torsion will be considered for this particular load case.

b. By default STAAD calculates natural periods of the structure in both X and Z directions respectively which are used in calculation for base shear. If `PX` and `PZ` are included, the program will consider these values for calculation of average response acceleration coefficient. If `ST` is used instead of `PX` and `PZ` values, then the program will calculate natural period depending upon the empirical expression given in IS: 1893 (Part 1)-2002 or IS: 1893 (Part 4)-2005.

c. In the case where no rigid floor diaphragm is present, STAAD identifies columns and shear walls (without openings) as vertical components for the purpose of computing lateral stiffness of the story.

The lateral stiffness of a column is calculated as:

$$12EI / L^3$$

where

E	=	Young's modulus
I	=	moment of inertia
L	=	length of the column

The lateral stiffness for a shear wall (without opening) is calculated as:

$$\frac{1}{\frac{Ph^3}{12EI} + \frac{1.2Ph}{AG}}$$

Which is the summation of inverse of flexural stiffness and inverse of shear stiffness, obtained as deflection of a cantilever wall under a single lateral load, P, at its top.

where

h	=	height
A	=	cross-sectional area
G	=	shear modulus of the wall

The summation of lateral stiffnesses of all columns and shear walls at a particular floor level constitutes the total lateral stiffness of that particular story or floor level. The program checks for a soft story of a building along both global X and Z directions respectively. This computation is valid only for those structures whose floors are treated as rigid diaphragm

Example

```
DEFINE 1893 LOAD
ZONE 0.36 RF 5 I 1 SS 1 ST 1 DM 0.05
JOINT WEIGHT
39 60 80 WEIGHT 100
LOAD 1 LOADTYPE Seismic  TITLE SS_(+X)
1893 LOAD X 1
LOAD 2 LOADTYPE Seismic  TITLE SS_(+Z)
1893 LOAD Z 1
```

Methodology

The design base shear is computed by STAAD.Pro for building structures as per IS: 1893 (Part 1) 2002 equation 7.5.3 or for industrial structures as per (Part 4) 2005:

$$V = A_{h.}W$$

Where:

$$A_h = \frac{Z}{2}\frac{I}{R}\frac{S_a}{g}$$

When site specific spectra is used per IS 1893 (Part 4) 2005, then:

$$A_h = \frac{I}{R}\frac{S_a}{g}$$

For stack-like structures, the design base shear is computed as per IS 1893 (Part 4) 2005 as:

$$V = C_v A_{h.} W \cdot D_v$$

Note: All symbols and notations in the above equation are as per IS: 1893(Part 1) 2002 and IS: 1893 (Part 4) 2005.

STAAD.Pro utilizes the following procedure to generate the lateral seismic loads:

1. You provide seismic zone coefficient and desired 1893 specs through the `DEFINE 1893 LOAD` command. Use the `PART 4` command option to specify using IS: 1893 (Part 4) 2005.
2. The program calculates the structure period, T.
3. The program calculates S_a/g utilizing T.
4. The program calculates V from the above equation. W is obtained from mass table data entered via `SELFWEIGHT`, `JOINT WEIGHT`(s), `MEMBER WEIGHT`(S), and/or `REFERENCE LOAD` you provide through the `DEFINE 1893 LOAD` command.
5. The total lateral seismic load (base shear) is then distributed by the program among different levels of the structure per the IS: 1893 procedures.

See TR.32.12 Generation of Loads (on page 2596) for additional information.

Soft Story Checking

Tip: When a TR.28.2 Floor Diaphragm (on page 2328) is used, a soft story check may be initiated within that command without some of the limitations imposed on soft story checking in a seismic load.

As per the IS1893-2002 code Clause 7.1, to perform well during an earthquake a building must have simple and regular configuration, adequate lateral strength, stiffness and ductility. This is because a building with simple regular geometry and uniformly distributed mass and stiffness in plan as well as in elevation, will suffer much less damage than buildings with irregular configurations.

According to this standard, a building can be considered irregular, if at least one of the conditions given in Table 4 - Plan Irregularities and Table 5 - Vertical Irregularities, of IS1893-2002 is applicable.

For IS 1893 2002, STAAD.Pro has implemented the methodology to find vertical stiffness irregularities, as given in IS 1893-2002 Table 5 Sl No. (1) i) a) and Sl No. (1) i) b), in the form of soft story checking.

- Stiffness Irregularities: Soft Story – As per this provision of the code, a soft story is one in which the lateral stiffness is less than 70 percent of that in the story above or less than 80 percent of the average lateral stiffness of the three story above.

- Stiffness Irregularities: Extreme Soft Story – As per this provision of the code, a extreme soft story is one in which the lateral stiffness is less than 60 percent of that in the story above or less than 70 percent of the average lateral stiffness of the three story above.

  Thus, if any story of a building is found to be soft or extremely soft, the building is likely to suffer much damage in an earthquake than a similar type of building but has more regular vertical stiffness.

Note: STAAD.Pro identifies column and shear wall (without opening) as vertical component for the purpose of computing lateral stiffness of the story. The vertical stiffness of a column is calculated as $12EI / L^3$ where E is the Young's modulus, I is the moment of inertia and L is the length of the column respectively and that for a shear wall (without opening) is calculated as $Ph^3/3EI + 1.2Ph/AG$ (i.e., summation of flexural stiffness and shear stiffness, obtained as deflection of a cantilever wall under a single lateral load P at its top) where h is the height, A is the cross-sectional area, and G is the shear modulus of the wall (E and I are Young's modulus of elasticity and moment of inertia, respectively). The summation of lateral stiffness of all columns and shear walls at a particular floor level constitute the total lateral stiffness of that particular story or floor level. The program checks soft story of a building along both global X and Z directions respectively. This computation is valid *only* for those structures whose floors are treated as rigid diaphragm.

TR.31.2.9.1 Identification of Floor Level

The following two ways can identify floor level:

- Program calculated
- User defined

For regular building which has well defined floors (i.e., does not contain shear wall, staggered flooring, etc), STAAD.Pro can identify floor level on its own. However, if floor level is not so well defined, it is better to define floor height to have more accurate result for the purpose of torsion and soft story checking.

Program calculated

In general, STAAD.Pro identifies floor levels in order of increasing magnitude of Y-coordinates of joints. The program sorts different values of Y-coordinates, from minimum to maximum values, in ascending order and consider each Y-coordinate value as each floor level. This is the method used by the `DEFINE UBC` or similar load generation features.

This feature has been enhanced to identify the beam-column junctions at each floor level, as identified by the method above. If no beam-column junctions are identified at that level, a floor level will not be considered at that level in the structure. Where beam-column junctions are found, the program identifies two beams, at the same level which span in two different directions from the same beam-column junction. If this true, this identified floor level will be considered as truly existing floor level in the structure.

The enhanced feature for finding floor level is being used by lateral load generation feature for response spectrum analysis and soft story checking as per IS1893-2002 code. For response spectrum analysis, story drift and soft story checking is performed only when floor heights are specified.

User defined

Floor heights should be defined before using the `DEFINE` command for any primary response spectrum load case. The following general format is used for a user-defined floor height:

```
FLOOR HEIGHT
    h1; h2; h3; …;hi -
    hi+1; …;hn
(BASE hb)
```

Where:

h1 … hn	The different floor heights in current length unit and **n** is the number of floor levels.
BASE *hb*	The base level with respect to which 1st story height will be calculated. If *hb* is not defined, the minimum Y-coordinate value present in the model will be taken as base level.

User-defined floor heights are used by lateral load generation for response spectrum analysis and soft story checking as per IS1893-2002 code.

See TR.32.12.2 Generation of Seismic Loads (on page 2598) for an example of the correct usage of this command.

Note: Floor height values *cannot* be used when the `FLOOR DIAPHRAGM` is used. Refer to TR.28.2 Floor Diaphragm (on page 2328) for details.

TR.31.2.11 IS:1893 (Part 1) 2016 Codes - Lateral Seismic Load

This feature enables one to generate seismic loads per the IS:1893 specifications using a static equivalent approach per Part 1 (2016) for building structures.

The seismic load generator can be used to generate lateral loads in the X and Z directions only. Y is the direction of gravity loads. This facility has not been developed for cases where the Z axis is set to be the vertical direction (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)).

General Format

```
DEFINE IS1893 2016 ( ACCIDENTAL ) LOAD
1893-2016-spec
wall-definitions
```

Refer to Wall Area Definitions (on page 2352) for information on defining walls.

```
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

where

```
1893-2016-spec =    ZONE f1 RF f2 I f3 { SS f4 | SA f11 } (ST f5) ( { DM f6 | DF f12 } ) (PX f7) (PZ f8) ( { DT f9 | GL f10 } ) (HT f13) (DX f14) (DZ f15)
```

ZONE *f1* Seismic zone factor. Refer to Table 3 (Clause 6.4.2) of IS:1893 (Part 1)-2016.

RF *f2* Response reduction factor. Refer Table 9 (Clause 7.2.6) of IS: 1893 (Part 1) -2016.

I *f3* Importance factor depending upon the functional use of the structures, characterized by hazardous consequences of its failure, post-earthquake functional needs, historical value, or economic importance. Refer Table 8 (Clause 7.2.3) of IS:1893 (Part 1)-2016.

SS *f4* Rock or soil sites factor. Depending on type of soil, average response acceleration coefficient S_a/g is calculated corresponding to 5% damping. Refer to Table 4 (Clause 6.4.2.1) of IS:1893 (Part 1) -2016.

1 = hard soil
2 = medium soil
3 = soft soil

Note: Use either `SS` *or*`SA` to specify site conditions. If both parameters are specified, `SS` is ignored.

ST *f5* Structure type of the seismic-resisting system. The program will calculate natural period as per Clause 7.6.2 of IS:1893(Part 1)-2016.

1 = RC moment-resisting frame building
2 = RC-Steel composite moment-resisting frame building
3 = Steel moment-resisting frame building
4 = Building with RC structural walls*
5 = All other buildings

Note: *ST 4 requires that wall data be entered in order to determine the natural period.

DM *f6* Damping ratio to obtain multiplying factor for calculating S_a/g for different damping. If no damping is specified 5% damping (default value 0.05) will be considered corresponding to which multiplying factor is 1.0. Refer to Clause 7.2.4 of IS:1893(Part 1)-2016.

Note: Use either `DM` *or*`DF` to specify damping. If both parameters are specified, `DM` is ignored.

This should be a value between 0 (zero) and 1.0, inclusive. For example, 7% damping should be specified as `0.07`.

PX *f7* Optional period of structure (in sec) in X direction. If this is defined this value will be used to calculate S_a/g for generation of seismic load along X direction.

PZ *f8* Optional period of structure (in sec) in Z direction. If this is defined this value will be used to calculate Sa/g for generation of seismic load along Z direction.

DT *f9* Depth of foundation below ground level. It should be defined in current units. If the depth of foundation is 30 m or more, the value of A_h is taken as half the value obtained. If the foundation is placed between the ground level and 30 m depth, this value is linearly interpolated between A_h and $0.5A_h$. Refer to Clause 6.4.5 of IS:1893(Part 1)-2016.

Note: Use either `DT` *or* `GL` to specify foundation depth. If both parameters are specified, `DT` is ignored. See Node d below.

GL *f10* Y coordinate of ground level (or global Z coordinate for `SET Z UP`). A reduced lateral force is applied to levels below this height, per Clause 6.4.5.

Note: Use either DT *or* GL to specify foundation depth. If both parameters are specified, DT is ignored. See Node d below.

SA *f11* Average response spectral acceleration coefficient corresponding to site specific spectra. Refer to Clause 6.4.7 of IS:1893(Part 1)-2016.

DF *f12* Multiplying factor for calculating S_a/g.

HT *f13* Height of the building. Refer Clause 7.6.2 (a) and Fig. 5 of IS 1893 2016

DX *f14* Base dimension of the building in X direction at the plinth level. Refer Clause 7.6.2(b) or (c)

DZ *f15* Base dimension of the building in Z direction at the plinth level. Refer Clause 7.6.2(b) or (c)

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Notes

a. If the ACCIDENTAL option is specified, the accidental torsion will be calculated per the IS 1893 specifications. The value of the accidental torsion is based on the center of mass for each level. The center of mass is calculated from the SELFWEIGHT, JOINT WEIGHT, and MEMBER WEIGHT commands you have specified.

The ACC option along with accidental eccentricity factor (generally 0.05 as per IS 1893 code) needs to be provided in the 1893 seismic primary load case (i.e., 1893 LOAD X / Z *f1* ACC *f3*). *f2* can be negative. See TR.32.12.2 Generation of Seismic Loads (on page 2598)

To consider horizontal torsion in cases where a floor diaphragm is present in the model, the ACCIDENTAL option should *not* be specified. Instead, dynamic eccentricity along with accidental eccentricity should be provided in the 1893 seismic primary load case (i.e., 1893 LOAD X / Z *f1* DEC *f2* ACC *f3*). For equivalent seismic analysis, *f2* is 1.5 and *f3* is 0.05 as per IS 1893 code. *f1* is always positive or zero, however *f2* can be negative. If *f2* is 0.0, only accidental torsion will be considered for this particular load case.

b. By default, STAAD.Pro calculates natural periods of the structure in both X and Z directions respectively which are used in calculation for base shear. If PX and PZ are included, the program will consider these values for calculation of average response acceleration coefficient. If ST is used instead of PX and PZ values, then the program will calculate natural period depending upon the empirical expression given in IS: 1893 (Part 1)-2016.

c. In the case where no rigid floor diaphragm is present, STAAD.Pro identifies columns and shear walls (without openings) as vertical components for the purpose of computing lateral stiffness of the story.

The lateral stiffness of a column is calculated as:

$$12EI / L^3$$

where

E	=	Young's modulus
I	=	moment of inertia
L	=	length of the column

The lateral stiffness for a shear wall (without opening) is calculated as:

$$\frac{1}{\frac{Ph^3}{12EI} + \frac{1.2Ph}{AG}}$$

Which is the summation of inverse of flexural stiffness and inverse of shear stiffness, obtained as deflection of a cantilever wall under a single lateral load, P, at its top.

where

h	=	height
A	=	cross-sectional area
G	=	shear modulus of the wall

The summation of lateral stiffnesses of all columns and shear walls at a particular floor level constitutes the total lateral stiffness of that particular story or floor level. The program checks for a soft story of a building along both global X and Z directions respectively. This computation is valid only for those structures whose floors are treated as rigid diaphragm

d. Clause 6.4.5 of IS:1893 part-I -2016 stipulates that for underground structures and foundation at a depth 30m or below, the design horizontal spectrum (A_h or A_k) value should be taken as half of the actual one for structures placed between ground level and 30 m depth the design horizontal acceleration spectrum must be interpolated between A_h and ($0.5\ A_h$). The reduction of A_h should be done on the potion of the structure (mass situated below GL) located below ground.

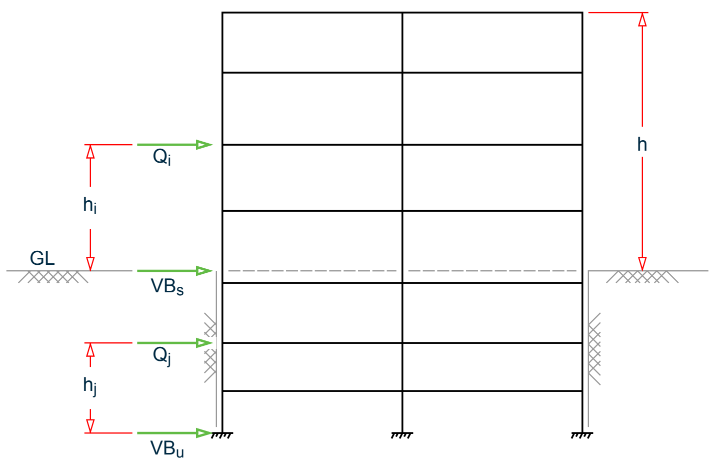

Figure 318: Base shear, VB, calculation above and below ground level, GL

You can provide DT *or* GL parameter to tell the program what your actual depth of foundation below the ground level.

Note: The parameter DT should not be used to reduce A_h. Only GL should be used.

The program will then evaluate the multiplication factor on A_h and calculate the base shear. This reduces the actual base shear for underground portion and the base shear, V_B is distributed into story shear of that portion (for static analysis).

- For the portion of the structure above the ground, the design lateral force at the i^th floor, Q_i:

$$Q_i = \left(\frac{W_i h_i^2}{\sum W_i h_i^2} \right) VB_S$$

where

W_i	=	seismic weight of ith floor above the ground
h_i	=	height of ith floor above the ground
VB_s	=	horizontal base shear = $A_h \cdot W_s$
W_s	=	seismic weight of the portion which is above the ground

- For the portion of the structure below the ground, the design lateral force at the jth floor, Q_j:

$$Q_j = \left(\frac{W_j h_j^2}{\sum W_j h_j^2} \right) VB_S$$

where

W_j	=	seismic weight of jth floor below the ground
h_j	=	height of jth floor below the ground
VB_u	=	horizontal base shear = $Ah_R \cdot W_u$
W_u	=	seismic weight of the portion which is below the ground

Example

```
DEFINE IS1893 2016 LOAD
ZONE 0.36 RF 5 I 1.2 SS 1 ST 1 DM 0.05
JOINT WEIGHT
39 60 80 WEIGHT 100
LOAD 1 LOADTYPE Seismic  TITLE SS_(+X)
1893 LOAD X 1
LOAD 2 LOADTYPE Seismic  TITLE SS_(+Z)
1893 LOAD Z 1
LOAD 3 LOADTYPE Seismic  TITLE SS_(+Y)
1893 LOAD Y 1
```

Methodology

The design base shear is computed by STAAD.Pro for building structures as per IS: 1893 (Part 1) 2016:

$$V = A_{h.}W$$

where

A_h	=	the design spectral acceleration based on Clause 6.4.2. This value is calculated for each mode.
		$= \frac{Z}{2}\frac{I}{R}\frac{S_a}{g}$
W	=	Seismic weight of the building which is determined from the loads. Iideally, this is defined in a reference load case of type Mass. Alternately, weights can be added in this definition.

Note: All symbols and notations in the above equation are as per IS: 1893(Part 1) 2016.

STAAD.Pro utilizes the following procedure to generate the lateral seismic loads:

1. You provide seismic zone coefficient and desired 1893 specs through the `DEFINE 1893 LOAD` command.
2. The program calculates the structure period, T.
3. The program calculates Sa/g utilizing T. For the Y direction, Sa/g = 2.5 per clause 6.4.6.
4. The program calculates V from the above equation. W is obtained from mass table data entered via `SELFWEIGHT`, `JOINT WEIGHT`(s), `MEMBER WEIGHT`(S), and/or `REFERENCE LOAD` you provide through the `DEFINE 1893 LOAD` command.
5. The total lateral seismic load (base shear) is then distributed by the program among different levels of the structure per the IS: 1893 procedures.

See TR.32.12 Generation of Loads (on page 2596) for additional information.

IS 1893 2016 Implementation

Note: STAAD.Pro can automatically comply with the reduced section property requirements of clause 6.4.3 for seismic loads with use of the `MEMBER CRACKED CODE IS1893 2016` command. Refer to TR.20.10 Member Property Reduction Factors (on page 2282) for details.

7.2 Lateral Force - The design spectral acceleration, A_h, is based on Clause 6.4.2. This value is calculated for each mode and is multiplied by the seismic weight at each degree of freedom.

- 7.2.2 - A minimum of lateral base shear which needs to be distributed to each floor (or each node of each floor) in a building is calculated per Table 7 and Clause 7.2.2. This is used to determine a minimum base shear value.
- 7.2.3 - An additional importance factor has been added.
- 7.2.4 - 5% damping should be used for all structures, regardless of the material. The program will accept other values in the `DM` parameter, but a warning will be issued in the output.
- 7.2.6 - The user interface includes a list of response reduction factors taken from Table 10 of IS 1893 2016.

7.6 Equivalent Static Method

- 7.6.2 - Calculation of the approximate time-period based on height of the building

  For point a, the time period is calculated as follows for reinforced-concrete and steel composite MRF builds: $T_a = 0.08^{0.75}$.
  For point b and point c, the time period is a function of the wall area. Therefore, the *`wall-data-pairs`* must provided to correctly calculate the time period for ST 4 or 5 (reinfroced concrete structural walls or all “other” buildings).

TR.31.2.12 IS:1893 (Part 4) 2015 Codes - Lateral Seismic Load

This feature enables one to generate seismic loads per the IS:1893 specifications using a static equivalent approach per Part 4 (2015) for industrial structures.

All industrial (plant and auxiliary) structures like main plants, process plants, water systems, and maintenance workshops are recognized as industrial structures.

The seismic load generator can be used to generate lateral loads in the X, Y, and Z directions. This facility has not been developed for cases where the Z axis is set to be the vertical direction (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)).

Note: This implementation is only applicable to industrial structures. It is *not* valid for stack-like structures.

General Format

```
DEFINE IS1893 2015 ( ACCIDENTAL )  LOAD PART4
```

```
1893-2015-P4-spec
```

```
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

where

```
1893-2015-P4-spec =    ZONE f1 RF f2 I f3 { SS f4 | SA f11 } (ST f5) ( { DM f6 | DF f12 } ) (PX f7) (PZ f8)
```

Note: The `ACCIDENTAL` option should only be used for `ST 4` structures.

ZONE *f1* Zone factor based on Table 14 (Clause 7.3.2) FOR 5% damping and Table 15 for Other damping Ratios.

RF *f2* Response Reduction factor. Refer Table 4 (Clause 8.6).

I *f3* Importance factor as per Table 3 (Clause 8.5).

SS *f4* Soil Type as per Annex B. (Clause 16) (Use if the `SA` parameter is not specified).

1 = Type I, rock or hard soil
2 = Type II, stiff soil
3 = Type III, soft soil

Note: Use either `SS` *or*`SA` to specify site conditions. If both parameters are specified, `SS` is ignored.

ST *f5* Structure Type as per Clause 8.1..

1 = Category 1, Failure can cause loss of life
2 = Category 2, Failure can lead to serious fire hazard
3 = Category 3, Failure will not be a serious hazard
4 = Category 4, All other structures

DM *f6* Damping ratio to obtain multiplying factor for calculating S_a/g for different damping. If no damping is specified 5% damping (default value 0.05) will be considered corresponding to which multiplying factor is 1.0. Damping is considered to be 5% for RC structures and 2% for Steel structures (Refer Table 2). Refer Clause 9.4 of IS:1893(Part 5) -2015.

Note: Use either `DM` *or*`DF` to specify damping. If both parameters are specified, `DM` is ignored.

This should be a value between 0 (zero) and 1.0, inclusive. For example, 7% damping should be specified as `0.07`.

PX *f7* Optional period of structure (in sec) in X direction. If this is defined this value will be used to calculate S_a/g for generation of seismic load along X direction.

PZ *f8* Optional period of structure (in sec) in Z direction. If this is defined this value will be used to calculate S_a/g for generation of seismic load along Z direction.

SA *f11* Average response spectral acceleration coefficient corresponding to site specific spectra. Refer to Clause 7.3. Use if SS is not specified.

DF *f12* Multiplying factor for calculating S_a/g.

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR.32.12.2 Generation of Seismic Loads (on page 2598).

Notes

a. If the `ACCIDENTAL` option is specified for an `ST 4` structure, the accidental torsion will be calculated per the IS 1893 specifications. The value of the accidental torsion is based on the center of mass for each level. The center of mass is calculated from the `SELFWEIGHT`, `JOINT WEIGHT`, and `MEMBER WEIGHT` commands you have specified. The `ACCIDENTAL` option is not applicable to other structure types.

The `ACCIDENTAL` option along with accidental eccentricity factor (generally 0.05 as per IS 1893 code) needs to be provided in the 1893 seismic primary load case (i.e., `1893 LOAD X / Z f1 ACC f3`). *f2* can be negative. See TR.32.12.2 Generation of Seismic Loads (on page 2598)

b. By default, STAAD.Pro calculates natural periods of the structure in both X and Z directions respectively which are used in calculation for seismic force at each node. If PX and PZ are included, the program will consider these values for calculation of average response acceleration coefficient. If ST is used instead of PX and PZ values, then the program will calculate natural period using the Rayleigh method.

Example

```
DEFINE IS1893 2015 LOAD PART4
ZONE 0.36 RF 5 I 1.25 SS 1 ST 1 DM 0.05
JOINT WEIGHT
39 60 80 WEIGHT 100
LOAD 1 LOADTYPE Seismic  TITLE SS_(+X)
1893 LOAD X 1
LOAD 2 LOADTYPE Seismic  TITLE SS_(+Z)
1893 LOAD Z 1
LOAD 3 LOADTYPE Seismic  TITLE SS_(+Y)
1893 LOAD Y 1
```

Methodology

The seismic force at each node is computed by STAAD.Pro for building structures as per IS: 1893 (Part 4) 2015:

$$V = A_h . W$$

where

A_h = the design seismic coefficient based on either clause 7.3.1 or 7.3.2. This value is calculated for each node.

For site-specific spectra, $A_h = {}^{S_a}/_{g} \times {}^{I}/_{R}$

For standard specific spectra, $A_h = {}^{Z}/_{2} \times {}^{I}/_{R} \times {}^{S_a}/_{g}$

W = Seismic weight of at each node.

Note: All symbols and notations in the above equation are as per IS: 1893(Part 1) 2016.

STAAD.Pro utilizes the following procedure to generate the lateral seismic loads:

1. You provide seismic zone coefficient and desired 1893 specs through the `DEFINE 1893 2015 LOAD PART4` command.
2. The program calculates the structure period, T using the Rayleigh method.
3. The program calculates S_a/g utilizing T.
4. Calculate Ah from section 7.3.
5. The program calculates V from the above equation at each node corresponding to the product of the seismic coefficient and mass at each node. W is obtained from mass table data entered via `SELFWEIGHT`, `JOINT WEIGHT`(s), `MEMBER WEIGHT`(S), and/or `REFERENCE LOAD` you provide through the `DEFINE 1893 2015 LOAD PART4` command.

See TR.32.12 Generation of Loads (on page 2596) for additional information.

TR.31.2.13 IBC 2000/2003 Load Definition

The specifications of the IBC 2000, and 2003 codes for seismic analysis of a building using a static equivalent approach have been implemented as described in this section. Depending on this definition, equivalent lateral loads will be generated in horizontal direction(s).

General Format

There are 2 stages of command specification for generating lateral loads. This is the first stage and is activated through the DEFINE IBC 2000 or 2003 LOAD command.

```
DEFINE IBC ( { 2000 | 2003 } ) (ACCIDENTAL) LOAD
 ibc-spec
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

```
ibc-spec = { SDS f1 SD1 f2 S1 f3 I  f4 RX f5 RZ f6 SCLASS f7 (CT f8) (PX f9) (PZ f10) }
```

SDS *f1*	Design spectral response acceleration at short periods. See equation 16-18, Section 1615.1.3 of IBC 2000 and equation 9.4.1.2.5-1 of ASCE7-02
SD1 *f2*	Design spectral response acceleration at 1-second period. See equation 16-19, Section 1615.1.3. of IBC 2000 and equation 9.4.1.2.5-2 of ASCE7-02
S1 *f3*	Mapped spectral acceleration for a 1-second period. See equation 16-17 of IBC 2000, and 9.4.1.2.4-2 of ASCE 7-02
I *f4*	Occupancy importance factor determined in accordance with Section 1616.2 of IBC 2000 and 2003, and section 9.1.4 (page 96) of ASCE 7-02
RX *f5*	The response modification factor for lateral load along the X direction. See Table 1617.6 of IBC 2000 (pages 365-368) and Table 1617.6.2 of IBC 2003 (page 334-337). It is used in equations 16-35, 16-36 & 16-38 of IBC 2000

RZ *f6* The response modification factor for lateral load along the Z direction. See Table 1617.6 of IBC 2000 (pages 365-368) and Table 1617.6.2 of IBC 2003 (page 334-337). It is used in equations 16-35, 16-36 & 16-38 of IBC 2000.

SCLASS *f7* Site class as defined in Section 1615.1.1 of IBC 2000 (page 350) & 2003 (page 322).

Table 250: Values of IBC soil class (SCLASS) used in STAAD

STAAD Value	IBC Value
1	A
2	B
3	C
4	D
5	E
6	F

CT *f8* Optional C_t value used to calculate time period, T_a. See section 1617.4.2.1, equation 16-39 of IBC 2000 and section 9.5.5.3.2, equation 9.5.5.3.2-1 of ASCE 7-02. If specified, it is your responsibility to provide the value in the correct system of units. Refer to Table 9.5.5.3.2 of AISC 7-02 for values.

If the value of C_t is not provided, then the program computes the average value of the modulus of elasticity of the model, $E_{avg} = \sum E / M$ (where M is the number of members) and uses this to determine the structure type:

i. $E_{avg} < 4{,}000\ ksi$, the program uses a C_t for a moment-resisting concrete frame.
ii. $E_{avg} > 10{,}000\ ksi$, the program uses a C_t for a moment-resisting steel frame.
iii. $4{,}000\ ksi \le E_{avg} \le 10{,}000\ ksi$, the program uses a C_t value for "all other structural systems".

Note: It is your responsibility to ensure that the structure type used actually matches the description for the automatically determined structure when C_t not specified. Refer to the IBC/ ASCE 7 code for detailed descriptions.

Table 9.5.5.3.2 of ASCE 7-02 also includes "Eccentrically braced steel frames". STAAD.Pro does not select this value automatically. For this structure type, you must specify C_t.

PX *f9* Optional Period of structure (in sec) in X-direction to be used as fundamental period of the structure instead of the value derived from section 1617.4.2 of IBC 2000, and section 9.5.5.3 of ASCE 7-02.

PZ *f10* Optional Period of structure (in sec) in Z or Y direction to be used as fundamental period of the structure instead of the value derived from section 1617.4.2 of IBC 2000, and section 9.5.5.3 of ASCE 7-02.

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

The seismic load generator can be used to generate lateral loads in the X & Z directions for Y up or X & Y for Z up. Y up or Z up is the vertical axis and the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)). All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.

The implementation details of the respective codes are as follows:

IBC 2000

On a broad basis, the rules described in section 1617.4 of the IBC 2000 code document have been implemented. These are described in pages 359 thru 362 of that document. The specific section numbers, those which are implemented, and those which are not implemented, are as follows:

Table 251: Sections of IBC 2000 implemented and omitted in the program

Implemented sections of IBC 2000	Omitted sections of IBC 2000
1617.4.1	1617.4.4.1
1617.4.1.1	1617.4.4.2
1617.4.2	1617.4.4.3
1617.4.2.1	1617.4.4.5
1617.4.3	1617.4.5
1617.4.4	1617.4.6
1617.4.4.4	

IBC 2003

On a broad basis, the rules described in section 1617.4 of the IBC 2003 code document have been implemented. This section directs the engineer to Section 9.5.5 of the ASCE 7 code. The specific section numbers of ASCE 7-2002, those which are implemented, and those which are not implemented, are shown in the table below. The associated pages of the ASCE 7-2002 code are 146 thru 149.

Table 252: Sections of IBC 2003 (ASCE 7-02) implemented and omitted in the program

Implemented sections of IBC 2003 (ASCE 7-02)	Omitted sections of IBC 2003 (ASCE 7-02)
9.5.5.2	9.5.5.5.1
9.5.5.2.1	9.5.5.5.2
9.5.5.3	9.5.5.6

9.5.5.3.2	
9.5.5.4	
9.5.5.5	
Portions of 9.5.5.5.2	

Methodology

The design base shear is computed in accordance with Eqn. 16-34 of IBC 2000 and Eqn. 9.5.5.2-1 of ASCE 7-02:

$$V = C_s W$$

The seismic response coefficient, C_s, is determined in accordance with Eqn. 16-35 of IBC 2000 / Eqn. 9.5.5.2.1-1 of ASCE 7-02:

$$C_s = \frac{S_{DS}}{R / I_E}$$

C_s need not exceed the limit given in Eqn. 16-36 of IBC 2000 / Eqn. 9.5.5.2.1-2 of ASCE 7-02:

$$C_s = \frac{S_{D1}}{(R / I_E)T}$$

C_s shall not be taken less than the lower limit given in Eqn. 16-37 of IBC 2000 / Eqn. 9.5.5.2.1-3 of ASCE 7-0:

$$C_s = 0.044\ S_{DS} I_E$$

In addition, for structures for which the 1-second spectral response, S_1, is equal to or greater than 0.6g, the value of the seismic response coefficient, C_s, shall not be taken less than the limit given in Eqn. 16-38 of IBC 2000 / Eqn. 9.5.5.2.1-4 of ASCE 7-02:

$$C_s = \frac{0.5 S_1}{R / I_E}$$

For an explanation of the terms used in the above equations, please refer to the relevant IBC and ASCE 7-02 codes.

Procedure Used by the Program

Steps used to calculate and distribute the base shear are as follows:

1. The Time Period of the structure is calculated based on section 1617.4.2 of IBC 2000, and section 9.5.5.3 of ASCE 7-02 (IBC 2003) This is reported in the output as T_a.
2. The period is also calculated in accordance with the Rayleigh method. This is reported in the output as T.
3. you may override the Rayleigh based period by specifying a value for `PX` or `PZ` depending on the direction of the IBC load.
4. The governing Time Period of the structure is then chosen between the above two periods, and the additional guidance provided in clause 1617.4.2 of IBC 2000, section 9.5.5.3 of ASCE 7-02 (IBC 2003) or section 12.8.2.1 of ASCE 7-05 (IBC 2006). The resulting value is reported as “Time Period used.”
5. The Design Base Shear is calculated based on equation 16-34 of IBC 2000, equation 9.5.5.2-1 of ASCE 7-02 (IBC 2003) or equation 12.8-1 of ASCE 7-05 (IBC 2006). It is then distributed at each floor using the rules of clause 1617.4.3, equations 16-41 and 16-42 of IBC 2000. For IBC 2003, using clause 9.5.5.4, equations 9.5.5.4-1 & 9.5.5.4-2 of ASCE 7-02.
6. If the `ACCIDENTAL` option is specified, the program calculates the additional torsional moment. The lever arm for calculating the torsional moment is obtained as 5% of the building dimension at each floor level perpendicular to the direction of the IBC load (clause 1617.4.4.4 of IBC 2000, and section 9.5.5.5.2 of ASCE 7-02 for IBC 2003). At each joint where a weight is located, the lateral seismic force acting at that joint is multiplied by this lever arm to obtain the torsional moment at that joint.

Example 1

```
DEFINE IBC 2003 LOAD
SDS 0.6 SD1 0.36 S1 0.31 I 1.0 RX 3 RZ 4 SCL 4 CT 0.032
SELFWEIGHT
JOINT WEIGHT
51 56 93 100 WEIGHT 1440
101 106 143 150 WEIGHT 1000
151 156 193 200 WEIGHT 720
```

Example 2

The following example shows the commands required to enable the program to generate the lateral loads. Refer to TR.32.12 Generation of Loads (on page 2596) for details.

```
LOAD 1 ( Seismic Load in X Direction )
IBC LOAD X 0.75
LOAD 2 ( Seismic Load in Z Direction )
IBC LOAD Z 0.75
```

The Examples manual contains examples illustrating load generation involving IBC and UBC load types.

TR.31.2.14 IBC 2006/2009 Seismic Load Definition

The specifications of the seismic loading chapters of the International Code Council 2006 & 2009 code and the ASCE 7-05 (including Supplement #2) code for seismic analysis of a building using a static equivalent approach are available in the program. Depending on the definition, equivalent lateral loads will be generated in the horizontal direction(s).

General Format

There are two stages of command specification for generating lateral loads. This is the first stage and is activated through the `DEFINE IBC 2006 LOAD` command.

```
DEFINE IBC 2006 (ACCIDENTAL) LOAD
```

```
map-spec ibc06-spec
```

```
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

map-spec = { ZIP f_1 | LAT f_2 LONG f_3 | SS f_4 S1 f_5 }

Where:

ZIP *f1* The zip code of the site location to determine the latitude and longitude and consequently the Ss and S1 factors. (ASCE 7-05 Chapter 22).

LAT ***f2*** The latitude and longitude, respectively, of the site used with the longitude to determine the Ss and S1 factors. (ASCE 7-05 Chapter 22).

LONG ***f3*** The latitude and longitude, respectively, of the site used with the longitude to determine the Ss and S1 factors. (ASCE 7-05 Chapter 22).

SS ***f4*** The mapped MCE for 0.2s spectral response acceleration. (IBC 2006/2009 Clause 1613.5.1, ASCE 7-05 Clause 11.4.1).

S1 ***f5*** The mapped MCE spectral response acceleration at a period of 1 second as determined in accordance with Section 11.4.1 ASCE7-05

```
ibc06-spec = { RX f6 RZ f7 I f8 TL f9 SCLASS f10 (CT f11) (PX f12) (PZ f13) (K f14) (FA f15) (FV f16) }
```

Where:

RX ***f6*** The response modification factor, R, for lateral load along the X direction, (ASCE Table 12.2.1). This is the value used for calculating C_s.

RZ ***f7*** The response modification factor, R, for lateral load along the Z direction, (ASCE Table 12.2.1) This is the value used for calculating C_s.

I ***f8*** Occupancy importance factor. (IBC 2006/2009 Clause 1604.5, ASCE 7-05 Table 11.5-1)

TL ***f9*** Long-Period transition period in seconds. (ASCE 7-05 Clause 11.4.5 and Chapter 22).

SCLASS ***f10*** Site class. Enter 1 through 6 in place of A through F, see table below. (IBC 2006/2009 Table 1613.5.2, ASCE 7-05 Section 20.3)

CTX ***f11*** Optional C_t value in X-direction to calculate time period. (ASCE 7-05 Table 12.8-2). If specified, it is your responsibility to provide the value in the correct system of units. Refer to AISC 7-05 for values.

If the value of C_t is not provided, then the program computes the average value of the modulus of elasticity of the model, $E_{avg} = \sum E / M$ (where M is the number of members) and uses this to determine the structure type:

i. E_{avg} < *4,000 ksi*, the program uses a C_t for a moment-resisting concrete frame.
ii. E_{avg} > *10,000 ksi*, the program uses a C_t for a moment-resisting steel frame.
iii. *4,000 ksi* ≤ E_{avg} ≤ *10,000 ksi*, the program uses a C_t value for "all other structural systems".

Note: It is your responsibility to ensure that the structure type used actually matches the description for the automatically determined structure when C_t not specified. Refer to the IBC/ ASCE 7 code for detailed descriptions.

ASCE 7-05 also includes "Eccentrically braced steel frames". STAAD.Pro does not select this value automatically. For this structure type, you must specify C_t.

CTZ ***f12*** Optional C_t value in Z-direction to calculate time period. (ASCE 7-05 Table 12.8-2). Refer to CTX for details.

PX ***f13*** Optional period of structure (in sec) in X-direction to be used as fundamental period of the structure. If not entered the value is calculated from the code. (ASCE 7-05 Table 12.8-2).

PZ ***f14*** Optional period of structure (in sec) in Z-direction to be used as fundamental period of the structure. If not entered the value is calculated from the code. (ASCE 7-05 Table 12.8-2).

XX *f15* Optional exponent value, x, in X-direction, used in equation 12.8-7, ASCE 7. (ASCE 7-05 table 12.8-2 p129). If the value of x is not provided, then the program computes the average value of the modulus of elasticity of the model to determine the structure type. Refer to CTX for details.

XZ *f16* Optional exponent value, x, in Z-direction, used in equation 12.8-7, ASCE 7. (ASCE 7-05 table 12.8-2 p129). If the value of x is not provided, then the program computes the average value of the modulus of elasticity of the model to determine the structure type. Refer to CTX for details.

FA *f17* Optional Short-Period site coefficient at 0.2s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2006/2009 Clause 1613.5.3, ASCE 7-05 Section 11.4.3).

FV *f18* Optional Long-Period site coefficient at 1.0s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2006/2009 Clause 1613.5.3, ASCE 7-05 Section 11.4.3).

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Implementation in STAAD.Pro

The seismic load generator can be used to generate lateral loads in the X & Z directions for Y up or X & Y for Z up. Y up or Z up is the vertical axis and the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)). All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.

The rules described in section 1613 of the ICC IBC-2006 code (except 1613.5.5) have been implemented. This section directs the engineer to the ASCE 7-2005 code. The specific section numbers of ASCE 7— those which are implemented, and those which are not implemented—are shown in the table below.

Table 253: Sections of IBC 2006 implemented and omitted in the program

Implemented sections of IBC 2006/2009 (ASCE 7-2005)	Omitted sections of IBC 2006/2009 (ASCE 7-2005)
11.4	12.8.4.1
11.5	12.8.4.3 and onwards
12.8	

Additionally, Supplement #2 of ASCE 7-05—as referenced by IBC 2009—specifies a different equation to be used for the lower bound of the seismic response coefficient, which has also been implemented.

Steps used to calculate and distribute the base shear are as follows:

1. The Time Period of the structure is calculated based on section 12.8.2.1 of ASCE 7-05 (IBC 2006/2009). This is reported in the output as T_a.
2. The period is also calculated in accordance with the Rayleigh method. This is reported in the output as T.
3. you may override the Rayleigh based period by specifying a value for PX or PZ (Items f7 and f8) depending on the direction of the IBC load.
4. The governing Time Period of the structure is then chosen between the above two periods, and the additional guidance provided in section 12.8.2 of ASCE 7-05 (IBC 2006). The resulting value is reported as “Time Period used” in the output file.

5. The Design Base Shear is calculated based on equation 12.8-1 of ASCE 7-05 (IBC 2006). It is then distributed at each floor using the rules of clause 12.83, equations 12.8-11, 12.8-12 and 12.8-13 of ASCE 7-05.
6. If the `ACCIDENTAL` option is specified, the program calculates the additional torsional moment. The lever arm for calculating the torsional moment is obtained as 5% of the building dimension at each floor level perpendicular to the direction of the IBC load (section 12.8.4.2 of ASCE 7-05 for IBC 2006). At each joint where a weight is located, the lateral seismic force acting at that joint is multiplied by this lever arm to obtain the torsional moment at that joint.
7. The amplification of accidental torsional moment, as described in Section 12.8.4.3 of the ASCE 7-05 code, is not implemented.
8. The story drift determination as explained in Section 12.8.6 of the ASCE 7-05 code is not implemented in STAAD.Pro.

Methodology

The design base shear is computed in accordance with the following equation (equation 12.8-1 of ASCE 7-05):

$$V = C_s W$$

The seismic response coefficient, C_s, is determined in accordance with the following equation (equation 12.8-2 of ASCE 7-05):

$$C_s = S_{DS}/[R/I_E]$$

For IBC 2006, C_s need not exceed the following limits defined in ASCE 7-05 (equations 12.8-3 and 12.8-4):

$C_s = S_{D1}/[T \cdot (R/I)]$ for $T \leq T_L$
$C_s = S_{D1} \cdot T_L/[T^2(R/I)]$ for $T > T_L$

However, C_s shall not be less than (equation 12.8-5 of ASCE 7-05, supplement #2):

$$C_s = 0.044 \cdot S_{DS} \cdot I \geq 0.01$$

In addition, per equation 12.8-6 of ASCE 7-05, for structures located where S_1 is equal to or greater than 0.6g, C_s shall not be less than

$$C_s = 0.5 \cdot S_1/(R/I)$$

For an explanation of the terms used in the above equations, please refer to the IBC 2006/2009 and ASCE 7-05 codes.

TR.31.2.15 IBC 2012 Seismic Load Definition

The specifications of the seismic loading chapters of the International Code Council 2012 code and the ASCE 7-10 code for seismic analysis of a building using a static equivalent approach have been implemented as described in this section. Depending on the definition, equivalent lateral loads will be generated in the horizontal direction(s).

General Format

Lateral loads generated by seismic loading are specified in two stages. The first is to define the IBC 2012 loading, as detailed here. The second is to include that specification in one or more load cases.

There are two stages of command specification for generating lateral loads. This is the first stage and is activated through the `DEFINE IBC 2012 LOAD` command.

```
DEFINE IBC 2012 (ACCIDENTAL) LOAD
map-spec ibc12-spec
(optional-weight-specs)
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

map-spec This identifies the mapped spectral accelerations at a given location by either ZIP (postal) code, latitude and longitude, or direct input. The ZIP code and latitude & longitude options are for use in mainland US only:

```
{ ZIP f1 | LAT f2 LONG f3 | SS f4 S1 f5 }
```

ibc12-spec This identifies the parameters needed to determine the lateral loading to be applied in a load case which references this definition.

```
{ RX f6 RZ f7 I f8 TL f9 SCLASS f10 (CTX f11) (CTZ f12) (PX f13) (PZ f14)
(XX f15) (XZ f16) (FA f17) (FV f18) }
```

The optional seismic weight option is provided for old files. It is recommended that instead the weights are defined using a one or more reference load cases of type `MASS`, (refer to TR.31.6 Defining Reference Load Types (on page 2453)). If the older format is used, refer to TR.31.2 Definitions for Static Force Procedures for Seismic Analysis (on page 2349) for the range of available weight commands that can be used.

The `ACCIDENTAL` option is used to include an additional torsional moment taken as the lateral load is applied at a horizontal eccentricity as 5% of the building dimension at each level. This option should *not* be used if the option to include the natural torsion in the application of seismic load (refer to TR.32.12.2 Generation of Seismic Loads (on page 2598) for additional details).

map-spec parameters:

ZIP *f1* The zip code of the site location to determine the latitude and longitude and consequently the Ss and S1 factors. (ASCE 7-10 Chapter 22).

LAT *f2* The latitude and longitude, respectively, of the site used with the longitude to determine the Ss and S1 factors. (ASCE 7-10 Chapter 22).

LONG *f3* The latitude and longitude, respectively, of the site used with the longitude to determine the Ss and S1 factors. (ASCE 7-10 Chapter 22).

SS *f4* The mapped MCE for 0.2s spectral response acceleration. (IBC 2012 Clause 1613.5.1, ASCE 7-10 Clause 11.4.1).

S1 *f5* The mapped MCE spectral response acceleration at a period of 1 second as determined in accordance with Section 11.4.1 ASCE7-10.

ibc12-spec parameters:

RX *f6* The response modification factor, R, for lateral load along the X direction, (ASCE 7-10 Table 12.2.1). This is the value used for calculating C_S.

RZ *f7* The response modification factor, R, for lateral load along the Z direction, (ASCE 7-10 Table 12.2.1) This is the value used for calculating C_S.

I *f8* Occupancy importance factor (IBC 2012 Clause 1604.5, ASCE 7-10 Table 11.5-1).

TL *f9* Long-Period transition period in seconds (ASCE 7-10 Clause 11.4.5 and Chapter 22).

SCLASS *f10* Site class. Enter 1 through 6 in place of A through F, see table below (IBC 2012 clause 1613.3.2, ASCE 7-10 Section 20.3)

CTX *f11* Optional C_t value in X-direction to calculate time period. (ASCE 7-10 Table 12.8-2). If specified, it is your responsibility to provide the value in the correct system of units. Refer to AISC 7-10 for values.

If the value of C_t is not provided, then the program computes the average value of the modulus of elasticity of the model, $E_{avg} = \sum E / M$ (where M is the number of members) and uses this to determine the structure type:

i. $E_{avg} < 4{,}000\ ksi$, the program uses a C_t for a moment-resisting concrete frame.
ii. $E_{avg} > 10{,}000\ ksi$, the program uses a C_t for a moment-resisting steel frame.
iii. $4{,}000\ ksi \le E_{avg} \le 10{,}000\ ksi$, the program uses a C_t value for “all other structural systems”.

Note: It is your responsibility to ensure that the structure type used actually matches the description for the automatically determined structure when C_t not specified. Refer to the IBC/ ASCE 7 code for detailed descriptions.

ASCE 7-10 also includes “Eccentrically braced steel frames”. STAAD.Pro does not select this value automatically. For this structure type, you must specify C_t.

CTZ *f12* Optional C_t value in Z-direction to calculate time period. (ASCE 7-10 Table 12.8-2).

Refer to CTX for details.

PX *f13* Optional period of structure (in sec) in X-direction to be used as fundamental period of the structure. If not entered the value is calculated from the code. (ASCE 7-10 Table 12.8-2).

PZ *f14* Optional period of structure (in sec) in Z-direction to be used as fundamental period of the structure. If not entered the value is calculated from the code. (ASCE 7-10 Table 12.8-2).

XX *f15* Optional exponent value, x, in X-direction, used in equation 12.8-7, ASCE 7. (ASCE 7-10 table 12.8-2). If the value of *x* is not provided, then the program computes the average value of the modulus of elasticity of the model to determine the structure type. Refer to CTX for details.

XZ *f16* Optional exponent value, x, in Z-direction, used in equation 12.8-7, ASCE 7. (ASCE 7-10 table 12.8-2). If the value of *x* is not provided, then the program computes the average value of the modulus of elasticity of the model to determine the structure type. Refer to CTX for details.

FA *f17* Optional Short-Period site coefficient at 0.2s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2012 Clause 1613.3.3, ASCE 7-10 Section 11.4.3).

FV *f18* Optional Long-Period site coefficient at 1.0s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2012 Clause 1613.3.3, ASCE 7-10 Section 11.4.3).

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Implementation in STAAD.Pro

Note: Refer to AD.2007-11.3.8 IBC 2012 / ASCE 7-10 Seismic Loads (on page 157) for additional information on using this feature.

The seismic load generator can be used to generate lateral loads in the X & Z directions for Y up or X & Y for Z up. Y up or Z up is the vertical axis and the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)). All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.

The rules described in section 1613 of the ICC IBC-2012 code (except 1613.5.5) have been implemented. This section directs the engineer to the ASCE 7-2010 code. The specific section numbers of ASCE 7 —those which are implemented, and those which are not implemented— are shown in the table below.

Table 254: Sections of IBC 2012 implemented and omitted in the program

Implemented sections of IBC 2012 (ASCE 7-10)	Omitted sections of IBC 2012 (ASCE 7-10)
11.4	12.8.4.1
11.5	12.8.4.3 and onwards
12.8	

Steps used to calculate and distribute the base shear are as follows:

1. The Time Period of the structure is calculated based on section 12.8.2.1 of ASCE 7-10 (IBC 2012). This is reported in the output as Ta.
2. The period is also calculated in accordance with the Rayleigh method. This is reported in the output as T.
3. You may override the Rayleigh based period by specifying a value for PX or PZ (Items f7 and f8) depending on the direction of the IBC load.
4. The governing Time Period of the structure is then chosen between the above two periods, and the additional guidance provided in section 12.8.2 of ASCE 7-10 (IBC 2012). The resulting value is reported as "Time Period used" in the output file.
5. The Design Base Shear is calculated based on equation 12.8-1 of ASCE 7-10 (IBC 2012). It is then distributed at each floor using the rules of clause 12.83, equations 12.8-11, 12.8-12 and 12.8-13 of ASCE 7-10.
6. If the `ACCIDENTAL` option is specified, the program calculates the additional torsional moment. The lever arm for calculating the torsional moment is obtained as 5% of the building dimension at each floor level perpendicular to the direction of the IBC load (section 12.8.4.2 of ASCE 7-10 for IBC 2012). At each joint where a weight is located, the lateral seismic force acting at that joint is multiplied by this lever arm to obtain the torsional moment at that joint.
7. The amplification of accidental torsional moment, as described in Section 12.8.4.3 of the ASCE 7-10 code, is not implemented.
8. The story drift determination as explained in Section 12.8.6 of the ASCE 7-10 code is not implemented in STAAD.

Methodology

The design base shear is computed in accordance with the following equation (equation 12.8-1 of ASCE 7-10):

$$V = C_s W$$

The seismic response coefficient, C_s, is determined in accordance with the following equation (equation 12.8-2 of ASCE 7-10):

$$C_s = S_{DS}/[R/I_E]$$

For IBC 2012, C_s need not exceed the following limits defined in ASCE 7-10 (equations 12.8-3 and 12.8-4):

$C_s = S_{D1}/[T \cdot (R/I)]$ for $T \le T_L$
$C_s = S_{D1} \cdot T_L/[T^2(R/I)]$ for $T > T_L$

However, C_s shall not be less than (equation 12.8-5 of ASCE 7-10):

$$C_s = 0.044 \cdot S_{DS} \cdot I \geq 0.01$$

In addition, per equation 12.8-6 of ASCE 7-10, for structures located where S_1 is equal to or greater than 0.6g, C_s shall not be less than

$$C_s = 0.5 \cdot S_1/(R/I)$$

For an explanation of the terms used in the above equations, please refer to the IBC 2012 and ASCE 7-10 codes.

TR.31.2.16 IBC 2015 Seismic Load Definition

The specifications of the seismic loading chapters of the International Code Council 2015 code and the ASCE 7-10 code for seismic analysis of a building using a static equivalent approach have been implemented as described in this section. Depending on the definition, equivalent lateral loads will be generated in the horizontal direction(s).

General Format

There are two stages of command specification for generating lateral loads. This is the first stage and is activated through the `DEFINE IBC 2015 LOAD` command.

```
DEFINE IBC 2015 (ACCIDENTAL) LOAD
map-spec  ibc15-spec
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

```
map-spec  = { ZIP f1 | LAT f2 LONG f3 | SS f4 S1 f5 }
```

Where:

ZIP *f1* The zip code of the site location to determine the latitude and longitude and consequently the Ss and S1 factors. (ASCE 7-10 Chapter 22).

LAT *f2* The latitude and longitude, respectively, of the site used with the longitude to determine the Ss and S1 factors. (ASCE 7-10 Chapter 22).

LONG *f3* The latitude and longitude, respectively, of the site used with the longitude to determine the Ss and S1 factors. (ASCE 7-10 Chapter 22).

SS *f4* The mapped MCE for 0.2s spectral response acceleration. (IBC 2015 Clause 1613.5.1, ASCE 7-10 Clause 11.4.1).

S1 *f5* The mapped MCE spectral response acceleration at a period of 1 second as determined in accordance with Section 11.4.1 ASCE7-10.

```
ibc15-spec  = { RX f6 RZ f7 I f8 TL f9 SCLASS f10 (CTX f11) (CTZ f12) (PX f13) (PZ
f14) (XX f15) (XZ f16) (FA f17) (FV f18) }
```

Where:

RX *f6* The response modification factor, R, for lateral load along the X direction, (ASCE 7-10 Table 12.2.1). This is the value used for calculating C_s.

RZ *f7* The response modification factor, R, for lateral load along the Z direction, (ASCE 7-10 Table 12.2.1) This is the value used for calculating C_s.

I *f8* Occupancy importance factor (IBC 2015 Clause 1604.5, ASCE 7-10 Table 11.5-1).

TL *f9* Long-Period transition period in seconds (ASCE 7-10 Clause 11.4.5 and Chapter 22).

SCLASS *f10* Site class. Enter 1 through 6 in place of A through F, see table below (IBC 2015 clause 1613.3.2, ASCE 7-10 Section 20.3)

CTX *f11* Optional CT value in X-direction to calculate time period. (ASCE 7-10 Table 12.8-2). If specified, it is your responsibility to provide the value in the correct system of units. Refer to AISC 7-10 for values.

If the value of C_t is not provided, then the program computes the average value of the modulus of elasticity of the model, $E_{avg} = \sum E / M$ (where M is the number of members) and uses this to determine the structure type:

i. $E_{avg} < 4{,}000\ ksi$, the program uses a C_t for a moment-resisting concrete frame.
ii. $E_{avg} > 10{,}000\ ksi$, the program uses a C_t for a moment-resisting steel frame.
iii. $4{,}000\ ksi \le E_{avg} \le 10{,}000\ ksi$, the program uses a C_t value for “all other structural systems”.

Note: It is your responsibility to ensure that the structure type used actually matches the description for the automatically determined structure when C_t not specified. Refer to the IBC/ ASCE 7 code for detailed descriptions.

ASCE 7-10 also includes “Eccentrically braced steel frames”. STAAD.Pro does not select this value automatically. For this structure type, you must specify C_t.

CTZ *f12* Optional CT value in Z-direction to calculate time period. (ASCE 7-10 Table 12.8-2).

Refer to CTX for details.

PX *f13* Optional period of structure (in sec) in X-direction to be used as fundamental period of the structure. If not entered the value is calculated from the code. (ASCE 7-10 Table 12.8-2).

PZ *f14* Optional period of structure (in sec) in Z-direction to be used as fundamental period of the structure. If not entered the value is calculated from the code. (ASCE 7-10 Table 12.8-2).

XX *f15* Optional exponent value, x, in X-direction, used in equation 12.8-7, ASCE 7. (ASCE 7-10 table 12.8-2). If the value of x is not provided, then the program computes the average value of the modulus of elasticity of the model to determine the structure type. Refer to CTX for details.

XZ *f16* Optional exponent value, x, in Z-direction, used in equation 12.8-7, ASCE 7. (ASCE 7-10 table 12.8-2). If the value of x is not provided, then the program computes the average value of the modulus of elasticity of the model to determine the structure type. Refer to CTX for details.

FA *f17* Optional Short-Period site coefficient at 0.2s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2015 Clause 1613.3.3, ASCE 7-10 Section 11.4.3).

FV *f18* Optional Long-Period site coefficient at 1.0s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2015 Clause 1613.3.3, ASCE 7-10 Section 11.4.3).

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Implementation and Methodology

Refer to TR.31.2.15 IBC 2012 Seismic Load Definition (on page 2409) for details on the implementation of the IBC 2015 / IBC 2012 / ASCE 7-10 static seismic method.

Example 1

TR.31.2.17 IBC 2018 Seismic Load Definition

The specifications of the seismic loading chapters of the International Code Council 2018 code and the ASCE 7-16 code for seismic analysis of a building using a static equivalent approach have been implemented as described in this section. Depending on the definition, equivalent lateral loads will be generated in the horizontal direction(s).

General Format

There are two stages of command specification for generating lateral loads. This is the first stage and is activated through the `DEFINE IBC 2018 LOAD` command.

```
DEFINE IBC 2018 (ACCIDENTAL) LOAD
```

```
map-spec  ibc18-spec
```

```
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

```
map-spec  = { ZIP f1 | LAT f2 LONG f3 | SS f4 S1 f5 }
```

Where:

ZIP *f1* The zip code of the site location to determine the latitude and longitude and consequently the Ss and S1 factors. (ASCE 7-16 Chapter 22).

LAT *f2* The latitude of the site used to determine the Ss and S1 factors. (ASCE 7-16 Chapter 22).

LONG *f3* The longitude of the site used to determine the Ss and S1 factors. (ASCE 7-16 Chapter 22).

SS *f4* The mapped MCE for 0.2s spectral response acceleration. (ASCE 7-16 Clause 11.4.2).

S1 *f5* The mapped MCE spectral response acceleration at a period of 1 second as determined in accordance with Section 11.4.2 ASCE7-16.

Note: The mapped spectral response acceleration values for IBC 2018 are retrieved from dynamic data provided by the USGS when `ZIP` code or `LAT`/`LONG` methods are used. An internet connection is required for this. If an internet connection is not available, then the values should be input using the `SS` and `S1` parameters.

```
ibc18-spec  = { RX f6 RZ f7 I f8 TL f9 SCLASS f10 (CTX f11) (CTZ f12) (PX f13) (PZ
f14) (XX f15) (XZ f16) (FA f17) (FV f18) }
```

Where:

RX *f6* The response modification factor, R, for lateral load along the X direction, (ASCE Table 12.2.1). This is the value used for calculating C_S.

RZ *f7* The response modification factor, R, for lateral load along the Z direction, (ASCE Table 12.2.1) This is the value used for calculating C_S.

I *f8* Occupancy importance factor. (IBC 2018 Clause 1604.5, ASCE 7-16 Table 11.5-1)

TL *f9* Long-Period transition period in seconds. (ASCE 7-16 Clause 11.4.5 and Chapter 22).

SCLASS *f10* Site class. Enter 1 through 6 in place of A through F, see table below. (IBC 2018 clause 1613.3.2, ASCE 7-16 Section 20.3)

CTX *f11* Optional CT value in X-direction to calculate time period. (ASCE 7-16 Table 12.8-2). If specified, it is your responsibility to provide the value in the correct system of units. Refer to AISC 7-16 for values.

If the value of C_t is not provided, then the program computes the average value of the modulus of elasticity of the model, $E_{avg} = \sum E / M$ (where M is the number of members) and uses this to determine the structure type:

i. $E_{avg} < 4{,}000\ ksi$, the program uses a C_t for a moment-resisting concrete frame.
ii. $E_{avg} > 10{,}000\ ksi$, the program uses a C_t for a moment-resisting steel frame.
iii. $4{,}000\ ksi \le E_{avg} \le 10{,}000\ ksi$, the program uses a C_t value for “all other structural systems”.

Note: It is your responsibility to ensure that the structure type used actually matches the description for the automatically determined structure when C_t not specified. Refer to the IBC/ ASCE 7 code for detailed descriptions.

ASCE 7-16 also includes “Eccentrically braced steel frames”. STAAD.Pro does not select this value automatically. For this structure type, you must specify C_t.

CTZ *f12* Optional CT value in Z-direction to calculate time period. (ASCE 7-16 Table 12.8-2).

Refer to CTX for details.

PX *f13* Optional period of structure (in sec) in X-direction to be used as fundamental period of the structure. If not entered the value is calculated from the code. (ASCE 7-15 Table 12.8-2).

PZ *f14* Optional period of structure (in sec) in Z-direction to be used as fundamental period of the structure. If not entered the value is calculated from the code. (ASCE 7-16 Table 12.8-2).

XX *f15* Optional exponent value, x, in X-direction, used in equation 12.8-7, ASCE 7. (ASCE 7-16 table 12.8-2). If the value of x is not provided, then the program computes the average value of the modulus of elasticity of the model to determine the structure type. Refer to CTX for details.

XZ *f16* Optional exponent value, x, in Z-direction, used in equation 12.8-7, ASCE 7. (ASCE 7-16 table 12.8-2). If the value of x is not provided, then the program computes the average value of the modulus of elasticity of the model to determine the structure type. Refer to CTX for details.

FA *f17* Optional Short-Period site coefficient at 0.2s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2018 Clause 1613.3.3, ASCE 7-16 Section 11.4.3).

FV *f18* Optional Long-Period site coefficient at 1.0s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2018 Clause 1613.3.3, ASCE 7-16 Section 11.4.3).

Implementation and Methodology

Refer to TR.31.2.15 IBC 2012 Seismic Load Definition (on page 2409) for details on the implementation of the IBC 2018 / IBC 2015 / IBC 2012 / ASCE 7-16 / ASCE 7-10 static seismic method.

Note: Exceptions 1 and 2 in Clause 11.4.8 of ASCE 7-16 are implemented.

In exception 1, for Site class E and $S_s > 0.75$, Fa value is taking the same for site class C. In this case, there is slight reduction in the seismic force generated.

In exception 2, for site class D, and $S_1 > 0.1$, the program checks if the time period, $T > 1.5T_s$. If that is the case then C_s value is taken as $1.5 \times C_s$ obtained from eqn. 12.8-3 or 12.8-4 (based on the time period). In this case the seismic force increases. In this case but when $T \leq 1.5T_s$, Cs as calculated by eqn 12.8-2 is used.

Example 1

```
DEFINE IBC 2018
LAT 38.0165 LONG -122.105 I 1.25 RX 2.5 RZ 2.5 SCLASS 4 -
TL 12 FA 1 FV 1.5
SELFWEIGHT
JOINT WEIGHT
51 56 93 100 WEIGHT 650
MEMBER WEIGHT
151 TO 156 158 159 222 TO 225 324 TO 331 UNI 45
```

Example 2

The following example shows the commands required to enable the program to generate the lateral loads. Refer to TR.32.12 Generation of Loads (on page 2596) for this information.

```
LOAD 1 (SEISMIC LOAD IN X DIRECTION)
IBC LOAD X 0.75
LOAD 2 (SEISMIC LOAD IN Z DIRECTION)
IBC LOAD Z 0.75
```

TR.31.2.18 Japanese Seismic Load

The purpose of this command is to define and generate static equivalent seismic loads as per Japanese specifications using a static equivalent approach similar to those outlined by UBC. Depending on this definition, equivalent lateral loads will be generated in horizontal direction(s). The implementation is as per Article 88 in the “Building Codes Enforcement Ordinance 2006”.

General Format

```
DEFINE  AIJ (ACCIDENTAL) LOAD
```

```
AIJ-spec
```

```
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

```
AIJ-spec
 = { ZONE f1 CO f2 TC f3 ALPHA f4 }
```

where:

ZONE *f1*	Zone factor (0.7, 0.8, 0.9 or 1.0)
CO *f2*	Normal coefficient of shear force (0.2 or 1.0)
TC *f3*	Period defined by ground support specification (0.4, 0.6 or 0.8 sec)
ALPHA *f4*	Ratio of steel height to overall building height, which are used in the calculation of Rt.

Generation of AIJ Seismic Load

General format to provide Japanese Seismic load in a primary load case:

```
LOAD i
```

```
AIJ LOAD {X | Y | Z} (f5) (ACC f6)
```

Where:

LOAD *i*	load case number
AIJ LOAD { X | Y | Z } *f5*	optional factor to multiply horizontal seismic load.
ACC *f6*	multiplying factor for Accidental Torsion, to be used to multiply the AIJ accidental torsion load (default = 1.0). May be negative (otherwise, the default sign for MY is used based on the direction of the generated lateral forces). **Note:** Choose horizontal directions only.

If the `ACCIDENTAL` option is specified, the accidental torsion will be calculated per the AIJ specifications. The value of the accidental torsion is based on the "center of mass" for each level. The "center of mass" is calculated from the SELFWEIGHT, JOINT WEIGHTs and MEMBER WEIGHTs you have specified

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

The seismic load generator can be used to generate lateral loads in the X & Z directions for Y up or X & Y for Z up. Y up or Z up is the vertical axis and the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)). All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.

Methodology

Seismic zone coefficient and parameter values are supplied by the user through the `DEFINE AIJ LOAD` command.

Program calculates the natural period of building *T* utilizing the following equation:

$$T = h(0.02 + 0.01\alpha)$$

where

h	=	height of building (m)
a	=	Alpha, ratio of steel height for overall height

Design spectral coefficient, R_t, is calculated utilizing T and T_c as follows:

$$R_t = \begin{cases} 1.0 \text{ when } T < T_c \\ 1 - 0.2(T / T_c - 1)^2 \text{ when } T_c \le T \le 2T_c \\ 1.6T_c / T \text{ when } 2T_c < T \end{cases}$$

where

T_c = Period defined by ground support specification for Rt.

a_i is calculated from the weight values provided in the Define AIJ Load command.

$$\alpha_i = W_i / W$$

where

W_i = sum of weight from a top to floor i.
W = all weight

The seismic coefficient of floor, C_i, is calculated using:

$$C_i = Z R_t A_i C_o$$

where

Z = zone factor
C_o = normal coefficient of shear force

$$A_i = 1 + \frac{2T\left(1/\sqrt{a_i} - a_i\right)}{1 + 3T}$$

Seismic load shear force, Q_i, of each floor is calculated by C_i and W_i:

$$Q_i = C_i W_i$$

where

W_i = sum of weight from a top to i floor

Load value of each floor Pi is calculated by seismic load shear force Qi.

$$P_i = Q_i - Q_{i+1}$$

The total lateral seismic load is distributed by the program among different levels.

Example

```
DEFINE AIJ LOAD
ZONE 0.8 CO 0.2 TC 0.6 ALPHA 1.0
JOINT WEIGHT
51 56 93 100 WEIGHT 1440
101 106 143 150 WEIGHT 1000
151 156 193 200 WEIGHT 720
LOAD 1 ( SEISMIC LOAD IN X)
AIJ LOAD X
```

TR.31.2.19 CFE (Comisión Federal De Electricidad) Seismic Load

The purpose of this command is to define and generate static equivalent seismic loads as per Manuel de Diseño por Sismo - Seismic Design Handbook Comisión Federal De Electricidad - Electric Power Federal Comission - October 1993 (Chapters 3.1, 3.2, 3.3 and 3.4) specifications. Depending on this definition, equivalent lateral loads will be generated in horizontal direction(s). This is a code used in the country of Mexico.

The seismic load generator can be used to generate lateral loads in the X & Z directions for Y up or X & Y for Z up. Y up or Z up is the vertical axis and the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)). All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.

General Format

```
DEFINE CFE (ACCIDENTAL) LOAD
```

```
cfe-spec
```

```
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

```
cfe-spec = { ZONE f1 QX f2 QZ f3 GROUP f4 STYP f5 (REGULAR) (TS f6) (PX f7) (PZ f8) }
```

ZONE *f1*	Zone number specified in number such as 1, 2, 3 or 4
QX *f2*	seismic behavior factor of the structure along X direction as a parameter according 3.2.4.
QZ *f3*	seismic behavior factor of the structure along Z direction as a parameter according 3.2.4.
GROUP *f4*	Group of structure entered as A or B
STYPE *f5*	Soil type entered as 1 or 2 or 3
TS *f6*	site characteristic period
PX *f7*	Optional Period of structure (in sec) in X-direction to be used as fundamental period of the structure instead of the value calculated by the program using Rayleigh-Quotient method
PZ *f8*	Optional Period of structure (in sec) in Z direction (or Y if SET Z UP is used) to be used as fundamental period of the structure instead of the value calculated by the program using Rayleigh-Quotient method

The optional parameter `REGULAR` is entered to consider the structure as a regular structure. By default, all structures are considered as irregular.

Generation of CFE Seismic Load

To provide a CFE Seismic load in any load case:

```
LOAD i
```

```
CFE LOAD {X | Y | Z} (f)
```

Where:

LOAD *i*	load case number
CFE LOAD { X | Y | Z | *f*	factor to multiply horizontal seismic load. Choose horizontal directions only

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Methodology

Seismic zone coefficient and parameter values are supplied by the user through the `DEFINE CFE LOAD` command.

Program calculates the natural period of building T utilizing Rayleigh-Quotient method. If time period is provided in the input file, that is used in stead of calculated period.

The acceleration a is calculated according to the following:

$$a = \begin{cases} a_0 + \left(c - a_0\right)\frac{T}{T_a} \text{when} T < T_a \\ c \text{when} T_a \le T \le T_b \\ c\left(T_b / T\right)^r \text{when} T_b < T \end{cases}$$

Where:

c = Seismic coefficient is extracted from table 3.1
a_0, T_a, T_b, and r are obtained form table 3.1

The ductility reduction factor Q' is calculated according to section 3.2.5.

$$Q' = \begin{cases} Q \text{when} T \ge T_a \\ 1 + \left(\frac{T}{T_a}\right)\left(Q - 1\right) \text{when} T < T_a \end{cases}$$

If not regular, then $Q' = Q' x\ 0.8$

If the period T_s of the soil is known and the soil type II or III T_a and T_b will be modified according to section 3.3.2.

Lateral loads for each direction are calculated for:

When $T \le T_b$, Eq. 4.5. Section 3.4.4.2 is used:

$$P_n = W_n h_n \frac{\sum_{n=1}^{N}\left(W_n\right)a}{\sum_{n=1}^{N}\left(W_n h_n\right)Q'}$$

When $T > T_b$, Eq. 4.6/7/8. Section 3.4.4.2 is used:

$$P_n = W_n\left(a / Q\right)\left(K_1 h_i + K_2 h_i^2\right)$$

Where:

$$K_1 = \frac{q\left[1 - r\left(1 - q\right)\right]\Sigma W_i}{\Sigma\left(W_i / h_i\right)}$$

$$K_2 = \frac{1.5rq\left(1 - q\right)\Sigma W_i}{\Sigma\left(W_i / h_i^2\right)}$$

q =

The base shear are distributed proportionally to the height if $T \le T_b$ or with the quadratic equation mentioned if $T > T_b$.

The distributed base shears are subsequently applied as lateral loads on the structure.

Example

```
UNIT KGS METER
DEFINE CFE LOAD
ZONE 2 QX .5 QZ 0.9 STYP 2 GROUP B TS 0.2

- *G.16.2 Seismic Load Generator* (on page 2135)

TR.31.2.20 NTC (Normas Técnicas Complementarias) Seismic Load

The purpose of this command is to define and generate static equivalent seismic loads as per Code of the México Federal District (Reglamento de Construcciones del Distrito Federal de México) and Complementary Technical Standards for Seismic Design (y Normas Técnicas Complementarias (NTC) para Diseño por Sismo -Nov. 1987) (Chapters 8.1 8.2 8.6 and 8.8) specifications. Depending on this definition, equivalent lateral loads will be generated in horizontal direction(s).

The seismic load generator can be used to generate lateral loads in the X & Z directions for Y up or X & Y for Z up. Y up or Z up is the vertical axis and the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)). All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.

General Format

```
DEFINE NTC LOAD
```

`ntc-spec`

`weight-data`

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

```
ntc-spec = { ZONE f1 QX f2 QZ f3 GROUP f4 (SHADOWED) (REGULAR) (REDUCE) (PX f5) (PZ f6) }
```

where:

ZONE *f1*	Zone number specified in number such as 1, 2, 3 or 4
QX *f2*	seismic behavior factor of the structure along X direction as a parameter according 3.2.4.

QZ *f3* seismic behavior factor of the structure along Z direction as a parameter according 3.2.4.

GROUP *f4* Group of structure entered as A or B

PX *f5* Optional Period of structure (in sec) in X-direction to be used as fundamental period of the structure instead of the value calculated by the program using Rayleigh-Quotient method

PZ *f6* Optional Period of structure (in sec) in Z-direction to be used as fundamental period of the structure instead of the value calculated by the program using Rayleigh-Quotient method

`REGULAR` is an optional parameter which is entered to consider the structure as a regular structure. By default, all structures are considered as irregular.

`SHADOWED` is an optional parameter which is used to define the shaded zone II as the site of the structure. By default regular zone II is used.

`REDUCE` is an optional parameter which allows to reduce the seismic factors as described above. Otherwise the following formula is used to calculate base shear, $V = \frac{c}{Q'} \sum_{n=1}^{N} W_n$

Generation of NTC Seismic Load

To provide NTC Seismic load in any load case:

```
LOAD i
```

```
NTC LOAD {X/Y/Z} (f)
```

where:

LOAD *i*	load case number
NTC LOAD { X | Y | Z } *f*	factor to multiply horizontal seismic load

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Methodology

The design base shear is computed in accordance with Sections 8.1 or 8.2 of the NTC as decided by the user.

A. Base Shear is given as

$$V_o / W_o = c / Q$$

where

c = Seismic Coefficient, which is obtained by the program from the following table

Table 255: Seismic coefficient per NTC

Seismic Coefficient, c	Group A	Group B
I	0.24	0.16
II not shaded	0.48	0.32

Seismic Coefficient, c	Group A	Group B
III (and II where shaded)	0.60	0.40

Q = is entered by the user as a parameter

B. Base shear is given as

Vo / Wo = a / Q'

Where Reduction of Shear Forces are requested

Time Period T of the structure is:calculated by the program based on using Rayleigh quotient technique.

you may override the period that the program calculates by specifying these in the input

a and Q' are calculated according to the sections 3 and 4 of the NTC, that is to say:

$$a = \begin{array}{l} \left(1 + 3\frac{T}{T_a}\right)\frac{c}{4} \text{when} T < T_a \\ c \text{when} T_a \le T \le T_b \\ q \cdot c \text{when} T_b < T \end{array}$$

Where:

$q = (T_b/T)^r$

$$Q' = \begin{array}{l} Q \text{when} T \ge T_a \\ 1 + \left(\frac{T}{T_a}\right)\left(Q - 1\right) \text{when} T < T_a \end{array}$$

If not regular, then $Q' = Q' \times 0.8$

T_a, T_b and r are taken from table 5-13 (Table 3.1 in the NTC).

Table 256: Values of T_a, T_b and r per NTC

Zone	T_a	T_b	r
I	0.2	0.6	1/2
II not shaded	0.3	1.5	2/3
III (and II where shaded)	0.6	3.9	1.0

a shall not be less than c/4

V_o for each direction is calculated:

$$V_o = \begin{array}{l} W_o a / Q' \text{when} T \le T_b \\ \frac{\Sigma W_i a}{Q'\left(K_1 h_i + K_2 h_i^2\right)} \text{when} T > T_b \end{array}$$

Where:

$$K_1 = \frac{q\left[1 - r\left(1 - q\right)\right]\Sigma W_i}{\Sigma\left(W_i / h_i\right)}$$

$$K_2 = \frac{1.5rq\left(1 - q\right)\Sigma W_i}{\Sigma\left(W_i / h_i^2\right)}$$

W_i and h_i the weight and the height of the i^{th} mass over the soil or embedment level.

The base shear are distributed proportionally to the height if $T \le T_b$ or with the quadratic equation mentioned if $T > T_b$. The distributed base shears are subsequently applied as lateral loads on the structure.

Example

```
UNIT KGS METER
DEFINE NTC LOAD
ZONE 2 QX .5 QZ 0.9 GROUP B
SELFWEIGHT
ELEMENT  WEIGHT
1577 TO 1619 PRESSURE 275
LOAD 1 ( SEISMIC LOAD IN X DIRECTION )
NTC  LOAD  X 1.0
LOAD 2 ( SEISMIC LOAD IN Z DIRECTION )
NTC  LOAD  Z 1.0
```

TR.31.2.21 Turkish Seismic Code

This set of commands may be used to define the parameters for generation of equivalent static lateral loads for seismic analysis per the specifications laid out in *Specification for Structures to be Built in Disaster Areas Part – III – Earthquake Disaster Prevention* Amended on 2.7.1998, Official Gazette No. 23390 (English Translation). This is referred to as the Turkish Seismic Provisions.

The seismic load generator can be used to generate lateral loads in the X & Z directions for Y up or X & Y for Z up. Y up or Z up is the vertical axis and the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)). All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.

General Format

STAAD utilizes the following format to generate the lateral seismic loads.

```
DEFINE TURKISH LOAD
```

```
tur-spec
```

```
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

```
tur-spec = { A f1 TA f2 TB f3 I f4 RX f5 RZ f6 (CT f7) (PX f8) (PZ f9) }
```

A *f1*	Effective Ground Acceleration Coefficient, Ao. Refer table 6.2

TA *f2*	Spectrum Characteristic Periods, TA and TB. These are user input and found in Table 6.4
TB *f3*	Spectrum Characteristic Periods, TA and TB. These are user input and found in Table 6.4
I *f4*	the earthquake importance factor of the structure.
RX *f5*	Structural Behavior Factors (R) along X and Z directions respectively. These are user input and please refer Table 6.5
RZ *f6*	Structural Behavior Factors (R) along X and Z directions respectively. These are user input and please refer Table 6.5
CT *f7*	Optional CT value to calculate time period. See section 1617.4.2.1, equation 16-39 of IBC 2000 and section 9.5.5.3.2, equation 9.5.5.3.2-1 of ASCE 7-02.
PX *f8*	Optional Period of structure (in sec) in X-direction to be used as fundamental period of the structure instead of the value derived from section 1617.4.2 of IBC 2000, and section 9.5.5.3 of ASCE 7-02.
PZ *f9*	Optional Period of structure (in sec) in Z-direction to be used as fundamental period of the structure instead of the value derived from section 1617.4.2 of IBC 2000, and section 9.5.5.3 of ASCE 7-02.
WEIGHT *w*	joint weight associated with list
UNI *v1 v2 v3*	Used when specifying a uniformly distributed load with a value of *v1* starting at a distance of *v2* from the start of the member and ending at a distance of *v3* from the start of the member. If *v2* and *v3* are omitted, the load is assumed to cover the entire length of the member.
CON *v4 v5*	Used when specifying a concentrated force with a value of *v4* applied at a distance of *v5* from the start of the member. If *v5* is omitted, the load is assumed to act at the center of the member.
PRESSURE *p1*	weight per unit area for the plates selected. Assumed to be uniform over the entire plate.

Element Weight is used if plate elements are part of the model, and uniform pressures on the plates are to be considered in weight calculation.

Floor Weight is used if the pressure is on a region bounded by beams, but the entity which constitutes the region, such as a slab, is not defined as part of the structural model. It is used in the same sort of situation in which one uses FLOOR LOADS (See TR.32.4.3 Floor Load Specification (on page 2483) for details).

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR.32.12.2 Generation of Seismic Loads (on page 2598).

Base Shear

The minimum lateral seismic force or base shear, V_t, is automatically calculated per equation 6.4 in section 6.7.1:

$$V_t = \frac{WA(T_1)}{R_a(T_1)}$$

where

T_1 = the fundamental time period of the structure

Except that V_t shall not be less than:

$$V_{t,\min} = 0.10 A_0 I W$$

Seismic Load Reduction Factor, R_a (T_1), in above equation is determined based on the following equations 6.3a and 6.3b in the code:

$$R_a(T_1) = \begin{cases} 1.5 + (R - 1.5)\dfrac{T_1}{T_a} \text{when} 0 \le T_1 \le T_a \\ R \text{when} T_1 > T_a \end{cases}$$

The Structural Behavior Factor in either direction, RX and RZ, are provided through user input (variables *f5* and *f5*) along the direction of calculation. Spectrum Characteristics Period, TA and TB, are also provided by user through the parameters (variables *f2* and *f3*).

where

R_a = the Structural Behavior Factor in either direction, RX and RZ, are provided through user input (variables *f5* and *f5*) along the direction of calculation

T_a, T_b = the Spectrum Characteristics Period are provided by user through the parameters (variables *f2* and *f3*)

T_1 = the fundamental Lateral period in the direction under consideration and is determined as:

a. Calculated by the empirical formulae as described below provided hn is in meter:

$$T_1 = C_T \, [hn]^{3/4}$$

Where C_T is assumed to be 0.075 for steel moment frames, 0.085 for concrete moment frames, or any user specified value.

b. The period is also calculated in accordance with the Rayleigh method but could be overridden by user specified time period (PX, PZ).

The time period calculated based on method (a) is used in further calculation unless it is greater than 1.0 sec and 1.3 times of this is greater than the same calculated based on method (b). In that case time period calculated based on method (b) is used.

$A(T_1)$ = the Spectral Acceleration Coefficient is determined as follows as per eq. 6.1,

$A(T_1) = Ao \, I \, S(T_1)$

A_o and I = in above equation are Effective Ground Acceleration Coefficient and Building Importance Factor are provided by the user through the load definition parameter and could be found in table 6.2 and 6.3 respectively in the code

$S(T_1)$ = the Spectrum Coefficient is found by following equations, could be found in eq. 6.2a, 6.2b and 6.3c in original code

$$S(T_1) = \begin{cases} 1 + 1.5\dfrac{T_1}{T_A} \text{when} 0 \le T < T_A \\ 2.5 \text{when} T_A \le T \le T_B \\ 2.5\left(\dfrac{T_B}{T_1}\right)^{0.8} \text{when} T_B < T \end{cases}$$

W = the weight of the building and shall be calculated internally using the following formula:

$$W = \sum_{i=1}^{n} W_i$$

W_i	=	the portion of W that is located at or assigned to level i

Vertical Distribution

As per 4.1.8.11(6), the total lateral seismic force, Vt, shall be distributed such that a portion, Ft shall be concentrated at the top of the building, where,

$$\Delta F_N = 0.07\, T_1\, V_t$$

but ΔF_N is not greater than $0.20 V_t$
and $\Delta F_N = 0$ when $H_N \le 25$ m.

The remainder (V- ΔF_N), shall be distributed along the height of the building, including the top level, in accordance with the following formula (per equation 6.9:

$$Fi = (Vt - \Delta FN)\ wi\ Hi / \Sigma\ wj\ Hj$$

where

F_i	=	the lateral force applied to level i
ΔF_N	=	the portion of Vt to be concentrated at the top of the structure
Wi, Wj	=	the portion of W that is located at or assigned to level i or j respectively
i	=	level i is any level in the building, i = 1 for first level above the base.
N	=	level N is uppermost in the main portion of the structure

Example

```
DEFINE TUR LOAD

TR.31.2.22 UBC 1994 or 1985 Load Definition

This set of commands may be used to define the parameters for generation of UBC-type equivalent static lateral loads for seismic analysis. Depending on this definition, equivalent lateral loads will be generated in horizontal direction(s).

General Format

```
DEFINE UBC (ACCIDENTAL) LOAD
{ ubc-1994-spec | ubc-1985-spec }
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Where:

```
ubc-1994-spec  = { ZONE f1 I f2 RWX f3 RWZ f4 S f5 (CT f8) (PX f9) (PZ f10) }
```

```
ubc-1985-spec = { ZONE f1 K f6 I f2 (TS f7) }
```

Where:

ZONE *f1*	The seismic zone coefficient (0.2, 0.3 etc.). Instead of using an integer value like 1, 2, 3 or 4, use the fractional value like 0.075, 0.15, 0.2, 0.3, 0.4, etc.
I *f2*	The importance factor. Used for both 1985 and 1994 specifications.
RWX *f3*	(UBC 1994 spec only) Numerical co-efficient R_w for lateral load in Z-directions
RWZ *f4*	(UBC 1994 spec only) Numerical co-efficient R_w for lateral load in Z-directions
S *f5*	(UBC 1994 spec only) Site co-efficient for soil characteristics
K *f6*	(UBC 1985 spec only) Horizontal force factor
TS *f7*	(UBC 1985 spec only) Period of structure (in seconds) in the X- direction.
CT *f8*	(UBC 1994 spec only) Value of the term C_t which appears in the equation of the period of the structure per Method A. See note f (on page 2431) for details.
PX *f9*	(UBC 1994 spec only) Period of structure (in seconds) in the X direction.
PZ *f10*	(UBC 1994 spec only) Period of structure (in seconds) in the Z direction. Used for Y if the `SET Z UP` command is used.

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Notes

a. If the option `ACCIDENTAL` is used, the accidental torsion will be calculated per UBC specifications. The value of the accidental torsion is based on the center of mass for each level. The center of mass is calculated from the `SELFWEIGHT`, `JOINT WEIGHT`, `MEMBER WEIGHT`, `ELEMENT WEIGHT`, `FLOOR WEIGHT`, and `ONEWAY WEIGHT` commands you have specified.

b. In *ubc-spec* for 1985 code, specification of TS is optional. If TS is specified, resonance co-efficient S is determined from the building period T and user provided TS using UBC equations. If TS is not specified, the default value of 0.5 is assumed.

c. By providing either PX or PZ or both, you may override the period calculated by STAAD for Method B of the UBC Code. The user defined value will then be used instead of the one recommended by UBC per equation 28.5 of UBC 94. If you do not define PX or PZ, the period for Method B will be calculated by the program per equation 28.5.

d. Some of the items in the output for the UBC analysis are explained below.

CALC / USED PERIOD

The CALC PERIOD is the period calculated using the Rayleigh method (Method B as per UBC code). For UBC in the x-direction, the USED PERIOD is PX. For the UBC in the z-direction, the USED PERIOD is PZ. If PX and PZ are not provided, then the used period is the same as the calculated period for that direction. The used period is the one substituted into the critical equation of the UBC code to calculate the value of C.

- **e.** In the analysis for UBC loads, all the supports of the structure have to be at the same level and have to be at the lowest elevation level of the structure.
- **f.** If the value of Ct is not specified, the program scans the Modulus of Elasticity (E) values of all members and plates to determine if the structure is made of steel, concrete or any other material. If the average E is smaller than 2000 ksi, Ct is set to 0.02. If the average E is between 2000 & 10000 ksi, Ct is set to 0.03. If the average E is greater than 10,000 ksi, Ct is set to 0.035. If the building material cannot be determined, Ct is set to 0.035. Ct is in units of seconds/feet$^{3/4}$ or in units of seconds/meter$^{3/4}$. Ct < 0.42 if the units are in feet, and Ct > 0.42 if the units are in meter.

Philosophy

The seismic load generator can be used to generate lateral loads in the X & Z directions for Y up or X & Y for Z up. Y up or Z up is the vertical axis and the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)). All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.

Total lateral seismic force or base shear is automatically calculated by STAAD using the appropriate UBC equations (All symbols and notations are per UBC).

UBC 1994: Equation 1

$$V = \frac{ZIC}{Rw} W$$

UBC 1984: Equation 2

$$V = ZIK \cdot C_S \cdot W$$

Base shear V may be calculated by STAAD using either the 1994 procedure (equation 1) or the 1985 procedure (equation 2). The user should use the appropriate "ubc-spec" (see General Format (on page 2429)) to instruct the program accordingly.

Procedure Used by the Program

STAAD utilizes the following procedure to generate the lateral seismic loads.

1. You must specify seismic zone co-efficient and desired *`ubc-spec`* (1985 or 1994) following the `DEFINE UBC LOAD` command.
2. Program calculates the structure period T.
3. Program calculates C from appropriate UBC equation(s) utilizing T.
4. Program calculates V from appropriate equation(s). W is obtained from `SELFWEIGHT`, `JOINT WEIGHT`, `MEMBER WEIGHT`, `ELEMENT WEIGHT`, `FLOOR WEIGHT`, and `ONEWAY WEIGHT` commands specified following the `DEFINE UBC LOAD` command. The weight data must be in the order shown.

   Note: If both mass table data (`SELFWEIGHT`, `JOINT WEIGHT`, `MEMBER WEIGHT`, etc. options) and a `REFERENCE LOAD` are specified, these will be added algebraically for a combined mass.

5. The total lateral seismic load (base shear) is then distributed by the program among different levels of the structure per UBC procedures.

Example

```
DEFINE UBC LOAD
ZONE 0.2 I 1.0 RWX 9 RWZ 9 S 1.5 CT 0.032
SELFWEIGHT
```

```
JOINT WEIGHT
17 TO 48 WEIGHT 2.5
49 TO 64 WEIGHT 1.25
LOAD 1
UBC LOAD X 0.75
SELFWEIGHT Y -1.0
JOINT LOADS
17 TO 48 FY -2.5
FLOOR WEIGHT
_SLAB1 FLOAD 0.045
ONEWAY LOAD
_ROOF ONE 0.035 GY
```

TR.31.2.23 UBC 1997 Load Definition

This feature enables one to generate horizontal seismic loads per the UBC 97 specifications using a static equivalent approach. Depending on this definition, equivalent lateral loads will be generated in horizontal direction(s).

The seismic load generator can be used to generate lateral loads in the X & Z directions for Y up or X & Y for Z up. Y up or Z up is the vertical axis and the direction of gravity loads (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)). All vertical coordinates of the floors above the base must be positive and the vertical axis must be perpendicular to the floors.

General Format

```
DEFINE UBC (ACCIDENTAL) LOAD
```

```
ubc-1997-spec
seismic-weights
```

Where:

```
ubc-1997-spec = { ZONE f1 I f2 RWX f3 RWZ f4 STYPE f5 NA f6 NV f7 (CT f8) (PX f9) (PZ f10)}
```

Where:

ZONE *f1* Seismic zone coefficient. Instead of using an integer value like 1, 2, 3 or 4, use the fractional value like 0.075, 0.15, 0.2, 0.3, 0.4, etc.

I *f2* Importance factor

RWX *f3* Numerical coefficient R for lateral load in X direction

RWZ *f4* Numerical coefficient R for lateral load in Z direction

STYPE *f5* Soil Profile type. Valid range of values are integers 1 through 5. These are related to the values shown in Table 16-J of the UBC 1997 code in the following manner:

1. S_A
2. S_B
3. S_C
4. S_D

5. S_E

Note: The soil profile type S_F is not supported.

NA *f6* Near source factor Na

NV *f7* Near source factor Nv

CT *f8* Optional CT value to calculate time period based on Method A (see Note 7 (on page 2434))

PX *f9* Optional Period of structure (in sec) in X-direction to be used in Method B

PZ *f10* Optional Period of structure (in sec) in Z-direction to be used in Method B

The seismic zone factor (`ZONE`) in conjunction with the soil profile type (`STYPE`), Near source factor (`NA`), and the Near source factor (`NV`), is used to determine the values of seismic coefficients Ca and Cv from Tables 16-Q and 16-R of the UBC 1997 code.

If the `ACCIDENTAL` option is specified, the accidental torsion will be calculated per the UBC specifications. The value of the accidental torsion is based on the “center of mass” for each level. The “center of mass” is calculated from the SELFWEIGHT, JOINT WEIGHTs and MEMBER WEIGHTs you have specified.

seismic-weights =

```
weight-data
```

Refer to Common Weight Data (on page 2351) for information on how to specify structure weight for seismic loads.

Note: For additional details on the application of a seismic load definition used to generate loads, refer to TR. 32.12.2 Generation of Seismic Loads (on page 2598).

Methodology

The design base shear is computed in accordance with Section 1630.2.1 of the UBC 1997 code. The primary equation, namely, 30-4 of UBC 1997, as shown below, is checked.

$$V = C_v I/(RT) \cdot W$$

In addition, the following equations are checked :

Equation 30-5 – The total design base shear shall not exceed

$$V = 2.5 \cdot C_a I/R \cdot W$$

Equation 30-6 - The total design base shear shall not be less than

$$V = 0.11 \cdot C_a IW$$

Equation 30-7 – In addition, for Seismic Zone 4, the total base shear shall also not be less than

$$V = 0.8 \cdot ZN_v I/R \cdot W$$

For an explanation of the terms used in the above equations, please refer to the UBC 1997 code.

There are two stages of command specification for generating lateral loads. This is the first stage and is activated through the `DEFINE UBC LOAD` command.

Procedure Used by the Program

Steps to calculate base shear are as follows:

1. Time Period of the structure is calculated based on clause 1630.2.2.1 (Method A) and 1630.2.2.2 (Method B).
2. You may override the period that the program calculates using Method B by specifying a value for PX or PZ (Items f9 and f10) depending on the direction of the UBC load. The specified value will be used in place of the one calculated using Method B.
3. The governing Time Period of the structure is then chosen between the above-mentioned two periods on the basis of the guidance provided in clause 1630.2.2.2.
4. From Table 16-Q and 16-R, Ca and Cv coefficients are calculated.
5. The Design Base Shear is calculated based on clause 1630.2.1 and distributed at each floor using the rules of clause 1630.5.
6. If the ACCIDENTAL option is specified, the program calculates the additional torsional moment. The lever arm for calculating the torsional moment is obtained as 5% of the building dimension at each floor level perpendicular to the direction of the UBC load (clause 1630.6). At each joint where a weight is located, the lateral seismic force acting at that joint is multiplied by this lever arm to obtain the torsional moment at that joint.
7. If the value of Ct is not specified, the program scans the Modulus of Elasticity (E) values of all members and plates to determine if the structure is made of steel, concrete or any other material. If the average E is smaller than 2000 ksi, Ct is set to 0.02. If the average E is between 2000 & 10000 ksi, Ct is set to 0.03. If the average E is greater than 10,000 ksi, Ct is set to 0.035. If the building material cannot be determined, Ct is set to 0.035. Ct is in units of seconds/feet$^{3/4}$ or in units of seconds/meter$^{3/4}$. Ct < 0.42 if the units are in feet, and Ct > 0.42 if the units are in meter.
8. Due to the abstractness of the expression “Height above foundation,” in STAAD, height, h, is measured above supports. If supports are staggered all over the vertical elevations of the structure, it is not possible to calculate "h" if one doesn't have a clear elevation level from where to measure "h". Also, the code deals with distributing the forces only on regions above the foundation. If there are lumped weights below the foundation, it is not clear as to how one should determine the lateral forces for those regions.

Example 1

```
DEFINE UBC LOAD
ZONE 0.38 I 1.0 STYP 2 RWX 5.6 RWZ 5.6 NA 1.3 NV 1.6 CT 0.037
SELFWEIGHT
JOINT WEIGHT
51 56 93 100 WEIGHT 1440
101 106 143 150 WEIGHT 1000
151 156 193 200 WEIGHT 720
MEMBER WEIGHT
12 17 24 UNI 25.7
FLOOR WEIGHT
YRA 9 11 FLOAD 200 XRA -1 21 ZR -1 41
ELEMENT WEIGHT
234 TO 432 PR 150
```

Example 2

The following example shows the commands required to enable the program to generate the lateral loads. See TR.32.12 Generation of Loads (on page 2596) for this information.

```
LOAD 1 ( SEISMIC LOAD IN X DIRECTION )
UBC  LOAD  X 0.75
```

```
LOAD 2 ( SEISMIC LOAD IN Z DIRECTION )
UBC LOAD  Z 0.75
```

The UBC / IBC input can be provided in two or more lines using the continuation mark (hyphen) as shown in the following example :

```
DEFINE UBC ACCIDENTAL LOAD
ZONE 3.000 -
I 1.00 RWX 1.100 -
RWZ 1.200 STYP 5.000 NA 1.40 NV 1.50 CT -
1.300 PX 2.100 PZ 2.200
```

- *G.16.2 Seismic Load Generator* (on page 2135)

TR.31.3 Definition of Wind Load

This set of commands may be used to define some of the parameters for generation of wind loads on the structure. See TR.32.12 Generation of Loads (on page 2596) for the definition of wind direction and the possible surfaces to be loaded. G.16.3 Wind Load Generator (on page 2136) describes the two types of structures on which this load generation can be performed.

The general wind load generator can be used to generate lateral loads in the horizontal –X and Z (or Y if Z up)–directions only.

Tip: The graphical user interface can be used to automatically generate the appropriate intensity values via the ASCE 7 Wind Load dialog box (on page 2882). See Persistence of Parameters used to Generate ASCE Wind Loads (on page 2441)

General Format

```
DEFINE WIND LOAD
TYPE j  ( optional_comment  )
{ intensity-definition  | code-parameters  }
EXPOSURE e1 { JOINT joint-list | YRANGE f1 f2 | ZRANGE f1 f2 }
```

Repeat EXPOSURE command up to 98 times.

Where:

Parameter	Description
TYPE *j* *optional_comment*	wind load system type number (integer) The optional comment is a text string comment or description used to help identify the wind load type.
intensity-definition or *code-parameters*	data is entered based on either custom or Russian code wind definitions. See Wind Intensity Definition (on page 2436) or See Russian Wind Loads (on page 2438)

Parameter	Description
EXPOSURE *e1*, *e2* … *em*	exposure factors. A value of 1.0 means that the wind force may be applied on the full influence area associated with the joint(s) if they are also exposed to the wind load direction. Limit: 99 factors. If the command `EXPOSURE` is not specified or if a joint is not listed in an Exposure, the exposure factor for those joints is chosen as 1.0.
JOINT *joint-list*	Joint list associated with Exposure Factor (joint numbers or `TO` or `BY`) or enter only a group name.
YRANGE | ZRANGE *f1 f2*	global coordinate values to specify Y (or Z if Z UP) vertical range for Exposure Factor. Use `YRANGE` when Y is Up and `ZRANGE` when Z is Up (See the `SET Z UP` command in TR.5 Set Command Specification (on page 2206)).

Wind Intensity Definition

For custom (including for ASCE 7) wind load definitions, the wind intensity at heights above ground are defined as follows:

```
intensity-definition  = INTENSITY p1 p2 p3 … pn HEIGHT h1 h2 h3 … hn
```

Note: These values are automatically generated for ASCE 7 wind loads when the ASCE-7: Wind Load dialog is used.

Where:

Parameter	Description
p_1,p_2,p_3… p_n	wind intensities (pressures) in force/area. Up to 100 different intensities can be defined in the input file per type.
h_1,h_2,h_3… h_n	corresponding heights in global vertical direction, measured in terms of actual Y (or Z for Z UP) coordinates up to which the corresponding intensities occur.

All intensities and heights are in current unit system. The heights specified are in terms of actual Y coordinate (or Z coordinates for Z UP) and not measured relative to the base of the structure. The first value of intensity (p_1) will be applied to any part of the structure for which the Y coordinate (or Z coordinate for Z UP) is equal to or less than h_1. The second intensity (p_2) will be applied to any part of the structure that has vertical coordinates between the first two heights (h_1 and h_2) and so on. Any part of the structure that has vertical coordinates greater than h_n will be loaded with intensity p_n.

Only exposed surfaces bounded by members (not by plates or solids) will be used. The joint influence areas are computed based on surface member selection data entered in TR.32.12.3 Generation of Wind Loads (on page

2603) and based on the wind direction for a load case. Only joints actually exposed to the wind and connected to members will be loaded. The individual bounded areas must be planar surfaces, to a close tolerance, or they will not be loaded.

Exposure factor (e) is the fraction of the influence area associated with the joint(s) on which the load may act if it is also exposed to the wind load. Total load on a particular joint is calculated as follows.

$$\text{Joint load} = (\text{Exposure Factor}) \times (\text{Influence Area}) \times (\text{Wind Intensity})$$

The exposure factor may be specified by a joint-list or by giving a vertical range within which all joints will have the same exposure. If an exposure factor is not entered or not specified for a joint, then it defaults to 1.0 for those joints; in which case the entire influence area associated with the joint(s) will be considered.

For load generation on a closed type structure defined as a PLANE FRAME, influence area for each joint is calculated considering unit width perpendicular to the plane of the structure. You can accommodate the actual width by incorporating it in the Exposure Factor as follows.

$$\text{Exposure Factor (User Specified)} = (\text{Fraction of influence area}) \times (\text{influence width for joint})$$

Notes:

a. All intensities, heights and ranges must be provided in the current unit system.

b. If necessary, the `INTENSITY` and `EXPOSURE` command lines can be continued on to additional lines by ending all but last line with a space and hyphen (-). Use up to 11 lines for a command.

Example

```
UNIT FEET
DEFINE WIND LOAD
TYPE 1
INTENSITY 0.1 0.15 HEIGHT 12 24
EXPOSURE 0.90 YRANGE 11 13
EXPOSURE 0.85 JOITN 17 20 22
LOAD 1 WIND LOAD IN X-DIRECTION
WIND LOAD X 1.2 TYPE 1
```

Note: For additional examples, see TR.32.12 Generation of Loads (on page 2596) and EX. US-15 Wind and Floor Load Generation on a Space Frame (on page 6423).

The Intensity line can be continued in up to 12 lines.

So the following

```
INT 0.008 0.009 0.009 0.009 0.01 0.01 0.01 0.011 0.011 0.012 0.012 0.012 HEIG
15 20 25 30 40 50 60 70 80 90 100 120
```

could be split as

```
INT 0.008 0.009 0.009 0.009 0.01 0.01 0.01 0.011 0.011 0.012 0.012 0.012 –
HEIG 15 20 25 30 40 50 60 70 80 90 100 120
```

or

```
INT 0.008 0.009 0.009 0.009 0.01 0.01-
0.01 0.011 0.011 0.012 0.012 0.012 HEIG 15 20 25 -
30 40 50 60 70 80 90 100 120
```

etc.

Russian Wind Loads

This specifies the definition of a wind load to the Russian wind code which will need to be referenced in a wind load command included in a primary load case. For wind loads per Russian codes SNiP 85 or SP20 2016, the code parameters are defined as follows:

```
code-parameters  =  SNIP 1985 PRESSURE f3 TERRAIN { A | B | C }
```

or

```
code-parameters  = { SP20 } PRESSURE f3 TERRAIN { A | B | C } REGION f4 LOG f5
```

Where:

`SNIP 1985` — design according to previous design Code SNiP 2.01.07-85
`SP20 2016` — design according to renewed design Code SP 20.13330.2016

Parameter	Description
PRESSURE *f3*	the characteristic value of wind pressure, always positive
TERRAIN	terrain roughness category: **A.** Coastal Zone. **B.** Urban Zone. **C.** Large City.
REGION *f4*	Wind region as per clause 11.5 of SNiP 2.01.07-85* 2016. This is used to determine the wind pressure in determine the dynamic wind component. 0 = region 1a 1 = region 1 2 = region 2 3 = region 3 4 = region 4 5 = region 5 6 = region 6 7 = region 7

Parameter	Description
LOG *f5*	logarithmic decrement of oscillations, Delta (see table 11.5 - Section 11.1.8 for the definition). Typically values are: 0.15 for steel towers, masts, lined chimneys, column means including the ones on the reinforced concrete pedestals 0.3 for reinforced concrete and stone structures as well as for buildings with steel framework if there are walling structures

Notes:

a. A structured modeled as a set of vertical members –such as is typically used to define a cylindrical stack or chimney structure, and thus doe snot define a closed panel such as defined by a frame formed from a number of columns and beams– is considered to be a "Stick Structure." Refer to TR.32.12.3 Generation of Wind Loads (on page 2603) for additional details.

b. The loading has two components: static and dynamic. The dynamic effect is determined by the number of modes included in the dynamic load case and changing the number of modes considered using the `CUT OFF MODE SHAPE` command may result in a change in the resulting wind force. Refer to TR.30.1 Cut-Off Frequency, Mode Shapes, or Time (on page 2344) for details.

   As the analysis will requires extraction of eigen solutions to determine the dynamic effects of the wind loading, the number of modes to be used will also affect the results. Thus setting the command `CUT OFF FREQUENCY` or `CUT OFF MODE` should be considered and specified as required prior to the definition of the load cases.

   If the cut-off command is omitted, six mode shapes are computed by default.

c. If the `PRINT STATICS CHECK` option is included in the analysis command, then the output file will include a section on the SNiP wind load. This output will indicate both the static and dynamic contributions to the wind load as well as the total applied at each node.

d. This command *cannot* be used with models that have been defined with the `SET Z UP` command.

e. The building classification for wind load definitions per SNiP 2.01.07-85 and SP 20.13330.2016 is limited to prismatic building structures. General type concrete and steel framed structures are not supported.

The General Format for Russian SNiP 1985 Wind Loads (on page 2608) must also be used in conjunction with the SNiP wind load definition.

STAAD.Pro can generate both static and dynamic wind loads per the SP 20.13330.2016 code.

Example

An example with various static wind loads from different directions that use a SNiP 1985 definition:

```
DEFINE WIND LOAD
TYPE 1
SNIP 1985 PRESSURE 0.38 TERRAIN A
EXP 0.5 JOINT 1 3 5 7 9 11
*
LOAD 1 LOADTYPE WIND TITLE Wind load in the +ve X direction
```

```
WIND LOAD X 1 CONFIG 0 NU 1 TYPE 1
* Mass model required in first wind load case
JOINT LOAD
3 TO 6 FZ 62.223
9 TO 12 FZ 62.223
*
LOAD 2 LOADTYPE WIND TITLE Wind load in the –ve X direction
WIND LOAD X -1 CONFIG 0 NU 1 TYPE 1
* No mass model or additional loads in this load case
*
LOAD 3 LOADTYPE WIND TITLE Wind load in the +ve Z direction
WIND LOAD Z 1 CONFIG 0 NU 1 TYPE 1
* No mass model or additional loads in this load case
*
LOAD 4 LOADTYPE WIND TITLE Wind load in the –ve Z direction
WIND LOAD Z -1 CONFIG 0 NU 1 TYPE 1
* No mass model or additional loads in this load case
*
LOAD 10 LOADTYPE DEAD TITLE Selfweight load case
SELF Y -1 ALL
*
LOAD COMBINATION 100 Wind plus selfweight
1 1.0 10 1.0
```

The following example uses SP 20.13330.2016 with both static and dynamic load cases:

```
DEFINE WIND LOAD
TYPE 1
SP20 2016 PRESSURE 0.38 TERRAIN A REGION 0 LOG 0.3
*
* Reference Mass Definition for Modal Analysis
DEFINE REFERENCE LOADS
LOAD R1 LOADTYPE Mass TITLE REF LOAD CASE 1
JOINT LOAD
3 TO 6 FX 62.223
3 TO 6 FZ 62.223
9 TO 12 FX 62.223
9 TO 12 FZ 62.223
END DEFINE REFERENCE LOADS
*
* Request mode shapes
CUT OFF MODE SHAPE 3

*
* Modal Analysis
LOAD 2 LOADTYPE None TITLE LOAD CASE 2
MODAL CALCULATION REQUESTED
*
* Dynamic Wind Load Command
LOAD 3 LOADTYPE None TITLE SNiP Dynamic
WIND LOAD X 1.0 TYPE 1 DYN 1
PERFORM ANALYSIS PRINT LOAD DATA
```

Persistence of Parameters used to Generate ASCE Wind Loads

In the Analytical Modeling workflow, in the Create Wind Type Definition dialog (on page 2880), you can click the **Calculate as per ASCE-7** button to generate the pressure versus height table per the ASCE 7 wind load specifications per the 1995, 2002, or 2010 editions. The parameters which go into the derivation of this table are not retained by the graphical environment but rather added into the STAAD input file so they may be edited as needed. These values are not read by the STAAD engine directly and, therefore, are not directly processed as a load but are rather used to generate the wind intensity values which are used by the engine. An example of it is shown below.

Example

```
DEFINE WIND LOAD
TYPE 1
This entire section of the input file must not be edited.<! STAAD PRO

TR.31.4 Definition of Time History Load

This set of commands may be used to define parameters for time history loading on the structure. The time history data may be specified using either explicit definition, function specification, a spectrum specification, or time history data provided in an external file.

General Format

```
DEFINE TIME HISTORY (DT x) ( MISSING MASS )

TYPE i { ACCELERATION | FORCE |  MOMENT } (SCALE f7) (SAVE)

{ t1 p1 t2 p2 … tn pn | function-spec  | spectrum-spec  | READ filename (f8) }
```

Repeat TYPE and Amplitude vs Time sets until all are entered, then:

```
ARRIVAL TIME
```

```
a1 a2 a3 … an
```

```
{ DAMPING d | CDAMP | MDAMP }
```

Entering the MISSING MASS parameter will include the missing mass procedure in the time history analysis.

The time history data can be explicitly defined using pairs of time and values of acceleration, force, or moment, where:

- ACCELERATION indicates that the time varying load type is a ground motion.
- FORCE indicates that it is a forcing function.
- MOMENT indicates that it is a moment forcing function.

Table 257: Parameters for explicitly defined time history load

Variable or Command	Default Value	Description
DT *x*	-	Solution time step used in the step-by-step integration of the uncoupled equations. Values smaller than 0.00001 will be reset to the default DT value of 0.0013888 seconds.
TYPE *i*	-	Type number of time varying load (integer). Up to 136 types may be provided. This number should be sequential.
SCALE *f7*	1.0	The scale factor option multiplies all forces, accelerations, and amplitudes entered, read or generated within this Type. Primarily used to convert acceleration in g's to current units (9.80665, 386.08858, etc.).
SAVE	-	The save option results in the creation of two files (input file name with .TIM and .FRC file extensions). The .TIM file contains the history of the displacements of every node. The .FRC file contains the history of the 12 end forces of every member of the structure at every time step, and the 6 reactions at each support at every step. Syntax: TYPE 1 FORCE SAVE

Variable or Command	Default Value	Description
t_1 p_1 t_2 p_2	-	Values of time (in sec.) and corresponding force (current force unit) or acceleration (current length unit/sec^2) depending on whether the time varying load is a forcing function or a ground motion. If the first point is not at zero time, then the forces before the first time (but after the arrival time) will be determined by extrapolation using the first two points entered. If the first point has a nonzero force, there will be a sudden application of that force over a single integration step (DT) at that time. Zero force will be assumed for all times after the last data point.
a_1 a_2 a_3 ... a_n	-	Values of the various possible arrival times (seconds) of the various dynamic load types. Arrival time is the time at which a load type begins to act at a joint (forcing function) or at the base of the structure (ground motion). The same load type may have different arrival times for different joints and hence all those values must be specified here. The arrival times and the times from the time-force pairs will be added to get the times for a particular set of joints in the TIME LOAD data (see TR.32.10.2 Time Varying Load for Response History Analysis (on page 2593)). The arrival times and the time-force pairs for the load types are used to create the load vector needed for each time step of the analysis. Refer to TR.32.10.2 Time Varying Load for Response History Analysis (on page 2593) for information on input specification for application of the forcing function and/or ground motion loads. Up to 999 arrival time values may be specified.
DAMPING *d*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If `CDAMP` is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If `MDAMP` is specified, then modal damping is calculated using the method defined in a `DEFINE DAMPING INFORMATION` command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)

The *function-spec* option can be used to specify harmonic loads. Both sine and cosine harmonic functions may be specified. The program will automatically calculate the harmonic load time history based on the following specifications.

For the function and amplitude option (:

```
function-spec =
{ SINE | COSINE }
AMPLITUDE f0 { FREQUENCY | RPM } f2 (PHASE f3) CYCLES f4 { SUBDIV f5 | STEP f6 }
```

Note: Please be aware that if a Cosine function or Sine with nonzero phase angle is entered, the force at the arrival time will be nonzero; there will be a sudden application of force over a single integration step (DT) at that time.

Where:

Table 258: Parameters for use with function time history load

Variable or Command	Default Value	Description
DT *x*	-	Solution time step used in the step-by-step integration of the uncoupled equations. Values smaller than 0.00001 will be reset to the default DT value of 0.0013888 seconds.
TYPE *i*	-	Type number of time varying load (integer). Up to 136 types may be provided. This number should be sequential.
SCALE *f7*	1.0	The scale factor option multiplies all forces, accelerations, and amplitudes entered, read or generated within this Type. Primarily used to convert acceleration in g's to current units (9.80665, 386.08858, etc.).
SAVE	-	The save option results in the creation of two files (input file name with .TIM and .FRC file extensions). The .TIM file contains the history of the displacements of every node. The .FRC file contains the history of the 12 end forces of every member of the structure at every time step, and the 6 reactions at each support at every step. Syntax: `TYPE 1 FORCE SAVE`
AMPLITUTDE *f0*	-	Max. Amplitude of the forcing function in current units.
FREQ | RPM *f2*	-	If FREQUENCY, then cyclic frequency (cycles / sec.) If RPM, then revolutions per minute.
PHASE *f3*	0	Phase Angle in degrees.
CYCLES *f4*	-	No. of cycles of loading.

Variable or Command	Default Value	Description
SUBDIV *f5*	3	Used to subdivide a ¼ cycle into this many integer time steps. **Note:** Only used to digitize the forcing function. It is not the DT used to integrate for the responses. More subdivisions will make the digitized force curve more closely match a sine wave. The default is usually adequate.
STEP *f6*	(p/12)	Time step of loading. Default is equal to one twelfth of the period corresponding to the frequency of the harmonic loading. (It is best to use the default) **Note:** Only used to digitize the forcing function. It is not the DT used to integrate for the responses. More subdivisions or smaller step size will make the digitized force curve more closely match a sine wave.
a_1 a_2 a_3 ... a_n	-	Values of the various possible arrival times (seconds) of the various dynamic load types. Arrival time is the time at which a load type begins to act at a joint (forcing function) or at the base of the structure (ground motion). The same load type may have different arrival times for different joints and hence all those values must be specified here. The arrival times and the times from the time-force pairs will be added to get the times for a particular set of joints in the TIME LOAD data (see TR.32.10.2 Time Varying Load for Response History Analysis (on page 2593)). The arrival times and the time-force pairs for the load types are used to create the load vector needed for each time step of the analysis. Refer to TR.32.10.2 Time Varying Load for Response History Analysis (on page 2593) for information on input specification for application of the forcing function and/or ground motion loads. Up to 999 arrival time values may be specified.
DAMPING *d*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If `CDAMP` is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If `MDAMP` is specified, then modal damping is calculated using the method defined in a `DEFINE DAMPING INFORMATION` command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)

The *spectrum-spec* option can be used to specify a synthetic ground motion acceleration time history based statistically on a user supplied acceleration spectrum.

The program will automatically calculate the acceleration time history based on the following specifications. Enter *f12*, *f13*, and *f14* to indicate the rise, steady, & decay times, respectively.

For the spectrum option:

```
spectrum-spec =
```

```
SPECTRUM (TMAX f9) (DTI f10) (DAMP f11) (T1 f12) (T2 f13) (T3 f14) (SEED f15)
```

```
OPTIONS NF f16 NITR f17 ( THPRINT f18 ) ( SPRINT f19 ) ( FREQ )
```

Starting on the next line, enter Spectra in the following input form:

```
P1, V1; P2, V2; … ; Pn, Vn
```

Where:

Table 259: Parameters used with the spectrum time history load

Variable or Command	Default Value	Description
DT *x*	-	Solution time step used in the step-by-step integration of the uncoupled equations. Values smaller than 0.00001 will be reset to the default DT value of 0.0013888 seconds.
TYPE *i*	-	Type number of time varying load (integer). Up to 136 types may be provided. This number should be sequential.
SCALE *f7*	1.0	The scale factor option multiplies all forces, accelerations, and amplitudes entered, read or generated within this Type. Primarily used to convert acceleration in g's to current units (9.80665, 386.08858, etc.).
SAVE	-	The save option results in the creation of two files (input file name with `.TIM` and `.FRC` file extensions). The `.TIM` file contains the history of the displacements of every node. The `.FRC` file contains the history of the 12 end forces of every member of the structure at every time step, and the 6 reactions at each support at every step. Syntax: `TYPE 1 FORCE SAVE`
TMAX *f9*	20 seconds	The Max. time (in seconds) in the generated time history. This value must be greater than *f14* (T3).
DTI *f10*	0.2	Delta time step (in seconds) in the generated time history.
DAMP *f11*	0.05	Damping ratio (5% is entered as 0.05) associated with the input spectrum.
T1 *f12*	4 seconds	Ending time of the acceleration rise time. This value must be greater than zero.

Variable or Command	Default Value	Description
T2 *f13*	9 seconds	Ending time of the steady acceleration. This value must be greater than zero and greater than *f12* (T1).
T3 *f14*	14 seconds	Ending time of the acceleration decay. This value must be greater than *f13* (T2).
SEED *f15*		Optional random Seed. Enter a positive integer (in the range of 1 to 2,147,483,647) to be used as a unique random number generation "seed." A unique time history will be produced for each seed value. Change this value when you want to produce a "different (from the time history generated with the prior seed value)" but statistically equivalent time history. Omit this entry to get the default value (normal option).
NF *f16*		The input shock spectrum will be re-digitized at `NF` equally spaced frequencies by interpolation. Default is the greater of 35 or the number of points in the input spectrum.
NITR *f17*	10	The number of iterations which will be used to perfect the computed time history.
THPRINT *f18*	1	Print the time history that is generated. Omit the `THPRINT` parameter to avoid printing. 1 = print beginning 54 values and last 54 values 2 = Print entire curve. >10 = print beginning *f18* values and last *f18* values
SPRINT *f19*	1	Print the spectrum generated from the time history that is generated. Omit the `SPRINT` parameter to avoid printing
FREQ		If entered, then frequency-spectra pairs are entered rather than period-spectra pairs.
P1, *V1* *P2*, *V2* … *Pn*, *Vn*		Data is part of input, immediately following `SPECTRUM` command. Period (or frequency if `FREQ` option entered above) Value pairs (separated by semi colons) are entered to describe the Spectrum curve. Enter the period in seconds (or frequency in Hz.) and the corresponding Value is in acceleration (current length unit/sec^2) units. Continue the curve data onto as many lines as needed (up to 999 spectrum pairs). Spectrum pairs must be in ascending or descending order of period (or frequency). **Note:** If data is in g acceleration units, then set `SCALE` to a conversion factor to the current length unit (9.807, 386.1, etc.). Also note, do not end these lines with a hyphen. Commas and semi-colons are optional.

Variable or Command	Default Value	Description
a_1 a_2 a_3 ... a_n	-	Values of the various possible arrival times (seconds) of the various dynamic load types. Arrival time is the time at which a load type begins to act at a joint (forcing function) or at the base of the structure (ground motion). The same load type may have different arrival times for different joints and hence all those values must be specified here. The arrival times and the times from the time-force pairs will be added to get the times for a particular set of joints in the TIME LOAD data (see TR.32.10.2 Time Varying Load for Response History Analysis (on page 2593)). The arrival times and the time-force pairs for the load types are used to create the load vector needed for each time step of the analysis. Refer to TR.32.10.2 Time Varying Load for Response History Analysis (on page 2593) for information on input specification for application of the forcing function and/or ground motion loads. Up to 999 arrival time values may be specified.
DAMPING *d*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If `CDAMP` is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If `MDAMP` is specified, then modal damping is calculated using the method defined in a `DEFINE DAMPING INFORMATION` command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)

Note: Please be aware that if a Cosine function or Sine with nonzero phase angle is entered, the force at the arrival time will be nonzero; there will be a sudden application of force over a single integration step (DT) at that time.

The time history data can also be defined in an external file, where:

Table 260: Parameters for a time history load defined in an external file

Variable or Command	Default Value	Description
DT *x*	-	Solution time step used in the step-by-step integration of the uncoupled equations. Values smaller than 0.00001 will be reset to the default DT value of 0.0013888 seconds.
TYPE *i*	-	Type number of time varying load (integer). Up to 136 types may be provided. This number should be sequential.

Variable or Command	Default Value	Description
SCALE *f7*	1.0	The scale factor option multiplies all forces, accelerations, and amplitudes entered, read or generated within this Type. Primarily used to convert acceleration in g's to current units (9.80665, 386.08858, etc.).
SAVE	-	The save option results in the creation of two files (input file name with `.TIM` and `.FRC` file extensions). The `.TIM` file contains the history of the displacements of every node. The `.FRC` file contains the history of the 12 end forces of every member of the structure at every time step, and the 6 reactions at each support at every step. Syntax: `TYPE 1 FORCE SAVE`
READ *filename*		Filename for an external file containing time varying load history data.
f8		The optional delta time spacing used for the external file data
a_1 a_2 a_3 ... a_n	-	Values of the various possible arrival times (seconds) of the various dynamic load types. Arrival time is the time at which a load type begins to act at a joint (forcing function) or at the base of the structure (ground motion). The same load type may have different arrival times for different joints and hence all those values must be specified here. The arrival times and the times from the time-force pairs will be added to get the times for a particular set of joints in the TIME LOAD data (see TR.32.10.2 Time Varying Load for Response History Analysis (on page 2593)). The arrival times and the time-force pairs for the load types are used to create the load vector needed for each time step of the analysis. Refer to TR.32.10.2 Time Varying Load for Response History Analysis (on page 2593) for information on input specification for application of the forcing function and/or ground motion loads. Up to 999 arrival time values may be specified.

Variable or Command	Default Value	Description
DAMPING *d*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If CDAMP is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If MDAMP is specified, then modal damping is calculated using the method defined in a `DEFINE DAMPING INFORMATION` command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)

Examples

Using Force and Acceleration options:

```
UNIT …
DEFINE TIME HISTORY
TYPE 1 FORCE
0.0 1.0 1.0 1.2 2.0 1.8 3.0 2.2
4.0 2.6 5.0 2.8
TYPE 2 ACCELERATION SCALE 9.80665
0.0 1.0 1.0 1.2 2.0 1.8 3.0 2.2
4.0 2.6 5.0 2.8
ARRIVAL TIME
0.0 1.0 1.8 2.2 3.5 4.4
DAMPING 0.075
```

Using the Spectrum option:

```
UNIT …
DEFINE TIME HISTORY
TYPE 1 ACCELERATION SCALE 9.80665
SPECTRUM TMAX 19 DTI 0.01 DAMP 0.03
OPTIONS NF 40
0.03 1.00 ; 0.05 1.35
0.1 1.95 ; 0.2 2.80
0.5 2.80 ; 1.0 1.60
ARRIVAL TIME
0.0 1.0 1.8 2.2 3.5 4.4
DAMPING 0.075
```

Using the Harmonic Loading Generator:

```
UNIT …
DEFINE TIME HISTORY
TYPE 1 FORCE
*Following lines for Harmonic Loading Generator
FUNCTION SINE
AMPLITUDE 6.2831 FREQUENCY 60 CYCLES 100 STEP 0.02
ARRIVAL TIME
0.0
DAMPING 0.075
```

To define more than one sinusoidal load, the input specification is as follows:

```
DEFINE TIME HISTORY
TYPE 1 FORCE
FUNCTION SINE
AMPLITUDE 1.925 RPM 10794.0 CYCLES 1000
TYPE 2 FORCE
FUNCTION SINE
AMPLITUDE 1.511 RPM 9794.0 CYCLES 1000
TYPE 3 FORCE
FUNCTION SINE
AMPLITUDE 1.488 RPM 1785.0 CYCLES 1000
ARRIVAL TIME
0.0 0.0013897 0.0084034
DAMPING 0.04
```

The data in the external file must be provided as one or more time-force pairs per line as shown in the following example.

Data in Input file

```
UNIT …
DEFINE TIME HISTORY
TYPE 1 FORCE
READ THFILE
ARRIVAL TIME
0.0
DAMPING 0.075
```

Data in the External file `THFILE`:

```
0.0 1.0 1.0 1.2
2.0 1.8
3.0 2.2
4.0 2.6
```

Notes

a. By default the response (displacements, forces etc.) will contain the contribution of only those modes whose frequency is less than or equal to 108 cps. Use the `CUT OFF FREQUENCY` command to change this limit. Contributions of modes with frequency greater than the Cut Off Frequency are not considered.

b. Results are the individual maximums over the time period. Thus, derived quantities such as section forces and stresses, plate surface stresses and principal stresses should not be used.

c. Results from harmonic input are the maximum over the time period including the start-up transient period. These results are not the steady-state results.

d. By default, the results do not include the time period after the time loads end. Use the `CUT OFF TIME` command to lengthen (or shorten) the time period. If an intense short-term loading is used, the loading should be continued until after the expected peak response is reached.

e. The `READ` *`filename`* command is to be provided only if the history of the time varying load is to be read from an external file. *`filename`* is the file name and may be up to 72 characters long. If the data on the file consists only of amplitudes, then enter *`f8`* as the delta time spacing.

TR.31.5 Definition of Snow Load

This set of commands may be used to define some of the parameters for generation of snow loads on the structure.

Refer to TR.32.12.4 Generation of Snow Loads (on page 2609) or the definition of additional parameters and the surfaces to be loaded.

General Format

```
DEFINE SNOW LOAD
```

```
TYPE f1 PG f2 CE f3 CT f4 IM f5
```

Where:

TYPE *f1* Type No: (limit of 100). The “Type No.” is an integer value (1, 2, 3, etc.) which denotes a number by which the snow load type will be identified. Multiple snow load types can be created in the same model. Include as many types as needed.

PG *f2* Ground Snow Load (Default = 0.0). The pressure or, weight per unit area, to be used for the calculation of the design snow load. Use a negative value to indicate loading acting towards the roof (upwards) as per section 7.2 of SEI/ASCE 7-02.

CE *f3* Exposure Factor (Default = 1.0). Exposure factor as per Table 7-2 of the SEI/ASCE-7-02 code. It is dependent upon the type of exposure of the roof (fully exposed/partially exposed/sheltered) and the terrain category, as defined in section 6.5.6 of the code.

CT *f4* Thermal Factor (Default = 0.0). Thermal factor as per Table 7-3 of the SEI/ASCE-7-02 code. It is dependent upon the thermal condition.

IM *f5* Importance Factor (Default = 1.0). Importance factor as per Table 7-4 of the SEI/ASCE-7-02 code. This value depends on the category the structure belongs to, as per section 1.5 and Table 1-1 of the code.

Example

```
START GROUP DEFINITION
FLOOR
_ROOFSNOW 102 TO 153 159 160 TO 170 179 195 TO 197
END GROUP DEFINITION
UNIT FEET POUND
```

TR.31.6 Defining Reference Load Types

Large models can include multiple load cases which do not require analysis in their own right and are simply the building blocks for inclusion in primary load cases. Thus Reference Loads may be defined for this purpose. This is similar to a REPEAT LOAD command (See TR.32.11 Repeat Load Specification (on page 2595)), but has the added benefit of not being solved in its own right.

This converts a real load case to something similar to a load case definition. A reference load case is solved only when it is later called in a load case. The benefit is that it enables you to define as many load cases as you wish, but instruct the program to actually solve only a limited number of "real" load cases, thus limiting the amount of results to be examined.

See TR.33 Reference Load Cases - Application (on page 2613) for a description of the procedure for specifying the reference load information in active load cases.

General Format

```
DEFINE REFERENCE LOADS

LOAD R(i) LOADTYPE (type) TITLE load_title

(Load items)

...

END DEFINE REFERENCE LOADS
```

Example

```

17 TO 48 FY -2.5
49 TO 64 FY -1.25
END DEFINE REFERENCE LOADS
```

Mass Modeling Using Reference Loads

A reference load case of type `MASS` can be created which can then be used to define the structure mass used for all dynamic analyses (i.e., seismic, response spectrum, time history, etc.). Some analysis methods require you to create separate weight tables in the form of `SELFWEIGHT`, `MEMBER WEIGHT`, `JOINT WEIGHT`, etc. for each analysis, thus resulting in repetition of the same information. Using a `LOADTYPE MASS` reduces the repetitive data entry and the need for manually creating a weight table.

A mass model using this method is defined once and then used for all dynamic analyses.

If the `LOADTYPE MASS` is missing and no mass is defined in the corresponding seismic or dynamic analysis load cases, the program will report error as mass is missing. If a mass table is provided in a seismic load definition, response spectrum definition, or time history loading definition, then that mass table will be used for analysis under those loads only instead of a mass model generated by a `REF LOAD TYPE MASS`. However, if no masses are defined within the individual seismic, response spectrum, or time history load definitions, then the program uses the mass reference load case when analyzing that seismic or dynamic load case.

TR.31.7 Definition of Direct Analysis Members

This set of commands may be used to define the members whose flexural stiffness or axial stiffness is considered to contribute to the lateral stability of the structure.

These parameters are then used by the program to analyze the structure as per guidelines provided in Chapter C of the AISC 360-10/16 specifications (Appendix 7 of AISC 360-05).

Note: The yield strength of the steel is taken from the TR.26.1 Define Material (on page 2303). If the material definition is not provided for a member, then a default value of $F_y = 36\ ksi$ is used.

General Format

```
DEFINE DIRECT
```

```
FLEX (f1) list-spec
```

```
AXIAL list-spec
```

Where:

```
list-spec = * { XR f4 f5 | YR f4 f5 | ZR f4 f5 | MEMBERS mem-list | LIST memb-list | ALL }
```

Parameter	Default Value	Description
FLEX *f1*	1.0	The initial τ_b value (See Chapter C of AISC 360-10/16 or Appendix 7 AISC 360-05). Members listed with FLEX will have their EI factored by 0.80 times τ_b while performing the global solution.
AXIAL	-	Members listed with AXIAL will have their EA factored by 0.80 while performing the global solution. Although reduced stiffness is considered for analysis, the program considers the full value of E for both flexural and axial design.
XR | YR | ZR *f4*, *f5*	-	Upper and lower range values, respectively, used when specifying a range for FLEX.

For specifying NOTIONAL LOADs, please see TR.32.13 Notional Loads (on page 2610). The notional loads and the factor used is specified entirely in the loading data.

Notes

τ_b is the value entered in the FLEX command. τ_b defaults to 1.0 if not entered.

TR.31.8 Mass Modeling

Each load case consisting of a response spectrum requires a mass definition. The following methods may be used to define masses for use with seismic loads.STAAD.Pro.

TR.31.8.1 Explicitly Defined Weights

This method uses different load items within the load case to define the weights for use with that specific response spectrum. Combinations of selfweight, joint weights, member weights, element weights, and floor weights can defined prior to the response spectrum parameters.

Static Seismic Weight Definition Table

```
seismic-weights =
SELFWEIGHT (f1)
JOINT WEIGHT
joint-list WEIGHT w
MEMBER WEIGHT
member-list { UNI v1 v2 v3 | CON v4 v5 }
ELEMENT WEIGHT
plate-list PRESS p1
FLOOR WEIGHT
floor-weight-spec
ONEWAY WEIGHT
oneway-weight-spec
REFERENCE LOAD { X | Y | Z }
Ri1 f2
```

Response Spectrum Weight Table

```
SELFWEIGHT { X | Y | Z } f1
JOINT LOADS
joint-loads
MEMBER LOADS
member-loads
```

Example

TR.31.8.2 Reference Load Mass Tables

This method uses loads defined in a reference load case as the weights for the response spectrum. You may also define in which global direction the loading is considered for base shear calculation. By default, the program will consider Global Y if no load direction is specified. If no applied loads are found in the Y direction, then it consider the maximum of the total loads in either X or Z directions.

General Format

Multiple reference load cases can be used in a single response spectrum, each with a separate load factor applied. This allows you to factor the reference loads for use with weights. For example, if a code-prescribed seismic load requires that 100% of the dead load mass but only 50% of the live load mass be used for seismic loads, then you can use factors of 1.0 for the reference dead load case and 0.5 for the reference live load case.

This has the advantage of allowing you to define a single mass model for use with both static seismic loading as well as response spectra. In order to accomplish this, simply define the response spectrum load case as a reference load and then utilize this reference load in both the static seismic and response spectrum primary load case.

Tip: You may also use the same reference load cases for modal analysis and calculating Rayleigh's frequency.

Related Links

- *G.17.3.2 Mass Modeling* (on page 2157)
- *M. To generate a mass model* (on page 899)

TR.31.8.3 Mass Model Using Reference Load

Mass type reference loads can be used to create mass model which will be used for all types of analysis, including seismic, response spectrum, time history, and any other dynamic analysis.

When a rigid floor diaphragm is present in the model, the program follows the following logic:

a. If a reference load type MASS is present, then the mass model is formed by combining all MASS reference loads.
b. If reference load type MASS is not present, then the mass model is formed by combining all gravity reference loads. Warnings are displayed in the analysis output to alert you to this fact.
c. If neither reference load types MASS nor gravity are present, then the mass model is formed by combining all DEAD reference loads. If any LIVE reference loads are present, then they will also be combined to this mass model. Warnings are displayed in the analysis output to alert you to this fact.

Mass model will be formed from Gravity or Dead/Live reference loads in case Mass reference load types are not present, only when rigid floor diaphragm is present in the model.

General Format

```
DEFINE REFERENCE LOADS
LOAD  Ri title
…
Load header and items
…
LOAD  Rj LOADTYPE MASS title
…
Load header and items
…
END DEFINE REFERENCE LOADS
DEFINE UBC/1893/… LOAD
ZONE …
LOAD 1 title
UBC/1893/… LOAD X f1
LOAD 2 title
UBC/1893/… LOAD Z f2
LOAD 3 title
SPECTRUM …
```

The mass model is defined using the LOADTYPE MASS command. This mass model will be used for all types of analysis, including static equivalent, response spectrum, time history, and simply Eigen solution. If the load type

MASS is missing and also no mass is defined in the corresponding seismic or dynamic analysis load cases, the program will report error as mass is missing

If a mass model using reference load type MASS is defined and also a seismic weight table is defined in DEFINE UBC/1893/… DEFINITION (or seismic mass is defined as part of a response spectrum or time history loading), the program will simply the later in place of the former for the seismic weight calculation. The program will issue a warning message in the analysis output. Care should be taken so that the mass model is not defined twice.

TR.31.9 Defining Starting Load

This command is used to directly specify the starting load vectors for use with load dependent Ritz vector method for the eigen solution.

General Format

```
DEFINE STARTING LOAD
```

```
MASS { X | Y | Z | XY | YZ | ZX } NGEN n
```

or

```
REFERENCE LOAD Ri NGEN n
```

```
END
```

You may specify one of each direction or direction pair when using the `MASS` option. You may specify any number of reference loads.

where

n	=	The number of Ritz vectors to be extracted corresponding to each starting load.
Ri	=	The reference load number to be used as a starting load.

Program Versus User-Generated Start Vectors

Using the program generated method, the starting load vector is generated using the mass model of the structure. Assuming mass matrix only has translational components, the resulting load vector will have force components in the directions of all the translational degrees of freedom (DOFs) and will have zero values for all the rotational DOFs. This will guarantee a static deflection with components in many directions to start with the initial mode assumption. As long as the initial mode assumption has a component in the direction of interest, it will yield a correct set of Ritz vectors.

With the user-defined starting load, the load vector will have a force component in one translational degree of freedom in the direction of the dynamic load. This results in a static deflection mainly in the direction of interest. In some models where mass participation is predominant in one translational direction for the initial few modes this method can achieve 90% mass participation with only few modes.

Note: A single set of Ritz vectors can be derived from a single starting load. If all starting loads that participate in dynamic loads are defined, a single set of Ritz vectors can be extracted from all participating starting loads. The STAAD.Pro Advanced Analysis can extract a single set of Ritz vector only from *one* single starting load. Thus, the use of user-defined start vectors is best suited if the structural response is predominant in one translational direction. If responses in multiple translational DOF are predominant, it is recommended to use the program generated starting load vector.

Notes

Use of this command (and specifying the eigen solution in general) requires the Advanced Analysis.

This command requires that the `SET EIGEN METHOD RITZ` command also be used previously in the input file. Refer to TR.5 Set Command Specification (on page 2206) for details.

Examples

The following uses starting loads in each direction, with 10 Ritz vectors in each except for the Y direction only, which will extract 5.

```
DEFINE STARTING LOAD
* Load components in X direction only
MASS X NGEN 10
* Load components in Y direction only
MASS Y NGEN 5
* Load components in Z direction only
MASS Z NGEN 10
* Load components in X & Y directions
MASS XY NGEN 10
* Load components in Y & Z directions
MASS YZ NGEN 10
* Load components in Z & X directions
MASS ZX NGEN 10
END
```

The following example contains four reference loads:

1. R1: all 3 translational degrees of freedom (X, Y, & Z)
2. R2: in X d.o.f. only
3. R3: in Y d.o.f. only
4. R4: in Z d.o.f. only

Twenty five Ritz vectors will be generated for each of the starting loads.

```
DEFINE STARTING LOAD
* Load components in all directions
REF LOAD R1 NGEN 25
* Load components in X direction only
REF LOAD R2 NGEN 25
* Load components in Y direction only
REF LOAD R3 NGEN 25
* Load components in Z direction only
REF LOAD R4 NGEN 25
END
```

TR.32 Loading Specifications

This section describes the various loading options available in STAAD.Pro. The following command may be used to initiate a new load case.

General Format

```
LOADING i1 ( LOADTYPE a1 ) ( REDUCIBLE ) ( TITLE any_load_title )
```

Where:

LOADING *i1* any unique integer number (up to five digits) to identify the load case. This number need not be sequential with the previous load number.

LOADTYPE *a1* one of the following:

Dead	Soil	Ice
Live	Rain Water/ Ice	Wind on Ice
Roof Live	Ponding	Crane Hook
Wind	Dust	Mass (Notes (on page 2461))
Seismic-H (horizontal, Notes (on page 2461))	Traffic	Gravity
Seismic-V (vertical, Notes (on page 2461))	Temperature	Push
Snow	Accidental	None
Fluids	Flood	

The words `LOADTYPE a` are necessary only if you intend to use the Automatic Load Combination generation tool in the graphic interface. For details, refer to the Auto Load Combination dialog (on page 2872).

The keyword `REDUCIBLE` should be used only when the load type is `Live` or `Roof Live`. It instructs the program to reduce –according to the provisions of UBC 1997, IBC 2000, or IBC 2003 codes– a floor live load specified using `FLOOR LOAD` or `ONEWAY LOAD` commands. For details, see TR.32.4 Area, One-way, and Floor Load Specifications (on page 2475).

Under this heading, all different loads related to this loading number can be input.

Notes

a. For Mass Model Loading in Dynamics, it is strongly recommended that you read G.17.3.2 Mass Modeling (on page 2157) and TR.31.8.3 Mass Model Using Reference Load (on page 2457). For the purpose of entering the mass distribution for the first dynamic load case, use the following sections:

A reference load can be used to create a mass model for all dynamic analyses.

The purpose of the mass modeling step is to create lumped masses at the joints that the eigensolution can use. The member/element loading is only a convenience in generating the joint masses. Analytically the masses are not in the elements but are lumped at the joints.

b. The absolute value of joint loads or loads distributed to joints from member/element loadings will be treated as weights. The moments applied to member/elements or computed at joints as a result of member/element loadings will be ignored. Only moments (actually weight moment of inertia, force-length^2 units) applied in the Joint.

c. The load command will be used in defining the weight moment of inertias at joints. For dependent joint directions, the associated joint weight or weight moment of inertia will be moved to the control. In addition, the translational weights at dependent joint directions will be multiplied by the square of the distance to the control to get the additional weight moment of inertia at the control. Cross-product weight moment of inertias at the control will be ignored.

d. When Y is set as "Up" (default), then the horizontal seismic loads act in the global X and Y directions. The vertical seismic loads act in the global Y direction.

When `SET Z UP` is used, then the horizontal seismic loads act in the global X and Z directions. The vertical seismic loads then act in the global Z direction.

TR.32.1 Joint Load Specification

This set of commands may be used to specify joint loads on the structure. For dynamic mass modeling see TR. 32.10 Dynamic Loading Specification (on page 2498) and G.17.3 Dynamic Analysis (on page 2154).

General Format

```
JOINT LOAD
```

```
joint-list (inclined-spec) *{ FX f8 | FY f9 | FZ f10 | MX f11 | MY f12 | MZ f13 }
```

Where:

```
inclined-spec = INCLINED { f1 f2 f3 | REF f4 f5 f6 | REFJT f7 }
```

Use the optional *inclined-spec* to specify a joint load in a inclined load axis. See Inclined Load Axis System (on page 2463) below for details.

f1, f2, f3	x, y, z relative distances from the joint in the global directions to the reference point
f4, f5, f6	x, y, z global coordinates of an arbitrary reference point

f7	a joint number whose x, y, z global coordinates are the reference point
f8, f9, f10	force values in the corresponding global direction (even at inclined support joints).
f11, f12, f13	moment values in the corresponding global direction.

Example

```
UNIT FEET KIP
*…
JOINT LOAD
3  TO  7  9  11  FY  -17.2  MZ  180.0
5  8  FX  15.1
UNIT INCH KIP
12  MX  180.0  FZ  6.3
```

Notes

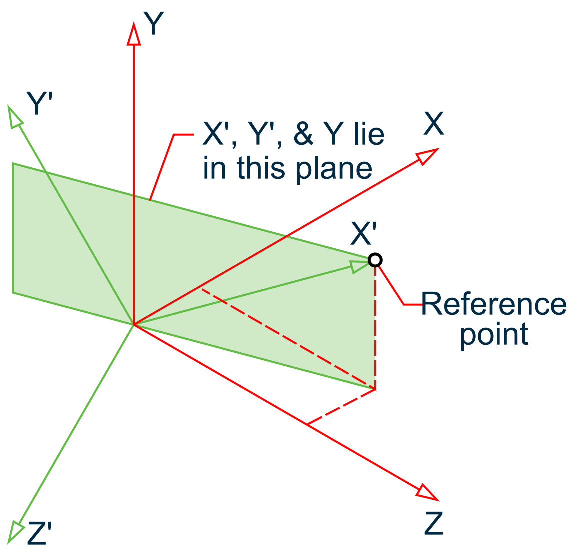
a. Joint numbers may be repeated where loads are meant to be additive in the joint.

b. A `UNIT` command may be on lines in between joint-list lines.

c. If moments are for dynamic mass, then the units are assumed to be force-length^2.

Inclined Load Axis System

If the joint loading is specified using the option `INCLINED`, then the axes in which the direct forces (and about which for moment forces) are applied are realigned from the global directions of X, Y, and Z to the directions x', y', and z' as shown below.



The reference point –whether it is specified using absolute coordinates, relative distances, or a reference joint– defines the direction of the x' axes from the loaded node to the reference point. The direction of the Y' axes is then defined as the direction perpendicular to x' that lies in the plane of X' and Y. In the special case of when X' is in the direction of Y, Y' is taken to be the direction of Z. The direction of Z' is then defined as the direction perpendicular to the plane X' and Y' and follows the right-hand rule as for all other axes systems used in STAAD.Pro.

Example

```
JOINT LOAD
4 INCLINED 1.0 -1.0 0.0 FX 10

JOINT LOAD
3 INCLINED REFJT 7 FZ -30
```

Related Links

- *G.15.1 Joint Loads* (on page 2128)
- *M. To add a nodal load* (on page 832)
- *G.15.1 Joint Loads* (on page 2128)

TR.32.2 Member Load Specification

This set of commands may be used to specify member loads on frame members

General Format

```
MEMBER LOAD
```

member-list { { UNI | UMOM } dir-spec f1 f2 f3 f4| { CON | CMOM } dir-spec f5 f6 f4| LIN dir-spec f7 f8 f9 | TRAP dir-spec f_{10} f_{11} f_{12} f_{13} }

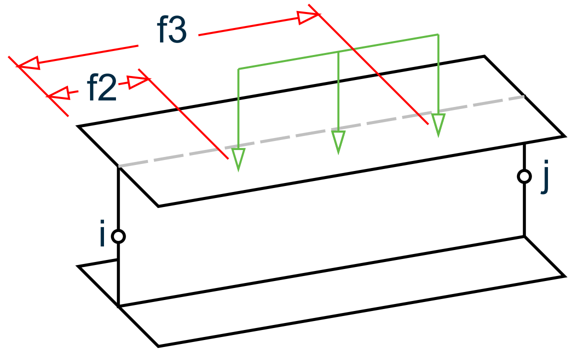
Where:

```
dir-spec = { X | Y | Z | GX | GY | GZ | PX | PY | PZ }
```

X, Y, & Z specify the direction of the load in the local (member) x, y and z-axes.
GX, GY, & GZ specify the direction of the load in the global X, Y, and Z-axes.
PX, PY, & PZ may be used if the load is to be along the projected length of the member in the corresponding global direction.

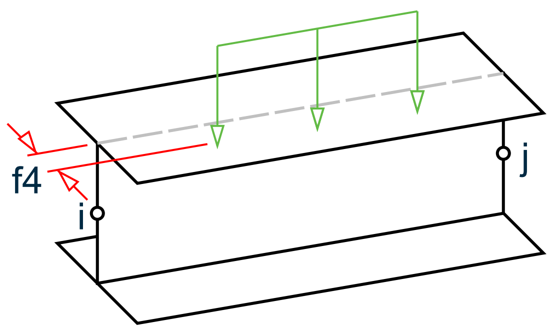
Note: Load start and end distances are measured along the member length and *not* the projected length.

f1	value of uniformly distributed load (UNI) or moment (UMOM).
f2, f3	distance of from the start of the member to the start of the load, and distance from the start of the member to the end of the load, respectively. The load is assumed to cover the full member length if f2 and f3 are omitted.



Note: Uniformly distributed moments can not be assigned to tapered members for analysis.

f4 Perpendicular distance from the member shear center to the local plane of loading. The value is positive in the general direction of the parallel (or close to parallel) local axis. If global or projected load is selected, then the local Y component of load is offset the `f4` distance; the local Z component is offset the `f4` distance; and the local X component is not offset.



Note: The local x component of force is not offset (i.e., no secondary moment is caused by axial load).

f5 value of concentrated force (`CON`) or moment (`CMOM`)

f6 distance of from the start of the member to concentrated force or moment. `f6` will default to half the member length if omitted.

f7, f8 `LIN` specifies a linearly decreasing or increasing, or a triangular load. If the load is linearly increasing or decreasing then `f7` is the value at the start of the member and `f8` is the value at the end.

f9 If the load is triangular, then `f7` and `f8` are input as zero and `f9` is the value of the load in the middle of the member.

f10, f11 The starting and ending load value for a trapezoidal linearly varying load (`TRAP`), respectively. The trapezoidal load may act over the full or partial length of a member and in a local, global or projected direction.

f12, f13 the loading starting point and stopping point, respectively. Both are measured from the start of the member. If `f12` and `f13` are not given, the load is assumed to cover the full member length.

Notes

a. If the member being loaded has offset distances (refer to TR.25.1 Member Offset Specification (on page 2296)), the location of the load is measured from the initial end offset distance instead of the coordinates of the starting node .

b. Trapezoidal loads are converted into a uniform load and 8 or more concentrated loads.

c. A `UNIT` command may be on lines in between member-list lines.

d. If a load location is less than zero (i.e., occurs off the starting end of the member), then it is reset to 0.0.

e. If a load location is greater than the length, then it is reset to the length.

Example

```
MEMBER LOAD
619 CON GY -2.35 5.827
68 TO 72 UNI GX -0.088 3.17 10.0
186 TRAP GY -0.24 -0.35 0.0 7.96
3212 LIN X -5.431 -3.335
41016 UNI PZ -0.075
3724 LIN GY -6.2 -7.8
```

Projected Loads

If a projected load direction is specified, then the length of the member considered is that projected on the plane perpendicular to the load direction. This is always less than or equal to the actual member length. Projected loads reduce the scale of the load proportional to the projected length.

For example, if an inclined beam of total length, L, with a uniform load, w, is given the `GY` (global Y) load direction, then the resulting reactions are $R = 1/2 \times L \times w$. However, if the `PY` (projected Y) load direction is used, then the projected component of the length, L_x, is used as the member length. The resulting reactions are $R = 1/2 \times L_x \times w$ in this case.

The projected load direction, PY, uses the component length in the XZ plane for the load effect.

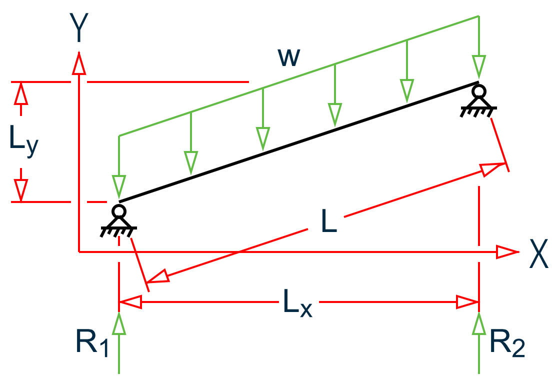


Figure 319: Example inclined beam parallel to the XY plane

TR.32.2.1 PMember Load Specification

This set of commands may be used to specify member loads on a physical member (pmember).

General Format

```
PMEMBER LOAD
```

```
pmember-list { { UNI | UMOM } dir-spec f1 f2 f3 f4 | { CON | CMOM } dir-spec f5 f6 f4 |
 TRAP dir-spec f7 f8 f9 f10 }
```

Where:

```
dir-spec = { X | Y | Z | GX | GY | GZ | PX | PY | PZ }
```

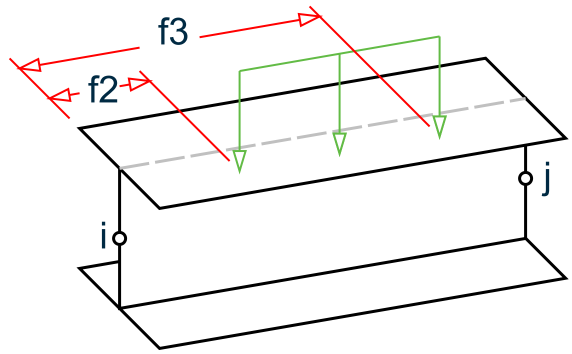
X, Y, & Z specify the direction of the load in the local (member) x, y and z-axes.

GX, GY, & GZ specify the direction of the load in the global X, Y, and Z-axes.

PX, PY, & PZ may be used if the load is to be along the projected length of the member in the corresponding global direction.

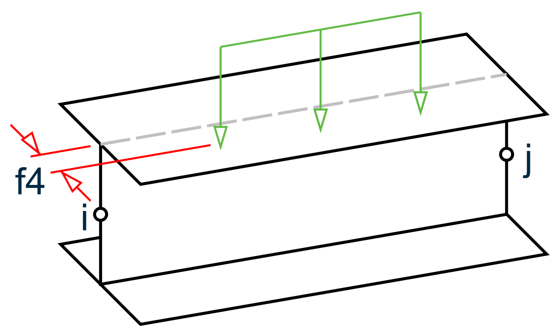
Note: Load start and end distances are measured along the member length and *not* the projected length.

f1	value of uniformly distributed load (UNI) or moment (UMOM).
f2, f3	distance of from the start of the member to the start of the load, and distance from the start of the member to the end of the load, respectively. The load is assumed to cover the full member length if *f2* and *f3* are omitted.



Note: Uniformly distributed moments can not be assigned to tapered members for analysis.

f4 Perpendicular distance from the member shear center to the local plane of loading. The value is positive in the general direction of the parallel (or close to parallel) local axis. If global or projected load is selected, then the local Y component of load is offset the *f4* distance; the local Z component is offset the *f4* distance; and the local X component is not offset.



Note: The local x component of force is not offset (i.e., no secondary moment is caused by axial load).

f5 value of concentrated force (`CON`) or moment (`CMOM`)

f6 distance of from the start of the member to concentrated force or moment. *f6* will default to half the member length if omitted.

f7*, *f8 The starting and ending load value for a trapezoidal linearly varying load (`TRAP`), respectively. The TRAP load may act over the full or partial length of a member and in a local, global or projected direction.

f9*, *f10 the loading starting point and stopping point, respectively. Both are measured from the start of the member. If *f9* and *f10* are not given, the load is assumed to cover the full member length.

TR.32.3 Element Load Specifications

This set of commands may be used to specify various types of loads on plate and solid elements.

Related Links

- *G.5 Finite Element Information* (on page 2099)

- *G.5.1 Plate and Shell Elements* (on page 2099)
- *G.5.2 Solid Elements* (on page 2110)
- *G.5.3 Surface Elements (Deprecated)* (on page 2113)

TR.32.3.1 Element Load Specification - Plates

This command may be used to specify various types of `ELEMENT LOADS` for plates.

Plate element loads must be applied following the expression

```
ELEMENT LOAD (PLATE)
```

using the format explained under the following options.

Option 1 - Load Applied in a Global Direction

```
element-list  PRESSURE {GX | GY | GZ} p1 (x1 y1) (x2 y2)
```

This is for specifying a pressure of magnitude *p1* in one of the global axis directions on the full element or a small rectangular part of an element.

- Partial Pressure - If applied on a small part, (x1,y1,x2 and y2) define the corners of the rectangular region where the load is applied.
- Concentrated Load - If only x1, y1 is provided, the load is assumed as a concentrated load applied at the specified point defined by (x1,y1).
- Full Plate Pressure - If (x1,y1,x2,y2) is not provided, the load is assumed to act over the full area of the element.

(x1,y1, x2 and y2) are measured from the center of the element in the local axis system (see figure later in this section). There is no option to apply the load over a projected area.

p1 has units of force per square of length for pressure and units of force for concentrated load.

GX, GY and GZ represent the global axis directions.

Option 2 - Load Applied Normal to Plate (Local z)

```
element-list PRESSURE p1 (x1 y1) (x2 y2)
```

This is for specifying a constant pressure of magnitude *p1* acting perpendicular to the plane of the element on the full element or a small rectangular part of an element. This coincides with the element's local Z axis.

- Partial Pressure - If applied on a small area, x1,y1,x2, and y2 define the corners of the rectangular region where the load is applied.
- Concentrated Load - If only x1, y1 is provided, the load is assumed as a concentrated load applied at the specified point defined by (x1,y1).
- Full Plate Pressure - If x1, y1, x2, and y2 are not provided, then the load is assumed to act over the full area of the element.

(x1,y1, x2 and y2) are measured from the center of the element in the local axis system (see figure later in this section). There is no option to apply the load over a projected area.

p1 has units of force per square of length for pressure and units of force for concentrated load.

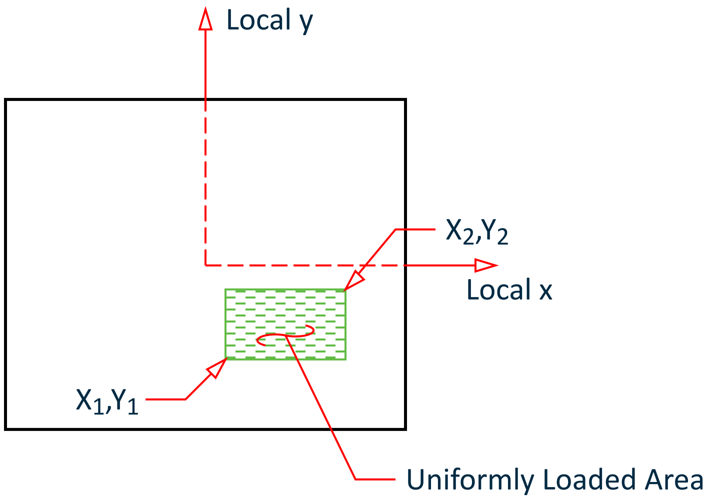

Figure 320: Coordinate values, x1,y1 & x2,y2, in the local coordinate system used in options 1 and 2

Option 3 - Pressure on Full Plate in Local X or Y or Projection

```
element-list PRESSURE {LX | LY | PX | PY | PZ} p2
```

This is for specifying a constant pressure of magnitude *p2* along the local X (LX) or Y (LY) axis of the element (parallel to the element surface) *or* along a global axis on the projected area of the plate. For example, in the case of a friction load you can use the LX or LY options.

A projected pressure is scaled down by a factor of the projected area onto the global plane perpendicular to the load direction to the element area. This is always equal to or less than the pressure in the global direction.

The resulting pressure, $p' = p\frac{A_{xz}}{A_{xyz}}$

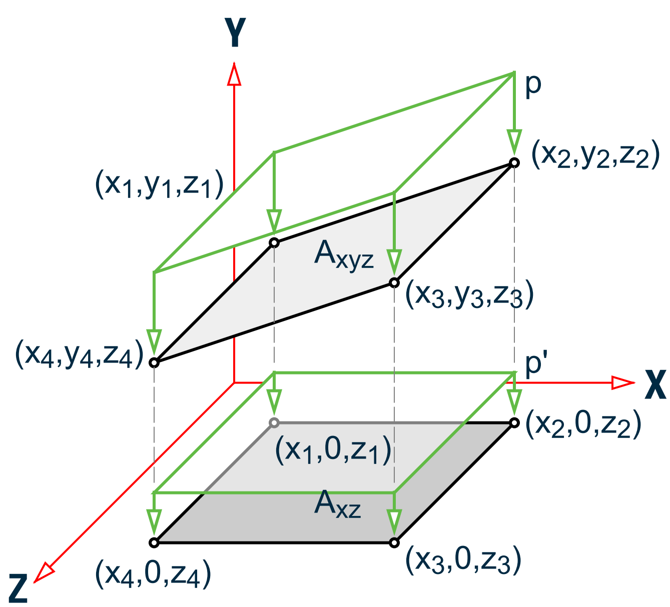

Figure 321: Projected pressure, p, in the PY direction

> **Note:** With this option, a load can be applied only on the full area of the element.

p_2 has units of force per square of length.

Option 4 - Trapezoidal Plate Load

```
element-list TRAP {GX | GY | GZ} {X | Y} f1 f2
```

This is for applying a trapezoidally varying load with the following characteristics:

a. The direction of action of the load is global (GX, GY or GZ), parallel to the surface (LX or LY as in friction type loads), or normal to the element surface (local Z). The last becomes the automatic direction of action if the global or tangential directions are not specified).

b. The load varies along the local X or Y directions (imagine the wall of a tank with hydrostatic pressure where pressure at the lower nodes is higher than at the upper nodes, and hence the load varies as one travels from the bottom edge of the elements to the top edge.)

This type of load has to be applied over the full area of the element. *f1* is the intensity at the I-J (or J-K) edge and *f2* is the intensity at the K-L (or L-I) edge depending on whether the load varies along "X" or "Y".

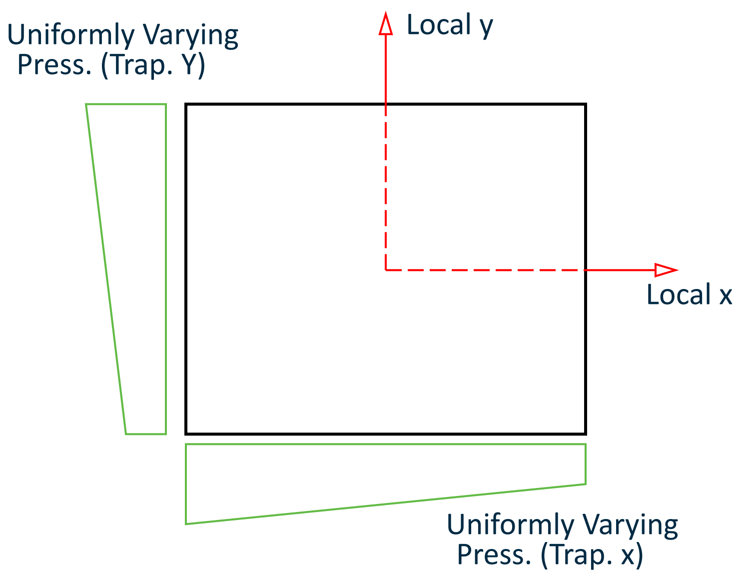

Figure 322: Center of the element is the origin defining the rectangular area on which the pressure is applied in option 4

The TRAP option should be used when a linearly varying pressure needs to be specified. The variation must be provided over the entire element.

X or Y - Direction of variation of element pressure. The TRAP X/Y option indicates that the variation of the Trapezoid is in the local X or in the local Y direction. The load acts in the global or local direction if selected, otherwise along the local Z axis.

f1 - Pressure intensity at start.
f2 - Pressure intensity at end.

Option 5 - Trapezoidal Loading Using Nodes

element-list TRAP {GX | GY | GZ | LX | LY} JT *f3 f4 f5 f6*

This is for specifying a trapezoidally varying load over the full area of the element where one happens to know the intensity at the joints (JT) of the element. The load is defined by intensities of *f3*, *f4*, *f5*, and *f6* at the 4 corners of a 4-noded element. For triangular elements, *f6* is not applicable. The load can act along the global directions (GX, GY and GZ) or along the local X and Y directions (LX and LY, like a friction load).

Notes

a. “Start” and “end” defined above are based on positive directions of the local X or Y axis.
b. Pressure intensities at the joints allows linear variation of pressure in both the X and Y local directions simultaneously.
c. The TRAP load with global directions may be used to apply a volumetric type of pressure. For example, consider a grain silo with a sloping wall. In the event of modeling it using non-uniform elements, by which we mean elements whose 3 or 4 nodes are all at different elevations, the grain height at each node will depend on the elevation of the node. One can apply the pressure by specifying the intensity at each node of each element.

Example

```
LOAD 4
ELEMENT LOAD
1 7 TO 10 PR 2.5
11 12 PR 2.5 1.5 2.5 5.5 4.5
15 TO 25 TRAP X 1.5 4.5
15 TO 20 TRAP GY JT 1.5 4.5 2.5 5.5
34 PR 5.0 2.5 2.5
35 TO 45 PR -2.5
15 25 TRAP GX Y 1.5 4.5
29 95 TRAP LX Y 3.7 8.7
```

- *G.5.3 Surface Elements (Deprecated)* (on page 2113)

TR.32.3.2 Element Load Specification - Solids

The following types of loads can be assigned on the individual faces of solid elements:

- A uniform pressure
- A volumetric type of pressure on a face where the intensity at one node of the face can be different from that at another node on the same face.

  An example of such a load is the weight of water on the sloping face of a dam. If the dam is modeled using solids, for the individual elements, the water height at the lower elevation nodes will be larger than those at the higher elevation nodes.

General Format

The syntax is as follows.

```
ELEMENT LOAD SOLIDS
```

```
elem-list FACE i1 PRESSURE { GX | GY | GZ } f1 f2 f3 f4
```

Where:

f_1 f_2 f_3 f_4 = Pressure values at the joints for each 3 or 4 joint face defined. Only f_1 needs to be specified for uniform pressure. In any case the pressure is provided over the entire face.

i_1= one of six face numbers to receive the pressure for the solids selected. See the figure in G.5.2 Solid Elements (on page 2110) for the following face definitions. Enter a pressure on all 4 joints even if the face is collapsed to 3 points.

Description

The first option above loads the solid by specifying one or more of the 6 faces to receive pressure.

The PRESSURE may be provided either in GLOBAL (GX, GY, GZ) directions or in local Z direction (normal to the element). If the GLOBAL direction is omitted, the applied loading is assumed to be normal to the face and a positive pressure is into the solid. The loads are proportional to the area, not the projected area.

Face Number	Surface Joints			
	f1	f2	f3	f4
1 front	Jt 1	Jt 4	Jt 3	Jt 2
2 bottom	Jt 1	Jt 2	Jt 6	Jt 5
3 left	Jt 1	Jt 5	Jt 8	Jt 4
4 top	Jt 4	Jt 8	Jt 7	Jt 3
5 right	Jt 2	Jt 3	Jt 7	Jt 6
6 back	Jt 5	Jt 6	Jt 7	Jt 8

Example

```
LOAD 4
ELEMENT LOAD SOLIDS
11 12 FACE 3 PR 2.5 1.5 2.5 5.5
```

Related Links

- *G.5.2 Solid Elements* (on page 2110)

TR.32.3.3 Element Load Specification - Joints

This command may be used to specify various types of element like loads for joints. Three or four joints are specified that form a plane area; pressure is specified for that area; then STAAD computes the equivalent joint loads. This command may be used as an alternative or supplement for the Area Load, Floor Load, and the other Element Load commands.

The PRESSURE may be provided either in GLOBAL (GX, GY, GZ) directions or in local Z direction (normal to the element). If the GLOBAL direction is omitted, the applied loading is assumed to be in the local Z direction as if the joints defined a plate. The loads are proportional to the area, not the projected area.

General Format

```
ELEMENT LOAD JOINTS
```

i_1 (BY i_2) i_3 (BY i_4) i_5 (BY i_6) i_7 (BY i_8) -

FACETS j_1 PRESSURE { GX | GY | GZ } f_1 f_2 f_3 f_4

Note: If this data is on more than one line, the hyphens must be within the joint data.

Where:

f_1 f_2 f_3 f_4 = Pressure values at the joints for each 3 or 4 joint facet defined. Only f_1 needs to be specified for uniform pressure. In any case the pressure is provided over the entire element.
j_1 = number of facets loaded.
i_1, i_3, i_5, i_7 = Joint numbers that define the first facet.
i_2, i_4, i_6, i_8 = each joint number is incremented by the BY value (1 if omitted).

Example

```
LOAD 4
ELEMENT LOAD JOINT
1 BY 1 2 BY 1 32 BY 1 31 BY 1 -
FACETS 5 PR GY 10 10 15 15
```

The above data is equivalent to the following:

```
LOAD 4
ELEMENT LOAD JOINT
1 2 32 31 FACETS 1 PRESSURE GY 10 10 15 15
2 3 33 32 FACETS 1 PRESSURE GY 10 10 15 15
3 4 34 33 FACETS 1 PRESSURE GY 10 10 15 15
4 5 35 34 FACETS 1 PRESSURE GY 10 10 15 15
5 6 36 35 FACETS 1 PRESSURE GY 10 10 15 15
```

So, the value following the word FACETS is like a counter for generation, indicating how many element faces the load command must be created for. Thus a value of 5 for facets means, a total of 5 imaginary element faces have been loaded.

BY is the value by which the individual corner node number is being incremented during the generation. In this example, the value is 1, which is same as the default. Instead, if it had been say,

```
1 BY 22 BY 2 32 BY 1 31 BY 1 -
FACETS 5 PRESSURE GY 10 10 15 15
```

we would have obtained

```
1 2 32 31 FACETS 1 PRESSURE GY 10 10 15 15
3 5 33 32 FACETS 1 PRESSURE GY 10 10 15 15
5 8 34 33 FACETS 1 PRESSURE GY 10 10 15 15
```

```
8 11 35 34 FACETS 1 PRESSURE GY 10 10 15 15
9 14 36 35 FACETS 1 PRESSURE GY 10 10 15 15
```

Notes

If a pressure or volumetric load is acting on a region or surface, and the entity which makes up the surface, like a slab, is not part of the structural model, one can apply the pressure load using this facility. The load is defined in terms of the pressure intensity at the 3 or 4 nodes which can be treated as the corners of the triangular or quadrilateral plane area which makes up the region. This command may be used as an alternative or supplement for the Area Load, Floor Load, Wind Load, and other pressure load situations.

In other words, the element pressure load can be applied along a global direction on any surface, without actually having elements to model that surface. Thus, for a sloping face of a building, if one wants to apply a wind pressure on the sloping face, one can do so by specifying the joints which make up the boundary of that face. Three or four joints are specified that form a plane area; pressure is specified for that area; then STAAD computes the equivalent joint loads.

TR.32.4 Area, One-way, and Floor Load Specifications

These commands may be used to specify loading over an area enclosed by beam members and the program will distribute the loading onto the perimeter beams as either a one way or two-way system. They are used mostly when the entity transmitting the load, such as a slab, is not part of the structural model. The `AREA LOAD` or `ONEWAY LOAD` may be used for modeling one-way distribution and the `FLOOR LOAD` may be used for modeling two-way distribution. There are three commands which should be used in the following way:

Area Load	The program will establish the direction of the shorter span and load the beams in that direction. This command is used for distributing a pressure load onto the beams that define a closed loop.
Floor Load	This command is used for distributing a pressure load onto all beams that define a closed loop assuming a two way distribution of load.
One-way	This may appear similar to the `AREA LOAD` command, but this command defines an area from which the program will search out closed loops of beams, similar to the `FLOOR LOAD` command and also has the option to define the direction of span. This command is an development of the principals defined in the `FLOOR LOAD` command, but the load is defined to span in a single direction.

Live Load Reduction

Floor loads and one-way loads can be made reducible according to Section 1607 of IBC 2000 if included in a Live Load case which is specified as Reducible. The following rules are implemented:

- Reduction only applies to live loads on members with a tributary area of greater than 150 ft^2.
- Live loads over 100 psf are not reduced.
- The reduction in live load (in percent) is = $0.08\times(A_{trib} - 150)$, with a maximum reduction amount of 40% for members carrying load from one level only.

Note: Live load reduction is *not* not available for area loads.

Related Links

- *G.15.3 Area, One-way, and Floor Loads* (on page 2130)

TR.32.4.1 Area Load Specification

Used for distributing a pressure load onto the beams that define a closed loop. The program will establish the direction of the shorter span and load the beams in that direction.

Note: The `AREA LOAD` command has been deprecated in favor of the `ONEWAY LOAD` or `FLOOR LOAD` commands.

General Format

```
AREA LOAD
```

```
memb-list ALOAD f1  { GX | GY | GZ }
```

Where:

f1 The value of the area load (units of weight over square length unit). If Global direction is omitted, then this load acts along the positive local y-axis [for the members of a floor analysis, the local y direction will coincide with global vertical axis in most cases]. If Global direction is included, then the load acts in that direction. The magnitude of the loads calculated is the same as if the positive local y axis option was selected. (For detailed description, refer to G.15.3 Area, One-way, and Floor Loads (on page 2130).)

Note: Area load should not be specified on members declared as `MEMBER CABLE`, `MEMBER TRUSS` or `MEMBER TENSION`.

Example

```
AREA LOAD
2 4 TO 8 A LOAD - 0.250
12 16 ALOAD -.0500
```

Notes

a. The structure has to be modeled in such a way that the specified global axis remains perpendicular to the floor plane(s).

b. For the `FLOOR LOAD` specification, a two-way distribution of the load is considered. For the `ONEWAY` and `AREA LOAD` specification, a one-way action is considered. For ONE WAY loads, the program attempts to find the shorter direction within panels for load generation purposes. So, if any of the panels are square in shape, no load will be generated for those panels. For such panels, use the `FLOOR LOAD` type.

c. The global horizontal direction options (GX and GZ) enables one to consider AREA LOADs, ONEWAY LOADSs, and FLOOR LOADs for mass matrix for frequency calculations.

Related Links

- *G.15.3 Area, One-way, and Floor Loads* (on page 2130)
- *M. To add an area load* (on page 839)
- *G.15.3 Area, One-way, and Floor Loads* (on page 2130)

TR.32.4.2 One-way Load Specification

Defines an area from which the program will search out closed loops of beams, similar to the TR.32.4.3 Floor Load Specification (on page 2483) command and also has the option to define the direction of span. This command is a development of the principals defined in the `FLOOR LOAD` command, but the load is defined to span in a single direction (similar to `AREA LOAD`).

The One-way Load specification be applied to groups and can also use live load reduction per IBC or UBC codes.

General Format

```
ONEWAY LOAD (SAVE { LOAD })
```

```
YRANGE  f1 f2 ONELOAD f3 (XRA f4 f5 ZRA f6 f7) { GX | GY | GZ } (TOWARDS f8) (PRINT
{MEMBER | LOAD})
```

or

```
XRANGE f1 f2 ONELOAD f3 (YRA f4 f5 ZRA f6 f7) { GX | GY | GZ } (TOWARDS f8) (PRINT
{MEMBER | LOAD})
```

or

```
ZRANGE f1 f2 ONELOAD f3 (XRA f4 f5 YRA f6 f7) { GX | GY | GZ } (TOWARDS f8) (PRINT
{MEMBER | LOAD})
```

or

```
_FloorGroupName ONELOAD f3 { GX | GY | GZ } (INCLINED) (TOWARDS f8)
```

Where:

f1 f2	Global coordinate values to specify Y, X, or Z range. The load will be calculated for all members lying in that global plane within the first specified global coordinate range.
f3	The value of the load (unit weight over square length unit). If the global direction is omitted, then this load acts parallel to the positive global Y if command begins with YRA and based on the area projected on a X-Z plane. Similarly, for commands beginning with XRA, the load acts parallel to the positive global X and based on the area projected on a Y-Z plane. Similarly, for commands beginning with ZRA, the load acts parallel to the positive global Z and based on the area projected on a X-Y plane.
f4-f7	Global coordinate values to define the corner points of the area on which the specified floor load (*f3*) acts. If not specified, the floor load will be calculated for all members in all floors within the first specified global coordinate range.
GX,GY,GZ	If a Global direction is included, then the load is re-directed to act in the specified direction(s) with a magnitude of the loads which is based on the area projected on a plane as if the Global direction was omitted. The Global direction option is especially useful in mass definition.
FloorGroupName	See TR.16.1 Listing of Entities by Specifying Groups (on page 2235) for the procedure for creating FLOORGROUPs. The member-list contained in this name will be the candidates that will receive the load generated from the floor pressure.
f8	Defines a member onto which the loading is directed and defines the span direction for the one way loading. If the `TOWARDS` option is not used, the program will default to distributing a one-way load to the longest side. See Note b below for square panels.

`INCLINED` - This option must be used when a `ONEWAY LOAD` is applied on a set of members that form a panel(s) which is inclined to the global XY, YZ, or ZX planes.

`PRINT` = This option is used when floor panel information printout is required. The total number of panels identified, total area of all panels and total load generated will be printed in the output file.

`PRINT MEMBER` = This option is used to print panel member numbers on which loads are generated along with the total number of panels identified, total area of all panels and total load generated.

`PRINT LOAD` = This option is used to print panel loading information. All other information available with `PRINT MEMBER` will also be printed in the output file.

`SAVE` = This option will give panel information in an external text file named *(filename)* `_FLD.TXT`. The information corresponding to `PRINT MEMBER` will be printed in this file.

`SAVE LOAD` = This option will give panel information in an external text file named *(filename)* `_FLD.TXT`. The information corresponding to `PRINT LOAD` will be printed in this file.

Note: It is recommended to use `SAVE` or `SAVE LOAD` option which will give same output printed in an external text file. If detailed output is printed in output (`.ANL` file) file using `PRINT MEMBER` or `PRINT LOAD` option, the size of the output file may increase to a large extent.

Tip: The `SET FLOOR LOAD TOLERANCE` command may be used to specify a specify the tolerance for out-of-plane nodes to be included in a floor load. See TR.5 Set Command Specification (on page 2206)

Notes

a. The structure has to be modeled in such a way that the specified global axis remains perpendicular to the floor plane(s).

b. For the `FLOOR LOAD` specification, a two-way distribution of the load is considered. For the `ONEWAY` and `AREA LOAD` specification, a one-way action is considered. For `ONE WAY` loads, the program attempts to find the shorter direction within panels for load generation purposes.

In V8i SELECTseries 6 build 20.07.11.50 and later: for one-way loads applied to square panels (i.e., span direction is the same in either direction), triangular loads are generated on the members forming the four sides of the square. The intensity of the loads, which are equal for all four members, is calculated on the basis of four triangles formed by the two intersecting diagonals of the square.

Alternately, you may use the `FLOOR LOAD` type.

c. The load per unit area may not vary for a particular panel and it is assumed to be continuous and without holes.

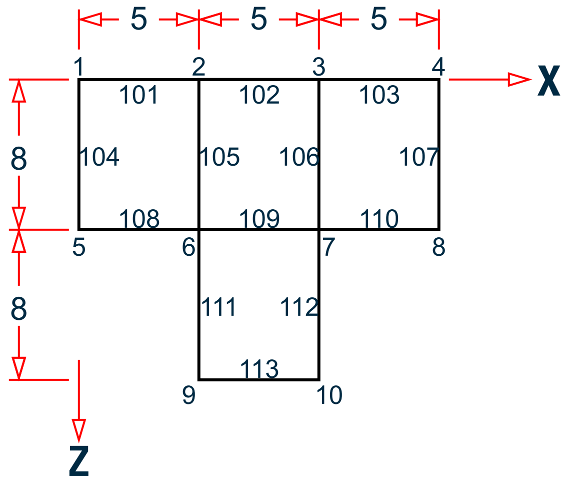
d. If the floor has a shape consisting of a mixture of convex and concave edges, then break up the floor load command into several parts, each for a certain region of the floor. This will force the program to localize the search for panels and the solution will be better.

The attached example illustrates a case where the floor has to be sub-divided into smaller regions for the floor load generation to yield proper results. The internal angle at node 6 between the sides 108 and 111 exceeds 180 degrees. A similar situation exists at node 7 also. As a result, the following command:

```
LOAD 1
FLOOR LOAD
YRANGE 11.9 12.1 FLOAD -0.35
```

will not yield acceptable results. Instead, the region should be subdivided as shown in the following example

```
LOAD 1
FLOOR LOAD
YRANGE 11.9 12.1 FLOAD -0.35 XRA -.01 15.1 ZRA -0.1 8.1
YRANGE 11.9 12.1 FLOAD -0.35 XRA 4.9 10.1 ZRA 7.9 16.1
```



e. At least one quadrilateral panel bounded on at least 3 sides by "complete" members has to be present within the bounds of the user-defined range of coordinates (XRANGE, YRANGE and ZRANGE) in order for the program to successfully generate member loads from the FLOOR/ONEWAY LOAD specification. A "complete" member is defined as one whose entire length between its start and end coordinates borders the specified panel.

The load distribution pattern depends upon the shape of the panel. If the panel is Rectangular, the distribution will be Trapezoidal and triangular as explained in the following diagram.

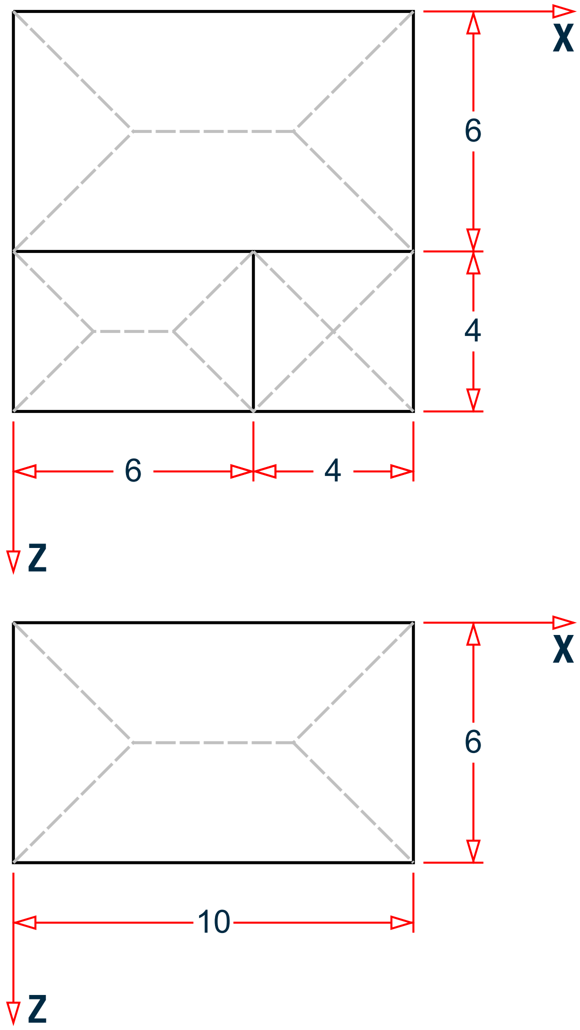


Figure 323: Trapezoidal and triangular load distribution for rectangular panels

First, the CG of the polygon is calculated. Then, each corner is connected to the CG to form triangles as shown. For each triangle, a vertical line is drawn from the CG to the opposite side. If the point of intersection of the vertical line and the side falls outside the triangle, the area of that triangle will be calculated and an equivalent uniform distributed load will be applied on that side. Otherwise a triangular load will be applied on the side.

Live Load Reduction per UBC and IBC Codes

The UBC 1997, IBC 2000, and IBC 2003 codes permit reduction of floor live loads under certain situations. The provisions of these codes have been incorporated in the manner described further below.

To utilize this facility, the following conditions have to be met when creating the STAAD.Pro model.

i. The live load must be applied using the `FLOOR LOAD` or `ONEWAY LOAD` option. This option is described above, and an example of its usage may be found in EX. US-15 Wind and Floor Load Generation on a Space Frame (on page 6423).

ii. As shown in TR.32 Loading Specifications (on page 2461), the load case has to be assigned a Type called Live at the time of creation of that case. Additionally, the option called **Reducible**, also has to be specified as shown.

```
LOAD n LOADTYPE Live REDUCIBLE
```

Where:

n is the load case number

The following figures show the load generated on members for the two situations.

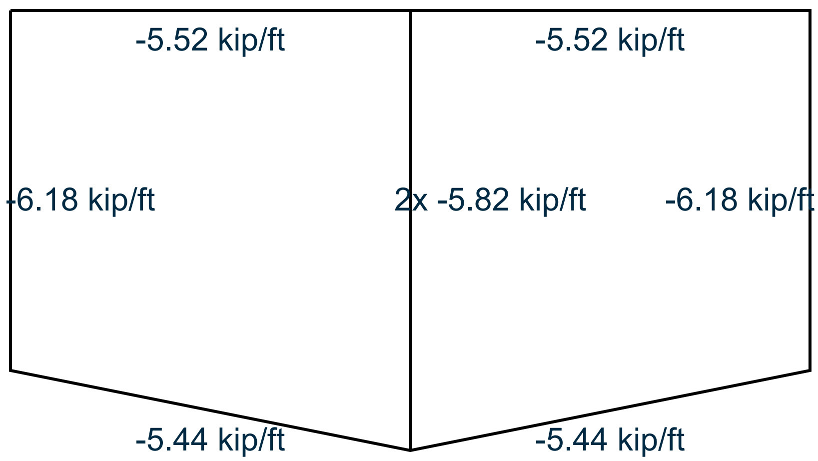

Figure 324: Load generated for the previously described cases

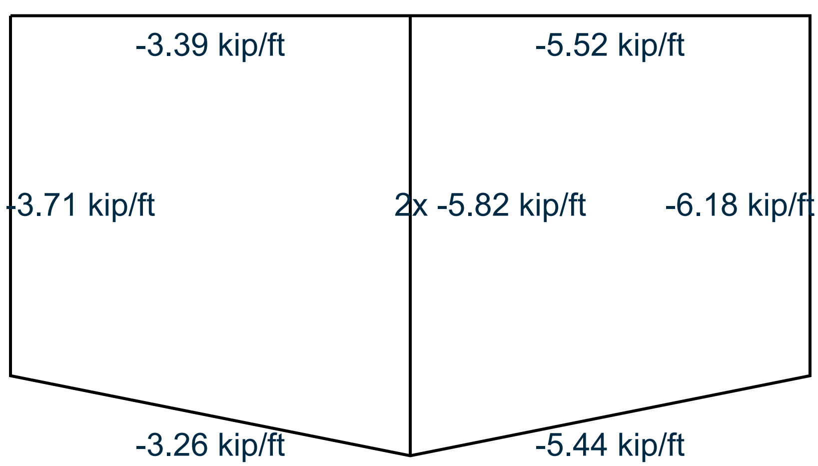

Table 261: Table - Details of the code implementation

Code Name	Section of code which has been implemented	Applicable Equations
UBC 1997	1607.5, page	Equation 7-1 R = r(A-150) for FPS units R = r(A-13.94) for SI units
IBC 2000	1607.9.2, page 302	Equation 16-2 R = r(A-150) for FPS units R = r(A-13.94) for SI units
IBC 2003	1607.9.2, page 277	Equation 16-22 R = r(A-150) for FPS units R = r(A-13.94) for SI units

where

A = area of floor supported by the member
R = reduction in percentage
= rate of reduction equal to 0.08 for floors.

Notes

a. Only the rules for live load on **Floors** have been implemented. The rules for live load on **Roofs** have not been implemented.
b. Since the medium of application of this method is the FLOOR LOAD or ONEWAY LOAD feature, and since STAAD performs load generation on beams only, the rules of the above-mentioned sections of the code for vertical members (columns) has not been implemented. The distributed load on those members found to satisfy the requirements explained in the code would have a lowered value after the reduction is applied.
c. Equation (7-2) of UBC 97, (16-3) of IBC 2000 and (16-23) of IBC 2003 have not been implemented.
d. In the IBC 2000 and 2003 codes, the first note says "A reduction shall not be permitted in Group A occupancies." In STAAD, there is no direct method for conveying to the program that the occupancy type is Group A. So, it is the user's responsibility to ensure that when he/she decides to utilize the live load reduction feature, the structure satisfies this requirement. If it does not, then the reduction should not be applied. STAAD does not check this condition by itself.
e. In the UBC 97 code, the last paragraph of section 1607.5 states that "The live load reduction shall not exceed 40 percent in garages for the storage of private pleasure cars having a capacity of not more than nine passengers per vehicle." Again, there is no method to convey to STAAD that the structure is a garage for storing private pleasure cars. Hence, it is the user's responsibility to ensure that the structure satisfies this requirement. If it does not, then the reduction should not be applied. STAAD does not check this condition by itself.
f. Because all the three codes follow the same rules for reduction, no provision is made available in the command syntax for specifying the code name according to which the reduction is to be done.

TR.32.4.3 Floor Load Specification

Used to distribute a pressure load onto all beams that define a closed loop assuming a two way distribution of load.

The Floor Load specification be applied to groups and can also use live load reduction per IBC or UBC codes.

General Format

```
FLOOR LOAD (SAVE { LOAD })
```

```
YRANGE  f1 f2 FLOAD f3 (XRA f4 f5 ZRA f6 f7) { GX | GY | GZ } (PRINT {MEMBER | LOAD})
```

or

```
XRANGE f1 f2 FLOAD f3 (YRA f4 f5 ZRA f6 f7) { GX | GY | GZ } (PRINT {MEMBER | LOAD})
```

or

```
ZRANGE f1 f2 FLOAD f3 (XRA f4 f5 YRA f6 f7) { GX | GY | GZ } (PRINT {MEMBER | LOAD})
```

or

```
_FloorGroupNameFLOAD f3 { GX | GY | GZ } (INCLINED) }
```

Where:

f1 f2	Global coordinate values to specify Y, X, or Z range. The load will be calculated for all members lying in that global plane within the first specified global coordinate range.
f3	The value of the load (unit weight over square length unit). If the global direction is omitted, then this load acts parallel to the positive global Y if command begins with YRA and based on the area projected on a X-Z plane. Similarly, for commands beginning with XRA, the load acts parallel to the positive global X and based on the area projected on a Y-Z plane. Similarly, for commands beginning with ZRA, the load acts parallel to the positive global Z and based on the area projected on a X-Y plane.
f4 - f7	Global coordinate values to define the corner points of the area on which the specified floor load (*f3*) acts. If not specified, the floor load will be calculated for all members in all floors within the first specified global coordinate range.
GX,GY,GZ	If a Global direction is included, then the load is re-directed to act in the specified direction(s) with a magnitude of the loads which is based on the area projected on a plane as if the Global direction was omitted. The Global direction option is especially useful in mass definition.
FloorGroupName	See TR.16.1 Listing of Entities by Specifying Groups (on page 2235) for the procedure for creating FLOORGROUPs. The member-list contained in this name will be the candidates that will receive the load generated from the floor pressure.

`INCLINED` - This option must be used when a `FLOOR LOAD` is applied on a set of members that form a panel(s) which is inclined to the global XY, YZ, or ZX planes.

`PRINT` = This option is used when floor panel information printout is required. The total number of panels identified, total area of all panels and total load generated will be printed in the output file.

PRINT MEMBER = This option is used to print panel member numbers on which loads are generated along with the total number of panels identified, total area of all panels and total load generated.

PRINT LOAD = This option is used to print panel loading information. All other information available with PRINT MEMBER will also be printed in the output file.

SAVE = This option will give panel information in an external text file named *(filename)* _FLD.TXT. The information corresponding to PRINT MEMBER will be printed in this file.

SAVE LOAD = This option will give panel information in an external text file named *(filename)* _FLD.TXT. The information corresponding to PRINT LOAD will be printed in this file.

Note: It is recommended to use SAVE or SAVE LOAD option which will give same output printed in an external text file. If detailed output is printed in output (.ANL file) file using PRINT MEMBER or PRINT LOAD option, the size of the output file may increase to a large extent.

Tip: The SET FLOOR LOAD TOLERANCE command may be used to specify a specify the tolerance for out-of-plane nodes to be included in a floor load. See TR.5 Set Command Specification (on page 2206)

Notes

a. The structure has to be modeled in such a way that the specified global axis remains perpendicular to the floor plane(s).
b. For the FLOOR LOAD specification, a two-way distribution of the load is considered. For the ONEWAY and AREA LOAD specification, a one-way action is considered. For ONE WAY loads, the program attempts to find the shorter direction within panels for load generation purposes. So, if any of the panels are square in shape, no load will be generated for those panels. For such panels, use the FLOOR LOAD type.
c. FLOOR LOAD from a slab is distributed on the adjoining members as trapezoidal and triangular loads depending on the length of the sides as shown in the diagram. Internally, these loads are converted to multiple point loads.

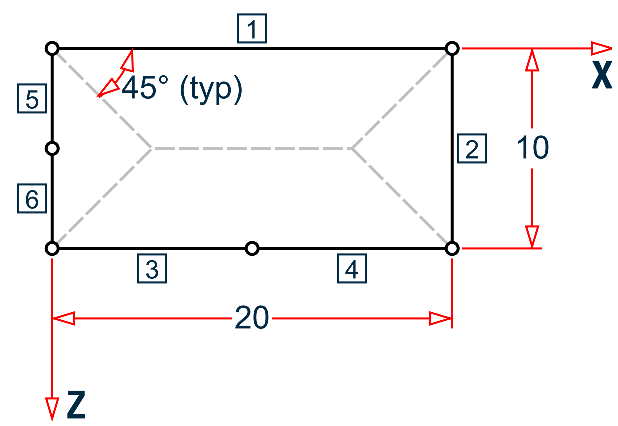

Figure 325: Members 1 and 2 get full trapezoidal and triangular loads respectively. Members 3 and 4 get partial trapezoidal loads and 5 and 6 get partial triangular load.

d. The load per unit area may not vary for a particular panel and it is assumed to be continuous and without holes.
e. The FLOOR LOAD facility is not available if the SET Z UP command is used (See Section 5.5.)

f. If the floor has a shape consisting of a mixture of convex and concave edges, then break up the floor load command into several parts, each for a certain region of the floor. This will force the program to localize the search for panels and the solution will be better.

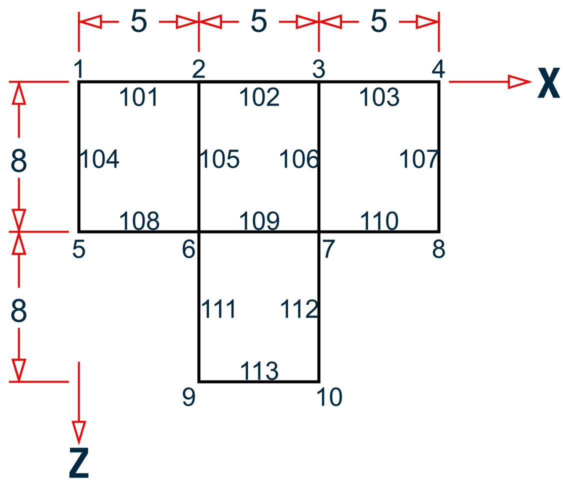
If the floor has a shape consisting of a mixture of convex and concave edges, then break up the floor load command into several parts, each for a certain region of the floor. This will force the program to localize the search for panels and the solution will be better.

The attached example illustrates a case where the floor has to be sub-divided into smaller regions for the floor load generation to yield proper results. The internal angle at node 6 between the sides 108 and 111 exceeds 180 degrees. A similar situation exists at node 7 also. As a result, the following command:

```
LOAD 1
FLOOR LOAD
YRANGE 11.9 12.1 FLOAD -0.35
```

will not yield acceptable results. Instead, the region should be subdivided as shown in the following example

```
LOAD 1
FLOOR LOAD
YRANGE 11.9 12.1 FLOAD -0.35 XRA -.01 15.1 ZRA -0.1 8.1
YRANGE 11.9 12.1 FLOAD -0.35 XRA 4.9 10.1 ZRA 7.9 16.1
```



g. The global horizontal direction options (GX and GZ) enables one to consider AREA LOADs, ONEWAY LOADSs and FLOOR LOADs for mass matrix for frequency calculations.

h. For ONE WAY loads, the program attempts to find the shorter direction within panels for load generation purposes. So, if any of the panels are square in shape, no load will be generated on the members circumscribing those panels. In such cases, one ought to use the FLOOR LOAD type.

Applying FLOOR LOAD onto a Floor Group

When applying a floor load using XRANGE, YRANGE and ZRANGE, there are two limitations that one may encounter:

a. If panels consist of members whose longitudinal axis cross each other in an X type, and if the members are not connected to each other at the point of crossing, the panel identification and hence the load generation in that panel may fail. A typical such situation is shown in the plan drawing shown in the next figure.

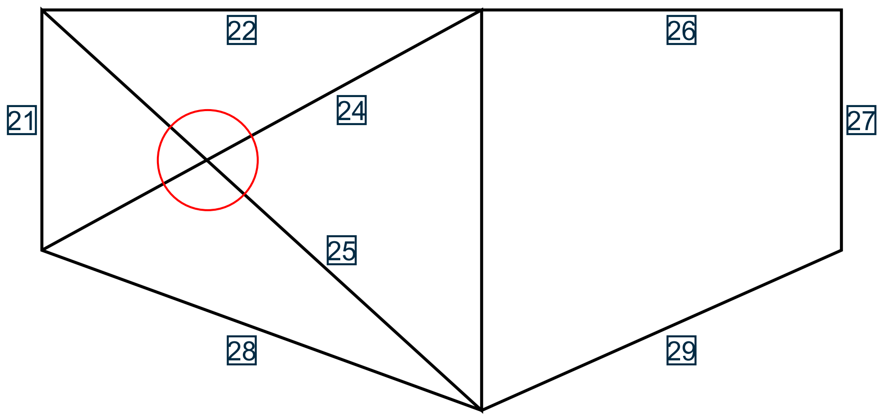


Figure 326: Load generation on a panel with members not connected at a point of crossing (members 24 and 24)

b. After the load is specified, if the user decides to change the geometry of the structure (X, Y or Z coordinates of the nodes of the regions over which the floor load is applied), she/he has to go back to the load and modify its data too, such as the XRANGE, YRANGE and ZRANGE values. In other words, the 2 sets of data are not automatically linked.

The above limitations may be overcome using a FLOOR GROUP. A GROUP name is a facility which enables us to cluster a set of entities – nodes, members, plates, solids, etc. into a single moniker through which one can address them. Details of this are available in section 5.16 of this manual.

The syntax of this command, as explained earlier in this section is:

```
FLOOR LOAD
```

```
Floor-group-name FLOAD  f3 { GX | GY | GZ }
```

Where:

f3 = pressure on the floor

To create equal loads in all 3 global directions for mass definition or other reasons, then enter direction labels for each direction desired; GY first then GX and/or GZ.

Example

```
START GROUP DEFINITION
FLOOR
_PNL5A  21 22 23 28
END GROUP DEFINITION
LOAD 2 FLOOR LOAD on intermediate panel @ Y = 10 ft
FLOOR LOAD
_PNL5A  FLOAD -0.45 GY
_PNL5A FLOAD -0.45 GY GX GZ
```

```
LOAD 5 LOAD ON SLOPING ROOF
FLOOR LOAD
_SLOPINGROOF FLOAD -0.5 GY INCLINED
```

Live Load Reduction per UBC and IBC Codes

The UBC 1997, IBC 2000, and IBC 2003 codes permit reduction of floor live loads under certain situations. The provisions of these codes have been incorporated in the manner described further below.

To utilize this facility, the following conditions have to be met when creating the STAAD.Pro model.

i. The live load must be applied using the `FLOOR LOAD` or `ONEWAY LOAD` option. This option is described above, and an example of its usage may be found in EX. US-15 Wind and Floor Load Generation on a Space Frame (on page 6423).
ii. As shown in TR.32 Loading Specifications (on page 2461), the load case has to be assigned a Type called Live at the time of creation of that case. Additionally, the option called **Reducible**, also has to be specified as shown.

```
LOAD n LOADTYPE Live REDUCIBLE
```

Where:

n is the load case number

The following figures show the load generated on members for the two situations.

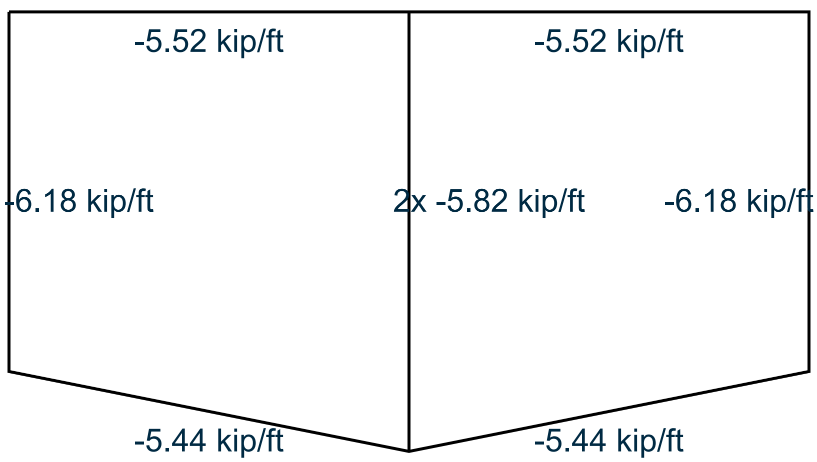

Figure 327: Load generated for the previously described cases

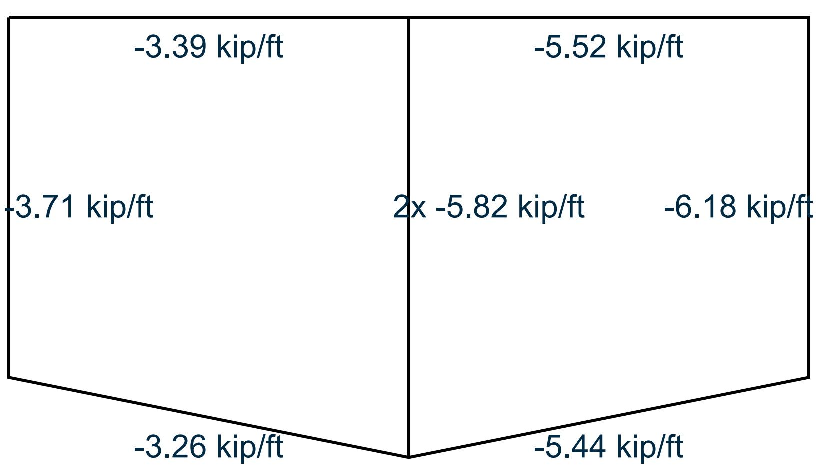

Table 262: Table - Details of the code implementation

Code Name	Section of code which has been implemented	Applicable Equations
UBC 1997	1607.5, page	Equation 7-1 R = r(A-150) for FPS units R = r(A-13.94) for SI units
IBC 2000	1607.9.2, page 302	Equation 16-2 R = r(A-150) for FPS units R = r(A-13.94) for SI units
IBC 2003	1607.9.2, page 277	Equation 16-22 R = r(A-150) for FPS units R = r(A-13.94) for SI units

where

A	=	area of floor supported by the member
R	=	reduction in percentage
		= rate of reduction equal to 0.08 for floors.

Notes

a. Only the rules for live load on **Floors** have been implemented. The rules for live load on **Roofs** have not been implemented.

b. Since the medium of application of this method is the FLOOR LOAD or ONEWAY LOAD feature, and since STAAD performs load generation on beams only, the rules of the above-mentioned sections of the code for vertical members (columns) has not been implemented. The distributed load on those members found to satisfy the requirements explained in the code would have a lowered value after the reduction is applied.

c. Equation (7-2) of UBC 97, (16-3) of IBC 2000 and (16-23) of IBC 2003 have not been implemented.

d. In the IBC 2000 and 2003 codes, the first note says “A reduction shall not be permitted in Group A occupancies.” In STAAD, there is no direct method for conveying to the program that the occupancy type is Group A. So, it is the user’s responsibility to ensure that when he/she decides to utilize the live load reduction feature, the structure satisfies this requirement. If it does not, then the reduction should not be applied. STAAD does not check this condition by itself.

e. In the UBC 97 code, the last paragraph of section 1607.5 states that “The live load reduction shall not exceed 40 percent in garages for the storage of private pleasure cars having a capacity of not more than nine passengers per vehicle.” Again, there is no method to convey to STAAD that the structure is a garage for storing private pleasure cars. Hence, it is the user’s responsibility to ensure that the structure satisfies this requirement. If it does not, then the reduction should not be applied. STAAD does not check this condition by itself.

f. Because all the three codes follow the same rules for reduction, no provision is made available in the command syntax for specifying the code name according to which the reduction is to be done.

TR.32.5 Prestress Load Specification

This command may be used to specify PRESTRESS loads on members of the structure.

General Format

```
MEMBER {PRESTRESS | POSTSTRESS } (LOAD)
```

```
memb-list FORCE f1 *{ ES f2 | EM f3 | EE f4 }
```

Where:

FORCE *f1*	Prestressing force. A positive value indicates precompression in the direction of the local x-axis. A negative value indicates pretension.
ES *f2*	specifies eccentricity (from the centroid) of the prestress force at the start of the member.
EM *f3*	specifies eccentricity (from the centroid) of the prestress force at the mid-point of the member.
EE *f4*	specifies eccentricity (from the centroid) of the prestress force at the end of the member.

Description

The first option, (MEMBER PRESTRESS LOAD), considers the effect of the prestressing force during its application. Thus, transverse shear generated at the ends of the member(s) subject to the prestressing force is transferred to the adjacent members.

The second option, (MEMBER POSTSTRESS LOAD), considers the effect of the existing prestress load after the prestressing operation. Thus, transverse shear at the ends of the member(s) subject to the prestressing force is not transferred to the adjacent members.

Example

```
MEMBER PRESTRESS
2 TO 7 11 FORCE 50.0
MEMBER POSTSTRESS
8 FORCE 30.0 ES 3.0 EM -6.0 EE 3.0
```

In the first example, a prestressing force of 50 force units is applied through the centroid (i.e., no eccentricity) of members 2 to 7 and 11. In the second example, a poststressing force of 30 force units is applied with an eccentricity of 3 length units at the start, -6.0 at the middle, and 3.0 at the end of member 8.

One of the limitations in using this command is that under any one load case, on any given member, a prestress or poststress load may be applied only once. If the given member carries multiple stressed cables or has a PRESTRESS and POSTSTRESS load condition, such a situation will have to be specified through multiple load cases for that member. See example below.

Incorrect Input:

```
LOAD 1
MEMBER PRESTRESS
6 7 FORCE 100 ES 2 EM -3 EE 2
6 FORCE 150 ES 3 EM -6 EE 3
PERFORM ANALYSIS
```

Correct Input:

```
LOAD 1 MEMBER PRESTRESS
6 7 FORCE 100 ES 2 EM -3 EE 2
LOAD 2
MEMBER PRESTRESS
6 FORCE 150 ES 3 EM -6 EE 3
LOAD COMBINATION 3
1 1.0 2 1.0
PERFORM ANALYSIS
```

Examples for Modeling Techniques

The following examples describe the partial input data for the members and cable profiles shown below.

TR.32.6 Temperature Load Specification for Members, Plates, and Solids

This command may be used to specify TEMPERATURE loads or strain loads on members, plates, and solids; or strain loads on members.

General Format

```
TEMPERATURE LOAD
```

```
memb/elem-list { TEMP f1 f2 f4 | STRAIN f3 | STRAINRATE f5 }
```

Where:

f1 The change in temperature which will cause axial elongation in the members or uniform volume expansion in plates and solids. The temperature unit is the same as the unit chosen for the coefficient of thermal expansion ALPHA under the CONSTANT command. (Members/Plates/Solids)

f2 The temperature differential from the top to the bottom of the member or plate ($T_{top\ surface}$-$T_{bottom\ surface}$). If *f2* is omitted, no bending will be considered. (Local Y axis) (Members/Plates). Section depth must be entered for prismatic.

f3 Initial axial elongation (+)/ shrinkage (-) in member due to misfit, etc. in length unit (Members only).

f4 The temperature differential from side to side of the member. (Local Z axis) (Members). Section or flange width must be entered for prismatic.

f5 Initial axial elongation (+)/ shrinkage (-) per unit length, of members only.

Example

```
UNIT MMS
TEMP LOAD
1 TO 9 15 17 TEMP 70.0
18 TO 23 TEMP 90.0 66.0
8 TO 13 STRAIN 3.0
15 27 STRAINRATE 0.4E-4
```

Notes

a. It is not necessary or possible to specify the units for temperature or for ALPHA. The user must ensure that the value provided for ALPHA is consistent in terms of units with the value provided for the temperature load. (See TR.26 Specifying and Assigning Material Constants (on page 2303)).

If ALPHA was provided by a material name (STEEL, CONCRETE, ALUMINUM) then the temperature here must be in degree Fahrenheit units (if English length units were in effect when Alpha was defined) or degree Celsius units (if metric length units were in effect when Alpha was defined).

Related Links

- *G.15.6 Temperature and Strain Load* (on page 2133)

TR.32.7 Fixed-End Load Specification

This command may be used to specify `FIXED END` loads on members (beams only) of the structure.

General Format

```
FIXED ( END ) LOAD
```

```
memb-list FXLOAD f1, f2, … f12
```

Where:

member_list	normal STAAD.Pro member list rules (TO and BY for generation; and - to continue list to next line).
f1 … f6	Force-x, shear-y, shear-z, torsion, moment-y, moment-z (all in local coordinates) at the start of the member.
f7 … f12	Same as above except at the end of the member.

If less than 12 load values are entered, zero values will be added to the end. The loads may be extended to one additional line by ending the first load line with a - (hyphen).

These loads are given in the member local coordinate system and the directions are opposite to the actual load on the member.

Related Links

- *G.15.4 Fixed End Member Load* (on page 2131)
- *M. To add fixed end member loads* (on page 837)
- *G.15.4 Fixed End Member Load* (on page 2131)

TR.32.8 Support Joint Displacement Specification

This command may be used to specify displacements (or generate loads to induce specified displacements) in supported directions (pinned, fixed, enforced, or spring).

General Format

```
SUPPORT DISPLACMENT
```

```
support-joint-list { FX | FY | FZ | MX | MY | MZ } f1
```

Where:

f1	Value of the corresponding displacement. For translational displacements, the unit is in the currently specified length unit, while for rotational displacements the unit is always in degrees.

FX, FY, FZ specify translational displacements in X, Y, and Z directions respectively. MX, MY, MZ specify rotational displacements in X, Y, and Z directions.

Description

There are two distinct modes of usage for this command. If any `ENFORCED` specifications were used in the support command then the “displacement mode” is used; otherwise the “load mode” is used. Despite the name of this command, if displacements are specified in spring directions, the displacement is at the joint not at the grounded end of the support spring. Displacement cannot be specified in a direction that does not have a support or a spring.

Displacement Mode

With this mode, the support joint displacement is modeled as an imposed joint displacement. The joint directions where displacement may be specified must be defined (same for all cases) in the `SUPPORT` command, see TR.27.1 Global Support Specification (on page 2316). Any beam members, springs or finite elements will be considered in the analysis. Other loading, inclined supports, and control/dependent are all considered. Any number of cases may have displacements entered. However, all cases will have zero displacements at the enforced directions if no displacement values are entered for that case. Displacements occur along global directions, even at inclined supports. Displacements may not be specified at dependent directions.

If some cases are to have spring supports and others enforced displacements at the same joint directions, then two `PERFORM ANALYSES` must be used with the `CHANGE` command in between. The first perform analysis could have the `SUPPORTS` with springs, no enforced directions, and with the load cases without displacements. The second perform analysis would then have `SUPPORTS` without springs but with enforced directions and the cases with displacements.

Displacement Mode Restrictions:

- The Support Displacement command may be entered only once per case.
- Spring directions and Enforced directions may not both be specified at the same joint direction in the same Perform Analysis step.

Load Mode

With this mode, the support joint displacement is modeled as a load. Only beam members (not springs or finite elements) are considered in computing the joint load distribution necessary to cause the displacement. Other loading, inclined supports, and control/ dependent specifications are also not considered. These unconsidered factors, if entered, will result in displacements other than those entered (results are superimposed). Only those cases with displacements entered will be affected.

Load Mode Restrictions:

- Support Displacements can be applied in up to four load cases only.
- The Support Displacement command may be entered only once per case.
- Finite elements should not be entered.
- Inclined supports must not be entered.
- Spring supports are not considered in calculating the load so their use will lead to displacements different from the input values.

Example

```
UNIT …
SUPPORT DISPL
5 TO 11 13 FY -0.25
19 21 TO 25 MX 15.0
```

In this example, the joints of the first support list will be displaced by 0.25 units in the negative global Y direction. The joints of the second support list will be rotated by 15 degrees about the global X-axis.

TR.32.9 Selfweight

Selfweight commands are used to calculate and apply the self weight of structural elements for analysis.

TR.32.9.1 Selfweight Loads

Used to calculate and apply the self weight of members, plates, and solids in the structure for analysis.

General Format

```
SELFWEIGHT ( { X | Y | Z } f1) ( LIST member-list | ALL )
```

Where:

X, Y, & Z	represent the global direction in which the selfweight acts. The default direction is along the Y axis.
f1	The factor to be used to multiply the selfweight. The default value is -1.0.
member-list	member, plate and/or solid list or group. All list specifications such as explicit list including TO and BY, range (XR, YR, ZR), parallel to (X, Y, Z) and groups are supported. If a group is used, the selfweight command must be repeated for each group. If list is not provided, all structural components are used for body weight calculation unless those are inactive either by INACTIVE command specification or internally set due to TENSION/COMPRESSION ONLY specification.

Description

This command is used if the self-weight of the members, plates, and solids within the structure is to be considered. The self-weight of every active element is calculated and applied as a uniformly distributed member load.

Note: Surfaces are not included in the selfweight command. The SSELFWT must be used to include the selfweight for surface elements. See TR.32.9.2 Surface Selfweight Load (on page 2497)

This command may also be used without any direction and factor specification. Thus, if specified as SELFWEIGHT, loads will be applied in the negative global Y direction with a factor of unity.

Notes

a. Density must be provided for calculation of the self weight.
b. The selfweight of finite elements is converted to joint loads at the connected nodes and is not used as an element pressure load.
c. The selfweight of a plate is placed at the joints, regardless of plate releases.

d. The `SELFWEIGHT` specification for definition of static method of seismic load generator also is capable of accepting a list. Only there is no direction specification for this command.

e. Similarly, the `SELFWEIGHT` specification when used in a Reference Load is also capable of handling a list.

Example

```
LOAD 1 DEAD AND LIVE LOAD
* includes the selfweight of all members, plates, and solids.  The following
two commands are functionally identical
SELF
SELFWEIGHT y -1.0 all
*
* Factored weight for members, plates, and solids 4 through 10 along global x
direction
SELFWEIGHT X 1.4 LIST 4 TO 10
* Includes weight of al members, plates, and solids associated with the group
_PLATEGRP1
SELF X 1.0 _PLATEGRP1
```

Related Links

- *M. To add selfweight load* (on page 831)

TR.32.9.2 Surface Selfweight Load

Used to calculate and apply the self weight of surface elements in the structure for analysis.

Note: This feature requires STAAD.Pro V8i (SELECTseries 3) or higher.

General Format

```
SSELFWEIGHT ( { X | Y | Z } f1) ( LIST surface-list | ALL )
```

Where:

X, Y, & Z	represent the global direction in which the selfweight acts. The default direction is along the Y axis.
f1	The factor to be used to multiply the selfweight. The default value is -1.0.
surface-list	surface element list or group. All list specifications such as explicit list including `TO` and `BY`, range (XR, YR, ZR), parallel to (X, Y, Z) and groups are supported. If a group is used, the selfweight command must be repeated for each group. If list is not provided, all structural components are used for body weight calculation unless those are inactive either by `INACTIVE` command specification or internally set due to TENSION/COMPRESSION ONLY specification.

See TR.32.9.1 Selfweight Loads (on page 2496) for Description and Notes pertaining to self weight.

Example

```

TR.32.10 Dynamic Loading Specification

The command specification needed to perform response spectrum analysis and time-history analysis is explained in the following sections.

Note: STAAD.Pro is also capable of generating floor spectrum responses for a time history analysis. Refer to TR.37.10 Floor Spectrum Command (on page 2657) for details on adding this to the analysis commands.

TR.32.10.1 Response Spectrum Analysis

Various methods for performing response spectrum analysis have been implemented in STAAD.Pro. They include a generic method that is described in most text books, as well as code based methods like those required by the IBC, Eurocode 8, IS 1893, etc. These are described in the following sections.

Table 263: Codes available in STAAD.Pro with Response Spectrum loads

Country	Code	Title
Canada	TR.32.10.1.2 Response Spectrum Specification per NRC 2005 (on page 2506)	National Building Code(NRC/CNRC) of Canada
	TR.32.10.1.3 Response Spectrum Specification per NRC 2010 (on page 2512)	National Building Code(NRC/CNRC) of Canada
China	TR.32.10.1.6 Response Spectrum Specification per GB 50011 2010 (on page 2531)	*Code for seismic design of buildings* GB50011-2010 (2016 Edition)
India	TR.32.10.1.7 Response Spectrum Specification per IS: 1893 (Part 1)-2002 (on page 2534)	Criteria for Earthquake Resistant Design of Structures - Part 1: General Provisions and Buildings and Part 4: Industrial structures including Stack-like structures
	TR.32.10.1.8 Response Spectrum Specification per IS: 1893 (Part 1)-2016 (on page 2544)	Criteria for Earthquake Resistant Design of Structures - Part 1: General Provisions

TR.32.10.1.1 Response Spectrum Specification - Custom

This command may be used to specify and apply a custom (i.e., “generic” method) `RESPONSE SPECTRUM` loading for dynamic analysis.

This command should appear as part of a loading specification. If it is the first occurrence, it should be accompanied by the load data to be used for frequency and mode shape calculations. Additional occurrences need no additional information. The maximum number of response spectrum load cases allowed in one run is 50.

Results of frequency and mode shape calculations may vary significantly depending upon the mass modeling. All masses that are capable of moving should be modeled as loads, applied in all possible directions of movement. For dynamic mass modeling, refer to TR.32 Loading Specifications (on page 2461) and G.17.3 Dynamic Analysis (on page 2154). An illustration of mass modeling is available, with explanatory comments, in Example Problem No.11.

General Format

```
SPECTRUM comb-method *{ X f1 | Y f2 | Z f3 } { ACCELERATION | DISPLACEMENT } (SCALE f4)
```

```
{DAMP f5 | CDAMP | MDAMP } ( { LINEAR | LOGARITHMIC } ) (MISSING f6) (ZPA f7) (FF1 f8)
(FF2 f9) ( { DOMINANT f10 | SIGN } ) (SAVE) (IMR f11) (STARTCASE f12)
```

Note: The data from SPECTRUM through SCALE above must be on the first line of the command, the remaining data can be on the first or subsequent lines with all but last ending with a hyphen (limit of four lines per spectrum).

Starting on the next line, enter Spectra in one of these two input forms (i.e., explicit values or an external file):

```
{ p1 v1; p2 v2; p3 v3; … | FILE filename }
```

Where:

Table 264: Parameters used for generic model response spectrum

Parameter	Default Value	Description
X *f1*, Y *f2*, Z *f3*	0.0	Factors for the input spectrum to be applied in X, Y, & Z directions. Any one or all directions can be input. Directions not provided will default to zero.
SCALE *f4*	1.0	Linear scale factor by which the spectra data will be multiplied. Usually used to factor g's to length/sec^2 units. This input is the appropriate value of acceleration due to gravity in the current unit system (thus, 9.81 m/s^2 or 32.2 ft/s^2).
DAMP *f5*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If CDAMP is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If MDAMP is specified, then modal damping is calculated using the method defined in a DEFINE DAMPING INFORMATION command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)

Parameter	Default Value	Description
MISSING *f6*	0	Optional parameter to use the "Missing Mass" method to include the static effect of the masses not represented in the modes. The spectral acceleration length/sec^2 for this missing mass mode is the *f6* value entered in length per second squared units (this value is not multiplied by `SCALE`). If *f6* is zero, then the spectral acceleration at the `ZPA` *f7* frequency is used. If *f7* is zero or not entered, then the spectral acceleration at 33Hz is used. The results of this calculation are SRSSed with the modal combination results. For SRSS, CQC, and TEN the results of this calculation are SRSSed with the modal combination results. For ABS, missing mass is ignored. For ASCE, the missing mass result is algebraically added with the rigid parts of the extracted modes. For ASCE, the MIS option is assumed to be on. If any of *f6*, *f7*, *f8*, or *f9* are not entered, the defaults will be used. Missing mass does not include the effect of masses lumped at the supports unless the support is a stiff spring or an Enforced support. **Note:** If the `MISSING` parameter is entered on any spectrum case it will be used for all spectrum cases.
ZPA *f7*	33 [Hz]	The zero period acceleration value for use with `MISSING` option only. Defaults to 33 Hz if not entered. The value is printed but not used if `MISSING f6` is entered.
FF1 *f8*	2 [Hz]	The *f1* parameter defined in the ASCE 4-98 standard in Hz units. For `ASCE` option only.
FF2 *f9*	33 [Hz]	The f2 parameter defined in the ASCE 4-98 standard in Hz units. For `ASCE` option only.
DOMINANT *f10*	1 (1st Mode)	The dominant mode method. All results will have the same sign as mode number *f10* alone would have if it were excited then the scaled results were used as a static displacements result. Defaults to mode 1 if no value entered. If a 0 value entered, then the mode with the greatest % participation in the excitation direction will be used (only one direction factor may be nonzero). **Note:** Do not enter the `SIGN` parameter with this option. Ignored for the `ABS` method of combining spectral responses from each mode.
IMR *f11*	1	The number of individual modal responses (scaled modes) to be copied into load cases. Defaults to one. If greater than the actual number of modes extracted (`NM`), then it will be reset to NM. Modes one through f11 will be used. Missing Mass modes are not output.
STARTCASE *f12*	Highest Load Case No. + 1	The primary load case number of mode 1 in the `IMR` parameter. Defaults to the highest load case number used so far plus one. If *f12* is not higher than all prior load case numbers, then the default will be used. For modes 2 through `NM`, the load case number is the prior case number plus one.

comb-method = { `SRSS` | `ABS` | `CQC` | `ASCE` | `TEN` | `CSM` | `GRP` } are methods of combining the responses from each mode into a total response.

The CQC and ASCE4-98 methods require damping. ABS, SRSS, CRM, GRP, and TEN methods do not use damping unless spectra-period curves are made a function of damping (see File option below). CQC, ASCE, CRM, GRP, and TEN include the effect of response magnification due to closely spaced modal frequencies. ASCE includes more algebraic summation of higher modes. ASCE and CQC are more sophisticated and realistic methods and are recommended.

SRSS Square Root of Summation of Squares method.

ABS Absolute sum. This method is very conservative and represents a worst case combination.

CQC Complete Quadratic Combination method (Default). This method is recommended for closely spaced modes instead of SRSS.

Resultants are calculated as:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

$$\rho_{nm} = \frac{8\zeta^2(1+r)r^{2/3}}{(1-r^2)^2 + 4\zeta^2 r(1+r)^2}$$

$$r = \omega_n / \omega_m \le 1.0$$

Note: The cross-modal coefficient array is symmetric and all terms are positive.

ASCE NRC Regulatory Guide Rev. 2 (2006) Gupta method for modal combinations and Rigid/Periodic parts of modes are used. The ASCE4-98 definitions are used where there is no conflict. ASCE4-98 Eq. 3.2-21 (modified Rosenblueth) is used for close mode interaction of the damped periodic portion of the modes.

TEN Ten Percent Method of combining closely spaced modes. NRC Reg. Guide 1.92 (Rev. 1.2.2, 1976).

CSM Closely Spaced Method as per IS:1893 (Part 1)-2002 procedures.

GRP Closely Spaced Modes Grouping Method. NRC Reg. Guide 1.92 (Rev. 1.2.1, 1976).

Note: If SRSS is selected, the program will internally check whether there are any closely spaced modes or not. If it finds any such modes, it will switch over to the CSM method. In the CSM method, the program will check whether all modes are closely spaced or not. If all modes are closely spaced, it will switch over to the CQC method.

`ACCELERATION` or `DISPLACEMENT` indicates whether **Acceleration** or **Displacement** spectra will be entered. The relationship between acceleration and displacement values in response spectra data is:

$$\text{Displacement} = \text{Acceleration} \times (1/\omega)^2$$

where

ω = 2π/Period (period given in seconds; ω in cycles per second)

`DAMP`, `MDAMP`, and `CDAMP` select source of damping input:

- `DAMP` indicates to use the *f2* value for all modes
- `MDAMP` indicates to use the damping entered or computed with the `DEFINE DAMP` command if entered, otherwise default value of 0.05 will be used

- CDAMP indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the CONSTANT specification

LINEAR or LOGARITHMIC — Select **Linear** or **Logarithmic** interpolation of the input Spectra versus Period curves for determining the spectra value for a mode given its period. Linear is the default. Since Spectra versus Period curves are often linear only on Log-Log scales, the logarithmic interpolation is recommended in such cases; especially if only a few points are entered in the spectra curve.

When FILE *filename* is entered, the interpolation along the damping axis will be linear.

> **Note:** The last interpolation parameter entered on the last of all of the spectrum cases will be used for all spectrum cases.

SAVE — This option results in the creation of a acceleration data file (with the model file name and an .acc file extension) containing the joint accelerations in g's and radians/sec^2. These files are plain text and may be opened and viewed with any text editor (e.g., Notepad).

SIGN — This option results in the creation of signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign. This command is ignored for ABS option.

> **Caution:** Do *not* enter DOMINANT parameter with this option.

Spectra data is input in one of these two input forms:

1. p1, v1; p2, v2; …. ; pn, vn. Data is part of input, immediately following the SPECTRUM command. Period – Value pairs (separated by semi colons) are entered to describe the Spectrum curve. Period is in seconds and the corresponding Value is either acceleration (current length unit/sec^2) or displacement (current length unit) depending on the ACC or DIS chosen. Continue the curve data onto as many lines as needed (up to 500 spectrum pairs). Spectrum pairs must be in ascending order of period. Note, if data is in g acceleration units, then set SCALE to a conversion factor to the current length unit (9.81, 386.4, etc.). Also note, do not end these lines with a hyphen (-). Each SPECTRUM command must be followed by Spectra data if this input form is used.
2. FILE *filename* data is in a separate file, using the format described in File Format for Spectra Data (on page 2504).

   When the File *filename* command has been provided, then you must have the spectra curve data on a file named filename prior to starting the analysis. The format of the FILE spectra data allows spectra as a function of damping as well as period.

> **Note:** If the FILE *filename* command is entered, it must be with the first spectrum case and will be used for all spectrum cases.

No File *filename* command needs to be entered with the remaining spectrum cases. The filename may not be more than 72 characters in length.

Examples

An example using joint loads and the SRSS combination method:

```
LOAD 2 SPECTRUM IN X-DIRECTION
SELFWEIGHT X 1.0
SELFWEIGHT Y 1.0
```

```
SELFWEIGHT Z 1.0
JOINT LOAD
10 FX 17.5
10 FY 17.5
10 FZ 17.5
SPECTRUM SRSS X 1.0 ACC SCALE 32.2
0.20 0.2 ; 0.40 0.25 ; 0.60 0.35 ; 0.80 0.43 ; 1.0 0.47
1.2 0.5 ; 1.4 0.65 ; 1.6 0.67 ; 1.8 0.55 ; 2.0 0.43
```

An example using member loads and the CQC combination method:

```
LOAD 2 SEISMIC LOADING
SELFWEIGHT X 1.0
SELFWEIGHT Y 1.0
MEMBER LOADS
5  CON  GX  5.0  6.0
5  CON  GY  5.0  6.0
5  CON  GX  7.5  10.0
5  CON  GY  7.5  10.0
5  CON  GX  5.0  14.0
5  CON  GY  5.0  14.0
SPECTRUM CQC X 1.0 ACC DAMP 0.05 SCALE 32.2
0.03  1.00  ;  0.05  1.35
0.1  1.95  ;  0.2  2.80
0.5  2.80  ;  1.0  1.60
```

Multiple Response Spectra

If there is more than one response spectrum defined in the input file, the load data (representing the dynamic weight) should accompany the first set of spectrum data only. In the subsequent load cases, only the spectra should be defined. See example below.

```
LOAD 1 SPECTRUM IN X-DIRECTION
SELFWEIGHT X 1.0
SELFWEIGHT Y 1.0
SELFWEIGHT Z 1.0
JOINT LOAD
10 FX 17.5
10 FY 17.5
10 FZ 17.5
SPECTRUM SRSS X 1.0 ACC SCALE 32.2  IMR 2 STARTCASE 11
0.20 0.2 ; 0.40 0.25 ; 0.60 0.35 ; 0.80 0.43 ; 1.0 0.47
1.2 0.5 ; 1.4 0.65 ; 1.6 0.67 ; 1.8 0.55 ; 2.0 0.43
PERFORM ANALYSIS
CHANGE
*
LOAD 2 SPECTRUM IN Y-DIRECTION
SPECTRUM SRSS Y 1.0 ACC SCALE 32.2
0.20 0.1 ; 0.40 0.15 ; 0.60 0.33 ; 0.80 0.45 ; 1.00 0.48
1.20 0.51 ; 1.4 0.63 ; 1.6 0.67 ; 1.8 0.54 ; 2.0 0.42
```

File Format for Spectra Data

The format of the `FILE` spectra data allows spectra as a function of damping as well as period. The format is:

```
   Dataset 1      MDAMPCV NPOINTCV                      (no of values = 2)
   Dataset 2      Damping Values in ascending order     (no of values = Mdampcv)
```

```
   Dataset 3a     Periods                                (no of values = Npointcv)
           3b     Spectra                                (no of values = Npointcv)
```

For ASCE, the MIS option is assumed to be on. If any of f6, f7, f8, f9 are not entered the defaults will be used.

Repeat Data set 3 *Mdampcv* times (3a,3b , 3a,3b , 3a,3b , etc.) (i.e., for each damping value).

Data sets 2, 3a and 3b must have exactly *Npointcv* values each. Blanks or commas separate the values. The data may extend to several lines. Do not end lines with a hyphen (-). No comment lines (*) or semi-colons. Multiple values may be entered per line.

where

MDAMPCV	=	Number of damping values for which there will be separate Spectra vs. Period curves.
NPOINTCV	=	Number of points in each Spectra vs. Period curve. If NPOINTCV is negative, then the period-spectra values are entered as pairs.

Examples of Spectra Data files

An example of spectral data for use in the X direction:

```
1,-10
0.05
0.20 0.2 0.40 0.25 0.60 0.35 0.80 0.43 1.0 0.47
1.2 0.5 1.4 0.65 1.6 0.67 1.8 0.55 2.0 0.43
```

An example of spectral data for use in the Z direction:

```
1 10
0.05
0.20 0.40 0.60 0.80 1.0 1.2 1.4 1.6 1.8 2.0
0.1 0.15 0.33 0.45 0.48 0.51 0.63 0.67 0.54 0.42
```

Note: It is important that any STAAD plain text file be encoded with ANSI/UTF-8. If you use a text editor in a non-English user interface, ensure that the correct encoding is used when saving the file.

Individual Modal Response Case Generation

Individual modal response (IMR) cases are simply the mode shape scaled to the magnitude that the mode has in this spectrum analysis case before it is combined with other modes. If the IMR parameter is entered, then STAAD.Pro will create load cases for the first specified number of modes for this response spectrum case (i.e., if five is specified then five load cases are generated, one for each of the first five modes). Each case will be created in a form like any other primary load case.

The results from an IMR case can be viewed graphically or through the print facilities. Each mode can therefore be assessed as to its significance to the results in various portions of the structure. Perhaps one or two modes could be used to design one area/floor and others elsewhere.

You can use subsequent load cases with TR.32.11 Repeat Load Specification (on page 2595) combinations of these scaled modes and the static live and dead loads to form results that are all with internally consistent signs (unlike the usual response spectrum solutions). The modal applied loads vector will be omega squared times mass times the scaled mode shape. Reactions will be applied loads minus stiffness matrix times the scaled mode shape.

With the Repeat Load capability, you can combine the modal applied loads vector with the static loadings and solve statically with P-Delta or tension only.

Note: When the IMR option is entered for a Spectrum case, then a TR.37 Analysis Specification (on page 2620) & TR.38 Change Specification (on page 2660) must be entered after each such Spectrum case.

TR.32.10.1.2 Response Spectrum Specification per NRC 2005

This command may be used to specify and apply the `RESPONSE SPECTRUM` loading as per the 2005 edition of the National Research Council specification *National Building Code of Canada* (NBC) , for dynamic analysis. The graph of frequency – acceleration pairs are calculated based on the input requirements of the command and as defined in the code.

General Format

```
SPECTRUM comb-method NRC 2005 ( TORSION (DECCENTRICITY f20) (ECCENTRICITY f21) ) *{ X
f1 | Y f2| Z f3} { ACC | DIS } ( SCALE f4)
```

```
{ DAMP f5| CDAMP | MDAMP } ( { LINEAR | LOGARITHMIC } ) (MISSING f6) (ZPA f7)
({ DOMINANT f10| SIGN }) (SAVE)  (IMR f11) (STARTCASE f12)
```

Note: The data from `SPECTRUM` through `SCALE` must be on the first line of the command. The data shown on the second line above can be continued on the first line or one or more new lines with all but last ending with a hyphen (limit of four lines per spectrum).

The command is completed with the following spectrum data which must be started on a new line:

```
{ p1 v1; p2 v2; p3 v3; … pn vn | FILE filename  }
```

Where:

Table 265: Parameters used for NRC 2005 response spectrum

Parameter	Default Value	Description
DECCENTRICITY *f20*	1.0	Factor to be multiplied with static eccentricity (i.e., eccentricity between center of mass and center of rigidity).
ECCENTRICITY *f21*	0.05	Factor for accidental eccentricity. Positive values indicate clockwise torsion and negative values indicate counterclockwise torsion.
X *f1*, Y *f2*, Z *f3*	0.0	Factors for the input spectrum to be applied in X, Y, & Z directions. Any one or all directions can be input. Directions not provided will default to zero.

Parameter	Default Value	Description
SCALE *f4*	1.0	Linear scale factor by which the spectra data will be multiplied. Usually used to factor g's to length/sec^2 units. This input is the appropriate value of acceleration due to gravity in the current unit system (thus, 9.81 m/s^2 or 32.2 ft/s^2).
DAMP *f5*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If `CDAMP` is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If `MDAMP` is specified, then modal damping is calculated using the method defined in a `DEFINE DAMPING INFORMATION` command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)
MISSING *f6*		Optional parameter to use "Missing Mass" method. The static effect of the masses not represented in the modes is included. The spectral acceleration for this missing mass mode is the *f6*value entered in length/sec^2 (this value is not multiplied by SCALE). If *f6*is zero, then the spectral acceleration at the `ZPA` *f7*frequency is used. If *f7*is zero or not entered, the spectral acceleration at 33Hz (Zero Period Acceleration, ZPA) is used. The results of this calculation are SRSSed with the modal combination results. **Note:** If the `MISSING` parameter is entered on any spectrum case it will be used for all spectrum cases.
ZPA *f7*	33 [Hz]	The zero period acceleration value for use with `MISSING` option only. Defaults to 33 Hz if not entered. The value is printed but not used if `MISSING f6` is entered.
DOMINANT *f10*	1 (1st Mode)	The dominant mode method. All results will have the same sign as mode number *f10* alone would have if it were excited then the scaled results were used as a static displacements result. Defaults to mode 1 if no value entered. If a 0 value entered, then the mode with the greatest % participation in the excitation direction will be used (only one direction factor may be nonzero). **Note:** Do not enter the `SIGN` parameter with this option. Ignored for the `ABS` method of combining spectral responses from each mode.
IMR *f11*	1	The number of individual modal responses (scaled modes) to be copied into load cases. Defaults to one. If greater than the actual number of modes extracted (`NM`), then it will be reset to NM. Modes one through f11 will be used. Missing Mass modes are not output.

Parameter	Default Value	Description
STARTCASE *f12*	Highest Load Case No. + 1	The primary load case number of mode 1 in the IMR parameter. Defaults to the highest load case number used so far plus one. If *f12* is not higher than all prior load case numbers, then the default will be used. For modes 2 through NM, the load case number is the prior case number plus one.

comb-method = { SRSS | ABS | CQC | ASCE | TEN | CSM | GRP } are methods of combining the responses from each mode into a total response.

The CQC and ASCE4-98 methods require damping. ABS, SRSS, CRM, GRP, and TEN methods do not use damping unless spectra-period curves are made a function of damping (see File option below). CQC, ASCE, CRM, GRP, and TEN include the effect of response magnification due to closely spaced modal frequencies. ASCE includes more algebraic summation of higher modes. ASCE and CQC are more sophisticated and realistic methods and are recommended.

SRSS Square Root of Summation of Squares method.

ABS Absolute sum. This method is very conservative and represents a worst case combination.

CQC Complete Quadratic Combination method (Default). This method is recommended for closely spaced modes instead of SRSS.

Resultants are calculated as:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

$$\rho_{nm} = \frac{8\zeta^2(1+r)r^{2/3}}{(1-r^2)^2 + 4\zeta^2 r(1+r)^2}$$

$$r = \omega_n / \omega_m \le 1.0$$

Note: The cross-modal coefficient array is symmetric and all terms are positive.

ASCE NRC Regulatory Guide Rev. 2 (2006) Gupta method for modal combinations and Rigid/Periodic parts of modes are used. The ASCE4-98 definitions are used where there is no conflict. ASCE4-98 Eq. 3.2-21 (modified Rosenblueth) is used for close mode interaction of the damped periodic portion of the modes.

TEN Ten Percent Method of combining closely spaced modes. NRC Reg. Guide 1.92 (Rev. 1.2.2, 1976).

CSM Closely Spaced Method as per IS:1893 (Part 1)-2002 procedures.

GRP Closely Spaced Modes Grouping Method. NRC Reg. Guide 1.92 (Rev. 1.2.1, 1976).

Note: If SRSS is selected, the program will internally check whether there are any closely spaced modes or not. If it finds any such modes, it will switch over to the CSM method. In the CSM method, the program will check whether all modes are closely spaced or not. If all modes are closely spaced, it will switch over to the CQC method.

TORSION indicates that the torsional moment (in the horizontal plane) arising due to eccentricity between the center of mass and center of rigidity needs to be considered. See Inherent and Accidental Torsion (on page 2510) for additional information.

Note: If TORSION is entered on any one spectrum case it will be used for all spectrum cases.

Lateral shears at story levels are calculated in global X and Z directions. For global Y direction the effect of torsion will not be considered.

ACCELERATION or DISPLACEMENT indicates whether **Acceleration** or **Displacement** spectra will be entered. The relationship between acceleration and displacement values in response spectra data is:

$$\text{Displacement} = \text{Acceleration} \times (1/\omega)^2$$

where

ω = 2π/Period (period given in seconds; ω in cycles per second)

DAMP, MDAMP, and CDAMP select source of damping input:

- `DAMP` indicates to use the *f2* value for all modes
- `MDAMP` indicates to use the damping entered or computed with the `DEFINE DAMP` command if entered, otherwise default value of 0.05 will be used
- `CDAMP` indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the `CONSTANT` specification

LINEAR or LOGARITHMIC Select **Linear** or **Logarithmic** interpolation of the input Spectra versus Period curves for determining the spectra value for a mode given its period. Linear is the default. Since Spectra versus Period curves are often linear only on Log-Log scales, the logarithmic interpolation is recommended in such cases; especially if only a few points are entered in the spectra curve.

When `FILE` *filename* is entered, the interpolation along the damping axis will be linear.

Note: The last interpolation parameter entered on the last of all of the spectrum cases will be used for all spectrum cases.

SIGN This option results in the creation of signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign. This command is ignored for `ABS` option.

Caution: Do *not* enter `DOMINANT` parameter with this option.

SAVE This option results in the creation of a acceleration data file (with the model file name and an `.acc` file extension) containing the joint accelerations in g's and radians/sec^2. These files are plain text and may be opened and viewed with any text editor (e.g., Notepad).

Spectra data is input in one of these two input forms:

1. `p1, v1; p2, v2; …. ; pn, vn.` Data is part of input, immediately following the `SPECTRUM` command. Period – Value pairs (separated by semi colons) are entered to describe the Spectrum curve. Period is in seconds and the corresponding Value is either acceleration (current length unit/sec^2) or displacement (current length unit) depending on the ACC or DIS chosen. Continue the curve data onto as many lines as needed (up to 500 spectrum pairs). Spectrum pairs must be in ascending order of period. Note, if data is in g acceleration units, then set SCALE to a conversion factor to the current length unit (9.81, 386.4, etc.). Also note, do not end these lines with a hyphen (-). Each SPECTRUM command must be followed by Spectra data if this input form is used.
2. FILE *filename* data is in a separate file, using the format described in File Format for Spectra Data (on page 2504).

When the `File filename` command has been provided, then you must have the spectra curve data on a file named `filename` prior to starting the analysis. The format of the FILE spectra data allows spectra as a function of damping as well as period.

Note: If the `FILE filename` command is entered, it must be with the first spectrum case and will be used for all spectrum cases.

No `File filename` command needs to be entered with the remaining spectrum cases. The `filename` may not be more than 72 characters in length.

Individual Modal Response Case Generation

Individual modal response (`IMR`) cases are simply the mode shape scaled to the magnitude that the mode has in this spectrum analysis case before it is combined with other modes. If the IMR parameter is entered, then STAAD.Pro will create load cases for the first specified number of modes for this response spectrum case (i.e., if five is specified then five load cases are generated, one for each of the first five modes). Each case will be created in a form like any other primary load case.

The results from an IMR case can be viewed graphically or through the print facilities. Each mode can therefore be assessed as to its significance to the results in various portions of the structure. Perhaps one or two modes could be used to design one area/floor and others elsewhere.

You can use subsequent load cases with TR.32.11 Repeat Load Specification (on page 2595) combinations of these scaled modes and the static live and dead loads to form results that are all with internally consistent signs (unlike the usual response spectrum solutions). The modal applied loads vector will be omega squared times mass times the scaled mode shape. Reactions will be applied loads minus stiffness matrix times the scaled mode shape.

With the Repeat Load capability, you can combine the modal applied loads vector with the static loadings and solve statically with P-Delta or tension only.

Note: When the IMR option is entered for a Spectrum case, then a TR.37 Analysis Specification (on page 2620) & TR.38 Change Specification (on page 2660) must be entered after each such Spectrum case.

TR.32.10.1.1 Response Spectrum Specification - Custom (on page 2499) for additional details on IMR load case generation.

Inherent and Accidental Torsion

In response spectrum analysis all the response quantities (i.e., joint displacements, member forces, support reactions, plate stresses, etc.) are calculated for each mode of vibration considered in the analysis. These response quantities from each mode are combined using a modal combination method (either by CQC, SRSS, ABS, TEN PERCENT, etc.) to produce a single positive result for the given direction of acceleration. This computed result represents a maximum magnitude of the response quantity that is likely to occur during seismic loading. The actual response is expected to vary from a range of negative to positive value of this maximum computed quantity.

No information is available from response spectrum analysis as to when this maximum value occurs during the seismic loading and what will be the value of other response quantities at that time. As for example, consider two joints J2 and J3 whose maximum joint displacement in global X direction come out to be X1 and X2 respectively. This implies that during seismic loading joint J1 will have X direction displacement that is expected to vary from -X1 to +X1 and that for joint J2 from -X2 to +X2. However, this does not necessarily mean that the point of time at which the X displacement of joint J1 is X1, the X displacement of joint J2 will also be X2.

For the reason stated above, torsional moment at each floor arising due to dynamic eccentricity along with accidental eccentricity (if any) is calculated for each mode. Lateral story shear from this torsion is calculated forming global load vectors for each mode. Static analysis is carried out with this global load vector to produce global joint displacement vectors for each mode due to torsion. These joint displacements from torsion for each mode are algebraically added to the global joint displacement vectors from response spectrum analysis for each mode. The final joint displacements from response spectrum along with torsion for all modes are combined using specified modal combination method to get final maximum possible joint displacements. Refer to the steps explained below.

Steps

For each mode following steps are performed to include Torsion provision.

1. Lateral story force at each floor is calculated.
2. At each floor design eccentricity is calculated.

   Thus, design eccentricity e_{di} = *f20*×e_{si} + *f12*×b_i where *f20* = 1.0 and *f21* = (±) 0.05

   where

e_{si}	=	static eccentricity between center of mass and center of rigidity at floor i
b_i	=	floor plan dimension in the direction of earthquake loading
3. Torsional moment is calculated at each floor.

   $M_{ik} = Q_{ik} \times e_{di}$ at floor i for mode k
4. The lateral nodal forces corresponding to torsional moment are calculated at each floor. These forces represent the additional story shear due to torsion.
5. Static analysis of the structure is performed with these nodal forces.
6. The analysis results (i.e., member force, joint displacement, support reaction, etc) from torsion are algebraically added to the corresponding modal response quantities from response spectrum analysis.
7. Steps 1 through 6 are performed for all modes considered and missing mass correction (if any). Finally, the peak response quantities from the different modal responses are combined as per the specified combination method (e.g., SRSS, CQC, TEN, etc.)

Dynamic Eccentricity

The static eccentricity is generally defined as the distance between the center of mass (CM) and the center of rigidity (CR) at respective floors levels. Accidental eccentricity generally accounts for factors such as:

- the rotational component of ground motion about the vertical axis,
- the difference between computed and actual values of the mass, stiffness, or strength, and
- uneven live mass distribution.

The provision for design eccentricity e_{di} at ith floor of a building is given by the following equation:

$$e_{di} = DEC \times e_{si} + ECC \times b_i$$

where

e_{si}	=	static eccentricity at ith floor
b_i	=	plan dimension of the ith floor normal to the direction of ground motion
ECC and DEC	=	Factors to determine the design eccentricity. These are input parameters.

TR.32.10.1.3 Response Spectrum Specification per NRC 2010

This command may be used to specify and apply the `RESPONSE SPECTRUM` loading as per the 2010 edition of the National Research Council specification *National Building Code of Canada* (NBC) , for dynamic analysis. The graph of frequency – acceleration pairs are calculated based on the input requirements of the command and as defined in the code.

General Format

```
SPECTRUM comb-method NRC 2010 ( TORSION  (DECCENTRICITY f20) (ECCENTRICITY f21) ) *{ X
f1 | Y f2| Z f3} { ACCELERARTION | DISCPLACEMENT } ( SCALE f4)
```

```
{ DAMP f5| CDAMP | MDAMP } ( {LINEAR | LOGARITHMIC } ) (MISSSING f6) (ZPA f7)
({ DOMINANT f10| SIGN }) (SAVE)  (IMR f11) (STARTCASE f12)
```

Note: The data from `SPECTRUM` through `SCALE` must be on the first line of the command. The data shown on the second line above can be continued on the first line or one or more new lines with all but last ending with a hyphen (limit of four lines per spectrum).

The command is completed with the following spectrum data which must be started on a new line:

```
{ p1 v1; p2 v2; p3 v3; … pn vn | FILE filename  }
```

Table 266: Parameters used for NRC 2010 response spectrum

Parameter	Default Value	Description
DECCENTRICITY *f20*	1.0	Factor to be multiplied with static eccentricity (i.e., eccentricity between center of mass and center of rigidity).
ECCENTRICITY *f21*	0.05	Factor for accidental eccentricity. Positive values indicate clockwise torsion and negative values indicate counterclockwise torsion.
X *f1*, Y *f2*, Z *f3*	0.0	Factors for the input spectrum to be applied in X, Y, & Z directions. Any one or all directions can be input. Directions not provided will default to zero.
SCALE *f4*	1.0	Linear scale factor by which the spectra data will be multiplied. Usually used to factor g's to length/sec^2 units. This input is the appropriate value of acceleration due to gravity in the current unit system (thus, 9.81 m/s^2 or 32.2 ft/s^2).
DAMP *f5*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If `CDAMP` is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If `MDAMP` is specified, then modal damping is calculated using the method defined in a `DEFINE DAMPING INFORMATION` command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)
MISSING *f6*		Optional parameter to use “Missing Mass” method. The static effect of the masses not represented in the modes is included. The spectral acceleration for this missing mass mode is the *f6*value entered in length/sec^2 (this value is not multiplied by SCALE). If *f6*is zero, then the spectral acceleration at the `ZPA` *f7*frequency is used. If *f7*is zero or not entered, the spectral acceleration at 33Hz (Zero Period Acceleration, ZPA) is used. The results of this calculation are SRSSed with the modal combination results. **Note:** If the `MISSING` parameter is entered on any spectrum case it will be used for all spectrum cases.
ZPA *f7*	33 [Hz]	The zero period acceleration value for use with `MISSING` option only. Defaults to 33 Hz if not entered. The value is printed but not used if `MISSING f6` is entered.

Parameter	Default Value	Description
DOMINANT *f10*	1 (1st Mode)	The dominant mode method. All results will have the same sign as mode number *f10* alone would have if it were excited then the scaled results were used as a static displacements result. Defaults to mode 1 if no value entered. If a 0 value entered, then the mode with the greatest % participation in the excitation direction will be used (only one direction factor may be nonzero). **Note:** Do not enter the `SIGN` parameter with this option. Ignored for the `ABS` method of combining spectral responses from each mode.
IMR *f11*	1	The number of individual modal responses (scaled modes) to be copied into load cases. Defaults to one. If greater than the actual number of modes extracted (`NM`), then it will be reset to NM. Modes one through f11 will be used. Missing Mass modes are not output.
STARTCASE *f12*	Highest Load Case No. + 1	The primary load case number of mode 1 in the `IMR` parameter. Defaults to the highest load case number used so far plus one. If *f12* is not higher than all prior load case numbers, then the default will be used. For modes 2 through `NM`, the load case number is the prior case number plus one.

comb-method = `{ SRSS | ABS | CQC | ASCE | TEN | CSM | GRP }` are methods of combining the responses from each mode into a total response.

The CQC and ASCE4-98 methods require damping. ABS, SRSS, CRM, GRP, and TEN methods do not use damping unless spectra-period curves are made a function of damping (see File option below). CQC, ASCE, CRM, GRP, and TEN include the effect of response magnification due to closely spaced modal frequencies. ASCE includes more algebraic summation of higher modes. ASCE and CQC are more sophisticated and realistic methods and are recommended.

SRSS Square Root of Summation of Squares method.

ABS Absolute sum. This method is very conservative and represents a worst case combination.

CQC Complete Quadratic Combination method (Default). This method is recommended for closely spaced modes instead of SRSS.

Resultants are calculated as:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

$$\rho_{nm} = \frac{8\zeta^2(1+r)r^{2/3}}{(1-r^2)^2 + 4\zeta^2 r(1+r)^2}$$

$$r = \omega_n / \omega_m \leq 1.0$$

Note: The cross-modal coefficient array is symmetric and all terms are positive.

ASCE NRC Regulatory Guide Rev. 2 (2006) Gupta method for modal combinations and Rigid/Periodic parts of modes are used. The ASCE4-98 definitions are used where there is no conflict. ASCE4-98 Eq. 3.2-21 (modified Rosenblueth) is used for close mode interaction of the damped periodic portion of the modes.

TEN Ten Percent Method of combining closely spaced modes. NRC Reg. Guide 1.92 (Rev. 1.2.2, 1976).

CSM Closely Spaced Method as per IS:1893 (Part 1)-2002 procedures.

GRP Closely Spaced Modes Grouping Method. NRC Reg. Guide 1.92 (Rev. 1.2.1, 1976).

Note: If SRSS is selected, the program will internally check whether there are any closely spaced modes or not. If it finds any such modes, it will switch over to the CSM method. In the CSM method, the program will check whether all modes are closely spaced or not. If all modes are closely spaced, it will switch over to the CQC method.

`TORSION` indicates that the torsional moment (in the horizontal plane) arising due to eccentricity between the center of mass and center of rigidity needs to be considered. See Inherent and Accidental Torsion (on page 2510) for additional information.

Note: If `TORSION` is entered on any one spectrum case it will be used for all spectrum cases.

Lateral shears at story levels are calculated in global X and Z directions. For global Y direction the effect of torsion will not be considered.

`ACCELERATION` or `DISPLACEMENT` indicates whether **Acceleration** or **Displacement** spectra will be entered. The relationship between acceleration and displacement values in response spectra data is:

$$\text{Displacement} = \text{Acceleration} \times (1 / \omega)^2$$

where

ω = 2π/Period (period given in seconds; ω in cycles per second)

`DAMP`, `MDAMP`, and `CDAMP` select source of damping input:

- `DAMP` indicates to use the *`f2`* value for all modes
- `MDAMP` indicates to use the damping entered or computed with the `DEFINE DAMP` command if entered, otherwise default value of 0.05 will be used
- `CDAMP` indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the `CONSTANT` specification

`LINEAR` or `LOGARITHMIC` Select **Linear** or **Logarithmic** interpolation of the input Spectra versus Period curves for determining the spectra value for a mode given its period. Linear is the default. Since Spectra versus Period curves are often linear only on Log-Log scales, the logarithmic interpolation is recommended in such cases; especially if only a few points are entered in the spectra curve.

When `FILE` *`filename`* is entered, the interpolation along the damping axis will be linear.

Note: The last interpolation parameter entered on the last of all of the spectrum cases will be used for all spectrum cases.

`SIGN` This option results in the creation of signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign. This command is ignored for `ABS` option.

Caution: Do *not* enter `DOMINANT` parameter with this option.

SAVE	This option results in the creation of a acceleration data file (with the model file name and an `.acc` file extension) containing the joint accelerations in g's and radians/sec^2. These files are plain text and may be opened and viewed with any text editor (e.g., Notepad).

Individual Modal Response Case Generation

Individual modal response (`IMR`) cases are simply the mode shape scaled to the magnitude that the mode has in this spectrum analysis case before it is combined with other modes. If the IMR parameter is entered, then STAAD.Pro will create load cases for the first specified number of modes for this response spectrum case (i.e., if five is specified then five load cases are generated, one for each of the first five modes). Each case will be created in a form like any other primary load case.

The results from an IMR case can be viewed graphically or through the print facilities. Each mode can therefore be assessed as to its significance to the results in various portions of the structure. Perhaps one or two modes could be used to design one area/floor and others elsewhere.

You can use subsequent load cases with TR.32.11 Repeat Load Specification (on page 2595) combinations of these scaled modes and the static live and dead loads to form results that are all with internally consistent signs (unlike the usual response spectrum solutions). The modal applied loads vector will be omega squared times mass times the scaled mode shape. Reactions will be applied loads minus stiffness matrix times the scaled mode shape.

With the Repeat Load capability, you can combine the modal applied loads vector with the static loadings and solve statically with P-Delta or tension only.

Note: When the IMR option is entered for a Spectrum case, then a TR.37 Analysis Specification (on page 2620) & TR.38 Change Specification (on page 2660) must be entered after each such Spectrum case.

TR.32.10.1.1 Response Spectrum Specification - Custom (on page 2499) for additional details on IMR load case generation.

Inherent and Accidental Torsion

In response spectrum analysis all the response quantities (i.e., joint displacements, member forces, support reactions, plate stresses, etc.) are calculated for each mode of vibration considered in the analysis. These response quantities from each mode are combined using a modal combination method (either by CQC, SRSS, ABS, TEN PERCENT, etc.) to produce a single positive result for the given direction of acceleration. This computed result represents a maximum magnitude of the response quantity that is likely to occur during seismic loading. The actual response is expected to vary from a range of negative to positive value of this maximum computed quantity.

No information is available from response spectrum analysis as to when this maximum value occurs during the seismic loading and what will be the value of other response quantities at that time. As for example, consider two joints J2 and J3 whose maximum joint displacement in global X direction come out to be X1 and X2 respectively. This implies that during seismic loading joint J1 will have X direction displacement that is expected to vary from -X1 to +X1 and that for joint J2 from -X2 to +X2. However, this does not necessarily mean that the point of time at which the X displacement of joint J1 is X1, the X displacement of joint J2 will also be X2.

For the reason stated above, torsional moment at each floor arising due to dynamic eccentricity along with accidental eccentricity (if any) is calculated for each mode. Lateral story shear from this torsion is calculated forming global load vectors for each mode. Static analysis is carried out with this global load vector to produce global joint displacement vectors for each mode due to torsion. These joint displacements from torsion for each mode are algebraically added to the global joint displacement vectors from response spectrum analysis for each mode. The final joint displacements from response spectrum along with torsion for all modes are combined using specified modal combination method to get final maximum possible joint displacements. Refer to the steps explained below.

Steps

For each mode following steps are performed to include Torsion provision.

1. Lateral story force at each floor is calculated.
2. At each floor design eccentricity is calculated.

   Thus, design eccentricity $e_{di} = f20 \times e_{si} + f12 \times b_i$ where *f20* = 1.0 and *f21* = (±) 0.05

   where

e_{si}	=	static eccentricity between center of mass and center of rigidity at floor i
b_i	=	floor plan dimension in the direction of earthquake loading

3. Torsional moment is calculated at each floor.

   $M_{ik} = Q_{ik} \times e_{di}$ at floor i for mode k
4. The lateral nodal forces corresponding to torsional moment are calculated at each floor. These forces represent the additional story shear due to torsion.
5. Static analysis of the structure is performed with these nodal forces.
6. The analysis results (i.e., member force, joint displacement, support reaction, etc) from torsion are algebraically added to the corresponding modal response quantities from response spectrum analysis.
7. Steps 1 through 6 are performed for all modes considered and missing mass correction (if any). Finally, the peak response quantities from the different modal responses are combined as per the specified combination method (e.g., SRSS, CQC, TEN, etc.)

Dynamic Eccentricity

The static eccentricity is generally defined as the distance between the center of mass (CM) and the center of rigidity (CR) at respective floors levels. Accidental eccentricity generally accounts for factors such as:

- the rotational component of ground motion about the vertical axis,
- the difference between computed and actual values of the mass, stiffness, or strength, and
- uneven live mass distribution.

The provision for design eccentricity e_{di} at ith floor of a building is given by the following equation:

$$e_{di} = DEC \times e_{si} + ECC \times b_i$$

where

e_{si}	=	static eccentricity at ith floor
b_i	=	plan dimension of the ith floor normal to the direction of ground motion
ECC and DEC	=	Factors to determine the design eccentricity. These are input parameters.

Example

This example input file demonstrates a seismic load using the equivalent force method and a seismic response spectrum analysis per NRC 2010.

TR.32.10.1.4 Response Spectrum Specification per Eurocode 8 1994

This command may be used to specify and apply the `RESPONSE SPECTRUM` loading as per the 1994 edition of Eurocode 8 (EC8) for dynamic analysis.

General Format

```
SPECTRUM comb-method  EURO {ELASTIC | DESIGN} *{ X f1| Y f2| Z f3} ACCELERATION
```

```
{DAMP f5| CDAMP | MDAMP } ( {LINEAR | LOGARITHMIC} ) (MISSING f6) (ZPA f7) ({ DOMINANT
f10| SIGN }) (SAVE)  (IMR f11) (STARTCASE f12)
```

Note: The data from `SPECTRUM` through `ACC` must be on the first line of the command, the remaining data can be on the first or subsequent lines with all but last ending with a hyphen (limit of four lines per spectrum).

Starting on the next line, the response spectra is input using following standard input parameters:

```
SOIL TYPE { A | B | C} ALPHA f8 Q f9
```

Unlike the custom defined response spectra, the EC 8 response spectra does not input use frequency-acceleration pairs. Based on the type of Response Spectra (Elastic/Design), Soil Type, Alpha, and Q, the program generates the applicable response spectra curve using the guidelines of section 4.2.2 or 4.2.4 of Eurocode 8 as applicable.

Where:

Table 267: Parameters used for Eurocode 8 1994 response spectrum

Parameter	Default Value	Description
X *f1*, Y *f2*, Z *f3*	0.0	Factors for the input spectrum to be applied in X, Y, & Z directions. Any one or all directions can be input. Directions not provided will default to zero.

Parameter	Default Value	Description
DAMP *f5*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If CDAMP is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If MDAMP is specified, then modal damping is calculated using the method defined in a DEFINE DAMPING INFORMATION command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)
MISSING *f6*		Optional parameter to use "Missing Mass" method. The static effect of the masses not represented in the modes is included. The spectral acceleration for this missing mass mode is the *f6*value entered in length/sec^2 (this value is not multiplied by SCALE). If *f6*is zero, then the spectral acceleration at the ZPA *f7*frequency is used. If *f7*is zero or not entered, the spectral acceleration at 33Hz (Zero Period Acceleration, ZPA) is used. The results of this calculation are SRSSed with the modal combination results. **Note:** If the MISSING parameter is entered on any spectrum case it will be used for all spectrum cases.
ZPA *f7*	33 [Hz]	The zero period acceleration value for use with MISSING option only. Defaults to 33 Hz if not entered. The value is printed but not used if MISSING *f6* is entered.
DOMINANT *f10*	1 (1st Mode)	The dominant mode method. All results will have the same sign as mode number *f10* alone would have if it were excited then the scaled results were used as a static displacements result. Defaults to mode 1 if no value entered. If a 0 value entered, then the mode with the greatest % participation in the excitation direction will be used (only one direction factor may be nonzero). **Note:** Do not enter the SIGN parameter with this option. Ignored for the ABS method of combining spectral responses from each mode.
IMR *f11*	1	The number of individual modal responses (scaled modes) to be copied into load cases. Defaults to one. If greater than the actual number of modes extracted (NM), then it will be reset to NM. Modes one through f11 will be used. Missing Mass modes are not output.
STARTCASE *f12*	Highest Load Case No. + 1	The primary load case number of mode 1 in the IMR parameter. Defaults to the highest load case number used so far plus one. If *f12* is not higher than all prior load case numbers, then the default will be used. For modes 2 through NM, the load case number is the prior case number plus one.

Parameter	Default Value	Description
ALPHA *f8*		The design ground acceleration expressed in terms of acceleration due to gravity(g). For most of the application of Eurocode 8, the hazard is described in terms of a single parameter (i.e., the value of effective peak ground acceleration in rock or firm soil). This acceleration is termed as the design ground acceleration.
Q *f9*		The behavior factor used to reduce the elastic response spectra to the design response spectra. The behavior factor is an approximation of the ratio of the seismic forces, that the structure would experience, if its response was completely elastic with 5% viscous damping, to the minimum seismic forces that may be used in design- with a conventional linear model still ensuring a satisfactory response of the structure.

comb-method = { `SRSS` | `ABS` | `CQC` | `ASCE` | `TEN` | `CSM` | `GRP` } are methods of combining the responses from each mode into a total response.

The CQC and ASCE4-98 methods require damping. ABS, SRSS, CRM, GRP, and TEN methods do not use damping unless spectra-period curves are made a function of damping (see File option below). CQC, ASCE, CRM, GRP, and TEN include the effect of response magnification due to closely spaced modal frequencies. ASCE includes more algebraic summation of higher modes. ASCE and CQC are more sophisticated and realistic methods and are recommended.

SRSS Square Root of Summation of Squares method.

ABS Absolute sum. This method is very conservative and represents a worst case combination.

CQC Complete Quadratic Combination method (Default). This method is recommended for closely spaced modes instead of SRSS.

Resultants are calculated as:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

$$\rho_{nm} = \frac{8\zeta^2 (1+r) r^{2/3}}{(1-r^2)^2 + 4\zeta^2 r(1+r)^2}$$

$$r = \omega_n / \omega_m \leq 1.0$$

Note: The cross-modal coefficient array is symmetric and all terms are positive.

ASCE NRC Regulatory Guide Rev. 2 (2006) Gupta method for modal combinations and Rigid/Periodic parts of modes are used. The ASCE4-98 definitions are used where there is no conflict. ASCE4-98 Eq. 3.2-21 (modified Rosenblueth) is used for close mode interaction of the damped periodic portion of the modes.

TEN Ten Percent Method of combining closely spaced modes. NRC Reg. Guide 1.92 (Rev. 1.2.2, 1976).

CSM Closely Spaced Method as per IS:1893 (Part 1)-2002 procedures.

GRP Closely Spaced Modes Grouping Method. NRC Reg. Guide 1.92 (Rev. 1.2.1, 1976).

Note: If SRSS is selected, the program will internally check whether there are any closely spaced modes or not. If it finds any such modes, it will switch over to the CSM method. In the CSM method, the program will check whether all modes are closely spaced or not. If all modes are closely spaced, it will switch over to the CQC method.

ELASTIC or DESIGN	The response spectrum loading can be based on either **Elastic** or **Design** response spectra. Refer to Eurocode 8. The capacity of structural systems to resist seismic actions in the nonlinear range generally permits their design for forces smaller than those corresponding to a linear elastic response. To avoid explicit nonlinear structural analysis in design, the energy dissipation capacity of the structure through mainly ductile behavior of its elements and/or other mechanisms, is taken into account by performing a linear analysis based on a response spectrum which is a reduced form of the corresponding elastic response spectrum. This reduction is accomplished by introducing the behavior factor Q and the reduced response spectrum is termed as "Design Response Spectrum." STAAD.Pro generates the Elastic Response Spectra using the guidelines of section 4.2.4 and Table 4.2 of Eurocode 8. So, if the structure is supposed to resist seismic actions in the nonlinear range the Design Response Spectra is to be used.
ACCELERATOIN	indicates that the Acceleration spectra will be entered. **Note:** Eurocode 8 does not have provisions displacement response spectra.
DAMP, MDAMP, and CDAMP	select source of damping input: • DAMP indicates to use the *f2* value for all modes • MDAMP indicates to use the damping entered or computed with the DEFINE DAMP command if entered, otherwise default value of 0.05 will be used • CDAMP indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the CONSTANT specification
LINEAR or LOGARITHMIC	Select **Linear** or **Logarithmic** interpolation of the input Spectra versus Period curves for determining the spectra value for a mode given its period. Linear is the default. Since Spectra versus Period curves are often linear only on Log-Log scales, the logarithmic interpolation is recommended in such cases; especially if only a few points are entered in the spectra curve. When FILE *filename* is entered, the interpolation along the damping axis will be linear. **Note:** The last interpolation parameter entered on the last of all of the spectrum cases will be used for all spectrum cases.
SIGN	This option results in the creation of signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign. This command is ignored for ABS option. **Caution:** Do *not* enter DOMINANT parameter with this option.
SAVE	This option results in the creation of a acceleration data file (with the model file name and an .acc file extension) containing the joint accelerations in g's and radians/sec^2. These files are plain text and may be opened and viewed with any text editor (e.g., Notepad).

`SOIL TYPE`	This parameter is used to define the subsoil conditions based on which the response spectra will be generated. Based on the subsoil conditions the soil types may be of three kinds • Type A: for Rock or stiff deposits of sand • Type B: for deep deposits of medium dense sand ,gravel or medium stiff clays. • Type C: Loose cohesionless soil deposits or deposits with soft to medium stiff cohesive soil. Refer to section 3.2 of Eurocode 8 for detailed guidelines regarding the choice of soil type.

Individual Modal Response Case Generation

Individual modal response (`IMR`) cases are simply the mode shape scaled to the magnitude that the mode has in this spectrum analysis case before it is combined with other modes. If the IMR parameter is entered, then STAAD.Pro will create load cases for the first specified number of modes for this response spectrum case (i.e., if five is specified then five load cases are generated, one for each of the first five modes). Each case will be created in a form like any other primary load case.

The results from an IMR case can be viewed graphically or through the print facilities. Each mode can therefore be assessed as to its significance to the results in various portions of the structure. Perhaps one or two modes could be used to design one area/floor and others elsewhere.

You can use subsequent load cases with TR.32.11 Repeat Load Specification (on page 2595) combinations of these scaled modes and the static live and dead loads to form results that are all with internally consistent signs (unlike the usual response spectrum solutions). The modal applied loads vector will be omega squared times mass times the scaled mode shape. Reactions will be applied loads minus stiffness matrix times the scaled mode shape.

With the Repeat Load capability, you can combine the modal applied loads vector with the static loadings and solve statically with P-Delta or tension only.

Note: When the IMR option is entered for a Spectrum case, then a TR.37 Analysis Specification (on page 2620) & TR.38 Change Specification (on page 2660) must be entered after each such Spectrum case.

See TR.32.10.1.1 Response Spectrum Specification - Custom (on page 2499) for additional details on IMR load case generation.

Description

This command should appear as part of a loading specification. If it is the first occurrence, it should be accompanied by the load data to be used for frequency and mode shape calculations. Additional occurrences need no additional information. Maximum response spectrum load cases allowed in one run is 4.

Results of frequency and mode shape calculations may vary significantly depending upon the mass modeling. All masses that are capable of moving should be modeled as loads, applied in all possible directions of movement. For dynamic mass modeling, see sections TR.32 Loading Specifications (on page 2461) and G.17.3 Dynamic Analysis (on page 2154).

Multiple Response Spectra

For special conditions more than one spectrum may be needed to adequately represent the seismic hazard over an area. This happens when the earthquake affecting the area are generated by sources varying widely in location and other parameters. In those cases different values of ALPHA as well as Q may be required to indicate the different shapes of response spectrum for each type of earthquake.

TR.32.10.1.5 Response Spectrum Specification per Eurocode 8 2004

This command may be used to specify and apply the RESPONSE SPECTRUM loading as per the 2004 edition of Eurocode 8, "General Rules, seismic actions and rules for buildings", BS EN 1998-1:2004. The graph of frequency – acceleration pairs are calculated based on the input requirements of the command and as defined in the code.

General Format

```
SPECTRUM comb-method EURO 2004 {ELASTIC | DESIGN} {RS1 | RS2} *{ X f1| Y f2| Z f3}
ACCELERATION
```

```
{DAMP f5| CDAMP | MDAMP } ( {LINEAR | LOGARITHMIC} ) (MISSING f6) (ZPA f7) ({ DOMINANT
f10 | SIGN }) (SAVE)  (IMR f11) (STARTCASE f12)
```

Note: The data SPECTRUM through ACC must be on the first line of the command, the remaining data can be on the first or subsequent lines with all but last ending with a hyphen (limit of four lines per spectrum).

Starting on the next line, the response spectra is input using following standard input parameters:

```
SOIL TYPE { A | B | C | D | E } ALPHA f8 Q f9
```

Unlike the custom defined response spectra the EC 8 response spectra is not input using frequency-acceleration pairs. Based on the type of Response Spectra(Elastic/Design), Soil Type, Alpha and Q the software generates the applicable response spectra curve using the guidelines of section 3.2.2.2 or 3.2.2.3 or 3.2.2.5 of Eurocode 8: 2004 as applicable.

Where:

Table 268: Parameters used for Eurocode 8 2004 response spectrum

Parameter	Default Value	Description
X *f1*, Y *f2*, Z *f3*	0.0	Factors for the input spectrum to be applied in X, Y, & Z directions. Any one or all directions can be input. Directions not provided will default to zero.
DAMP *f5*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If `CDAMP` is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If `MDAMP` is specified, then modal damping is calculated using the method defined in a `DEFINE DAMPING INFORMATION` command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)
MISSING *f6*		Optional parameter to use "Missing Mass" method. The static effect of the masses not represented in the modes is included. The spectral acceleration for this missing mass mode is the *f6*value entered in length/sec^2 (this value is not multiplied by SCALE). If *f6*is zero, then the spectral acceleration at the `ZPA` *f7*frequency is used. If *f7*is zero or not entered, the spectral acceleration at 33Hz (Zero Period Acceleration, ZPA) is used. The results of this calculation are SRSSed with the modal combination results. **Note:** If the `MISSING` parameter is entered on any spectrum case it will be used for all spectrum cases.
ZPA *f7*	33 [Hz]	The zero period acceleration value for use with `MISSING` option only. Defaults to 33 Hz if not entered. The value is printed but not used if `MISSING f6` is entered.
DOMINANT *f10*	1 (1st Mode)	The dominant mode method. All results will have the same sign as mode number *f10* alone would have if it were excited then the scaled results were used as a static displacements result. Defaults to mode 1 if no value entered. If a 0 value entered, then the mode with the greatest % participation in the excitation direction will be used (only one direction factor may be nonzero). **Note:** Do not enter the `SIGN` parameter with this option. Ignored for the `ABS` method of combining spectral responses from each mode.

Parameter	Default Value	Description
IMR *f11*	1	The number of individual modal responses (scaled modes) to be copied into load cases. Defaults to one. If greater than the actual number of modes extracted (NM), then it will be reset to NM. Modes one through f11 will be used. Missing Mass modes are not output.
STARTCASE *f12*	Highest Load Case No. + 1	The primary load case number of mode 1 in the IMR parameter. Defaults to the highest load case number used so far plus one. If *f12* is not higher than all prior load case numbers, then the default will be used. For modes 2 through NM, the load case number is the prior case number plus one.
ALPHA *f10*		Alpha is the “Ground Acceleration On Type A Ground” and defined in Eurocode 8 as a_g, as used in equations 3.2 – 3.5. Refer to the Eurocode for further information. **Note:** The specified alpha factor in STAAD.Pro is given as the *ratio* of the ground acceleration (a_g) to acceleration due to gravity. That is, the value for *f10*should be a factor of G, not an actual acceleration (e.g., if the value of $a_g = 1.5\ m/s^2$, then enter the ALPHA value of $1.5\ m/s^2\ /\ 9.81\ m/s^2 = 0.15$).
Q *f11*		Q is the 'Behaviour Factor' and is an approximation of the ratio of the seismic forces that the structure would experience if its response was completely elastic with 5% viscous damping, to the seismic forces that may be used in design, with a conventional elastic analysis model, still ensuring a satisfactory response of the structure.

comb-method = { SRSS | ABS | CQC | ASCE | TEN | CSM | GRP } are methods of combining the responses from each mode into a total response.

The CQC and ASCE4-98 methods require damping. ABS, SRSS, CRM, GRP, and TEN methods do not use damping unless spectra-period curves are made a function of damping (see File option below). CQC, ASCE, CRM, GRP, and TEN include the effect of response magnification due to closely spaced modal frequencies. ASCE includes more algebraic summation of higher modes. ASCE and CQC are more sophisticated and realistic methods and are recommended.

SRSS Square Root of Summation of Squares method.

ABS Absolute sum. This method is very conservative and represents a worst case combination.

CQC Complete Quadratic Combination method (Default). This method is recommended for closely spaced modes instead of SRSS.

Resultants are calculated as:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

$$\rho_{nm} = \frac{8\zeta^2(1+r)r^{2/3}}{(1-r^2)^2 + 4\zeta^2 r(1+r)^2}$$

$$r = \omega_n/\omega_m \leq 1.0$$

> **Note:** The cross-modal coefficient array is symmetric and all terms are positive.

ASCE NRC Regulatory Guide Rev. 2 (2006) Gupta method for modal combinations and Rigid/Periodic parts of modes are used. The ASCE4-98 definitions are used where there is no conflict. ASCE4-98 Eq. 3.2-21 (modified Rosenblueth) is used for close mode interaction of the damped periodic portion of the modes.

TEN Ten Percent Method of combining closely spaced modes. NRC Reg. Guide 1.92 (Rev. 1.2.2, 1976).

CSM Closely Spaced Method as per IS:1893 (Part 1)-2002 procedures.

GRP Closely Spaced Modes Grouping Method. NRC Reg. Guide 1.92 (Rev. 1.2.1, 1976).

> **Note:** If SRSS is selected, the program will internally check whether there are any closely spaced modes or not. If it finds any such modes, it will switch over to the CSM method. In the CSM method, the program will check whether all modes are closely spaced or not. If all modes are closely spaced, it will switch over to the CQC method.

See G.17.3 Dynamic Analysis (on page 2154), TR.30 Miscellaneous Settings for Dynamic Analysis (on page 2344), and TR.34 Frequency Calculation (on page 2614)

The keywords EURO 2004 is mandatory to denote that the applied loading is as per the guidelines of Eurocode 8.

ELASTIC or DESIGN The response spectrum loading can be based on either **Elastic** or **Design** response spectra. Refer to Eurocode 8.

The capacity of structural systems to resist seismic actions in the nonlinear range generally permits their design for forces smaller than those corresponding to a linear elastic response. To avoid explicit nonlinear structural analysis in design, the energy dissipation capacity of the structure through mainly ductile behavior of its elements and/or other mechanisms, is taken into account by performing a linear analysis based on a response spectrum which is a reduced form of the corresponding elastic response spectrum. This reduction is accomplished by introducing the behavior factor Q and the reduced response spectrum is termed as “Design Response Spectrum.” STAAD.Pro generates the Elastic Response Spectra using the guidelines of section 4.2.4 and Table 4.2 of Eurocode 8.

So, if the structure is supposed to resist seismic actions in the nonlinear range the Design Response Spectra is to be used.

RS1 or RS2 Two types of response spectra curve can be generated based on either response spectra type 1 curve (RS1) or response spectra type 2 curve (RS2).

ACCELERATOIN indicates that the Acceleration spectra will be entered.

> **Note:** Eurocode 8 does not have provisions displacement response spectra.

DAMP, MDAMP, and CDAMP select source of damping input:

- DAMP indicates to use the $f2$ value for all modes
- MDAMP indicates to use the damping entered or computed with the `DEFINE DAMP` command if entered, otherwise default value of 0.05 will be used
- CDAMP indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the `CONSTANT` specification

LINEAR or LOGARITHMIC	Select **Linear** or **Logarithmic** interpolation of the input Spectra versus Period curves for determining the spectra value for a mode given its period. Linear is the default. Since Spectra versus Period curves are often linear only on Log-Log scales, the logarithmic interpolation is recommended in such cases; especially if only a few points are entered in the spectra curve. When `FILE` *`filename`* is entered, the interpolation along the damping axis will be linear. **Note:** The last interpolation parameter entered on the last of all of the spectrum cases will be used for all spectrum cases.
SIGN	This option results in the creation of signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign. This command is ignored for `ABS` option. **Caution:** Do *not* enter `DOMINANT` parameter with this option.
SAVE	This option results in the creation of a acceleration data file (with the model file name and an `.acc` file extension) containing the joint accelerations in g's and radians/sec^2. These files are plain text and may be opened and viewed with any text editor (e.g., Notepad).
SOIL TYPE	This parameter is used to define the subsoil conditions based on which the response spectra will be generated as defined in Table 3.1 Ground Types. Based on the subsoil conditions the soil types may be of five kinds: • Type `A`: rock or other rock-like geographical formation. • Type `B`: very dense sand, gravel or very stiff clay. • Type `C`: Deep deposits of dense or medium dense sand, gravel or stiff clay. • Type `D`: Deposits of loose-to-medium cohesionless soil or of predominantly soft to firm cohesive soil. • Type `E`: Surface alluvium layer Please refer section 3.2 of Eurocode 8 for detailed guidelines regarding the choice of soil type.

Individual Modal Response Case Generation

Individual modal response (`IMR`) cases are simply the mode shape scaled to the magnitude that the mode has in this spectrum analysis case before it is combined with other modes. If the IMR parameter is entered, then STAAD.Pro will create load cases for the first specified number of modes for this response spectrum case (i.e., if five is specified then five load cases are generated, one for each of the first five modes). Each case will be created in a form like any other primary load case.

The results from an IMR case can be viewed graphically or through the print facilities. Each mode can therefore be assessed as to its significance to the results in various portions of the structure. Perhaps one or two modes could be used to design one area/floor and others elsewhere.

You can use subsequent load cases with TR.32.11 Repeat Load Specification (on page 2595) combinations of these scaled modes and the static live and dead loads to form results that are all with internally consistent signs (unlike the usual response spectrum solutions). The modal applied loads vector will be omega squared times mass times the scaled mode shape. Reactions will be applied loads minus stiffness matrix times the scaled mode shape.

With the Repeat Load capability, you can combine the modal applied loads vector with the static loadings and solve statically with P-Delta or tension only.

Note: When the IMR option is entered for a Spectrum case, then a TR.37 Analysis Specification (on page 2620) & TR.38 Change Specification (on page 2660) must be entered after each such Spectrum case.

See TR.32.10.1.1 Response Spectrum Specification - Custom (on page 2499) for additional details on IMR load case generation.

Description

This command should appear as part of a loading specification. If it is the first occurrence, it should be accompanied by the load data to be used for frequency and mode shape calculations. Additional occurrences need no additional information.

Results of frequency and mode shape calculations may vary significantly depending upon the mass modeling. All masses that are capable of moving should be modeled as loads, applied in all possible directions of movement. For dynamic mass modeling, see TR.32 Loading Specifications (on page 2461) and G.17.3 Dynamic Analysis (on page 2154).

Multiple Response Spectra

For special conditions more than one spectrum may be needed to adequately represent the seismic hazard over an area. This happens when the earthquake affecting the area is generated by sources varying widely in location and other parameters. In such cases different values of ALPHA as well as Q may be required to indicate the different shapes of response spectrum for each type of earthquake.

Example

```
LOAD 2 SPECTRUMIN X-DIRECTION
SELFWEIGHT X 1.0

TR.32.10.1.6 Response Spectrum Specification per GB 50011 2010

This command may be used to specify and apply the `RESPONSE SPECTRUM` loading as per the 2016 edition of the Chinese specification *Code for seismic design of building*, for dynamic analysis. The graph of frequency – acceleration pairs are calculated based on the input requirements of the command and as defined in the code.

General Format

```
SPECTRUM { CQC | SRSS } GB50011 (2010) (TORSION) (DECCENTRICITY f8) (ECCENTRICITY f9)
*{ X f1 | Y f2| Z f3 } ALPHA-
```

```
{DAMP f4 | CDAMP | MDAMP }  ( { LINEAR | LOGARITHMIC } ) (MISSING f5) ( ZPA f6 )
({ DOMINANT f10| SIGN }) (SAVE)  (IMR f11) (STARTCASE f12) -
```

```
{ ( INTENSITY f9 ) ( FREQUENT | FORTIFIED | RARE ) ( GROUP f11 ) ( SCLASS f12 ) }
```

Note: The data from `SPECTRUM` through `ALPHA` must be on the first line of the command. The data shown on the second line above can be continued on the first line or one or more new lines with all but last ending with a hyphen (limit of four lines per spectrum).

Where:

Table 269: Parameters used for GB 50011-2010 response spectrum

Parameter	Default Value	Description
DECCENTRICITY *f8*	0	(Optional input) It is a factor which when multiplied with static eccentricity (i.e., eccentricity between center of mass and center of rigidity) gives dynamic eccentricity. Since the applied load is acting at the center of mass, the effect of inherent torsion arising due to static eccentricity is included in the analysis. **Note:** The torsion arising due to dynamic eccentricity (i.e,. static eccentricity multiplied by dynamic amplification factor) between center of mass and center of rigidity is applied along with accidental torsion. The dynamic eccentricity is automatically calculated by the program while you can specify the amount of accidental eccentricity (if not specified, the default of 5% of lateral dimension of the floor in the direction of the earthquake will be considered).
ECCENTRICITY *f9*	0.05	A factor which indicates the extent of accidental eccentricity. For all buildings this factor is to be provided as 0.05. However, for highly irregular buildings this factor may be increased to 0.10. This factor is to be externally provided to calculate design eccentricity. Since accidental eccentricity can be on either side, you must consider lateral force acting at a floor level to be accompanied by a clockwise or a counterclockwise accidental torsion moment. If the value is positive, it indicates clockwise torsion whereas a negative value indicates counterclockwise torsion.

Parameter	Default Value	Description
X *f1*, Y *f2*, Z *f3*	-	Factors for the input spectrum to be applied in X, Y, & Z directions. Any one or all directions can be input. Directions not provided will default to zero if the global axis is not specified. If the direction is specified, then the default factor for X and Z is 1.0 where as the default factor for Y is 0.65. At least one direction must be specified. Any directions that is not specified will default to zero.
DAMP *f4*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If `CDAMP` is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If `MDAMP` is specified, then modal damping is calculated using the method defined in a `DEFINE DAMPING INFORMATION` command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)
MISSING *f5*		Optional parameter to use "Missing Mass" method. The static effect of the masses not represented in the modes is included. The spectral acceleration for this missing mass mode is the *f6*value entered in length/sec^2. If the "missing mass" option is used, then this value must be provided. **Note:** If the `MISSING` parameter is entered on any spectrum case it will be used for all spectrum cases.
ZPA *f6*	33 (Hz)	The zero-period acceleration value used with the MISSING option only.
DOMINANT *f7*	1 (1st Mode)	Dominant mode method. All results will have the same sign as mode number *f7* alone would have if it were excited then the results were used as a static displacements result. Defaults to mode 1 if no value is entered. If a value of 0 is entered, then the mode with the greatest % participation in the excitation direction will be used (only 1 direction factor may be nonzero).
IMR *f11*	1	The number of individual modal responses (scaled modes) to be copied into load cases. Defaults to one. If greater than the actual number of modes extracted (NM), then it will be reset to NM. Modes one through *f11* will be used. Missing Mass modes are not output.
STARTCASE *f12*	Highest Load Case No. + 1	The primary load case number of mode 1 in the IMR parameter. Defaults to the highest load case number used so far plus one. If *f12* is not higher than all prior load case numbers, then the default will be used. For modes 2 through NM, the load case number is the prior case number plus one.

Parameter	Default Value	Description
INTENSITY *f9*	7	Fortification seismic intensity. Permitted values are: 6, 7, 7A, 8, 8A, or 9
GROUP *f10*	2	Design seismic group.
SCLASS *f11*	2	Site class.

`{ SRSS | CQC }` are methods of combining the responses from each mode into a total response. The CQC methods requires damping. SRSS method do not use damping unless spectra-period curves are made a function of damping. CQC includes the effect of response magnification due to closely spaced modal frequencies. CQC is a more sophisticated and realistic method and is recommended.

SRSS Square Root of Summation of Squares method.

CQC Complete Quadratic Combination method (Default). This method is recommended for closely spaced modes instead of SRSS.

Resultants are calculated as:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

$$\rho_{nm} = \frac{8\zeta^2(1+r)r^{2/3}}{(1-r^2)^2 + 4\zeta^2 r(1+r)^2}$$

$$r = \omega_n / \omega_m \le 1.0$$

Note: The cross-modal coefficient array is symmetric and all terms are positive.

DAMP, MDAMP, and CDAMP select source of damping input:

- `DAMP` indicates to use the *f2* value for all modes
- `MDAMP` indicates to use the damping entered or computed with the `DEFINE DAMP` command if entered, otherwise default value of 0.05 will be used
- `CDAMP` indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the `CONSTANT` specification

LINEAR | LOGARITHMIC Specifies the type of interpolation of the input seismic coefficient versus time period curves for determining the seismic coefficient value for a mode given its period. Linear is the default if not specified.

SIGN This option results in the creation of signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign.

Warning: Do *not* enter `DOMINANT` parameter with this option.

SAVE This option results in the creation of a acceleration data file (with the model file name and an `.acc` file extension) containing the joint accelerations in g's and radians/sec^2. These files are plain text and may be opened and viewed with any text editor (e.g., Notepad).

FREQUENT | FORTIFIED | RARE	The earthquake type.

Inherent and Accidental Torsion

Note: STAAD.Pro does not support the coupled torsion methodology as per GB50011-2010. This implementation enables the general "inherent and accidental torsion" for GB50011 response spectrum analysis. Note that this implementation does *not* comply with Cl. 5.2.3 of GB50011-2010.

In response spectrum analysis all the response quantities (i.e., joint displacements, member forces, support reactions, plate stresses, etc.) are calculated for each mode of vibration considered in the analysis. These response quantities from each mode are combined using a modal combination method (either CQC or SRSS) to produce a single positive result for the given direction of acceleration. This computed result represents a maximum magnitude of the response quantity that is likely to occur during seismic loading. The actual response is expected to vary from a range of negative to the positive value of this maximum computed quantity.

No information is available from response spectrum analysis as to when this maximum value occurs during the seismic loading and what will be the value of other response quantities at that time. For example, consider two joints J2 and J3 whose maximum joint displacement in the global X direction come out to be X1 and X2 respectively. This implies that during seismic loading joint J1 will have X-direction displacement that is expected to vary from -X1 to +X1 and that for joint J2 from -X2 to +X2. However, this does not necessarily mean that the point of time at which the X displacement of joint J1 is X1, the X displacement of joint J2 will also be X2.

For the reason stated above, the torsional moment at each floor arising due to dynamic eccentricity along with accidental eccentricity (if any) is calculated for each mode. Lateral story shear from this torsion is calculated forming global load vectors for each mode. Static analysis is carried out with this global load vector to produce global joint displacement vectors for each mode due to torsion. These joint displacements from torsion for each mode are algebraically added to the global joint displacement vectors from response spectrum analysis for each mode. The final joint displacements from the response spectrum along with torsion for all modes are combined using a specified modal combination method to get the final maximum possible joint displacements.

TR.32.10.1.7 Response Spectrum Specification per IS: 1893 (Part 1)-2002

This command may be used to specify and apply the `RESPONSE SPECTRUM` loading as per IS: 1893 (Part 1)-2002 for dynamic analysis.

The seismic load generator can be used to generate lateral loads in the X, Y, and Z directions.

Note: This facility has *not* been developed for cases where the Z axis is set to be the vertical direction using the `SET Z UP` command.

General Format

The data in the following format can be contained all on a single line or broken into two or three lines, so long as the second and third lines start with the ACC and DOMINANT or SIGN commands, respectively.

```
SPECTRUM comb-method 1893 ( TORSION (DECCENTRICITY f8) (ECCENTRICITY f9) ) *{ X f1 | Y
f2 | Z f3 }
```

```
{ ACCELERATION | DISPLACEMENT } (SCALE f4) {DAMP f5 | CDAMP | MDAMP } (MISSING f6)
(ZPA f7) (IGNNORE f13)
({ DOMINANT f10 | SIGN }) (SAVE) (IMR f11) (STARTCASE f12)
```

The following command (SOIL TYPE parameter *or* response spectra data pairs) must be in a separate line.

```
{ SOIL TYPE f11 | *{ P1,V1; P2,V2; P3,V3;…PN,VN } }
```

The following command, if present, must be on a separate line. This performs the option al soft story check.

```
( CHECK SOFT STORY )
```

The following command, if present, must be on a separate line. This performs the story drift check.

```
( CHECK STORY DRIFT ) (RF f14)
```

Where:

Table 270: Parameters used for IS: 1893 (Part 1) 2002 response spectrum

Parameter	Default Value	Description
DECCENTRICITY *f8*	When ECC > 0, DEC defaults to 1.5 When ECC < 0, DEC defaults to 1.0	(Optional input) It is a factor which when multiplied with static eccentricity (i.e., eccentricity between center of mass and center of rigidity) gives dynamic eccentricity. Since the applied load is acting at the center of mass, the effect of inherent torsion arising due to static eccentricity is included in the analysis. **Note:** The torsion arising due to dynamic eccentricity (i.e,. static eccentricity multiplied by dynamic amplification factor) between center of mass and center of rigidity is applied along with accidental torsion, as per the recommendations of Cl. 7.8.2 of the code. The dynamic eccentricity is automatically calculated by the program while you can specify the amount of accidental eccentricity (if not specified, the default of 5% of lateral dimension of the floor in the direction of the earthquake will be considered). For details See Torsion Methodology (on page 2542).

Parameter	Default Value	Description
ECCENTRICITY *f9*	0.05	It is a factor which indicates the extent of accidental eccentricity. For all buildings this factor is to be provided as 0.05. However, for highly irregular buildings this factor may be increased to 0.10. This factor is to be externally provided to calculate design eccentricity. Since accidental eccentricity can be on either side, you must consider lateral force acting at a floor level to be accompanied by a clockwise or a counterclockwise accidental torsion moment. If the *f9* value is positive, it indicates clockwise torsion whereas a negative value indicates counterclockwise torsion.
X *f1*, Y *f2*, Z *f3*	0.0	Factors for the input spectrum to be applied in X, Y, & Z directions. Any one or all directions can be input. Directions not provided will default to zero.
SCALE *f4*	1.0	Linear scale factor by which the spectra data will be multiplied. Usually used to factor g's to length/sec^2 units. This input is the appropriate value of acceleration due to gravity in the current unit system (thus, 9.81 m/s^2 or 32.2 ft/s^2).
DAMP *f5*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If `CDAMP` is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If `MDAMP` is specified, then modal damping is calculated using the method defined in a `DEFINE DAMPING INFORMATION` command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)
MISSING *f6*		Optional parameter to use "Missing Mass" method. The static effect of the masses not represented in the modes is included. The spectral acceleration for this missing mass mode is the *f6*value entered in length/sec^2 (this value is not multiplied by SCALE). If *f6*is zero, then the spectral acceleration at the `ZPA` *f7*frequency is used. If *f7*is zero or not entered, the spectral acceleration at 33Hz (Zero Period Acceleration, ZPA) is used. The results of this calculation are SRSSed with the modal combination results. **Note:** If the `MISSING` parameter is entered on any spectrum case it will be used for all spectrum cases.
ZPA *f7*	33 [Hz]	The zero period acceleration value for use with `MISSING` option only. Defaults to 33 Hz if not entered. The value is printed but not used if `MISSING f6` is entered.

Parameter	Default Value	Description
IGNORE *f13*	0.009	(Optional input) It indicates the mass participation (in percent) of those modes to be excluded while considering torsion provision of IS-1893. Depending upon the model it may be found that there are many local modes and torsional modes whose mass participation is practically negligible. These modes can be excluded without much change in the final analysis result. If not provided all modes will be considered. If none provided the default value of 0.009% will be considered. If IGN is entered on any one spectrum case it will be used for all spectrum cases. **Note:** If the value of *f14* is considerable it may lead to considerable variation of analysis result from the actual one. Hence caution must be taken while using `IGNORE` command. If the `MODE SELECT` command is provided along with the `IGNORE` command, the number of modes excluded from the analysis will be those deselected by the `MODE SELECT` command and *also* those deselected by the `IGNORE` command.
DOMINANT *f10*	1 (1st Mode)	The dominant mode method. All results will have the same sign as mode number *f10* alone would have if it were excited then the scaled results were used as a static displacements result. Defaults to mode 1 if no value entered. If a 0 value entered, then the mode with the greatest % participation in the excitation direction will be used (only one direction factor may be nonzero). **Note:** Do not enter the `SIGN` parameter with this option. Ignored for the `ABS` method of combining spectral responses from each mode.
IMR *f11*	1	The number of individual modal responses (scaled modes) to be copied into load cases. Defaults to one. If greater than the actual number of modes extracted (`NM`), then it will be reset to NM. Modes one through f11 will be used. Missing Mass modes are not output.
STARTCASE *f12*	Highest Load Case No. + 1	The primary load case number of mode 1 in the `IMR` parameter. Defaults to the highest load case number used so far plus one. If *f12* is not higher than all prior load case numbers, then the default will be used. For modes 2 through `NM`, the load case number is the prior case number plus one.

Parameter	Default Value	Description
SOIL TYPE *f11*		The soil type present. Depending upon time period, types of soil and damping, average response acceleration coefficient, S_a/g is calculated. 1 = for rocky or hard soil 2 = medium soil 3 = soft soil sites
custom P1,V1; P2,V2; P3,V3; … Pn,Vn		Data is part of input immediately following spectrum command for a "custom" response spectrum. Period - Value pairs (pairs separated by semicolons) are entered to describe the spectrum curve. Period is in seconds and the corresponding Value is acceleration (current length unit/ sec^2). If data is in g acceleration units then the factor by which spectra data will be multiplied is g to the current length unit (9.81, 386.4, etc). **Note:** Do not enter if a SOIL TYPE *f11* value is specified.
RF *f14*		The response reduction factor. If not specified, the program will look for the factor defined under `DEFINE 1893 LOAD` (refer to TR.31.2.10 IS:1893 (Part 1) 2002 & Part 4 (2005) Codes - Lateral Seismic Load (on page 2387)). If none is provided there either, a factor of 1.0 is assumed. The response reduction factor represents ratio of maximum seismic force on a structure during specified ground motion if it were to remain elastic to the design seismic force. Actual seismic force is reduced by a factor `RF` to obtain design force.)

`1893` indicates the analysis as per IS:1893(Part 1)-2002 procedures.

comb-method = { `SRSS` | `ABS` | `CQC` | `ASCE` | `TEN` | `CSM` | `GRP` } are methods of combining the responses from each mode into a total response.

Note: CQC, SRSS, and CSM Grouping methods are recommended by IS:1893 (Part 1) –2002.

SRSS Square Root of Summation of Squares method.

ABS Absolute sum. This method is very conservative and represents a worst case combination.

CQC Complete Quadratic Combination method (Default). This method is recommended for closely spaced modes instead of SRSS.

Resultants are calculated as:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

$$\rho_{nm} = \frac{8\zeta^2(1 + r)r^{2/3}}{(1 - r^2)^2 + 4\zeta^2 r(1 + r)^2}$$

r = $\omega_n / \omega_m \leq 1.0$

> **Note:** The cross-modal coefficient array is symmetric and all terms are positive.

ASCE NRC Regulatory Guide Rev. 2 (2006) Gupta method for modal combinations and Rigid/Periodic parts of modes are used. The ASCE4-98 definitions are used where there is no conflict. ASCE4-98 Eq. 3.2-21 (modified Rosenblueth) is used for close mode interaction of the damped periodic portion of the modes.

TEN Ten Percent Method of combining closely spaced modes. NRC Reg. Guide 1.92 (Rev. 1.2.2, 1976).

CSM Closely Spaced Method as per IS:1893 (Part 1)-2002 procedures.

GRP Closely Spaced Modes Grouping Method. NRC Reg. Guide 1.92 (Rev. 1.2.1, 1976).

`TORSION` indicates that the torsional moment (in the horizontal plane) arising due to eccentricity between the center of mass and center of rigidity needs to be considered. See Torsion (on page 2542) for additional information.

> **Note:** If `TORSION` is entered on any one spectrum case it will be used for all spectrum cases.

Lateral shears at story levels are calculated in global X and Z directions. For global Y direction the effect of torsion will not be considered.

`ACCELERATION or DISPLACEMENT` indicates whether **Acceleration** or **Displacement** spectra will be entered. The relationship between acceleration and displacement values in response spectra data is:

$$\text{Displacement} = \text{Acceleration} \times (1/\omega)^2$$

where

ω = 2π/Period (period given in seconds; ω in cycles per second)

`DAMP`, `MDAMP`, and `CDAMP` select source of damping input:

- `DAMP` indicates to use the *f2* value for all modes
- `MDAMP` indicates to use the damping entered or computed with the `DEFINE DAMP` command if entered, otherwise default value of 0.05 will be used
- `CDAMP` indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the `CONSTANT` specification

`SIGN` This option results in the creation of signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign. This command is ignored for `ABS` option.

> **Caution:** Do *not* enter `DOMINANT` parameter with this option.

`SAVE` This option results in the creation of a acceleration data file (with the model file name and an `.acc` file extension) containing the joint accelerations in g's and radians/sec^2. These files are plain text and may be opened and viewed with any text editor (e.g., Notepad).

`CHECK SOFT STORY` indicates that soft story checking will be performed. If omitted from input, there will be no soft story checking. Refer to TR.28.2.1 Soft Story Checking (on page 2331) for details.

`CHECK STORY DRIFT` indicates that a story drift check is to be performed.

Tip: This is done in place of post-analysis story drift checks for IS 1893-2002.

Methodology

The design lateral shear force at each floor in each mode is computed by STAAD.Pro in accordance with the Indian IS: 1893 (Part 1)-2002 equations 7.8.4.5c and 7.8.4.5d.

$$Q_{ik} = A_k \cdot \phi_{ik} \cdot P_k \cdot W_k$$

and

$$V_{ik} = \sum_{i=i+1}^{n} Q_{ik}$$

Note: All symbols and notations in the above equation are as per IS: 1893(Part 1)-2002.

STAAD.Pro utilizes the following procedure to generate the lateral seismic loads.

1. You provide the value for $Z/2 \cdot I/R$ as factors for input spectrum. You calculate the expression $Z/2 \cdot I/R$ and provide these values using the terms `f1`, `f2`, and `f3` and applicable, where these terms an explained in the table below.
2. The program calculates time periods for first six modes or as specified.
3. The program calculates Sa/g for each mode utilizing time period and damping for each mode.
4. The program calculates the design horizontal acceleration spectrum value A_k for each mode.
5. The program then calculates mode participation factor for each mode.
6. The peak lateral seismic force at each floor in each mode is calculated.
7. All response quantities for each mode are calculated.
8. The peak response quantities are then combined as per the specified method (`SRSS, CQC, ABS, CSM` or `TEN`) to get the final results.

Note: For vertical motions (i.e., when forces are applied in the Y direction), the resulting forces are taken as 2/3 of the horizontal forces as per 6.4.5 of the IS 1893 2002 code.

Individual Modal Response Case Generation

Individual modal response (`IMR`) cases are simply the mode shape scaled to the magnitude that the mode has in this spectrum analysis case before it is combined with other modes. If the IMR parameter is entered, then STAAD.Pro will create load cases for the first specified number of modes for this response spectrum case (i.e., if five is specified then five load cases are generated, one for each of the first five modes). Each case will be created in a form like any other primary load case.

The results from an IMR case can be viewed graphically or through the print facilities. Each mode can therefore be assessed as to its significance to the results in various portions of the structure. Perhaps one or two modes could be used to design one area/floor and others elsewhere.

You can use subsequent load cases with TR.32.11 Repeat Load Specification (on page 2595) combinations of these scaled modes and the static live and dead loads to form results that are all with internally consistent signs (unlike the usual response spectrum solutions). The modal applied loads vector will be omega squared times mass times the scaled mode shape. Reactions will be applied loads minus stiffness matrix times the scaled mode shape.

With the Repeat Load capability, you can combine the modal applied loads vector with the static loadings and solve statically with P-Delta or tension only.

Note: When the IMR option is entered for a Spectrum case, then a TR.37 Analysis Specification (on page 2620) & TR.38 Change Specification (on page 2660) must be entered after each such Spectrum case.

Refer to TR.32.10.1.1 Response Spectrum Specification - Custom (on page 2499) for additional details on IMR load case generation.

Notes

a. The design base shear V_B, calculated from the Response Spectrum method, is compared with the base shear V_b, calculated by empirical formula for the fundamental time period. If V_B is less than V_b, all of the response quantities are multiplied by V_b / V_B as per Clause 7.8.2.

For this, the following input is necessary before defining any primary load case.

```
DEFINE  1893  LOAD
ZONE f1 1893-spec
SELFWEIGHT
JOINT WEIGHT
joint-list   WEIGHT w
MEMBER  WEIGHT
...
UNI   v1 v2 v3
mem-list
CON v4  v5
...
CHECK SOFT STORY

1893-Spec  = {RF f2, I f3, SS f4, (ST f5), DM f6, (PX f7), (PZ f8), (DT f9)}
```

Refer to TR.31.2.10 IS:1893 (Part 1) 2002 & Part 4 (2005) Codes - Lateral Seismic Load (on page 2387) for full details on this command structure.

Note: STAAD.Pro does not calculate the fundamental frequency of the structure needed for the empirical base shear V_b. calculation; so you must enter either the ST parameter or the PX and PZ parameters in the `DEFINE 1893 LOAD` data.

b. The following interpolation formula is adopted for interpolation between damping values as given in Table 3.

Interpolation and/or extrapolation of ground response acceleration for a particular mode has been made for determining the spectrum ordinates corresponding to the modal damping value for use in Response Spectrum analysis. The relationship that shall be used for this purpose is defined by:

$$Sa = Ae^{-\xi} + B/\xi$$

where

Sa = Spectrum ordinate

ξ = damping ratio

Constants A and B are determined using two known spectrum ordinates Sa_1 and Sa_2 corresponding to damping rations ξ_1 and ξ_2, respectively, for a particular time period and are as follows:

$$A = \frac{Sa_1\xi_1 - Sa_2\xi_2}{\xi_1 e^{-\xi_1} - \xi_2 e^{-\xi_2}}$$

$$B = \frac{\xi_1\xi_2\left(Sa_2 e^{-\xi_1} - Sa_1 e^{-\xi_2}\right)}{\xi_1 e^{-\xi_1} - \xi_2 e^{-\xi_2}}$$

Where:

$\xi_1 < \xi < \xi_2$

c. The story drift in any story shall not exceed 0.004 times the story height as per Clause 7.11.1. To check this, the following command should be given after the analysis command.

```
PRINT STOREY DRIFT
```

A warning message will be printed if story drift exceeds this limitation.

d. If any soft story (as per definition in Table 5 of IS:1893-2002) is detected, a warning message will be printed in the output.

Torsion

The torsion arising due to dynamic eccentricity (i.e., static eccentricity multiplied by dynamic amplification factor) between center of mass and center of rigidity is applied along with accidental torsion, as per the recommendations of Cl. 7.9.2 of the IS 1893 code. The dynamic eccentricity is automatically calculated by the program (in both cases of `TOR` and `TOR OPP` options), while the amount of accidental eccentricity can be specified through the `ECC` option (if not specified, default of 5% of lateral dimension of the floor in the direction of the earthquake will be considered).

Non-symmetric or torsionally unbalanced buildings are prone to earthquake damage due to coupled lateral and torsional movements (i.e., the translational vibration of the building couples with its torsional vibrations within elastic range). The level of coupling between lateral and torsional vibrations of the building can be larger, thus leading to significantly higher lateral-torsional coupling than that predicted by elastic analysis.

- Cl. 7.8.4.5 of IS 1893 (Part 1) : 2002 is valid for buildings with *regular* or *nominally irregular* plan configurations. For buildings which are *irregular* in plan, it is better to consider torsion from dynamic eccentricity into analysis; even if torsionally coupled vibration is considered during response spectrum analysis.
- Cl. 7.9.2 Note 2 of Amendment No. 1 January 2005 states that, in the case that a 3D dynamic analysis is carried out, the dynamic amplification factor 1.5—as given by Cl. 7.9.2—can be replaced by 1.0. This implies that the code also recommends to use Cl. 7.9.2 for all types of buildings by including torsion from both dynamic and accidental eccentricity in the response spectrum analysis.

Torsion Methodology

As per IS1893-2002 code, provision shall be made in all buildings for increase in shear forces on the lateral force resisting elements resulting from the horizontal torsional moment arising due to eccentricity between the center of mass and the center of rigidity.

In response spectrum analysis all the response quantities (i.e. joint displacements, member forces, support reactions, plate stresses, etc) are calculated for each mode of vibration considered in the analysis. These response quantities from each mode are combined using a modal combination method (either by CQC, SRSS, ABS, TEN PERCENT, etc) to produce a single positive result for the given direction of acceleration. This computed result represents a maximum magnitude of the response quantity that is likely to occur during seismic loading. The actual response is expected to vary from a range of negative to positive value of this maximum computed quantity.

No information is available from response spectrum analysis as to when this maximum value occurs during the seismic loading and what will be the value of other response quantities at that time. As for example, consider two joints J2 and J3 whose maximum joint displacement in global X direction come out to be X1 and X2 respectively. This implies that during seismic loading joint J1 will have X direction displacement that is expected to vary from -X1 to +X1 and that for joint J2 from -X2 to +X2. However, this does not necessarily mean that the point of time at which the X displacement of joint J1 is X1, the X displacement of joint J2 will also be X2.

For the reason stated above, torsional moment at each floor arising due to dynamic eccentricity along with accidental eccentricity (if any) is calculated for each mode. Lateral story shear from this torsion is calculated forming global load vectors for each mode. Static analysis is carried out with this global load vector to produce global joint displacement vectors for each mode due to torsion. These joint displacements from torsion for each mode are algebraically added to the global joint displacement vectors from response spectrum analysis for each mode. The final joint displacements from response spectrum along with torsion for all modes are combined using specified modal combination method to get final maximum possible joint displacements. Refer to the steps explained below.

Steps

For each mode following steps are performed to include Torsion provision.

1. Lateral story force at each floor is calculated. Refer Cl. 7.8.4.5c of IS 1893 (Part 1) : 2002. (Q_{ik} at floor i for mode k)
2. At each floor design eccentricity is calculated. Refer Cl. 7.9.2 and Cl. 7.9.2 Note 2 of Amendment No. 1 January 2005 of IS 1893 (Part 1) : 2002.

   Thus, design eccentricity $e_{di} = f15 \times e_{si} + f12 \times b_i$ where f15 = 1.0 and f12 = (±) 0.05

   Where:

   e_{si} = dynamic eccentricity arising due to center of mass and center of rigidity at floor i (static eccentricity multiplied by dynamic amplification factor 1.0 for response spectrum analysis),
   b_i = floor plan dimension in the direction of earthquake loading.
3. Torsional moment is calculated at each floor. ($M_{ik} = Q_{ik} \times e_{di}$ at floor i for mode k)
4. The lateral nodal forces corresponding to torsional moment are calculated at each floor. These forces represent the additional story shear due to torsion.
5. Static analysis of the structure is performed with these nodal forces.
6. The analysis results (i.e., member force, joint displacement, support reaction, etc) from torsion are algebraically added to the corresponding modal response quantities from response spectrum analysis.

Modal Combination

Steps 1 to 6 are performed for all modes considered and missing mass correction (if any). Finally the peak response quantities from different modal response are combined as per `CQC` or `SRSS` or `TEN PERCENT` or `CSM` method.

Notes

After the analysis is complete following files are generated.

a. Story shear for each mode for each load case is given in the file `<filename>_RESP1893.txt`.
b. Rotational stiffness of each floor is given in the file `<filename>_ROT1893.txt`.
c. Center of mass, center of rigidity, design eccentricity at each floor level and additional shear due to torsion at each floor level for each mode for each load case is given in the file `<filename>_TOR1893.txt`.

Dynamic Eccentricity

The static eccentricity is generally defined as the distance between the center of mass (CM) and the center of rigidity (CR) at respective floors levels. Accidental eccentricity generally accounts for factors such as:

- the rotational component of ground motion about the vertical axis,
- the difference between computed and actual values of the mass, stiffness, or strength, and
- uneven live mass distribution.

The provision for design eccentricity e_{di} at ith floor of a building is given by the following equation:

$$e_{di} = DEC \times e_{si} + ECC \times b_i$$

where

e_{si}	=	static eccentricity at ith floor
b_i	=	plan dimension of the ith floor normal to the direction of ground motion
ECC and DEC	=	Factors to determine the design eccentricity. These are input parameters.

IS 1893-2002 clause 7.8.2 defines two equations:

$$e_{di} = 1.5 \times e_{si} + 0.05 \times b_i$$

$$e_{di} = 1.0 \times e_{si} - 0.05 \times b_i$$

By including the optional command `TORSION`, the first equation is used by default. To account for the second equation, you may simply specify `DEC -0.05` (at which point the default for ECC is then 1.0).

Example

Refer to V. IS 1893 2002 Response Spectrum (on page 3588) for a detailed explanation of this example.

```
LOAD 1 LOADTYPE None  TITLE RS_X
SPECTRUM SRSS 1893 X 0.036 ACC DAMP 0.05
SOIL TYPE 1
```

TR.32.10.1.8 Response Spectrum Specification per IS: 1893 (Part 1)-2016

This command may be used to specify and apply the `RESPONSE SPECTRUM` loading as per IS: 1893 (Part 1)-2016 for dynamic analysis.

The seismic load generator can be used to generate lateral loads in the X, Y, and Z directions.

Note: This facility has *not* been developed for cases where the Z axis is set to be the vertical direction using the `SET Z UP` command.

General Format

The data in the following format can be contained all on a single line or broken into two or three lines, so long as the second and third lines start with the `ACC` and `DOMINANT` or `SIGN` commands.

```
SPECTRUM comp-method IS1893 2016 ( TORSION (DECCENTRICITY f8) (ECCENTRICITY f9) ) *{ X
f1 | Y f2  | Z f3 }
```

```
{ ACCELERATION | DISPLACEMENT } (SCALE f4) {DAMP f5 | CDAMP | MDAMP } ( { LINEAR |
LOGARITHMIC } ) (MISSING f6) (ZPA f7) (IGNORE f13)
({ DOMINANT f10 | SIGN }) (IMR f11) (STARTCASE f12)
```

The following command (`SOIL TYPE` parameter *or* response spectra data pairs) must be in a separate line.

```
{ SOIL TYPE f11 | *{ P1,V1; P2,V2; P3,V3;…PN,VN } }
```

Note: The spectrum type options `ACCELERATION` or `DISPLACEMENT` should only be used with custom soil types for IS 1893 2016.

The following command, if present, must be on a separate line. This performs the story drift check.

```
( CHECK STORY DRIFT ) (RF f14)
```

Where:

Table 271: Parameters used for IS: 1893 (Part 1) 2016 response spectrum

Parameter	**Default Value**	**Description**
DECCENTRICITY *f8*	When ECC > 0, DEC defaults to 1.5 When ECC < 0, DEC defaults to 1.0	(Optional input) It is a factor which when multiplied with static eccentricity (i.e., eccentricity between center of mass and center of rigidity) gives dynamic eccentricity. Since the applied load is acting at the center of mass, the effect of inherent torsion arising due to static eccentricity is included in the analysis. **Note:** The torsion arising due to dynamic eccentricity (i.e,. static eccentricity multiplied by dynamic amplification factor) between center of mass and center of rigidity is applied along with accidental torsion, as per the recommendations of Cl. 7.8.2 of the code. The dynamic eccentricity is automatically calculated by the program while you can specify the amount of accidental eccentricity (if not specified, the default of 5% of lateral dimension of the floor in the direction of the earthquake will be considered). For details See Torsion Methodology (on page 2553).

Parameter	Default Value	Description
ECCENTRICITY *f9*	0.05	It is a factor which indicates the extent of accidental eccentricity. For all buildings this factor is to be provided as 0.05. However, for highly irregular buildings this factor may be increased to 0.10. This factor is to be externally provided to calculate design eccentricity. Since accidental eccentricity can be on either side, you must consider lateral force acting at a floor level to be accompanied by a clockwise or a counterclockwise accidental torsion moment. If the *f9* value is positive, it indicates clockwise torsion whereas a negative value indicates counterclockwise torsion.
X *f1*, Y *f2*, Z *f3*	0.0	Factors for the input spectrum to be applied in X, Y, & Z directions. Any one or all directions can be input. Directions not provided will default to zero.
SCALE *f4*	1.0	Linear scale factor by which the spectra data will be multiplied. Usually used to factor g's to length/sec^2 units. This input is the appropriate value of acceleration due to gravity in the current unit system (thus, 9.81 m/s^2 or 32.2 ft/s^2).
DAMP *f5*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If `CDAMP` is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If `MDAMP` is specified, then modal damping is calculated using the method defined in a `DEFINE DAMPING INFORMATION` command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)
MISSING *f6*		Optional parameter to use "Missing Mass" method. The static effect of the masses not represented in the modes is included. The spectral acceleration for this missing mass mode is the *f6*value entered in length/sec^2 (this value is not multiplied by SCALE). If *f6*is zero, then the spectral acceleration at the `ZPA` *f7*frequency is used. If *f7*is zero or not entered, the spectral acceleration at 33Hz (Zero Period Acceleration, ZPA) is used. The results of this calculation are SRSSed with the modal combination results. **Note:** If the `MISSING` parameter is entered on any spectrum case it will be used for all spectrum cases.
ZPA *f7*	33 [Hz]	The zero period acceleration value for use with `MISSING` option only. Defaults to 33 Hz if not entered. The value is printed but not used if `MISSING` *f6* is entered.

Parameter	Default Value	Description
IGNORE *f13*	0.009	(Optional input) It indicates the mass participation (in percent) of those modes to be excluded while considering torsion provision of IS-1893. Depending upon the model it may be found that there are many local modes and torsional modes whose mass participation is practically negligible. These modes can be excluded without much change in the final analysis result. If not provided all modes will be considered. If none provided the default value of 0.009% will be considered. If IGN is entered on any one spectrum case it will be used for all spectrum cases. **Note:** If the value of *f14* is considerable it may lead to considerable variation of analysis result from the actual one. Hence caution must be taken while using `IGNORE` command. If the `MODE SELECT` command is provided along with the `IGNORE` command, the number of modes excluded from the analysis will be those deselected by the `MODE SELECT` command and *also* those deselected by the `IGNORE` command.
DOMINANT *f10*	1 (1st Mode)	The dominant mode method. All results will have the same sign as mode number *f10* alone would have if it were excited then the scaled results were used as a static displacements result. Defaults to mode 1 if no value entered. If a 0 value entered, then the mode with the greatest % participation in the excitation direction will be used (only one direction factor may be nonzero). **Note:** Do not enter the `SIGN` parameter with this option. Ignored for the `ABS` method of combining spectral responses from each mode.
IMR *f11*	1	The number of individual modal responses (scaled modes) to be copied into load cases. Defaults to one. If greater than the actual number of modes extracted (`NM`), then it will be reset to NM. Modes one through f11 will be used. Missing Mass modes are not output.
STARTCASE *f12*	Highest Load Case No. + 1	The primary load case number of mode 1 in the `IMR` parameter. Defaults to the highest load case number used so far plus one. If *f12* is not higher than all prior load case numbers, then the default will be used. For modes 2 through `NM`, the load case number is the prior case number plus one.

Parameter	Default Value	Description
SOIL TYPE *f11*		The soil type present. Depending upon time period, types of soil and damping, average response acceleration coefficient, S_a/g is calculated. 1 = for rocky or hard soil 2 = medium soil 3 = soft soil sites
custom P1,V1; P2,V2; P3,V3; … Pn,Vn		Data is part of input immediately following spectrum command for a "custom" response spectrum. Period - Value pairs (pairs separated by semicolons) are entered to describe the spectrum curve. Period is in seconds and the corresponding Value is acceleration (current length unit/ sec^2). If data is in g acceleration units then the factor by which spectra data will be multiplied is g to the current length unit (9.81, 386.4, etc). **Note:** Do not enter if a SOIL TYPE *f11* value is specified.
RF *f14*		The response reduction factor. If not specified, the program will look for the factor defined under `DEFINE 1893 2016 LOAD` (refer to TR.31.2.11 IS:1893 (Part 1) 2016 Codes - Lateral Seismic Load (on page 2393)). If none is provided there either, a factor of 1.0 is assumed. The response reduction factor represents ratio of maximum seismic force on a structure during specified ground motion if it were to remain elastic to the design seismic force. Actual seismic force is reduced by a factor `RF` to obtain design force.)

1893 indicates the analysis as per IS:1893(Part 1)-2016 procedures.

comb-method = { `SRSS` | `ABS` | `CQC` | `ASCE` | `TEN` | `CSM` | `GRP` } are methods of combining the responses from each mode into a total response.

Note: CQC, SRSS, and CSM Grouping methods are recommended by IS:1893 (Part 1) –2016.

SRSS Square Root of Summation of Squares method.

ABS Absolute sum. This method is very conservative and represents a worst case combination.

CQC Complete Quadratic Combination method (Default). This method is recommended for closely spaced modes instead of SRSS.

Resultants are calculated as:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

$$\rho_{nm} = \frac{8\zeta^2(1+r)r^{2/3}}{(1-r^2)^2 + 4\zeta^2 r(1+r)^2}$$

$$r = \omega_n / \omega_m \leq 1.0$$

Note: The cross-modal coefficient array is symmetric and all terms are positive.

ASCE NRC Regulatory Guide Rev. 2 (2006) Gupta method for modal combinations and Rigid/Periodic parts of modes are used. The ASCE4-98 definitions are used where there is no conflict. ASCE4-98 Eq. 3.2-21 (modified Rosenblueth) is used for close mode interaction of the damped periodic portion of the modes.

TEN Ten Percent Method of combining closely spaced modes. NRC Reg. Guide 1.92 (Rev. 1.2.2, 1976).

CSM Closely Spaced Method as per IS:1893 (Part 1)-2002 procedures.

GRP Closely Spaced Modes Grouping Method. NRC Reg. Guide 1.92 (Rev. 1.2.1, 1976).

`TORSION` indicates that the torsional moment (in the horizontal plane) arising due to eccentricity between the center of mass and center of rigidity needs to be considered. See Torsion (on page 2552) for additional information.

Note: If `TORSION` is entered on any one spectrum case it will be used for all spectrum cases.

Lateral shears at story levels are calculated in global X and Z directions. For global Y direction the effect of torsion will not be considered.

`ACCELERATION` or `DISPLACEMENT` indicates whether **Acceleration** or **Displacement** spectra will be entered. The relationship between acceleration and displacement values in response spectra data is:

$$\text{Displacement} = \text{Acceleration} \times (1 / \omega)^2$$

where

ω = 2π/Period (period given in seconds; ω in cycles per second)

`DAMP`, `MDAMP`, and `CDAMP` select source of damping input:

- `DAMP` indicates to use the $f2$ value for all modes
- `MDAMP` indicates to use the damping entered or computed with the `DEFINE DAMP` command if entered, otherwise default value of 0.05 will be used
- `CDAMP` indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the `CONSTANT` specification

`LINEAR` or `LOGARITHMIC` Select **Linear** or **Logarithmic** interpolation of the input Spectra versus Period curves for determining the spectra value for a mode given its period. Linear is the default. Since Spectra versus Period curves are often linear only on Log-Log scales, the logarithmic interpolation is recommended in such cases; especially if only a few points are entered in the spectra curve.

Note: The last interpolation parameter entered on the last of all of the spectrum cases will be used for all spectrum cases.

Note: The `LINEAR` or `LOGARITHMIC` option can only be used for custom soil types (e.g., when response spectra data pairs are specified). Do not use these commands when the `SOIL TYPE` command is used.

`SIGN` This option results in the creation of signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign. This command is ignored for ABS option.

Caution: Do *not* enter DOMINANT parameter with this option.

SAVE This option results in the creation of a acceleration data file (with the model file name and an .acc file extension) containing the joint accelerations in g's and radians/sec^2. These files are plain text and may be opened and viewed with any text editor (e.g., Notepad).

Note: In order to perform a soft story check per IS 1893 2016, use the TR.28.2.1 Soft Story Checking (on page 2331) command.

Methodology

The design lateral shear force at each floor in each mode is computed by STAAD.Pro in accordance with the Indian IS: 1893 (Part 1)-2016 equations 7.8.4.5c and 7.8.4.5d.

$$Q_{ik} = A_k \cdot \phi_{ik} \cdot P_k \cdot W_k$$

and

$$V_{ik} = \sum_{i=i+1}^{n} Q_{ik}$$

Note: All symbols and notations in the above equation are as per IS: 1893(Part 1)-2016.

STAAD.Pro utilizes the following procedure to generate the lateral seismic loads.

1. You provide the value for $Z/2 \cdot I/R$ as factors for input spectrum. You calculate the expression $Z/2 \cdot I/R$ and provide these values using the terms f1, f2, and f3 and applicable, where these terms an explained in the table below.
2. The program calculates time periods for first six modes or as specified.
3. The program calculates Sa/g for each mode utilizing time period and damping for each mode, based on IS 1893 2016 Clause 6.4.2 and Fig. 2(b).

   For the Y direction, Sa/g is always equal to 2.5 per Clause 6.4.6.
4. The program calculates the design horizontal acceleration spectrum value A_k for each mode.
5. The program then calculates mode participation factor for each mode.
6. The peak lateral seismic force at each floor in each mode is calculated.
7. All response quantities for each mode are calculated.
8. The peak response quantities are then combined as per the specified method (SRSS, CQC, ABS, CSM or TEN) to get the final results.

Note: For vertical motions (i.e., when forces are applied in the Y direction), the resulting forces are taken as 2/3 of the horizontal forces as per 6.4.6 of the IS 1893 Part 1 2016 code.

According to clause 7.7.3b, the scale factor for the earthquake in the vertical direction shall be take as the maximum of the scale factors in both the X and Z direction (see also Notes below). There are broadly three cases which the program considers to evaluate this maximum. These are load lists defined containing one of the following cases

i. response spectra in X, response spectra in Y, and response spectra in Z separately in load cases in any order

ii. response spectra in XY, response spectra in YZ, and response spectra in XYZ in individual load cases in any order
iii. a mix of the first two cases in any order

For a scale factor for any load case with a vertical component (that is, response spectra of Y, XY, YZ, or XYZ types), the program will use the maximum of the scale factor for all preceding load cases that are listed*after* a previous load case with a Y component. For example, for model with the following 11 load cases, the following scale factors will be used:

Load Case No.	Type	Scale Factor	Load Case Used for Scale Factor
1	X	2.18	1
2	XY	2.18	2
3	YZ	1	3
4	XZ	2.18	4
5	Y	2.18	max(3,4) = 4
6	X	2.18	6
7	Z	1	7
8	Y	2.18	max(6,7) = 6
9	XY	2.18	9
10	XZ	2.18	10
11	Y	2.18	max(9 ,10) = 9 = 10

Individual Modal Response Case Generation

Individual modal response (`IMR`) cases are simply the mode shape scaled to the magnitude that the mode has in this spectrum analysis case before it is combined with other modes. If the IMR parameter is entered, then STAAD.Pro will create load cases for the first specified number of modes for this response spectrum case (i.e., if five is specified then five load cases are generated, one for each of the first five modes). Each case will be created in a form like any other primary load case.

The results from an IMR case can be viewed graphically or through the print facilities. Each mode can therefore be assessed as to its significance to the results in various portions of the structure. Perhaps one or two modes could be used to design one area/floor and others elsewhere.

You can use subsequent load cases with TR.32.11 Repeat Load Specification (on page 2595) combinations of these scaled modes and the static live and dead loads to form results that are all with internally consistent signs (unlike the usual response spectrum solutions). The modal applied loads vector will be omega squared times mass times the scaled mode shape. Reactions will be applied loads minus stiffness matrix times the scaled mode shape.

With the Repeat Load capability, you can combine the modal applied loads vector with the static loadings and solve statically with P-Delta or tension only.

Note: When the IMR option is entered for a Spectrum case, then a TR.37 Analysis Specification (on page 2620) & TR.38 Change Specification (on page 2660) must be entered after each such Spectrum case.

Refer to TR.32.10.1.1 Response Spectrum Specification - Custom (on page 2499) for additional details on IMR load case generation.

Notes

a. The design base shear, VB_RS, calculated from the response spectrum method, is compared with the base shear, VB_SS, calculated by the empirical formula for the fundamental time period based on Clause 7.2.1. If VB_RS is less than VB_RS, all of the response quantities are multiplied by VB_SS/VB_RS as per Clause 7.7.3(a) for each of the orthogonal directions and by $_{max}\left[\left(\frac{VB\_SS}{VB\_RS}\right)_X, \left(\frac{VB\_SS}{VB\_RS}\right)_Z\right]$ for response amplification when considering response spectrum load in the vertical direction based on Clause 7.7.3(b).

For this, the following input is necessary before defining any primary load case.

```
DEFINE IS1893 2016 LOAD
...
...
```

Refer to TR.31.2.11 IS:1893 (Part 1) 2016 Codes - Lateral Seismic Load (on page 2393) for full details on this command structure.

> **Note:** STAAD.Pro does not calculate the fundamental frequency of the structure needed for the empirical base shear VB_SS. calculation; so you must enter either the ST parameter or the PX and PZ parameters in the DEFINE IS1893 2016 LOAD data.

b. Although IS 1893 2016 recommends a damping ratio of 0.05, you may use any other damping and the values will be calculated based on Table 3. A warning will be printed in the output.

c. The story drift in any story shall not exceed 0.004 times the story height as per Clause 7.11.1. To check this, the following command should be given after the analysis command.

```
PRINT STORY DRIFT
```

A warning message will be printed if the story drift exceeds this limitation.

d. If any soft story (as per definition in Table 5 of IS:1893-2016) is detected, a warning message will be printed in the output.

Torsion

The torsion arising due to dynamic eccentricity (i.e., static eccentricity multiplied by dynamic amplification factor) between center of mass and center of rigidity is applied along with accidental torsion, as per the recommendations of Cl. 7.8 of the IS 1893 2016 code. The dynamic eccentricity is automatically calculated by the program (in both cases of TOR and TOR OPP options), while the amount of accidental eccentricity can be specified through the ECC option (if not specified, default of 5% of lateral dimension of the floor in the direction of the earthquake will be considered).

Non-symmetric or torsionally unbalanced buildings are prone to earthquake damage due to coupled lateral and torsional movements (i.e., the translational vibration of the building couples with its torsional vibrations within elastic range). The level of coupling between lateral and torsional vibrations of the building can be larger, thus leading to significantly higher lateral-torsional coupling than that predicted by elastic analysis.

- Cl. 7.7.5.4 of IS 1893 (Part 1) : 2016 is valid for buildings with *regular* or *nominally irregular* plan configurations. For buildings which are *irregular* in plan, it is better to consider torsion from dynamic eccentricity into analysis; even if torsionally coupled vibration is considered during response spectrum analysis.

- Cl. 7.8 states that, in the case that a 3D dynamic analysis is carried out, the dynamic amplification factor 1.5—as given by Cl. 7.8—can be replaced by 1.0. This implies that the code also recommends to use Cl. 7.8 for all types of buildings by including torsion from both dynamic and accidental eccentricity in the response spectrum analysis.

Torsion Methodology

As per IS1893-2016 code, provision shall be made in all buildings for increase in shear forces on the lateral force resisting elements resulting from the horizontal torsional moment arising due to eccentricity between the center of mass and the center of rigidity.

In response spectrum analysis all the response quantities (i.e. joint displacements, member forces, support reactions, plate stresses, etc) are calculated for each mode of vibration considered in the analysis. These response quantities from each mode are combined using a modal combination method (either by CQC, SRSS, ABS, TEN PERCENT, etc) to produce a single positive result for the given direction of acceleration. This computed result represents a maximum magnitude of the response quantity that is likely to occur during seismic loading. The actual response is expected to vary from a range of negative to positive value of this maximum computed quantity.

No information is available from response spectrum analysis as to when this maximum value occurs during the seismic loading and what will be the value of other response quantities at that time. As for example, consider two joints J2 and J3 whose maximum joint displacement in global X direction come out to be X1 and X2 respectively. This implies that during seismic loading joint J1 will have X direction displacement that is expected to vary from -X1 to +X1 and that for joint J2 from -X2 to +X2. However, this does not necessarily mean that the point of time at which the X displacement of joint J1 is X1, the X displacement of joint J2 will also be X2.

For the reason stated above, torsional moment at each floor arising due to dynamic eccentricity along with accidental eccentricity (if any) is calculated for each mode. Lateral story shear from this torsion is calculated forming global load vectors for each mode. Static analysis is carried out with this global load vector to produce global joint displacement vectors for each mode due to torsion. These joint displacements from torsion for each mode are algebraically added to the global joint displacement vectors from response spectrum analysis for each mode. The final joint displacements from response spectrum along with torsion for all modes are combined using specified modal combination method to get final maximum possible joint displacements. Refer to the steps explained below.

Steps

For each mode following steps are performed to include Torsion provision.

1. Lateral story force at each floor is calculated. Refer Cl. 7.7.5.4(c) of IS 1893 (Part 1) : 2016. (Q_{ik} at floor i for mode k)
2. At each floor design eccentricity is calculated. Refer Cl. 7.8.

   Thus, design eccentricity e_{di} = *f15*×e_{si} + *f12*×b_i. See Dynamic Eccentricity (on page 2554) for details.
3. Torsional moment is calculated at each floor. ($M_{ik} = Q_{ik} \times e_{di}$ at floor i for mode k)
4. The lateral nodal forces corresponding to torsional moment are calculated at each floor. These forces represent the additional story shear due to torsion.
5. Static analysis of the structure is performed with these nodal forces.
6. The analysis results (i.e., member force, joint displacement, support reaction, etc) from torsion are algebraically added to the corresponding modal response quantities from response spectrum analysis.

Modal Combination

Steps 1 to 6 are performed for all modes considered and missing mass correction (if any). Finally the peak response quantities from different modal response are combined as per `CQC` or `SRSS` or `TEN PERCENT` or `CSM` method.

Notes

After the analysis is complete following files are generated.

a. Story shear for each mode for each load case is given in the file `<filename>_RESP1893.txt`.
b. Rotational stiffness of each floor is given in the file `<filename>_ROT1893.txt`.
c. Center of mass, center of rigidity, design eccentricity at each floor level and additional shear due to torsion at each floor level for each mode for each load case is given in the file `<filename>_TOR1893.txt`.

Dynamic Eccentricity

The static eccentricity is generally defined as the distance between the center of mass (CM) and the center of rigidity (CR) at respective floors levels. Accidental eccentricity generally accounts for factors such as:

- the rotational component of ground motion about the vertical axis,
- the difference between computed and actual values of the mass, stiffness, or strength, and
- uneven live mass distribution.

The provision for design eccentricity e_{di} at ith floor of a building is given by the following equation:

$$e_{di} = \mathrm{DEC} \times e_{si} + \mathrm{ECC} \times b_i$$

where

e_{si}	=	static eccentricity at ith floor
b_i	=	plan dimension of the ith floor normal to the direction of ground motion
ECC and DEC	=	Factors to determine the design eccentricity. These are input parameters.

IS 1893-2016 clause 7.8.2 defines two equations:

$$e_{di} = 1.5 \times e_{si} + 0.05 \times b_i$$

$$e_{di} = 1.0 \times e_{si} - 0.05 \times b_i$$

By including the optional command `TORSION`, the first equation is used by default. To account for the second equation, you may simply specify `ECC -0.05` (at which point the default for `DEC` is then 1.0). The defaults for `ECC` and `DEC` provided to meet the requirements but the parameters may be specified manually.

Example

Refer to V. IS 1893 2016 Response Spectrum (on page 3498) for a detailed explanation of this example.

```
LOAD 1 LOADTYPE None  TITLE RS_X
SPECTRUM SRSS IS1893 2016 X 0.0432 DAMP 0.05
SOIL TYPE 1
```

- *V. IS 1893 2016 Response Spectrum* (on page 3498)

TR.32.10.1.9 Response Spectrum Specification per IS: 1893 (Part 4)-2015

This command may be used to specify and apply the `RESPONSE SPECTRUM` loading as per IS: 1893 (Part 4)-2015 for dynamic analysis of industrial and stack-like structures.

The seismic load generator can be used to generate lateral loads in the X, Y, and Z directions.

> **Note:** This facility has *not* been developed for cases where the Z axis is set to be the vertical direction using the `SET Z UP` command.

> **Note:** For vertical motions (i.e., when forces are applied in the Y direction), the resulting forces are taken as 2/3 of the horizontal forces as per 6.4.6 of the IS 1893 2016 Part 1 code.

General Format

The data in the following format can be contained all on a single line or broken into two or three lines, so long as the second and third lines start with the `ACC` and `DOMINANT` or `SIGN` commands.

```
SPECTRUM comp-method IS1893 2015-P4 LOAD ( TORSION (DECCENTRICITY f8) (ECCENTRICITY
f9) ) *{ X f1 | Y f2  | Z f3 }
```

```
{ ACCELERATION | DISPLACEMENT } (SCALE f4) {DAMP f5 | CDAMP | MDAMP } (MISSING f6)
(ZPA f7) (IGNORE f13)
({ DOMINANT f10 | SIGN }) (IMR f11) (STARTCASE f12) (RSMIN f14 )
```

The following command (`SOIL TYPE` parameter *or* response spectra data pairs) must be in a separate line.

```
{ SOIL TYPE f11 | *{ P1,V1; P2,V2; P3,V3;…PN,VN } }
```

> **Note:** The spectrum type options ACCELERATION or `DISPLACEMENT` should only be used with custom soil types for IS 1893 2015 (Part 4).

Where:

Table 272: Parameters used for IS: 1893 (Part 4) 2015 response spectrum

Parameter	Default Value	Description
DECCENTRICITY *f8*	When ECC > 0, DEC defaults to 1.5 When ECC < 0, DEC defaults to 1.0	(Optional input) It is a factor which when multiplied with static eccentricity (i.e., eccentricity between center of mass and center of rigidity) gives dynamic eccentricity. Since the applied load is acting at the center of mass, the effect of inherent torsion arising due to static eccentricity is included in the analysis. **Note:** The torsion arising due to dynamic eccentricity (i.e,. static eccentricity multiplied by dynamic amplification factor) between center of mass and center of rigidity is applied along with accidental torsion, as per the recommendations of Cl. 7.8.2 of the IS 1893 Part 1 specification. The dynamic eccentricity is automatically calculated by the program while you can specify the amount of accidental eccentricity (if not specified, the default of 5% of lateral dimension of the floor in the direction of the earthquake will be considered). For details See Torsion Methodology (on page 2553).
ECCENTRICITY *f9*	0.05	It is a factor which indicates the extent of accidental eccentricity. For all buildings this factor is to be provided as 0.05. However, for highly irregular buildings this factor may be increased to 0.10. This factor is to be externally provided to calculate design eccentricity. Since accidental eccentricity can be on either side, you must consider lateral force acting at a floor level to be accompanied by a clockwise or a counterclockwise accidental torsion moment. If the *f9* value is positive, it indicates clockwise torsion whereas a negative value indicates counterclockwise torsion.
X *f1* | Y *f2* | Z *f3*	0	Factors for the input spectrum to be applied in X, Y, & Z directions. These must be entered as the product of $[(Z/2)\times(I/R)]$ for standard specific spectra. Any one or all directions can be input. Directions not provided will default to zero. Based on Clause7.3 of IS 1893(Part 4): 2015.
SCALE *f4*	1	Linear scale factor by which design horizontal acceleration spectrum will be multiplied. This factor signifies that the structures and foundations, at which level base shear will be calculated, are placed below the ground level. **Note:** If site specific spectra curve is used then f4 value is to be multiplied by the scale factor by which spectra data will be multiplied. Usually to factor g's to length/sec^2 units.

Parameter	Default Value	Description
DAMP *f5*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If CDAMP is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If MDAMP is specified, then modal damping is calculated using the method defined in a DEFINE DAMPING INFORMATION command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)
MISSING *f6*		Optional parameter to use "Missing Mass" method. The static effect of the masses not represented in the modes is included. The spectral acceleration for this missing mass mode is the *f6*value entered in length/sec^2 (this value is not multiplied by SCALE). If *f6*is zero, then the spectral acceleration at the ZPA *f7*frequency is used. If *f7*is zero or not entered, the spectral acceleration at 33Hz (Zero Period Acceleration, ZPA) is used. The results of this calculation are SRSSed with the modal combination results. **Note:** If the MISSING parameter is entered on any spectrum case it will be used for all spectrum cases.
ZPA *f7*	33 [Hz]	The zero period acceleration value for use with MISSING option only. Defaults to 33 Hz if not entered. The value is printed but not used if MISSING *f6* is entered.
DOMINANT *f10*	1 (1st Mode)	The dominant mode method. All results will have the same sign as mode number *f10* alone would have if it were excited then the scaled results were used as a static displacements result. Defaults to mode 1 if no value entered. If a 0 value entered, then the mode with the greatest % participation in the excitation direction will be used (only one direction factor may be nonzero). **Note:** Do not enter the SIGN parameter with this option. Ignored for the ABS method of combining spectral responses from each mode.
IMR *f11*	1	The number of individual modal responses (scaled modes) to be copied into load cases. Defaults to one. If greater than the actual number of modes extracted (NM), then it will be reset to NM. Modes one through f11 will be used. Missing Mass modes are not output.

Parameter	Default Value	Description
STARTCASE *f12*	Highest Load Case No. + 1	The primary load case number of mode 1 in the `IMR` parameter. Defaults to the highest load case number used so far plus one. If *f12* is not higher than all prior load case numbers, then the default will be used. For modes 2 through `NM`, the load case number is the prior case number plus one.
SOIL TYPE *f11*	2	The soil type present. Depending upon time-period, types of soil and damping, average response acceleration coefficient, Sa/ g is calculated from reference to Fig.1 of this code where: 1 = Type 1 - for rocky or hard soil 2 = Type 2 - medium soil 3 = Type 3 - soft soil sites
custom P1,V1; P2,V2; P3,V3; ... Pn,Vn		Data is part of input immediately following spectrum command for a “custom” response spectrum. Period - Value pairs (pairs separated by semicolons) are entered to describe the spectrum curve. Period is in seconds and the corresponding Value is acceleration (current length unit/ sec^2). If data is in g acceleration units then the factor by which spectra data will be multiplied is g to the current length unit (9.81, 386.4, etc). **Note:** Do not enter if a SOIL TYPE *f11* value is specified.
IGNORE *f13*	0.009	(Optional input) It indicates the mass participation (in percent) of those modes to be excluded while considering torsion provision of IS-1893. Depending upon the model it may be found that there are many local modes and torsional modes whose mass participation is practically negligible. These modes can be excluded without much change in the final analysis result. If not provided all modes will be considered. If none provided the default value of 0.009% will be considered. If IGN is entered on any one spectrum case it will be used for all spectrum cases. **Note:** If the value of *f14* is considerable it may lead to considerable variation of analysis result from the actual one. Hence caution must be taken while using `IGNORE` command. If the `MODE SELECT` command is provided along with the `IGNORE` command, the number of modes excluded from the analysis will be those deselected by the `MODE SELECT` command and *also* those deselected by the `IGNORE` command.

Parameter	Default Value	Description
RSMIN *f14*	2.0	Used to enter a factor, given in percent, to multiply by the total seismic weight of the structure to obtain a minimum base shear value. This percentage is taken from Table 2 of IS:1839(Part 4)-2015. This percentage must match a value in this table. The default value is taken for a structure category 1 and zone 2. If the minimum base shear value exceed the calculated response spectrum base shear, then all analysis results of the response spectrum load case are scaled by the ratio of the minimum base shear to the calculated response spectrum base shear. This multiplying factor will be noted in the output.

`1893 2015-P4` indicates the analysis as per IS:1893(Part 4)-2015 procedures.

comb-method = { `SRSS` | `ABS` | `CQC` | `ASCE` | `TEN` | `CSM` | `GRP` } are methods of combining the responses from each mode into a total response.

Note: CQC, SRSS, and CSM Grouping methods are recommended by IS:1893 (Part 4) –2015.

SRSS Square Root of Summation of Squares method.

ABS Absolute sum. This method is very conservative and represents a worst case combination.

CQC Complete Quadratic Combination method (Default). This method is recommended for closely spaced modes instead of SRSS.

Resultants are calculated as:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

$$\rho_{nm} = \frac{8\zeta^2(1+r)r^{2/3}}{(1-r^2)^2 + 4\zeta^2 r(1+r)^2}$$

$$r = \omega_n / \omega_m \leq 1.0$$

Note: The cross-modal coefficient array is symmetric and all terms are positive.

ASCE NRC Regulatory Guide Rev. 2 (2006) Gupta method for modal combinations and Rigid/Periodic parts of modes are used. The ASCE4-98 definitions are used where there is no conflict. ASCE4-98 Eq. 3.2-21 (modified Rosenblueth) is used for close mode interaction of the damped periodic portion of the modes.

TEN Ten Percent Method of combining closely spaced modes. NRC Reg. Guide 1.92 (Rev. 1.2.2, 1976).

CSM Closely Spaced Method as per IS:1893 (Part 1)-2002 procedures.

GRP Closely Spaced Modes Grouping Method. NRC Reg. Guide 1.92 (Rev. 1.2.1, 1976).

`TORSION` indicates that the torsional moment (in the horizontal plane) arising due to eccentricity between the center of mass and center of rigidity needs to be considered. See Torsion (on page 2552) for additional information.

Note: If `TORSION` is entered on any one spectrum case it will be used for all spectrum cases.

Lateral shears at story levels are calculated in global X and Z directions. For global Y direction the effect of torsion will not be considered.

The Torsion methodology as per Clause 10.4 of IS 1893 (Part4): 2015 remains same as Torsion (on page 2552) and is only applicable for ST=4.

ACCELERATION or DISPLACEMENT indicates whether **Acceleration** or **Displacement** spectra will be entered. The relationship between acceleration and displacement values in response spectra data is:

$$\text{Displacement} = \text{Acceleration} \times (1/\omega)^2$$

where

ω = 2π/Period (period given in seconds; ω in cycles per second)

DAMP, MDAMP, and CDAMP select source of damping input:

- `DAMP` indicates to use the $f2$ value for all modes
- `MDAMP` indicates to use the damping entered or computed with the `DEFINE DAMP` command if entered, otherwise default value of 0.05 will be used
- `CDAMP` indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the `CONSTANT` specification

For response spectra analysis, the damping ratio coefficients for steel and concrete that are recommended (other than the default value of 5%) for industrial structures as per Clause 9.4 (Table 5) are as follows:

Material	DBE	MCE
Steel	0.02	0.04
Reinforced concrete	0.05	0.07
Prestressed concrete	0.03	0.05

Note: For combined material structures, the damping ratio coefficient shall be determined based on well established procedures. If a composite damping ratio coefficient is not evaluated, it shall be taken as that corresponding to material having lower value of damping.

LINEAR or LOGARITHMIC Select **Linear** or **Logarithmic** interpolation of the input Spectra versus Period curves for determining the spectra value for a mode given its period. Linear is the default. Since Spectra versus Period curves are often linear only on Log-Log scales, the logarithmic interpolation is recommended in such cases; especially if only a few points are entered in the spectra curve.

Note: The last interpolation parameter entered on the last of all of the spectrum cases will be used for all spectrum cases.

Note: The `LINEAR` or `LOGARITHMIC` option can only be used for custom soil types (e.g., when response spectra data pairs are specified). Do not use these commands when the `SOIL TYPE` command is used.

SIGN This option results in the creation of signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign. This command is ignored for `ABS` option.

Caution: Do *not* enter `DOMINANT` parameter with this option.

SAVE This option results in the creation of a acceleration data file (with the model file name and an `.acc` file extension) containing the joint accelerations in g's and radians/sec^2. These files are plain text and may be opened and viewed with any text editor (e.g., Notepad).

Individual Modal Response Case Generation

Individual modal response (`IMR`) cases are simply the mode shape scaled to the magnitude that the mode has in this spectrum analysis case before it is combined with other modes. If the IMR parameter is entered, then STAAD.Pro will create load cases for the first specified number of modes for this response spectrum case (i.e., if five is specified then five load cases are generated, one for each of the first five modes). Each case will be created in a form like any other primary load case.

The results from an IMR case can be viewed graphically or through the print facilities. Each mode can therefore be assessed as to its significance to the results in various portions of the structure. Perhaps one or two modes could be used to design one area/floor and others elsewhere.

You can use subsequent load cases with TR.32.11 Repeat Load Specification (on page 2595) combinations of these scaled modes and the static live and dead loads to form results that are all with internally consistent signs (unlike the usual response spectrum solutions). The modal applied loads vector will be omega squared times mass times the scaled mode shape. Reactions will be applied loads minus stiffness matrix times the scaled mode shape.

With the Repeat Load capability, you can combine the modal applied loads vector with the static loadings and solve statically with P-Delta or tension only.

Note: When the IMR option is entered for a Spectrum case, then a TR.37 Analysis Specification (on page 2620) & TR.38 Change Specification (on page 2660) must be entered after each such Spectrum case.

Refer to TR.32.10.1.1 Response Spectrum Specification - Custom (on page 2499) for additional details on IMR load case generation.

Example

```
LOAD 1 LOADTYPE None  TITLE RS_X
SPECTRUM SRSS IS1893 2015-P4 LOAD X 0.0432 DAMP 0.05
SOIL TYPE 1
```

TR.32.10.1.10 Response Spectrum Specification per IBC 2006

This command may be used to specify and apply the `RESPONSE SPECTRUM` loading as per the 2006 edition of the ICC specification *International Building Code* (IBC), for dynamic analysis. The graph of frequency – acceleration pairs are calculated based on the input requirements of the command and as defined in the code.

General Format

```
SPECTRUM comb-method IBC 2006 *{ X f1| Y f2| Z f3} ACCELERATION
```

```
{DAMP f5| CDAMP | MDAMP } ( { LINEAR | LOGARITHMIC } ) (MISSING f6) (ZPA f7)
({ DOMINANT f10 | SIGN }) (SAVE)  (IMR f11) (STARTCASE f12)
```

Note: The data from SPECTRUM through ACC must be on the first line of the command. The data shown on the second line above can be continued on the first line or one or more new lines with all but last ending with a hyphen (limit of four lines per spectrum).

The command is completed with the following data which must be started on a new line:

```
{ZIP f8| LAT f9 LONG f13| SS f14S1 f15} SITE CLASS (f16) (FA f17 FV f18) TL f19
```

Where:

Table 273: Parameters used for IBC 2006 response spectrum

Parameter	Default Value	Description
X *f1*, Y *f2*, Z *f3*	0.0	Factors for the input spectrum to be applied in X, Y, & Z directions. Any one or all directions can be input. Directions not provided will default to zero.
DAMP *f5*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If CDAMP is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If MDAMP is specified, then modal damping is calculated using the method defined in a DEFINE DAMPING INFORMATION command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)
MISSING *f6*		Optional parameter to use “Missing Mass” method. The static effect of the masses not represented in the modes is included. The spectral acceleration for this missing mass mode is the *f6*value entered in length/sec^2 (this value is not multiplied by SCALE). If *f6*is zero, then the spectral acceleration at the ZPA *f7*frequency is used. If *f7*is zero or not entered, the spectral acceleration at 33Hz (Zero Period Acceleration, ZPA) is used. The results of this calculation are SRSSed with the modal combination results. **Note:** If the MISSING parameter is entered on any spectrum case it will be used for all spectrum cases.
ZPA *f7*	33 [Hz]	The zero period acceleration value for use with MISSING option only. Defaults to 33 Hz if not entered. The value is printed but not used if MISSING *f6* is entered.

Parameter	Default Value	Description
DOMINANT *f10*	1 (1st Mode)	The dominant mode method. All results will have the same sign as mode number *f10* alone would have if it were excited then the scaled results were used as a static displacements result. Defaults to mode 1 if no value entered. If a 0 value entered, then the mode with the greatest % participation in the excitation direction will be used (only one direction factor may be nonzero). **Note:** Do not enter the `SIGN` parameter with this option. Ignored for the `ABS` method of combining spectral responses from each mode.
IMR *f11*	1	The number of individual modal responses (scaled modes) to be copied into load cases. Defaults to one. If greater than the actual number of modes extracted (`NM`), then it will be reset to NM. Modes one through f11 will be used. Missing Mass modes are not output.
STARTCASE *f12*	Highest Load Case No. + 1	The primary load case number of mode 1 in the `IMR` parameter. Defaults to the highest load case number used so far plus one. If *f12* is not higher than all prior load case numbers, then the default will be used. For modes 2 through `NM`, the load case number is the prior case number plus one.
ZIP *f8*		The zip code of the site location to determine the latitude and longitude and consequently the S_s and S_1 factors. (IBC 2006, ASCE 7-02 Chapter 22)
LAT *f9*		The latitude of the site used with the longitude to determine the S_s and S_1 factors. (IBC 2006, ASCE 7-02 Chapter 22)
LONG *f13*		The longitude of the site used with the latitude to determine the S_s and S_1 factors. (IBC 2006, ASCE 7-02 Chapter 22)
SS *f14*		Mapped MCE for 0.2s spectral response acceleration. (IBC 2006, ASCE 7-02 Chapter 22)
S1 *f15*		Mapped spectral acceleration for a 1-second period. (IBC 2000, equation 16-17. IBC 2003, ASCE 7-02 section 9.4.1.2.4-2. IBC 2006, ASCE 7-05 Section 11.4.1)
SITE CLASS *f16*		Enter A through F for the Site Class as defined in the IBC code. (IBC 2000, Section 1615.1.1 page 350. IBC 2003, Section 1615.1.1 page 322. IBC 2006 ASCE 7-05 Section 20.3)
FA *f17*		Optional Short-Period site coefficient at 0.2s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2006, ASCE 7-05 Section 11.4.3)
FV *f18*		Optional Long-Period site coefficient at 1.0s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2006, ASCE 7-05 Section 11.4.3)
TL *f19*		Long-Period transition period in seconds. (IBC 2006, ASCE 7-02 Chapter 22)

`IBC 2006` indicates that the spectrum should be calculated as defined in the IBC 2006 specification.

comb-method = { `SRSS | ABS | CQC | ASCE | TEN | CSM | GRP` } are methods of combining the responses from each mode into a total response.

The CQC and ASCE4-98 methods require damping. ABS, SRSS, CRM, GRP, and TEN methods do not use damping unless spectra-period curves are made a function of damping (see File option below). CQC, ASCE, CRM, GRP, and TEN include the effect of response magnification due to closely spaced modal frequencies. ASCE includes more algebraic summation of higher modes. ASCE and CQC are more sophisticated and realistic methods and are recommended.

SRSS Square Root of Summation of Squares method.

ABS Absolute sum. This method is very conservative and represents a worst case combination.

CQC Complete Quadratic Combination method (Default). This method is recommended for closely spaced modes instead of SRSS.

Resultants are calculated as:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

$$\rho_{nm} = \frac{8\zeta^2(1+r)r^{2/3}}{(1-r^2)^2 + 4\zeta^2 r(1+r)^2}$$

$$r = \omega_n/\omega_m \leq 1.0$$

Note: The cross-modal coefficient array is symmetric and all terms are positive.

ASCE NRC Regulatory Guide Rev. 2 (2006) Gupta method for modal combinations and Rigid/Periodic parts of modes are used. The ASCE4-98 definitions are used where there is no conflict. ASCE4-98 Eq. 3.2-21 (modified Rosenblueth) is used for close mode interaction of the damped periodic portion of the modes.

TEN Ten Percent Method of combining closely spaced modes. NRC Reg. Guide 1.92 (Rev. 1.2.2, 1976).

CSM Closely Spaced Method as per IS:1893 (Part 1)-2002 procedures.

GRP Closely Spaced Modes Grouping Method. NRC Reg. Guide 1.92 (Rev. 1.2.1, 1976).

Note: If SRSS is selected, the program will internally check whether there are any closely spaced modes or not. If it finds any such modes, it will switch over to the CSM method. In the CSM method, the program will check whether all modes are closely spaced or not. If all modes are closely spaced, it will switch over to the CQC method.

`ACCELERATOIN` indicates that the Acceleration spectra will be entered.

Note: IBC / ASCE 7 does not have provisions for displacement response spectra.

`DAMP`, `MDAMP`, and `CDAMP` select source of damping input:

- `DAMP` indicates to use the *f2* value for all modes
- `MDAMP` indicates to use the damping entered or computed with the `DEFINE DAMP` command if entered, otherwise default value of 0.05 will be used

- CDAMP indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the CONSTANT specification

LINEAR or LOGARITHMIC

Select **Linear** or **Logarithmic** interpolation of the input Spectra versus Period curves for determining the spectra value for a mode given its period. Linear is the default. Since Spectra versus Period curves are often linear only on Log-Log scales, the logarithmic interpolation is recommended in such cases; especially if only a few points are entered in the spectra curve.

When FILE *filename* is entered, the interpolation along the damping axis will be linear.

Note: The last interpolation parameter entered on the last of all of the spectrum cases will be used for all spectrum cases.

SIGN

This option results in the creation of signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign. This command is ignored for ABS option.

Caution: Do *not* enter DOMINANT parameter with this option.

SAVE

This option results in the creation of a acceleration data file (with the model file name and an .acc file extension) containing the joint accelerations in g's and radians/sec^2. These files are plain text and may be opened and viewed with any text editor (e.g., Notepad).

Methodology

The methodology for calculating the response spectra is defined in ASCE7-05, section 11.4. The following is a quick summary:

a. Input S_s and S_1 (this could have been searched from database or entered explicitly)

b. Calculate

$$S_{ms} = F_a \text{ x } S_s$$

and

$$S_{m1} = F_v \text{ x } S_1$$

Where:

F_a and F_v are determined from the specified site classes A – E and using tables 11.4-1 and 11.4-2. For site class F, the values must be supplied. These are required to be provided by the user. You may also specify values for F_a and F_v in lieu of table values.

c. Calculate

$$S_{ds} = (2/3)\ S_{ms}$$

and

$$S_{d1} = (2/3)\ S_{m1}$$

The spectrum is generated as per section 11.4.5.

Individual Modal Response Case Generation

Individual modal response (IMR) cases are simply the mode shape scaled to the magnitude that the mode has in this spectrum analysis case before it is combined with other modes. If the IMR parameter is entered, then STAAD.Pro will create load cases for the first specified number of modes for this response spectrum case (i.e., if five is specified then five load cases are generated, one for each of the first five modes). Each case will be created in a form like any other primary load case.

The results from an IMR case can be viewed graphically or through the print facilities. Each mode can therefore be assessed as to its significance to the results in various portions of the structure. Perhaps one or two modes could be used to design one area/floor and others elsewhere.

You can use subsequent load cases with TR.32.11 Repeat Load Specification (on page 2595) combinations of these scaled modes and the static live and dead loads to form results that are all with internally consistent signs (unlike the usual response spectrum solutions). The modal applied loads vector will be omega squared times mass times the scaled mode shape. Reactions will be applied loads minus stiffness matrix times the scaled mode shape.

With the Repeat Load capability, you can combine the modal applied loads vector with the static loadings and solve statically with P-Delta or tension only.

Note: When the IMR option is entered for a Spectrum case, then a TR.37 Analysis Specification (on page 2620) & TR.38 Change Specification (on page 2660) must be entered after each such Spectrum case.

See TR.32.10.1.1 Response Spectrum Specification - Custom (on page 2499) for additional details on IMR load case generation.

TR.32.10.1.11 Response Spectrum Specification per IBC 2012

This command may be used to specify and apply the `RESPONSE SPECTRUM` loading as per the 2012 edition of the ICC specification *International Building Code* (IBC) and ASCE 7-10, for dynamic analysis. The graph of frequency – acceleration pairs are calculated based on the input requirements of the command and as defined in the code.

General Format

```
SPECTRUM comb-method IBC 2012 ( TORSION (DECCENTRICITY f20) (ECCENTRICITY f21) ) *{ X
f1 | Y f2 | Z f3 } ACCELERATION
```

```
{DAMP f5 | CDAMP | MDAMP } ( {LIN | LOG} ) (MIS f6) (ZPA f7) ({ DOMINANT f10 | SIGN })
(SAVE) (IMR f11) (STARTCASE f12)
```

Note: The data from SPECTRUM through ACC must be on the first line of the command. The data shown on the second line above can be continued on the first line or one or more new lines with all but last ending with a hyphen (limit of four lines per spectrum).

The command is completed with the following data which must be started on a new line:

```
{ZIP f8 | LAT f9 LONG f13 | SS f14 S1 f15 } SITE CLASS (f16) (FA f17 FV f18) TL f19
```

Where:

Table 274: Parameters used for IBC 2012 response spectrum

Parameter	Default Value	Description
DECCENTRICITY *f20*	1.0	Factor to be multiplied with static eccentricity (i.e., eccentricity between center of mass and center of rigidity).
ECCENTRICITY *f21*	0.05	Factor for accidental eccentricity. Positive values indicate clockwise torsion and negative values indicate counterclockwise torsion.
X *f1*, Y *f2*, Z *f3*	0.0	Factors for the input spectrum to be applied in X, Y, & Z directions. Any one or all directions can be input. Directions not provided will default to zero.
DAMP *f5*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If CDAMP is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If MDAMP is specified, then modal damping is calculated using the method defined in a DEFINE DAMPING INFORMATION command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)

Parameter	Default Value	Description
MISSING *f6*		Optional parameter to use "Missing Mass" method. The static effect of the masses not represented in the modes is included. The spectral acceleration for this missing mass mode is the *f6*value entered in length/sec^2 (this value is not multiplied by SCALE). If *f6*is zero, then the spectral acceleration at the `ZPA` *f7*frequency is used. If *f7*is zero or not entered, the spectral acceleration at 33Hz (Zero Period Acceleration, ZPA) is used. The results of this calculation are SRSSed with the modal combination results. **Note:** If the `MISSING` parameter is entered on any spectrum case it will be used for all spectrum cases.
ZPA *f7*	33 [Hz]	The zero period acceleration value for use with `MISSING` option only. Defaults to 33 Hz if not entered. The value is printed but not used if `MISSING` *f6* is entered.
DOMINANT *f10*	1 (1st Mode)	The dominant mode method. All results will have the same sign as mode number *f10* alone would have if it were excited then the scaled results were used as a static displacements result. Defaults to mode 1 if no value entered. If a 0 value entered, then the mode with the greatest % participation in the excitation direction will be used (only one direction factor may be nonzero). **Note:** Do not enter the `SIGN` parameter with this option. Ignored for the `ABS` method of combining spectral responses from each mode.
IMR *f11*	1	The number of individual modal responses (scaled modes) to be copied into load cases. Defaults to one. If greater than the actual number of modes extracted (`NM`), then it will be reset to NM. Modes one through f11 will be used. Missing Mass modes are not output.
STARTCASE *f12*	Highest Load Case No. + 1	The primary load case number of mode 1 in the `IMR` parameter. Defaults to the highest load case number used so far plus one. If *f12* is not higher than all prior load case numbers, then the default will be used. For modes 2 through `NM`, the load case number is the prior case number plus one.
ZIP *f11*		The zip code of the site location to determine the latitude and longitude and consequently the S_s and S_1 factors. (IBC 2012, ASCE 7-10 Chapter 22)
LAT *f12*		The latitude of the site used with the longitude to determine the S_s and S_1 factors. (IBC 2012, ASCE 7-10 Chapter 22)
LONG *f13*		The longitude of the site used with the latitude to determine the S_s and S_1 factors. (IBC 2012, ASCE 7-10 Chapter 22)

Parameter	Default Value	Description
SS *f14*		Mapped MCE for 0.2s spectral response acceleration. (IBC 2012, ASCE 7-10 Chapter 22)
S1 *f15*		Mapped spectral acceleration for a 1-second period. (IBC 2000, equation 16-17. IBC 2003, ASCE 7-02 section 9.4.1.2.4-2. IBC 2006, ASCE 7-05 Section 11.4.1)
SITE CLASS *f16*		Enter A through F for the Site Class as defined in the IBC code. (IBC 2000, Section 1615.1.1 page 350. IBC 2003, Section 1615.1.1 page 322. IBC 2006 ASCE 7-05 Section 20.3)
FA *f17*		Optional Short-Period site coefficient at 0.2s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2006, ASCE 7-05 Section 11.4.3)
FV *f18*		Optional Long-Period site coefficient at 1.0s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2006, ASCE 7-05 Section 11.4.3)
TL *f19*		Long-Period transition period in seconds. (IBC 2012, ASCE 7-10 Chapter 22)

comb-method = { `SRSS` | `ABS` | `CQC` | `ASCE` | `TEN` | `CSM` | `GRP` } are methods of combining the responses from each mode into a total response.

The CQC and ASCE4-98 methods require damping. ABS, SRSS, CRM, GRP, and TEN methods do not use damping unless spectra-period curves are made a function of damping (see File option below). CQC, ASCE, CRM, GRP, and TEN include the effect of response magnification due to closely spaced modal frequencies. ASCE includes more algebraic summation of higher modes. ASCE and CQC are more sophisticated and realistic methods and are recommended.

SRSS Square Root of Summation of Squares method.

ABS Absolute sum. This method is very conservative and represents a worst case combination.

CQC Complete Quadratic Combination method (Default). This method is recommended for closely spaced modes instead of SRSS.

Resultants are calculated as:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

$$\rho_{nm} = \frac{8\zeta^2(1+r)r^{2/3}}{(1-r^2)^2 + 4\zeta^2 r(1+r)^2}$$

$$r = \omega_n / \omega_m \leq 1.0$$

Note: The cross-modal coefficient array is symmetric and all terms are positive.

ASCE NRC Regulatory Guide Rev. 2 (2006) Gupta method for modal combinations and Rigid/Periodic parts of modes are used. The ASCE4-98 definitions are used where there is no conflict. ASCE4-98 Eq. 3.2-21 (modified Rosenblueth) is used for close mode interaction of the damped periodic portion of the modes.

TEN Ten Percent Method of combining closely spaced modes. NRC Reg. Guide 1.92 (Rev. 1.2.2, 1976).

CSM Closely Spaced Method as per IS:1893 (Part 1)-2002 procedures.

GRP Closely Spaced Modes Grouping Method. NRC Reg. Guide 1.92 (Rev. 1.2.1, 1976).

Note: If SRSS is selected, the program will internally check whether there are any closely spaced modes or not. If it finds any such modes, it will switch over to the CSM method. In the CSM method, the program will check whether all modes are closely spaced or not. If all modes are closely spaced, it will switch over to the CQC method.

`IBC 2012` indicates that the spectrum should be calculated as defined in the IBC 2012 specification.

TORSION indicates that the torsional moment (in the horizontal plane) arising due to eccentricity between the center of mass and center of rigidity needs to be considered. See "Torsion" for additional information.

Note: If `TORSION` is entered on any one spectrum case it will be used for all spectrum cases.

Lateral shears at story levels are calculated in global X and Z directions. For global Y direction the effect of torsion will not be considered.

ACCELERATOIN indicates that the Acceleration spectra will be entered.

Note: IBC / ASCE 7 does not have provisions for displacement response spectra.

DAMP, MDAMP, and CDAMP select source of damping input:

- `DAMP` indicates to use the *f2* value for all modes
- `MDAMP` indicates to use the damping entered or computed with the `DEFINE DAMP` command if entered, otherwise default value of 0.05 will be used
- `CDAMP` indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the `CONSTANT` specification

LINEAR or LOGARITHMIC Select **Linear** or **Logarithmic** interpolation of the input Spectra versus Period curves for determining the spectra value for a mode given its period. Linear is the default. Since Spectra versus Period curves are often linear only on Log-Log scales, the logarithmic interpolation is recommended in such cases; especially if only a few points are entered in the spectra curve.

When `FILE` *filename* is entered, the interpolation along the damping axis will be linear.

Note: The last interpolation parameter entered on the last of all of the spectrum cases will be used for all spectrum cases.

SIGN This option results in the creation of signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign. This command is ignored for `ABS` option.

Caution: Do *not* enter `DOMINANT` parameter with this option.

SAVE	This option results in the creation of a acceleration data file (with the model file name and an `.acc` file extension) containing the joint accelerations in g's and radians/sec^2. These files are plain text and may be opened and viewed with any text editor (e.g., Notepad).

Methodology

The methodology for calculating the response spectra is defined in ASCE 7-2010, section 11.4. The following is a quick summary:

a. Input S_s and S_1 (this could have been searched from database or entered explicitly)

b. Calculate

$$S_{ms} = F_a \times S_s$$

and

$$S_{m1} = F_v \times S_1$$

Where:

F_a and F_v are determined from the specified site classes A – E and using tables 11.4-1 and 11.4-2. For site class F, the values must be supplied. These are required to be provided by the user. You may also specify values for F_a and F_v in lieu of table values.

c. Calculate

$$S_{ds} = (2/3)\ S_{ms}$$

and

$$S_{d1} = (2/3)\ S_{m1}$$

The spectrum is generated as per section 11.4.5.

See TR.32.10.1.1 Response Spectrum Specification - Custom (on page 2499) for additional details on IMR load case generation.

Torsion

In response spectrum analysis all the response quantities (i.e., joint displacements, member forces, support reactions, plate stresses, etc.) are calculated for each mode of vibration considered in the analysis. These response quantities from each mode are combined using a modal combination method (either by CQC, SRSS, ABS, TEN PERCENT, etc.) to produce a single positive result for the given direction of acceleration. This computed result represents a maximum magnitude of the response quantity that is likely to occur during seismic loading. The actual response is expected to vary from a range of negative to positive value of this maximum computed quantity.

No information is available from response spectrum analysis as to when this maximum value occurs during the seismic loading and what will be the value of other response quantities at that time. As for example, consider two joints J2 and J3 whose maximum joint displacement in global X direction come out to be X1 and X2 respectively. This implies that during seismic loading joint J1 will have X direction displacement that is expected to vary from -X1 to +X1 and that for joint J2 from -X2 to +X2. However, this does not necessarily mean that the point of time at which the X displacement of joint J1 is X1, the X displacement of joint J2 will also be X2.

For the reason stated above, torsional moment at each floor arising due to dynamic eccentricity along with accidental eccentricity (if any) is calculated for each mode. Lateral story shear from this torsion is calculated forming global load vectors for each mode. Static analysis is carried out with this global load vector to produce global joint displacement vectors for each mode due to torsion. These joint displacements from torsion for each mode are algebraically added to the global joint displacement vectors from response spectrum analysis for each mode. The final joint displacements from response spectrum along with torsion for all modes are combined using specified modal combination method to get final maximum possible joint displacements. Refer to the steps explained below.

Steps

For each mode following steps are performed to include Torsion provision.

1. Lateral story force at each floor is calculated.
2. At each floor design eccentricity is calculated.

   Thus, design eccentricity $e_{di} = f20 \times e_{si} + f12 \times b_i$ where f20 = 1.0 and f21 = (±) 0.05

   Where:

   e_{si} = static eccentricity between center of mass and center of rigidity at floor i.
   b_i = floor plan dimension orthogonal to the direction of earthquake loading.
3. Torsional moment is calculated at each floor.

   $M_{ik} = Q_{ik} \times e_{di}$ at floor i for mode k
4. The lateral nodal forces corresponding to torsional moment are calculated at each floor. These forces represent the additional story shear due to torsion.
5. Static analysis of the structure is performed with these nodal forces.
6. The analysis results (i.e., member force, joint displacement, support reaction, etc) from torsion are algebraically added to the corresponding modal response quantities from response spectrum analysis.
7. Steps 1 through 6 are performed for all modes considered and missing mass correction (if any). Finally, the peak response quantities from the different modal responses are combined as per the specified combination method (e.g., SRSS, CQC, TEN, etc.)

Example

Refer to V. IBC 2012 Response Spectrum (on page 3472) for a detailed explanation of this example.

```

Where:

Table 275: Parameters used for IBC 2015 response spectrum

Parameter	Default Value	Description
DECCENTRICITY *f20*	1.0	Factor to be multiplied with static eccentricity (i.e., eccentricity between center of mass and center of rigidity).
ECCENTRICITY *f21*	0.05	Factor for accidental eccentricity. Positive values indicate clockwise torsion and negative values indicate counterclockwise torsion.
X *f1*, Y *f2*, Z *f3*	0.0	Factors for the input spectrum to be applied in X, Y, & Z directions. Any one or all directions can be input. Directions not provided will default to zero.
DAMP *f5*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If `CDAMP` is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If `MDAMP` is specified, then modal damping is calculated using the method defined in a `DEFINE DAMPING INFORMATION` command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)

Parameter	Default Value	Description
MISSING *f6*		Optional parameter to use "Missing Mass" method. The static effect of the masses not represented in the modes is included. The spectral acceleration for this missing mass mode is the *f6*value entered in length/sec^2 (this value is not multiplied by SCALE). If *f6*is zero, then the spectral acceleration at the ZPA *f7*frequency is used. If *f7*is zero or not entered, the spectral acceleration at 33Hz (Zero Period Acceleration, ZPA) is used. The results of this calculation are SRSSed with the modal combination results. **Note:** If the MISSING parameter is entered on any spectrum case it will be used for all spectrum cases.
ZPA *f7*	33 [Hz]	The zero period acceleration value for use with MISSING option only. Defaults to 33 Hz if not entered. The value is printed but not used if MISSING *f6* is entered.
DOMINANT *f10*	1 (1st Mode)	The dominant mode method. All results will have the same sign as mode number *f10* alone would have if it were excited then the scaled results were used as a static displacements result. Defaults to mode 1 if no value entered. If a 0 value entered, then the mode with the greatest % participation in the excitation direction will be used (only one direction factor may be nonzero). **Note:** Do not enter the SIGN parameter with this option. Ignored for the ABS method of combining spectral responses from each mode.
IMR *f11*	1	The number of individual modal responses (scaled modes) to be copied into load cases. Defaults to one. If greater than the actual number of modes extracted (NM), then it will be reset to NM. Modes one through f11 will be used. Missing Mass modes are not output.
STARTCASE *f12*	Highest Load Case No. + 1	The primary load case number of mode 1 in the IMR parameter. Defaults to the highest load case number used so far plus one. If *f12* is not higher than all prior load case numbers, then the default will be used. For modes 2 through NM, the load case number is the prior case number plus one.
ZIP *f11*		The zip code of the site location to determine the latitude and longitude and consequently the S_s and S_1 factors. (IBC 2015, ASCE 7-10 Chapter 22)
LAT *f12*		The latitude of the site used with the longitude to determine the S_s and S_1 factors. (IBC 2015, ASCE 7-10 Chapter 22)
LONG *f13*		The longitude of the site used with the latitude to determine the S_s and S_1 factors. (IBC 2015, ASCE 7-10 Chapter 22)

Parameter	Default Value	Description
SS *f14*		Mapped MCE for 0.2s spectral response acceleration. (IBC 2015, ASCE 7-10 Chapter 22)
S1 *f15*		Mapped spectral acceleration for a 1-second period. (IBC 2000, equation 16-17. IBC 2003, ASCE 7-02 section 9.4.1.2.4-2. IBC 2006, ASCE 7-05 Section 11.4.1)
SITE CLASS *f16*		Enter A through F for the Site Class as defined in the IBC code. (IBC 2000, Section 1615.1.1 page 350. IBC 2003, Section 1615.1.1 page 322. IBC 2006 ASCE 7-05 Section 20.3)
FA *f17*		Optional Short-Period site coefficient at 0.2s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2006, ASCE 7-05 Section 11.4.3)
FV *f18*		Optional Long-Period site coefficient at 1.0s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2006, ASCE 7-05 Section 11.4.3)
TL *f19*		Long-Period transition period in seconds. (IBC 2015, ASCE 7-10 Chapter 22)

comb-method = { `SRSS` | `ABS` | `CQC` | `ASCE` | `TEN` | `CSM` | `GRP` } are methods of combining the responses from each mode into a total response.

The CQC and ASCE4-98 methods require damping. ABS, SRSS, CRM, GRP, and TEN methods do not use damping unless spectra-period curves are made a function of damping (see File option below). CQC, ASCE, CRM, GRP, and TEN include the effect of response magnification due to closely spaced modal frequencies. ASCE includes more algebraic summation of higher modes. ASCE and CQC are more sophisticated and realistic methods and are recommended.

SRSS Square Root of Summation of Squares method.

ABS Absolute sum. This method is very conservative and represents a worst case combination.

CQC Complete Quadratic Combination method (Default). This method is recommended for closely spaced modes instead of SRSS.

Resultants are calculated as:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

$$\rho_{nm} = \frac{8\zeta^2(1 + r) r^{2/3}}{(1 - r^2)^2 + 4\zeta^2 r(1 + r)^2}$$

$$r = \omega_n / \omega_m \leq 1.0$$

Note: The cross-modal coefficient array is symmetric and all terms are positive.

ASCE NRC Regulatory Guide Rev. 2 (2006) Gupta method for modal combinations and Rigid/Periodic parts of modes are used. The ASCE4-98 definitions are used where there is no conflict. ASCE4-98 Eq. 3.2-21 (modified Rosenblueth) is used for close mode interaction of the damped periodic portion of the modes.

TEN Ten Percent Method of combining closely spaced modes. NRC Reg. Guide 1.92 (Rev. 1.2.2, 1976).

CSM Closely Spaced Method as per IS:1893 (Part 1)-2002 procedures.

GRP Closely Spaced Modes Grouping Method. NRC Reg. Guide 1.92 (Rev. 1.2.1, 1976).

Note: If SRSS is selected, the program will internally check whether there are any closely spaced modes or not. If it finds any such modes, it will switch over to the CSM method. In the CSM method, the program will check whether all modes are closely spaced or not. If all modes are closely spaced, it will switch over to the CQC method.

`IBC 2015` indicates that the spectrum should be calculated as defined in the IBC 2015 specification.

TORSION	indicates that the torsional moment (in the horizontal plane) arising due to eccentricity between the center of mass and center of rigidity needs to be considered. See "Torsion" for additional information. **Note:** If `TORSION` is entered on any one spectrum case it will be used for all spectrum cases. Lateral shears at story levels are calculated in global X and Z directions. For global Y direction the effect of torsion will not be considered.
ACCELERATOIN	indicates that the Acceleration spectra will be entered. **Note:** IBC / ASCE 7 does not have provisions for displacement response spectra.
DAMP, MDAMP, and CDAMP	select source of damping input: • `DAMP` indicates to use the *`f2`* value for all modes • `MDAMP` indicates to use the damping entered or computed with the `DEFINE DAMP` command if entered, otherwise default value of 0.05 will be used • `CDAMP` indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the `CONSTANT` specification
LINEAR or LOGARITHMIC	Select **Linear** or **Logarithmic** interpolation of the input Spectra versus Period curves for determining the spectra value for a mode given its period. Linear is the default. Since Spectra versus Period curves are often linear only on Log-Log scales, the logarithmic interpolation is recommended in such cases; especially if only a few points are entered in the spectra curve. When `FILE` *`filename`* is entered, the interpolation along the damping axis will be linear. **Note:** The last interpolation parameter entered on the last of all of the spectrum cases will be used for all spectrum cases.
SIGN	This option results in the creation of signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign. This command is ignored for `ABS` option. **Caution:** Do *not* enter `DOMINANT` parameter with this option.

SAVE	This option results in the creation of a acceleration data file (with the model file name and an `.acc` file extension) containing the joint accelerations in g's and radians/sec^2. These files are plain text and may be opened and viewed with any text editor (e.g., Notepad).

Methodology

The methodology for calculating the response spectra is defined in ASCE 7-2010, section 11.4. The following is a quick summary:

a. Input S_s and S_1 (this could have been searched from database or entered explicitly)

b. Calculate

$$S_{ms} = F_a \times S_s$$

and

$$S_{m1} = F_v \times S_1$$

Where:

F_a and F_v are determined from the specified site classes A – E and using tables 11.4-1 and 11.4-2. For site class F, the values must be supplied. These are required to be provided by the user. You may also specify values for F_a and F_v in lieu of table values.

c. Calculate

$$S_{ds} = (2/3)\ S_{ms}$$

and

$$S_{d1} = (2/3)\ S_{m1}$$

The spectrum is generated as per section 11.4.5.

See TR.32.10.1.1 Response Spectrum Specification - Custom (on page 2499) for additional details on IMR load case generation.

Steps

For each mode following steps are performed to include Torsion provision.

1. Lateral story force at each floor is calculated.
2. At each floor design eccentricity is calculated.

   Thus, design eccentricity $e_{di} = f20 \times e_{si} + f12 \times b_i$ where f20 = 1.0 and f21 = (±) 0.05

   Where:

   e_{si} = static eccentricity between center of mass and center of rigidity at floor i.
   b_i = floor plan dimension orthogonal to the direction of earthquake loading.
3. Torsional moment is calculated at each floor.

   $M_{ik} = Q_{ik} \times e_{di}$ at floor i for mode k
4. The lateral nodal forces corresponding to torsional moment are calculated at each floor. These forces represent the additional story shear due to torsion.
5. Static analysis of the structure is performed with these nodal forces.
6. The analysis results (i.e., member force, joint displacement, support reaction, etc) from torsion are algebraically added to the corresponding modal response quantities from response spectrum analysis.

7. Steps 1 through 6 are performed for all modes considered and missing mass correction (if any). Finally, the peak response quantities from the different modal responses are combined as per the specified combination method (e.g., SRSS, CQC, TEN, etc.)

Example

Refer to V. IBC 2015 Response Spectrum (on page 3462) for a detailed explanation of this example.

(SAVE) (IMR f11) (STARTCASE f12)
```

Note: The data from SPECTRUM through ACC must be on the first line of the command. The data shown on the second line above can be continued on the first line or one or more new lines with all but last ending with a hyphen (limit of four lines per spectrum).

The command is completed with the following data which must be started on a new line:

```
{ZIP f8 | LAT f9 LONG f13 | SS f14 S1 f15 } SITE CLASS (f16) (FA f17 FV f18) TL f19
```

Where:

Table 276: Parameters used for IBC 2015 response spectrum

Parameter	Default Value	Description
DECCENTRICITY *f20*	1.0	Factor to be multiplied with static eccentricity (i.e., eccentricity between center of mass and center of rigidity).
ECCENTRICITY *f21*	0.05	Factor for accidental eccentricity. Positive values indicate clockwise torsion and negative values indicate counterclockwise torsion.

Parameter	Default Value	Description
X *f1*, Y *f2*, Z *f3*	0.0	Factors for the input spectrum to be applied in X, Y, & Z directions. Any one or all directions can be input. Directions not provided will default to zero.
DAMP *f5*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If `CDAMP` is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If `MDAMP` is specified, then modal damping is calculated using the method defined in a `DEFINE DAMPING INFORMATION` command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)
MISSING *f6*		Optional parameter to use "Missing Mass" method. The static effect of the masses not represented in the modes is included. The spectral acceleration for this missing mass mode is the *f6*value entered in length/sec^2 (this value is not multiplied by SCALE). If *f6*is zero, then the spectral acceleration at the `ZPA` *f7*frequency is used. If *f7*is zero or not entered, the spectral acceleration at 33Hz (Zero Period Acceleration, ZPA) is used. The results of this calculation are SRSSed with the modal combination results. **Note:** If the `MISSING` parameter is entered on any spectrum case it will be used for all spectrum cases.
ZPA *f7*	33 [Hz]	The zero period acceleration value for use with `MISSING` option only. Defaults to 33 Hz if not entered. The value is printed but not used if `MISSING f6` is entered.
DOMINANT *f10*	1 (1st Mode)	The dominant mode method. All results will have the same sign as mode number *f10* alone would have if it were excited then the scaled results were used as a static displacements result. Defaults to mode 1 if no value entered. If a 0 value entered, then the mode with the greatest % participation in the excitation direction will be used (only one direction factor may be nonzero). **Note:** Do not enter the `SIGN` parameter with this option. Ignored for the `ABS` method of combining spectral responses from each mode.
IMR *f11*	1	The number of individual modal responses (scaled modes) to be copied into load cases. Defaults to one. If greater than the actual number of modes extracted (`NM`), then it will be reset to NM. Modes one through f11 will be used. Missing Mass modes are not output.

Parameter	Default Value	Description
STARTCASE *f12*	Highest Load Case No. + 1	The primary load case number of mode 1 in the `IMR` parameter. Defaults to the highest load case number used so far plus one. If *f12* is not higher than all prior load case numbers, then the default will be used. For modes 2 through `NM`, the load case number is the prior case number plus one.
ZIP *f11*		The zip code of the site location to determine the latitude and longitude and consequently the S_s and S_1 factors. (IBC 2018, ASCE 7-16 Chapter 22)
LAT *f12*		The latitude of the site used with the longitude to determine the S_s and S_1 factors. (IBC 2018, ASCE 7-16 Chapter 22)
LONG *f13*		The longitude of the site used with the latitude to determine the S_s and S_1 factors. (IBC 2018, ASCE 7-16 Chapter 22)
SS *f14*		Mapped MCE for 0.2s spectral response acceleration. (IBC 2018, ASCE 7-16 Section 11.4.1) This is obtained using the USGS web service.
S1 *f15*		Mapped spectral acceleration for a 1-second period. (IBC 2018, ASCE 7-2016 Section 11.4.1) This is obtained using the USGS web service.
CLASS *f16*		Enter A through F for the Site Class as defined in the IBC code. (IBC 2018 ASCE 7-2016 Section 20.3)
FA *f17*		Optional Short-Period site coefficient at 0.2s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2018, ASCE 7-2016 Section 11.4.3)
FV *f18*		Optional Long-Period site coefficient at 1.0s. Value must be provided if SCLASS set to F (i.e., 6). (IBC 2018, ASCE 7-2016 Section 11.4.3)
TL *f19*		Long-Period transition period in seconds. (IBC 2018, ASCE 7-16 Chapter 22)

comb-method = { `SRSS` \| `ABS` \| `CQC` \| `ASCE` \| `TEN` \| `CSM` \| `GRP` } are methods of combining the responses from each mode into a total response.

The CQC and ASCE4-98 methods require damping. ABS, SRSS, CRM, GRP, and TEN methods do not use damping unless spectra-period curves are made a function of damping (see File option below). CQC, ASCE, CRM, GRP, and TEN include the effect of response magnification due to closely spaced modal frequencies. ASCE includes more algebraic summation of higher modes. ASCE and CQC are more sophisticated and realistic methods and are recommended.

SRSS Square Root of Summation of Squares method.

ABS Absolute sum. This method is very conservative and represents a worst case combination.

CQC Complete Quadratic Combination method (Default). This method is recommended for closely spaced modes instead of SRSS.

Resultants are calculated as:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

$$\rho_{nm} = \frac{8\zeta^2 (1 + r) r^{2/3}}{(1 - r^2)^2 + 4\zeta^2 r (1 + r)^2}$$

$$r = \omega_n / \omega_m \le 1.0$$

Note: The cross-modal coefficient array is symmetric and all terms are positive.

ASCE NRC Regulatory Guide Rev. 2 (2006) Gupta method for modal combinations and Rigid/Periodic parts of modes are used. The ASCE4-98 definitions are used where there is no conflict. ASCE4-98 Eq. 3.2-21 (modified Rosenblueth) is used for close mode interaction of the damped periodic portion of the modes.

TEN Ten Percent Method of combining closely spaced modes. NRC Reg. Guide 1.92 (Rev. 1.2.2, 1976).

CSM Closely Spaced Method as per IS:1893 (Part 1)-2002 procedures.

GRP Closely Spaced Modes Grouping Method. NRC Reg. Guide 1.92 (Rev. 1.2.1, 1976).

Note: If SRSS is selected, the program will internally check whether there are any closely spaced modes or not. If it finds any such modes, it will switch over to the CSM method. In the CSM method, the program will check whether all modes are closely spaced or not. If all modes are closely spaced, it will switch over to the CQC method.

`IBC 2018` indicates that the spectrum should be calculated as defined in the IBC 2018 specification.

`TORSION` indicates that the torsional moment (in the horizontal plane) arising due to eccentricity between the center of mass and center of rigidity needs to be considered. See "Torsion" for additional information.

Note: If `TORSION` is entered on any one spectrum case it will be used for all spectrum cases.

Lateral shears at story levels are calculated in global X and Z directions. For global Y direction the effect of torsion will not be considered.

`ACCELERATOIN` indicates that the Acceleration spectra will be entered.

Note: IBC / ASCE 7 does not have provisions for displacement response spectra.

`DAMP`, `MDAMP`, and `CDAMP` select source of damping input:

- `DAMP` indicates to use the *f2* value for all modes
- `MDAMP` indicates to use the damping entered or computed with the `DEFINE DAMP` command if entered, otherwise default value of 0.05 will be used
- `CDAMP` indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the `CONSTANT` specification

`LINEAR` or `LOGARITHMIC`	Select **Linear** or **Logarithmic** interpolation of the input Spectra versus Period curves for determining the spectra value for a mode given its period. Linear is the default. Since Spectra versus Period curves are often linear only on Log-Log scales, the logarithmic interpolation is recommended in such cases; especially if only a few points are entered in the spectra curve. When `FILE` *`filename`* is entered, the interpolation along the damping axis will be linear. **Note:** The last interpolation parameter entered on the last of all of the spectrum cases will be used for all spectrum cases.
`SIGN`	This option results in the creation of signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign. This command is ignored for `ABS` option. **Caution:** Do *not* enter `DOMINANT` parameter with this option.
`SAVE`	This option results in the creation of a acceleration data file (with the model file name and an `.acc` file extension) containing the joint accelerations in g's and radians/sec^2. These files are plain text and may be opened and viewed with any text editor (e.g., Notepad).

Methodology

The methodology for calculating the response spectra is defined in ASCE 7-2016, section 11.4. The following is a quick summary:

a. Input S_s and S_1 (this could have been searched from database or entered explicitly)

b. Calculate

$$S_{ms} = F_a \times S_s$$

and

$$S_{m1} = F_v \times S_1$$

Where:

F_a and F_v are determined from the specified site classes A – E and using tables 11.4-1 and 11.4-2. For site class F, the values must be supplied. These are required to be provided by the user. You may also specify values for F_a and F_v in lieu of table values.

c. Calculate

$$S_{ds} = (2/3)\ S_{ms}$$

and

$$S_{d1} = (2/3)\ S_{m1}$$

The spectrum is generated as per section 11.4.5.

Notes:

- Exceptions 1 in Clause 11.4.8 of ASCE 7-16 is implemented. In exception 1, for Site class E and S_s > 1.0, Fa value is taking the same for site class C. In this case, there is slight reduction in the seismic force generated.
- The exception of Clause 2 in 11.4.8 of ASCE 7-16 is *not* implemented in STAAD.Pro for response spectra.

- The vertical ground motion for seismic design as described in clause 11.9 is *not* implemented as the program cannot determine the vertical time period, T_v.
- ASCE 7-2016 Clause 12.9.1.4 stipulates that if the combined response for modal base shear, V, is less than that of the calculated base shear from the equivalent lateral force procedure, V_t, then the response spectra values should be scaled up by V/V_t. STAAD.Pro does not automatically check this nor increase the response quantities in this situation. You can check this by simply analyzing TR.31.2.17 IBC 2018 Seismic Load Definition (on page 2416) and comparing the base shear values. The X, Y, or Z factors for the response spectrum can be then increased accordingly if required.

Inherent and Accidental Torsion

In response spectrum analysis all the response quantities (i.e., joint displacements, member forces, support reactions, plate stresses, etc.) are calculated for each mode of vibration considered in the analysis. These response quantities from each mode are combined using a modal combination method (either by CQC, SRSS, ABS, TEN PERCENT, etc.) to produce a single positive result for the given direction of acceleration. This computed result represents a maximum magnitude of the response quantity that is likely to occur during seismic loading. The actual response is expected to vary from a range of negative to positive value of this maximum computed quantity.

No information is available from response spectrum analysis as to when this maximum value occurs during the seismic loading and what will be the value of other response quantities at that time. As for example, consider two joints J2 and J3 whose maximum joint displacement in global X direction come out to be X1 and X2 respectively. This implies that during seismic loading joint J1 will have X direction displacement that is expected to vary from -X1 to +X1 and that for joint J2 from -X2 to +X2. However, this does not necessarily mean that the point of time at which the X displacement of joint J1 is X1, the X displacement of joint J2 will also be X2.

For the reason stated above, torsional moment at each floor arising due to dynamic eccentricity along with accidental eccentricity (if any) is calculated for each mode. Lateral story shear from this torsion is calculated forming global load vectors for each mode. Static analysis is carried out with this global load vector to produce global joint displacement vectors for each mode due to torsion. These joint displacements from torsion for each mode are algebraically added to the global joint displacement vectors from response spectrum analysis for each mode. The final joint displacements from response spectrum along with torsion for all modes are combined using specified modal combination method to get final maximum possible joint displacements. Refer to the steps explained below.

See TR.32.10.1.1 Response Spectrum Specification - Custom (on page 2499) for additional details on IMR load case generation.

Steps

For each mode following steps are performed to include Torsion provision.

1. Lateral story force at each floor is calculated.
2. At each floor design eccentricity is calculated.

   Thus, design eccentricity $e_{di} = f20 \times e_{si} + f12 \times b_i$ where f20 = 1.0 and f21 = (±) 0.05

   Where:

   e_{si} = static eccentricity between center of mass and center of rigidity at floor i.
   b_i = floor plan dimension orthogonal to the direction of earthquake loading.
3. Torsional moment is calculated at each floor.

   $M_{ik} = Q_{ik} \times e_{di}$ at floor i for mode k

4. The lateral nodal forces corresponding to torsional moment are calculated at each floor. These forces represent the additional story shear due to torsion.
5. Static analysis of the structure is performed with these nodal forces.
6. The analysis results (i.e., member force, joint displacement, support reaction, etc) from torsion are algebraically added to the corresponding modal response quantities from response spectrum analysis.
7. Steps 1 through 6 are performed for all modes considered and missing mass correction (if any). Finally, the peak response quantities from the different modal responses are combined as per the specified combination method (e.g., SRSS, CQC, TEN, etc.)

Dynamic Eccentricity

The static eccentricity is generally defined as the distance between the center of mass (CM) and the center of rigidity (CR) at respective floors levels. Accidental eccentricity generally accounts for factors such as:

- the rotational component of ground motion about the vertical axis,
- the difference between computed and actual values of the mass, stiffness, or strength, and
- uneven live mass distribution.

The provision for design eccentricity e_{di} at ith floor of a building is given by the following equation:

$$e_{di} = DEC \times e_{si} + ECC \times b_i$$

where

e_{si}	=	static eccentricity at ith floor
b_i	=	plan dimension of the ith floor normal to the direction of ground motion
ECC and DEC	=	Factors to determine the design eccentricity. These are input parameters.

Refer to Cl. 12.9.2.2.2 for the requirements of accidental torsion per the ASCE 7-16 code.

TR.32.10.1.14 Response Spectrum Specification per SNiP II-7-81

This command may be used to specify and apply the `RESPONSE SPECTRUM` loading as per SNiP II-7-81 for dynamic analysis.

General Format

```
SPECTRUM comb-method SNIP A f1 *{ {X f2 | KWX f3 KX1 f4} | { Y f5 | KWY f6 KY1 f7 } |
{ Z f8 | KWZ f9 KZ1 f10 } ACCELERATION (SCALE f11)
```

```
{DAMP f12 | CDAMP | MDAMP } ( { LINEAR | LOGARITHMIC } ) (MISSING f13) (ZPA f14)
({ DOMINANT f15 | SIGN }) SOIL { 1 | 2 | 3} (SAVE)
```

The data from `SPECTRUM` through `SCALE` above must be on the first line of the command, the remaining data can be on the first or subsequent lines with all but last ending with a hyphen (limit of four lines per spectrum).

Where:

Table 277: Parameters for SNiP II-7-81 response spectrum

Parameter	Default Value	Description
A *f1*		Zoning factor, A, which is based on maximum acceleration factor for the seismic zone. This factor must be modified for `SOIL` types other than 2. The exact zone factor value used for a specific location requires engineering judgment. The following table serves as a guide for accelerations and corresponding zone factors which would be used.
X *f2* Y *f5* Z *f8*	0.0	Factors for the input spectrum to be applied in X, Y, & Z directions. Any one or all directions can be input. Directions not provided will default to zero. Alternatively, you may input individual parameters such as `KWX`, `KX1` the product of which would be used as the factor along that direction.
SCALE *f11*		Linear scale factor by which the spectra data will be multiplied. Usually used to factor g's to length/sec^2 units. This input is the appropriate value of acceleration due to gravity in the current unit system (thus, 9.81 m/s^2 or 32.2 ft/s^2).
DAMP *f12*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If `CDAMP` is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If `MDAMP` is specified, then modal damping is calculated using the method defined in a `DEFINE DAMPING INFORMATION` command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)

Parameter	Default Value	Description
MISSING *f13*		Optional parameter to use the "Missing Mass" method to include the static effect of the masses not represented in the modes. The spectral acceleration length/sec^2 for this missing mass mode is the *f13* value entered in length per second squared units (this value is not multiplied by SCALE). If *f13* is zero, then the spectral acceleration at the `ZPA` *f14* frequency is used. If *f14* is zero or not entered, then the spectral acceleration at 33Hz is used. The results of this calculation are SRSSed with the modal combination results. For SRSS and CQC, the results of this calculation are SRSSed with the modal combination results. If either *f13* or *f14* are not entered, the defaults will be used. Missing mass does not include the effect of masses lumped at the supports unless the support is a stiff spring or an Enforced support. **Note:** If the `MISSING` parameter is entered on any spectrum case it will be used for all spectrum cases.
ZPA *f14*		The zero period acceleration value for use with `MISSING` option only. Defaults to 33 Hz if not entered. The value is printed but not used if `MISSING` *f13* is entered.
DOMINANT *f15*		The dominant mode method. All results will have the same sign as mode number *f15* alone would have if it were excited then the scaled results were used as a static displacements result. Defaults to mode 1 if no value entered. If a 0 value entered, then the mode with the greatest % participation in the excitation direction will be used (only one direction factor may be nonzero). **Note:** Do not enter the `SIGN` parameter with this option.

comb-method = `{ SRSS | CQC }` are methods of combining the responses from each mode into a total response.

The CQC method requires damping. The SRSS method does not use damping unless spectra-period curves are made a function of damping (see File option below). CQC includes the effect of response magnification due to closely spaced modal frequencies. CQC is a more sophisticated and realistic methods and is recommended.

SRSS Square root of summation of squares method as prescribed by the SNiP II-7-81 code.

CQC Complete Quadratic Combination method (Default). This method is recommended for closely spaced modes instead of SRSS.

Resultants are calculated as:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

$$\rho_{nm} = \frac{8\zeta^2 (1+r) r^{2/3}}{(1-r^2)^2 + 4\zeta^2 r (1+r)^2}$$

$$r = \omega_n / \omega_m \leq 1.0$$

Note: The cross-modal coefficient array is symmetric and all terms are positive.

The specifier `SNIP` is mandatory to denote that the applied loading is as per the guidelines of SNiP II-7-81.

ACCELERATOIN
indicates that the Acceleration spectra will be entered.

Note: SNiP II-7-81 / SP 14.13330.2011 do not have provisions for displacement response spectra.

DAMP, MDAMP, and CDAMP
select source of damping input:

- `DAMP` indicates to use the *f2* value for all modes
- `MDAMP` indicates to use the damping entered or computed with the `DEFINE DAMP` command if entered, otherwise default value of 0.05 will be used
- `CDAMP` indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the `CONSTANT` specification

LINEAR or LOGARITHMIC
Select **Linear** or **Logarithmic** interpolation of the input Spectra versus Period curves for determining the spectra value for a mode given its period. Linear is the default. Since Spectra versus Period curves are often linear only on Log-Log scales, the logarithmic interpolation is recommended in such cases; especially if only a few points are entered in the spectra curve.

When `FILE` *filename* is entered, the interpolation along the damping axis will be linear.

Note: The last interpolation parameter entered on the last of all of the spectrum cases will be used for all spectrum cases.

SIGN
This option results in the creation of signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign. This command is ignored for `ABS` option.

Caution: Do *not* enter `DOMINANT` parameter with this option.

SOIL
Defines the subsoil conditions on which the response spectrum will be generated.

Note: The Zoning Factor, `A (f1)`, must be adjusted for soil types other than type 2.

1. Non-weathered rock and rocklike geological formation or permafrost subsoil.
2. Weathered rock or deep deposits of medium dense sand, gravel or medium stiff clays.
3. Loose cohesion less soil deposits or deposits with soft to medium stiff cohesive soil.

SAVE
This option results in the creation of a acceleration data file (with the model file name and an `.acc` file extension) containing the joint accelerations in g's and radians/sec^2. These files are plain text and may be opened and viewed with any text editor (e.g., Notepad).

Description

Results of frequency and mode shape calculations may vary significantly depending upon the mass modeling. All masses that are capable of moving should be modeled as loads, applied in all possible directions of movement. For dynamic mass modeling, see sections TR.32 Loading Specifications (on page 2461) and G.17.3 Dynamic Analysis (on page 2154). An illustration of mass modeling is available, with explanatory comments, in the sample file
C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Rus\Seismic_Russ.STD.

Example 1

The definition of a SNiP response spectrum in the X direction on a structure built on weather rock and where the Zoning Factor is 0.7071. As this is the first load case with a response spectrum, then the masses are modeled as loads.

```

TR.32.10.1.15 Response Spectrum Specification per SP 14.13330.2011

This command may be used to specify and apply the `RESPONSE SPECTRUM` loading as per SP 14.13330.2011 for dynamic analysis.

General Format

```
SPECTRUM { SRSS | CQC } SP11 (ECCENTRICITY) A f1 *{ {X f2 | Y f3 | Z f4} ACCELERATION
(SCALE f5)
(DAMP f6 ) (LOG) (MIS f7) (ZPA f8) ({ DOMINANT f9 | SIGN }) SOIL { 1 | 2 | 3}
```

The data from `SPECTRUM` through `SCALE` above must be on the first line of the command, the remaining data can be on the first or subsequent lines with all but last ending with a hyphen (limit of four lines per spectrum).

Where:

Table 278: Parameters for SP 14.13330.2011 response spectrum

Parameter	Default Value	Description
A *f1*		Zoning factor, A, which is based on maximum acceleration factor for the seismic zone. This factor must be modified for SOIL types other than 2.
X *f2* Y *f3* Z *f5*	0.0	Factors for the input spectrum to be applied in X, Y, & Z directions. Any one or all directions can be input. Directions not provided will default to zero.

Parameter	Default Value	Description
SCALE *f5*		A linear scaling factor by which the spectrum data will be multiplied according to the provisions of SP 14.13330.2011.
DAMP *f6*	0.05	The damping ratio. Specify a value of exactly 0.0000011 to ignore damping. If `CDAMP` is specified, then composite damping is used as determined by the values for material damping (and spring damping, if specified). Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) If `MDAMP` is specified, then modal damping is calculated using the method defined in a `DEFINE DAMPING INFORMATION` command, which must be included in the input file. Refer to TR.26.4 Modal Damping Information (on page 2312)
MISSING *f7*		Optional parameter to use the "Missing Mass" method to include the static effect of the masses not represented in the modes. The spectral acceleration length/sec^2 for this missing mass mode is the *f7* value entered in length per second squared units (this value is not multiplied by `SCALE`). If *f7* is zero, then the spectral acceleration at the `ZPA` *f8* frequency is used. If *f8* is zero or not entered, then the spectral acceleration at 33Hz is used. The results of this calculation are SRSSed with the modal combination results. For SRSS and CQC, the results of this calculation are SRSSed with the modal combination results. If either of *f7* or *f8* are not entered, the defaults will be used. Missing mass does not include the effect of masses lumped at the supports unless the support is a stiff spring or an Enforced support. **Note:** If the `MISSING` parameter is entered on any spectrum case it will be used for all spectrum cases.
ZPA *f8*	33.0 Hz	The zero period acceleration value for use with `MISSING` option only. Defaults to 33 Hz if not entered. The value is printed but not used if `MISSING` *f7* is entered.
DOMINANT *f9*	1	The dominant mode method. All results will have the same sign as mode number *f9* alone would have if it were excited then the scaled results were used as a static displacements result. Defaults to mode 1 if no value entered. If a 0 value entered, then the mode with the greatest % participation in the excitation direction will be used (only one direction factor may be nonzero). **Note:** Do not enter the `SIGN` parameter with this option.

comb-method = `{ SRSS | CQC }` are methods of combining the responses from each mode into a total response.

The CQC method requires damping. The SRSS method does not use damping unless spectra-period curves are made a function of damping (see File option below). CQC includes the effect of response magnification due to closely spaced modal frequencies. CQC is a more sophisticated and realistic methods and is recommended.

SRSS Square root of summation of squares method as prescribed by the SNiP II-7-81 code.

CQC Complete Quadratic Combination method (Default). This method is recommended for closely spaced modes instead of SRSS.

Resultants are calculated as:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

$$\rho_{nm} = \frac{8\zeta^2(1+r)r^{2/3}}{(1-r^2)^2 + 4\zeta^2 r(1+r)^2}$$

$$r = \omega_n / \omega_m \le 1.0$$

Note: The cross-modal coefficient array is symmetric and all terms are positive.

The specifier `SP11` is mandatory to denote that the applied loading is as per the guidelines of SP 14.13330.2011.

`ECCENTRICITY` automatic introduction of artificial mass eccentricity according to SP 14.13330.2011.

`ACCELERATOIN` indicates that the Acceleration spectra will be entered.

Note: SNiP II-7-81 / SP 14.13330.2011 do not have provisions for displacement response spectra.

`DAMP`, `MDAMP`, and `CDAMP` select source of damping input:

- `DAMP` indicates to use the *`f2`* value for all modes
- `MDAMP` indicates to use the damping entered or computed with the `DEFINE DAMP` command if entered, otherwise default value of 0.05 will be used
- `CDAMP` indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the `CONSTANT` specification

`LINEAR` or `LOGARITHMIC` Select **Linear** or **Logarithmic** interpolation of the input Spectra versus Period curves for determining the spectra value for a mode given its period. Linear is the default. Since Spectra versus Period curves are often linear only on Log-Log scales, the logarithmic interpolation is recommended in such cases; especially if only a few points are entered in the spectra curve.

When `FILE` *`filename`* is entered, the interpolation along the damping axis will be linear.

Note: The last interpolation parameter entered on the last of all of the spectrum cases will be used for all spectrum cases.

`SIGN` This option results in the creation of signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign. This command is ignored for `ABS` option.

> **Caution:** Do *not* enter `DOMINANT` parameter with this option.

SOIL Defines the subsoil conditions on which the response spectrum will be generated.

> **Note:** The Zoning Factor, `A (f1)`, must be adjusted for soil types other than type 2.

1. Non-weathered rock and rocklike geological formation or permafrost subsoil.
2. Weathered rock or deep deposits of medium dense sand, gravel or medium stiff clays.
3. Loose cohesion less soil deposits or deposits with soft to medium stiff cohesive soil.

Description

Results of frequency and mode shape calculations may vary significantly depending upon the mass modeling. All masses that are capable of moving should be modeled as loads, applied in all possible directions of movement. For more information on dynamic mass modeling, refer to sections TR.32 Loading Specifications (on page 2461) and G.17.3 Dynamic Analysis (on page 2154)

TR.32.10.2 Time Varying Load for Response History Analysis

Used to apply loads which are defined with a changing magnitude of acceleration, force, or moment (refer to TR. 31.4 Definition of Time History Load (on page 2441)). These can either be assigned to specific nodes (as a FORCE or MOMENT type) and/or globally to the all the supports on the model as a ground motion (as an ACCELERATION type). In addition to the data produced from a general modal analysis, a load case which includes time history loading will produce a set of graphs in the post processing mode to indicate how the displacement, velocity or acceleration of a selected node changes in each of the three global directions over the time period of the applied dynamic loading.

General Format

The following set of commands may be used to model time history loading on the structure for response time history analysis. Nodal time histories and ground motion time histories may both be provided within one load case.

```
TIME LOAD
```

```
joint-list *{ FX | FY  | FZ | MX | MY | MZ } It Ia f2
```

```
GROUND MOTION { ABSOLUTE | (RELATIVE ) } { X | Y | Z } It Ia f2
```

Where:

Parameter	Description
ABSOLUTE	nodal results are absolute (elastic response + motion of ground). If entered on any ground command, all results will be absolute.
RELATIVE	nodal results are relative (elastic response). (Default if neither ABS or REL are specified)
It	sequential position in the input data of type number of time varying load. To refer to first type number entered, use a 1 here regardless of actual type number entered. Ground Motion must have an Acceleration Type; Time Load forces must have a Force type; and Time Load moments must have a Moment Type (refer to TR. 31.4 Definition of Time History Load (on page 2441)).
Ia	Arrival time number (integer). This is the sequential number of the arrival time in the list explained in TR.31.4 Definition of Time History Load (on page 2441). Thus the arrival time number of a_3 is 3 and of a_n is n.
f2	The Force, Moment, or Acceleration Amplitude at this joint and direction will be multiplied by this factor (default = 1.0). For accelerations, if the amplitude-time curve was in g’s, please use the Scale Factor in the Define Time History command to convert g’s to the acceleration units used in that command. This is recommended due to possible unit changes between that command and this command.

Note: Multiple loads at a joint-direction pair for a particular (I_t I_a) pair will be summed. However there can be no more than four (I_t I_a) pairs associated with a particular joint-direction pair, the first four such entries will be used. Loads at dependent joint directions will be ignored.

Either `TIME LOAD`, `GROUND MOTION`, or both may be specified under one load case. More than one load case for time history analysis is *not* permitted.

For `TIME LOAD` data, multiple direction specifiers can be in one entry as follows (the direction specifiers must be on one line and missing values are assumed to be 1):

```
TIME LOAD
2  3  FX  1  FZ  1  4  -2.1  MX  2  2
6  7  FX  FY  FZ
```

Notes

a. A Time History analysis requires the mode shapes. These are calculated using the mass matrix determined from the loading specified in the first dynamic load case. (refer to TR.34.2 Modal Calculation Command (on page 2615))

b. The Node Displacement table reports the maximum displacement that occurs at each node over the entire time range.

c. The displacement of the model at a specific time instance can be displayed by using the time slider bar on the Results toolbar when displaying a load case with time history loading.

d. If any Node Groups are defined, the time history graphs can be set to display the average results for the group. The name of the selected node or group being displayed is given in the graph title bar.

e. A model can include only one load case with time history loads.

Note: STAAD.Pro is also capable of generating floor spectrum responses for a time history analysis. Refer to TR. 37.10 Floor Spectrum Command (on page 2657) for details on adding this to the analysis commands.

Example

```
LOAD 1
SELFWEIGHT X  1.0
SELFWEIGHT Y  1.0
SELFWEIGHT Z  1.0
MEMBER LOADS
5 CON GX 7.5 10.0
5 CON GY 7.5 10.0
5 CON GZ 7.5 10.0
TIME LOAD
2  3  FX  1  3
5  7  FX  1  6
GROUND MOTION REL X  2 1
```

In this example, the permanent masses in the structure are provided in the form of selfweight and member loads (refer to TR.32 Loading Specifications (on page 2461) and G.17.3 Dynamic Analysis (on page 2154)) for obtaining the mode shapes and frequencies. The mass model can also be created using a Reference Load case with the Load type of Mass (refer to TR.31.6 Defining Reference Load Types (on page 2453)). The rest of the data is the input for application of the time varying loads on the structure. Forcing function type 1 is applied at joints 2 and 3 starting at arrival time number 3. (Arrival time number 3 is 1.8 seconds in example shown in TR.31.4 Definition of Time History Load (on page 2441)). Similarly, forcing function type 1 is applied at joints 5 and 7 starting at arrival time number 6 (4.4 seconds). A ground motion (type 2) acts on the structure in the x-direction starting at arrival time number 1 (0.0 seconds).

TR.32.11 Repeat Load Specification

This command is used to create a primary load case using combinations of previously defined primary load cases.

General Format

```
REPEAT LOAD
```

```
i1, f1, i2, f2 … in, fn
```

Where:

i1, i2 … in	primary load case numbers
f1, f2 … fn	corresponding factors

This command can be continued to additional lines by ending all but last with a hyphen. Limit of 550 prior cases may be factored. Prior cases to be factored may also contain the `REPEAT LOAD` command.

Description

This command may be used to create a primary load case using combinations of previously defined primary load case(s). The `REPEAT LOAD` differs from the load `COMBINATION` command (See TR.35 Load Combination Specification (on page 2616)) in two ways:

1. A `REPEAT LOAD` is treated as a new primary load. Therefore, a P-Delta analysis will reflect correct secondary effects. (`LOAD COMBINATIONS`, on the other hand, algebraically combine the results such as displacements, member forces, reactions and stresses of previously defined primary loadings evaluated independently).
2. In addition to previously defined primary loads, you can also add new loading conditions within a load case in which the `REPEAT LOAD` is used.
3. The `REPEAT LOAD` option is available to factor prior load case data and add those forces into the current load case.

   The load case data types that will be factored include Joint Loads, Member loads, Element loads, Inertia Loads, Fixed End loads, Selfweight loads, Displacements, Area loads, Prestress loading, and Temperature loads. Floor loads, Wind loads Snow loads, and UBC loads are first converted to equivalent member loads and then factored.

   Modal dynamic analysis load cases (Response Spectrum, Time History, Steady State) should not be used in `REPEAT LOAD`. It is also not available for loads generated using some of the program's load generation facilities such as `MOVING LOAD` Generation. However load cases with `WIND LOAD` may be used in Repeat Load.

UBC cases may only be used in `REPEAT LOAD` if there is a `PERFORM ANALYSIS` and `CHANGE` command after each UBC case. See notes with UBC LOAD command.

Prestress on a given member from 2 or more load cases cannot be combined.

Example:

```
LOAD 1 DL + LL
SELFWEIGHT Y -1.4
MEMBER LOAD
1 TO 7 UNIFORM Y -3.5
LOAD 2 DL + LL + WL
REPEAT LOAD
1 1.10
```

4. For a load case that is defined using the `REPEAT LOAD` attribute, the constituent load cases themselves can also be `REPEAT LOAD` cases. See load case 4 below.

```
LOAD 1
SELFWEIGHT Y -1.0
LOAD 2
MEMBER LOAD
2 UNI GY -1.5
LOAD 3
REPEAT LOAD
1 1.5
LOAD 4
REPEAT LOAD
2 1.2 3 1.25
```

TR.32.12 Generation of Loads

This command is used to generate Moving Loads, UBC Seismic loads and Wind Loads using previously specified load definitions.

Primary load cases may be generated using previously defined load systems. The following sections describe generation of moving loads, UBC seismic loads and Wind Loads.

TR.32.12.1 Generation of Moving Loads

This command is used to generate Moving Loads using previously specified load definitions.

Predefined moving load system types may be used to generate the desired number of primary load cases, each representing a particular position of the moving load system on the structure. This procedure will simulate the movement of a vehicle in a specified direction on a specified plane on the structure.

General Format

```
LOAD GENERATION n (ADD LOAD i )
```

```
TYPE j x1 y1 z1 *{ XINC f1 | YINC f2 | ZINC f3 } ( { YRANGE | ZRANGE } r)
```

Where:

n total number of primary load cases to be generated

i load case number for the previously defined load case to be added to the generated loads

j type number of previously defined load system

x1, y1, z1 x, y and z coordinates (global) of the initial position of the reference load

f1, f2, f3 x, y, or z (global) increments of position of load system to be used for generation of subsequent load cases.

Use only XINC & ZINC if Y up; Use only XINC & YINC if Z up.

r (Optional) defines section of the structure along global vertical direction to carry moving load. This r value is added and subtracted to the reference vertical coordinate (y_1 or z_1)in the global vertical direction to form a range. The moving load will be externally distributed among all members within the vertical range thus generated. r always should be a positive number. In other words, the program always looks for members lying in the range *y1* and *y1*+ABS(*r*) or *z1* and *z1*+ABS(*r*). The default *r* value is very small, so entering *r* is recommended.

The `ADD LOAD` specification may be used to add a previously defined load case to all the load cases generated by the `LOAD GENERATION` command. In the example below, the `SELFWEIGHT` specified in load case 1 is added to all the generated load cases.

Sequential load case numbers will be assigned to the series of generated primary load cases. Numbering will begin at one plus the immediate previous load case number. Allow for these when specifying load cases after load case generation.

Notes

a. Primary load cases can be generated from Moving Load systems for frame members only. This feature does not work on finite elements.

b. This facility works best when the roadway, as well as the movement of the vehicle are along one of the global horizontal (X or Z) or (X or Y) directions.

For bridge decks which are skewed with respect to the global axes, the load generation may not yield the most satisfactory results. In such cases, the M. Bridge Deck workflow (on page 908) is recommended is recommended. The Bridge Deck workflow works on the influence line/influence surface method, and is considerably superior to the moving load generator. It also has the advantage of being able to calculate the critical load positions on decks modeled using plate elements.

c. The x_1, y_1, z_1 values of the starting position of the reference wheel must be provided bearing in mind that the reference wheel has to be at the elevation of the deck. An improper set of values of these parameters may result in the wheels being positioned incorrectly, and consequently, no load may be generated at all.

Example

```
LOAD 1 DL Only
SELFWEIGHT
LOAD GENERATION 20 ADD LOAD 1
TYPE 1 0. 5. 10. Xi 10.
TYPE 2 0. 10. 10. Zi 15.
LOAD 22 Live Load on Pavement
MEMBER LOAD
10 TO 20 30 TO 40 UNI GY -5.0
```

```
LOAD COMBINATION 31 10 0.75 22 0.75
PERFORM ANALYSIS
```

TR.32.12.2 Generation of Seismic Loads

This command is used to generate seismic loads using previously specified load definitions.

Built-in algorithms will automatically distribute the base shear among appropriate levels and the roof per the relevant code specifications. The following general format should be used to generate loads in a particular direction.

General Format

```
LOAD i
```

```
code LOAD { X | Y | Z } (f1) (DECCENTRICITY f2) (ACCIDENTAL f3)
```

Where:

```
code = { 1893 | AIJ | COL | CFE | GB | IBC | NRC | NTC | RPA | TUR | UBC}
```

Note: The specified code should correspond to the seismic definition defined earlier in the input file. Refer to TR. 31.2 Definitions for Static Force Procedures for Seismic Analysis (on page 2349) for details.

Parameter	Default Value	Description
LOAD *i*	-	Load case number.
X | Y | Z *f1*	1.0	Optional factor to be used to multiply the seismic Load. May be negative. **Note:** Only apply in the horizontal directions (i.e., X and Z for Y-up or X and Y for Z-up models).
DEC *f2*	0.0	Multiplying factor for natural torsion –arising due to static eccentricity which is the difference between center of mass and center of rigidity of a rigid floor diaphragm– to be used to multiply the seismic horizontal torsion load. Must be a positive value (greater than 1.0) or exactly 0.0.
ACC *f3*	1.0	Multiplying factor for accidental torsion, to be used to multiply the seismic accidental torsion load. May be negative (otherwise, the default sign for MY is used based on the direction of the generated lateral forces).

Use only horizontal directions. This means that seismic loads should only be applied in the X and Z directions with Y up (or X and Y directions with Z up).

To include horizontal torsional moment arising due to static eccentricity for a rigid floor diaphragm, the following conditions must be satisfied:

a. The floor must be modeled as a rigid diaphragm.

b. A positive value (greater than 1.0) for `DEC` must be provided. Seismic load is applied at center of mass instead of center of rigidity which incorporates the effect that a value less than or equal to 1.0 will yield. Placing seismic load at center of mass of a rigid diaphragm automatically includes inherent torsion in analysis corresponding to static eccentricity (the difference between center of mass and center of rigidity). Providing `DEC` parameter as 0.0 for a model having rigid diaphragm to ignore inherent torsion is not possible.

c. The `ACC` command must not be present in seismic definition (i.e., in the `DEFINE *code* LOAD` command). If present, the natural torsion factor will be ignored and only the accidental torsion for all seismic loads will be considered.

The design eccentricity for calculating horizontal torsion is the `DEC` + `ACC` values. When `ACC` is negative, it becomes `DEC` - `ACC` (i.e., the torsion magnitudes are always additive).

Note: Refer to Notes (on page 2389) for additional information on using this command in conjunction with IS 1893 static seismic loads.

Dynamic Eccentricity

The static eccentricity is generally defined as the distance between the center of mass (CM) and the center of rigidity (CR) at respective floors levels. Accidental eccentricity generally accounts for factors such as:

- the rotational component of ground motion about the vertical axis,
- the difference between computed and actual values of the mass, stiffness, or strength, and
- uneven live mass distribution.

The provision for design eccentricity e_{di} at ith floor of a building is given by the following equation:

$$e_{di} = DEC \times e_{si} + ECC \times b_i$$

where

e_{si}	=	static eccentricity at ith floor
b_i	=	plan dimension of the ith floor normal to the direction of ground motion
`ECC` and `DEC`	=	Factors to determine the design eccentricity. These are input parameters.

Only `TOR ECC 0.05` or `TOR ECC -0.05` can also be defined without specifying `DEC 1.0` since it is the default that is included in the analysis.

Notes

a. The static seismic load cases should be provided as the first set of load cases. Other (non-seismic) primary load case specified before a seismic load case is not acceptable. Additional loads such as `MEMBER LOADS` and `JOINT LOADS` may be specified along with the seismic load under the same load case.

Example of *Incorrect* Usage: The error here is that the UBC cases appear as the 3rd and 4th cases, when they should be the 1st and 2nd cases.

```
⋮
LOAD 1
```

```
SELFWEIGHT Y -1
LOAD 2
JOINT LOAD
3 FX 45
LOAD 3
UBC LOAD X 1.2
JOINT LOAD
3 FY -4.5
LOAD 4
UBC LOAD Z 1.2
MEMEBER LOAD
3 UNI GY -4.5
PERFORM ANALYSIS
```

Example of Correct Usage

```
⋮
SET NL 10
⋮
LOAD 1
UBC LOAD X 1.2
JOINT LOAD
3 FY -4.5
PERFORM ANALYSIS
CHANGE
LOAD 2
UBC LOAD Z 1.2
MEMBER LOAD
3 UNI GY -4.5
PERFORM ANALYSIS
CHANGE
LOAD 3
SELFWEIGHT Y -1
LOAD 4
JOINT LOAD
3 FX 45
PERFORM ANALYSIS
LOAD LIST ALL
```

b. If the static seismic cases

are to be factored later in a `REPEAT LOAD` command;
or if the static seismic case is to be used in a tension/compression analysis;
or if re-analysis (i.e., two analysis commands without a `CHANGE` or new load case in between);

then each seismic case should be followed by `PERFORM ANALYSIS` then `CHANGE` commands as shown in the example above. Otherwise the `PERFORM ANALYSIS` then `CHANGE` can be omitted. Using the `CHANGE` command will require the `SET NL` command to define the maximum number of load cases being entered in the analysis. Also `LOAD LIST ALL` should be entered after the last `PERFORM ANALYSIS` command.

Example of *Incorrect* Usage: The error here is that the `CHANGE` command is missing before Load Case 2.

```
⋮
LOAD 1
UBC LOAD X 1.2
SELFWEIGHT Y -1
JOINT LOAD
3 FY -4.5
PDELTA ANALYSIS
```

```
LOAD 2
UBC LOAD Z 1.2
SELFWEIGHT Y -1
JOINT LOAD
3 FY -4.5
PDELTA ANALYSIS
```

Example of Correct Usage

```
⋮
LOAD 1
UBC LOAD X 1.2
SELFWEIGHT Y -1
JOINT LOAD
3 FY -4.5
PDELTA ANALYSIS
Change
LOAD 2
UBC LOAD Z 1.2
SELFWEIGHT Y -1
JOINT LOAD
3 FY -4.5
PDELTA ANALYSIS
CHANGE
```

c. Up to 8 sesimic load cases may be entered.
d. The `REPEAT LOAD` specification cannot be used for load cases involving seismic load generation unless each seismic case is followed by an analysis command then `CHANGE`.

   Example of repeat load using a seismic load case:

```
⋮
LOAD 1
UBC LOAD X 1.0
PDELTA ANALYSIS
CHANGE
LOAD 2
SELFWEIGHT Y -1
PDELTA ANALYSIS
CHANGE
LOAD 3
REPEAT LOAD
1 1.4 2 1.2
PDELTA ANALYSIS
```

e. If seismic load generation is performed for the X and the Z (or Y if Z up) directions, the command for the X direction must precede the command for the Z (or Y if Z up) direction.

UBC Example

In the following example, notice that the first three load cases are UBC load cases. They are specified before any other load cases.

```
DEFINE UBC LOAD
ZONE 0.2 K 1.0 I 1.5 TS 0.5
SELFWEIGHT
JOINT WEIGHT
1 TO 100 WEIGHT 5.0
101 TO 200 WEIGHT 7.5
LOAD 1 UBC in X-Direction
UBC LOAD X DEC 1.0 ACC 0.05
```

```
JOINT LOAD
5 25 30 FY -17.5
PERFORM ANALYSIS
CHANGE
LOAD 2 UBC in X-Direction
UBC LOAD X DEC 1.0 ACC -0.05
JOINT LOAD
5 25 30 FY -17.5
PERFORM ANALYSIS
CHANGE
LOAD 3 UBC in Z-Direction
UBC LOAD Z DEC 0.0 ACC 0.05
PERFORM ANALYSIS
CHANGE
LOAD 4 Dead load
SELFWEIGHT
LOAD COMBINATION 4
1 0.75 2 0.75 3 1.0
```

IS 1893 Example

In the following example, the first two load cases are the 1893 load cases. They are specified before any other load case.

```
DEFINE 1893 Load
ZONE 0.05 RF 1.0 I 1.5 SS 1.0
SELFWEIGHT
JOINT WEIGHT
7 TO 12 WEIGHT 17.5
13 TO 20 WEIGHT 18.0
MEMEBER WEIGHT
1 TO 20 UNI 2.0
LOAD 1 1893 Load in X-Direction
1893 LOAD X
JOINT LOAD
5 25 30 FY -17.5
LOAD 2 1893 Load in Z-Direction
1893 LOAD Z
LOAD 3 Dead Load
SELFWEIGHT
LOAD COMBINATION 4
1 0.75 2 0.75 3 10
```

TR.32.12.3 Generation of Wind Loads

This command is used to generate Wind Loads using previously specified load definitions. This command should be part of a load case.

The built-in wind load generation facility can be used to calculate the wind loads based on the parameters defined in TR.31.3 Definition of Wind Load (on page 2435). The following general format should be used to perform the wind load generation. See G.16.3 Wind Load Generator (on page 2136) for the two types of structures on which the load can be generated. For closed type structures, the vertical panel areas bounded by beam members only (and ground), and exposed to the wind, are used to define loaded areas (plates and solids are ignored). The loads generated are applied only at the joints at vertices of the bounded areas. For open type structures also, generation is done considering only the members in the model.

The automated load generator should only be used for vertical panels. Panels not parallel to the global Y axis (for Y UP) should be loaded separately.

General Format

```
LOAD i

WIND LOAD (-){ X | Y | Z } (f) TYPE j (OPEN) { { XR f1 f2  | YR f3 f4 ZR | f5 f6 }* |
LIST memb-list | ALL }
```

Where:

LOAD *i*	load case number
(-){ X | Y | Z }	Direction of wind in global axis system. Use horizontal directions only.
f	The factor to be used to multiply the wind loads. Negative signs may be used to indicate opposite direction of resulting load (default=1.0). Using X, -X, Z or –Z and the *f* factor. With respect to the axis, a minus sign indicates that suction occurs on the other side of the selected structure. If all of the members are selected and X (or Z) is used and the factor is positive, then the exposed surfaces facing in the –x (or –z) direction will be loaded in the positive x (or z) direction (normal wind in positive direction). See diagrams that follow. If X and a negative factor is used, then the exposed surfaces facing in the +x direction will be loaded in the negative x direction (normal wind in negative direction). [If –X is entered and a negative factor, then the exposed surfaces facing in the -x direction will be loaded in the negative x direction (suction). If –X is entered and a positive factor, then the exposed surfaces facing in the +x direction will be loaded in the positive x direction (suction).]

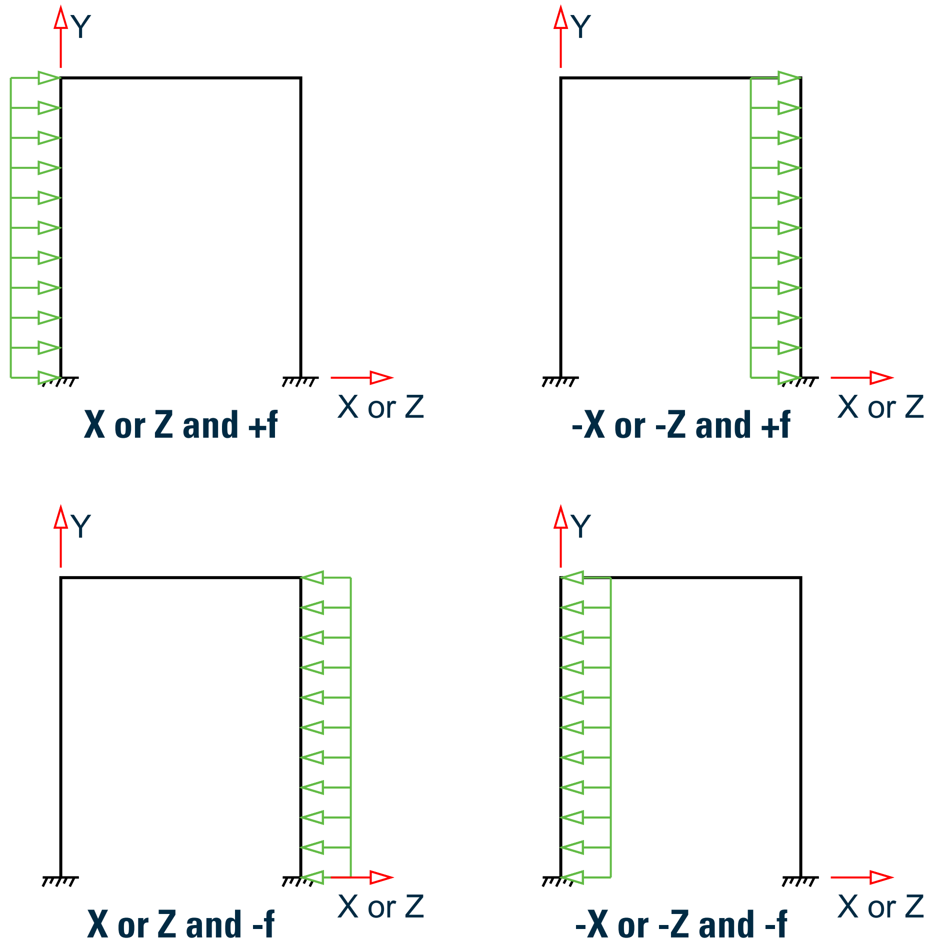

Figure 333: Sign convention for internal and external pressure

TYPE ***j***	Type number of previously defined systems
OPEN	optional word to be used if loading is to be generated on “open” type of structures. If this not specified, load will be generated assuming the panels are “closed”.
XR ***f1 f2***	global coordinate values to specify X or Y or Z range for member selection

A member list or a range of coordinate values (in global system) may be used. All members which have both end coordinates within the range are assumed to be candidates (for closed type structures) for defining a surface which may be loaded if the surface is exposed to the wind. The loading will be in the form of joint loads (not member loads). 1, 2, or 3 ranges can be entered to form a “layer”, “tube”, or “box” for selecting members in the combined ranges. Use ranges to speed up the calculations on larger models. Using multiple, overlapping ranges (in a sequence of `WIND LOAD` entries within the same load case) may be used to further control the automatic panel identification.

Example

```
DEFINE WIND LOAD
TYPE 1
INTENSITY 0.1 0.12 HEIGHT 100 200
EXP 0.6 JOI 1 TO 25 BY 7 29 TO 37 BY 4 22 23
```

```
TYPE 2
INT 0.1 0.12 HEIGHT 100 900
EXP 0.3 YR 0 500
LOAD 1
SELF Y -1.0
LOAD 2
WIND LOAD Z 1.2 TYPE 2 ZR 10 11
LOAD 3
WIND LOAD X TYPE 1 XR 7 8 ZR 14 16
LOAD 4 SUCTION ON LEEWARD SIDE
WIND LOAD -X 1.2 LIST 21 22 42
```

Example

For open structures

```
LOAD 1 WIND LOAD IN Z DIRECTION
WIND LOAD 2 -1.2 TYPE 1 OPEN
```

Notes

a. For closed type structures, panels or closed surfaces are generated by the program based on the members in the ranges specified and their end joints. The area within each closed surface is determined and the share of this area (influence area) for each node in the list is then calculated. The individual bounded areas must be planar surfaces, to a close tolerance, or they will not be loaded.

Hence, one should make sure that the members/joints that are exposed to the wind make up a closed surface (ground may form an edge of the closed surface). Without a proper closed surface, the area calculated for the region may be indeterminate and the joint force values may be erroneous. Consequently, the number of exposed joints should be at least three.

b. Plates and solids are not considered for wind load generation. On such entities, wind must be applied using pressure loading facilities for plates and solids.

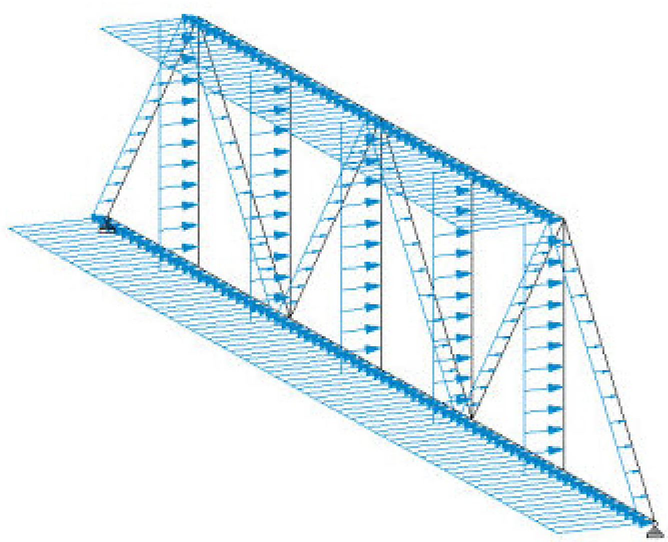

Figure 334: Load diagram for wind on open structures

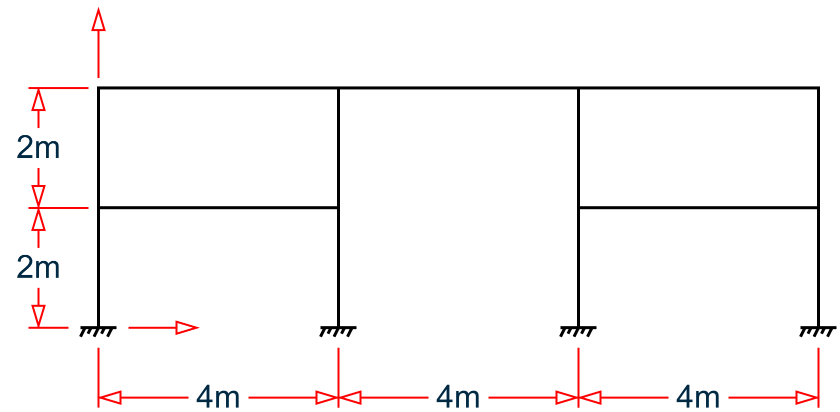
c. The program identifies the panels for wind load generation based on the geometry of the structure. However, the panel identification routine may fail to identify some open-ended panels (i.e., panels bound by the "ground" at the bottom rather than a member). In this case, you may use multiple, overlapping ranges or member lists to further refine the panel identification.

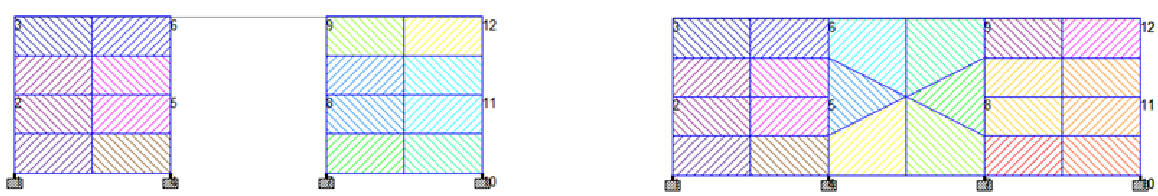
Controlling Open-Ended Panel Identification

The following structure is a wall with a large door opening. The wind is intended to applied across the entire wall. When a single range is used (Case A) to identify the wind load, the center panel is not correctly identified.



```
DEFINE WIND LOAD
TYPE 1 WIND 1
INT 0.1 HEIG  12
EXP 1 JOINT 1 TO 3 10 12
LOAD 1 LOADTYPE Wind  TITLE Wind Using Single Range
WIND LOAD X -1 TYPE 1 YR 0 4 ZR 0 12
```

A series of three ranges which overlap along the global Z direction (Case B) can be used to force the program to evaluate each bay individually.



Case A Case B

```
DEFINE WIND LOAD
…
LOAD 2 LOADTYPE Wind  TITLE Wind Using Overlapping Ranges
WIND LOAD X -1 TYPE 1 YR 0 4 ZR -0.1 4.1
WIND LOAD X -1 TYPE 1 YR 0 4 ZR 3.9 8.1
WIND LOAD X -1 TYPE 1 YR 0 4 ZR 7.9 12.1
```

Similarly, a series of three wind loads could be added to a load case, each with a member list (or a predefined group of those members) that represent each bay.

```
DEFINE WIND LOAD
…
LOAD 3 LOADTYPE Wind  TITLE Wind Using Member Lists
```

```
WIND LOAD X -1 TYPE 1 LIST 1 TO 4 9 10
WIND LOAD X -1 TYPE 1 LIST 3 TO 6 11
WIND LOAD X -1 TYPE 1 LIST 5 TO 8 12 13
```

Tip: Alternatively, you could specify a pair of uniform loads along the columns either side of the middle bay. There are situations where this may, in fact, be a closer approximately of the load distribution path.

General Format for SP 20.13330.2016 Wind Loads

STAAD.Pro can generate both static and dynamic wind loads per the SP 20.13330.2016 code.

Format for the static SP 20.13330.2016 wind load:

```
LOAD i
WIND LOAD { X | Z | -X | -Z } f1 CONFIGURATION k ( NU fNU )
TYPE j { XRANGE f1 f2 | YRANGE f1 f2 | ZRANGE f1 f2 | LIST member-list | ALL }
```

Format for the dynamic SP 20.13330.2016 wind load:

```
LOAD i
(mass-data)
WIND LOAD { X | Z} f1 WALONG f2 WACROSS f3 ( GL f4 ) ( FRQ ) ( ORT ) TYPE j ( DYN k )
```

Where:

mass-data	Mass load defined within the dynamic wind load when a separate load case for modal analysis is not previously defined in the STAAD input file.
f1	Correction factor along specified direction. This needs to be used in combination with the WIND LOAD setting.
CONFIGURATION *k*	The configuration used (from 0 to 12)
NU *fNU*	Wind pressure coefficient.
WALONG *f2*	Effective length of the structure parallel to wind direction.
WACROSS *f3*	Effective projection of the structure facing the wind direction.
GL *f4*	Vertical coordinate of ground level. It should be a positive value (zero or greater) defined in current input units. If not provided ground level is automatically calculated from the lowest Y coordinate.
FRQ	Optional parameter which results in computation of dynamic wind load vector for all mode shapes extracted from Modal Analysis provided it is within code stipulated frequency limit. Absence of the parameter will result in calculation taking the 1st mode shape only.
ORT	Optional parameter to include orthogonal directions in the load case.
TYPE *j*	Wind definition type number. This definition must be of type `SP20 2016`. Both static and dyanmic wind loads per the 2016 Russian code use this wind definition.
DYN *k*	Optional parameter that indicates that the wind loading should include the dynamic component determined from the modal response and the static wind load defined in

primary load case *k*. If this option is omitted, then only the static loads from the load definition will be calculated.

General Format for Russian SNiP 1985 Wind Loads

The format for applying wind loads per the older editions of the Russian codes are as follows:

```
LOAD i
WIND LOAD { X | Z | -X | -Z} f1 CONFIGURATION k ( NU fNU )
TYPE j { XRANGE f1 f2 | YRANGE f1 f2 | ZRANGE f1 f2 | LIST member-list  | ALL }
```

The value X or Z defines the wind direction. Use of a negative sign defines a leeward wind load.

Where:

f the wind pressure factor. A negative value defines a reverse wind loading.

k For a SNiP 1985 wind load definition, a configuration parameter defined for prismatic buildings with a valid range of values is -1 to 12, where these values represent:

-1. Prismatic building structure - rectangular building. Outstanding architectural details on the left facade.
0. Prismatic building structure - rectangular building. Both facade faces are smooth (no outstanding architectural details).
1. Prismatic building structure - rectangular building. Outstanding architectural details on the right facade.
2. Prismatic building structure - rectangular building. Outstanding architectural details on both side facades.
3. Prismatic building structure - triangular building.
4. Prismatic building structure - rhombic building.
5. to 12. Prismatic building structure - number of polygon vertices in building from 5 to 12.

fNU the wind pressure correlation coefficient. If the parameter is 1, a computed value is used. For rectangular buildings, the calculated value is always used (any input is ignored).

Note: The Russian wind load routines establish the applied wind forces from a dynamic response of the structure. Either a dynamic load case should be defined before any wind load cases or loads that represent masses should also be included in the first lad case that includes Russian wind load assignments. This in effect becomes a dynamic load case. Thus, if the effects of these forces are to be combined to the effects of static load cases, then this should be done using a `LOAD COMBINATION` command.

Dynamic Wind Load per Russian SP 20.13330.2016

In order to perform dynamic wind load generation in STAAD.Pro you must previously define a static load case. The static load case could be any primary static load case which is defined before the Russian dynamic load case, including a static wind loading per the same code. This static load case will provide static load vector to the dynamic wind load module.

As the Russian dynamic wind load component requires modal masses and eigen vectors to calculate the dynamic wind load component at nodes, modal analysis must be performed before the dynamic wind load definition. Therefore, you must also include a separate load case for modal analysis with reference mass defined before the load case. See G.17.3.2 Mass Modeling (on page 2157) for details. Alternatively, if the mass loads are not needed for use with other load cases (that is, a reference load case is not needed for other loads), then you may define the mass loads within the dynamic load case prior to the `WIND LOAD` command.

The overall wind load effect will be determined by the sum of effects of the static load and an SRSS of all of the contributing modes of the dynamic wind effect which will be used to increase the magnitude of the static load effect.

$$w = w_m + w_p$$

where

w_m	=	mean wind pressure
w_p	=	quasi-static wind fluctuation component

STAAD.Pro uses the static wind load and the modal results to create a combined dynamic load from which modal loads are calculated. The modal loads are analyzed and the overall dynamic effect is determined by combining all these with an SRSS combination which is used to increase the effect of the static wind component.

TR.32.12.4 Generation of Snow Loads

This command is used to generate Snow Loads using previously specified Snow load definitions. This input should be a part of a load case.

General Format

```
SNOW LOAD
```

```
_flr_groupTYPE j CS f1 { BALANCED | UNBALANCED } { OBSTRUCTED | UNOBSTRUCTED } { MONO |
 HIP | GABLE }
```

Where:

Parameter	Default Value	Description
_flr_group	-	The members that form the roof and that are to be loaded by snow load must be listed in a floor group (See TR.16 Entities as Single Objects (on page 2235)).
TYPE *j*	-	The type number of previously defined snow load system.
CS *f1*	0.0	Roof Slope factor (CS). For sloped roofs, the roof slope factor is described in section 7.4 of the SEI/ASCE-7-02. A value of 0 indicates that the roof is horizontal.

Parameter	Default Value	Description
BALA or UNBA	BALA	Balanced or unbalanced snow load. Default is balanced. These terms are described in section 7.6, and figures 7.3 and 7.5 of ASCE 7-02.
OBST or UNOB	UNOB	Obstructed or unobstructed.
MONO or HIP or GABLE	NONO	Roof geometry type.

Use as many floor groups and types as necessary in each load case.

Related Links

TR.32.13 Notional Loads

A notional load is a lateral load (horizontal load) which is derived from an existing vertical load case. This load type has been introduced to accommodate a requirement in design codes. The AISC 360-05 specification for example defines notional loads as lateral loads that are applied at each framing level and are specified in terms of gravity loads.

Description

Both Principal and Reference load cases can be selected and moved into the Notional Load Definition where the required factor and direction can be specified. The notional loads are calculated and applied as joint loads.

Note: The actual values of the applied loading are not displayed in the User Interface until *after* the analysis has been performed.

General Format

```
LOAD nLoad LOADTYPE type TITLE title
...
Load items
...
NOTIONAL LOAD
n { X | Z } (f1)
```

Where:

Parameter	Default Value	Description
n	-	Load case number of the primary load case or reference load case which contains the vertical load items.

Parameter	Default Value	Description
f1	0.002 (or user-specified)	Factor by which the contents of LN are to be multiplied. Typically, codes recommend 0.2 to 0.3 % (0.002 to 0.003). The default is 0.002 or the factor specified in `DIRECT ANALYSIS` definition block.

Multiple load items can be specified under any `NOTIONAL LOAD` and there can be one or more blocks of `NOTIONAL LOAD` command(s) in any load case.

Note: Notional Loads can be derived from gravity load cases specified under the `DEFINE REFERENCE LOAD` table which are described in TR.31.6 Defining Reference Load Types (on page 2453).

Example 1

```
LOAD 1 : DEAD
JOINT LOAD
13 TO 16 29 TO 32 45 TO 48 61 TO 64 FY -100
LOAD 2: DEAD NOTIONAL LOAD
NOTIONAL LOAD
1 X 0.002
…
LOAD 10: IMPOSED
JOINT LOAD
13 TO 16 29 TO 32 45 TO 48 61 TO 64 FY -50
LOAD 11:IMPOSED NOTIONAL LOAD
NOTIONAL LOAD
10 X 0.002
```

Example 2

If we want to combine the load cases in Example 1, two methods are available:

```
LOAD 3 : DEAD LOAD + IMPOSED LOAD + Notional Loads
REPEAT LOAD
1 1.0 10 1.0
NOTIONAL LOAD
1 X 0.002 10 X 0.002
```

As an alternative, the following could be used:

```
LOAD 3 : DEAD LOAD + IMPOSED LOAD + Notional Loads
REPEAT LOAD
1 1.0 2 1.0 10 1.0 11 1.0
```

Example 3

Similarly,

```
Load 1 LOADTYPE None TITLE DEAD
SELFWEIGHT Y -1.15
```

```
MEMBER LOAD
143 145 CON GY -16
*
Load 2 LOADTYPE None TITLE DEAD-NOTIONAL
NOTIONAL LOAD
1 X 1.0
*
Load 3 LOADTYPE None TITLE DEAD AND NOTIONAL
REPEAT LOAD
1 1.0
NOTIONAL LOAD
1 X 1.0
```

Alternatively the following could be used to define load case 3:

```
Load 3 LOADTYPE None TITLE DEAD AND NOTIONAL
REPEAT LOAD
1 1.0 2 1.0
```

Example 4

Using Notional loads with REFERENCE loads

```
DEFINE REFERENCE LOADS
LOAD R1 LOADTYPE Dead TITLE REF DEAD LOAD
SELFWEIGHT Y -1 LIST 1 TO 120
FLOOR LOAD
YRANGE 19 21 FLOAD -0.05 GY
YRANGE 39 41 FLOAD -0.05 GY
LOAD R2 LOADTYPE Live TITLE REF LIVE LOAD
FLOOR LOAD
YRANGE 19 21 FLOAD -0.03 GY
YRANGE 39 41 FLOAD -0.03 GY
END DEFINE REFERENCE LOADS
**********************************************
* LOAD COMBINATIONS INCLUDING NOTIONAL LOADS *
**********************************************
*
*DEAD + LIVE +/- NOTIONAL LOAD
*
LOAD 1
REFERENCE LOAD
R1 1.2 R2 1.6
NOTIONAL LOAD
R1 X 0.0024 R2 X 0.0032
LOAD 2
REFERENCE LOAD
R1 1.2 R2 1.6
NOTIONAL LOAD
R1 X -0.0024 R2 X -0.0032
LOAD 3
REFERENCE LOAD
R1 1.2 R2 1.6
NOTIONAL LOAD
R1 Z 0.0024 R2 Z 0.0032
LOAD 4
REFERENCE LOAD
```

```
R1 1.2 R2 1.6
NOTIONAL LOAD
R1 Z -0.0024 R2 Z -0.0032
```

If a `PRINT STATIC CHECK` or `PRINT LOAD DATA` command is added with any analysis specification in the input file, the generated NOTIONAL LOADs would be printed as in the following:

```
   NOTIONAL LOAD - (POUN,FEET)
    LOADING    4  DL+NDLX
      JOINT          DIRECTION                   LOAD
…
        6117           X     -0.00200 X      74124.266 =        -148.249
        6118           X     -0.00200 X     115504.569 =        -231.009
        6119           X     -0.00200 X      38397.157 =        -76.794
        6120           X     -0.00200 X      15551.155 =        -31.102
        6121           X     -0.00200 X      17347.718 =        -34.695
        6122           X     -0.00200 X      29341.723 =        -58.683
        6123           X     -0.00200 X      39771.147 =        -79.542
        6124           X     -0.00200 X      39712.750 =        -79.426
        6125           X     -0.00200 X      34006.254 =        -68.013
                             ==============================================
48554642.872     -97109.290

TR.33 Reference Load Cases - Application

Describes how you can call the data specified under those types in actual load cases. Reference Load types are described in TR.31.6 Defining Reference Load Types (on page 2453).

General Format

The format of a reference to a Reference Load in a primary load (j) case is thus:

```
LOAD j LOADTYPE (type) load_title
REFERENCE LOAD
R(i) 1.0
…
```

Example

```
LOAD 1 LOADTYPE None TITLE D+L
REFERENCE  LOAD
R1  1.0 R2 1.0
LOAD  2 LOADTYPE None TITLE DEAD+SNOW
REFERENCE  LOAD
R1  1.0 R3 1.0
LOAD  3 LOADTYPE None TITLE D+H
```

```
REFERENCE  LOAD
R1  1.0 R4 1.0
ELEMENT  LOAD
1212  1267 TRAP GY JT -0.54 -0.44 -0.44 -0.54.
```

TR.34 Frequency Calculation

There are two methods available in STAAD for calculating the frequencies of a structure:

1. an approximate method called the Rayleigh method and
2. a more exact method which involves the solution of an eigenvalue problem.

Both methods are explained in the following sections.

Related Links

- *G.17.3 Dynamic Analysis* (on page 2154)
- *G.17.3 Dynamic Analysis* (on page 2154)
- *G.17.3 Dynamic Analysis* (on page 2154)
- *G.17.3.1 Solution of the Eigenproblem* (on page 2155)
- *G.17.3 Dynamic Analysis* (on page 2154)

TR.34.1 Rayleigh Frequency Calculation

This command may be used to calculate the Rayleigh method approximate frequency of the structure for vibration corresponding to the general direction of deflection generated by the load case that precedes this command. Thus, this command typically follows a load case.

General Format

```
CALCULATE RAYLEIGH (FREQUENCY)
```

Description

This command is specified after all other load specifications of any primary load case for which the Rayleigh frequency is calculated. This Rayleigh frequency calculation is based on the Rayleigh iteration method using 1 iteration. If a more accurate, full-scale eigensolution is required, the `MODAL CALCULATION` command (see next section) may be used. A full eigensolution is automatically performed if a `RESPONSE SPECTRUM` or `TIME HISTORY` is specified in any load case.

Example

```
LOADING 1
SELFWEIGHT X 1.0
CALCULATE RAYLEIGH FREQUENCY
LOADING 2
SELFWEIGHT Z 1.0
```

```
CALCULATE RAYLEIGH FREQUENCY
LOADING 3 WIND LOAD
```

In this example, the Rayleigh frequency is calculated for the X direction mode of vibration in load case 1, and the Z direction in case 2.

In case 1, the structure is being displaced by `SELFWEIGHT` applied statically along global X. For most frames which are supported only at their base, this produces a deflected shape resembling the lowest mode shape along global X. Hence, this frequency will resemble that for the lowest X direction mode.

Similarly, the frequency calculated for load case 2 ought to be similar to that for the lowest Z direction mode because the selfweight is applied statically along global Z.

Tip: If you want a mode or frequency to be for lateral motion (X or Z), then enter the loads in the X or Z directions. Entering loads in the vertical direction when the lowest modes are in the lateral direction is a common mistake.

The output will consist of the value of the frequency in cycles per second (cps), the maximum deflection along with that global direction and the joint number where that maximum occurs.

Notes

This command is based on the Rayleigh method of iteration using 1 iteration. The frequency calculated estimates the frequency as if the structure were constrained to vibrate in the static deflected shape generated by the loads in the load case.

In many instances, the forces should be in one global direction to get the mode and frequency associated with that direction.

- *G.17.3 Dynamic Analysis* (on page 2154)

TR.34.2 Modal Calculation Command

This command may be used to obtain a full scale eigensolution to calculate relevant frequencies and mode shapes. It should not be entered if this case or any other case is a `TIME LOAD` or `RESPONSE SPECTRUM` case. For Steady State/Harmonic analysis this command must be included in the load case that defines the weights and weight moment of inertias for eigensolutions

General Format

```
MODAL CALCULATION ( REQUESTED ) ( MISSING MASS )
```

This command is typically used in a load case after all loads are specified. The loads will be treated as weights and weight moment of inertias for eigensolutions (see G.17.3 Dynamic Analysis (on page 2154) and TR.32 Loading Specifications (on page 2461)). You are advised to specify the loads keeping this in mind.

This case will be independently solved statically and dynamically. Static results using the loads will include joint displacements, member forces, support reactions, and other outputs computed from a normal static analysis without any dynamic effects included.

STAAD.Pro can include the stress stiffening effect (geometric stiffness) based on the axial member forces/plate in-plane stresses from a selected load case when calculating the modes & frequencies of a structure.

In addition, the Dynamic results (using loads as masses) will include Mode Shapes and Frequencies.

Note: The `MODAL CALCULATION` command can be included in any of the primary load cases, but only in one of them.

For Steady State/Harmonic analysis, enter the `MISSING MASS` parameter to include the missing mass procedure in the analysis.

TR.35 Load Combination Specification

This command may be used to combine the results of the analysis. The structure will *not* be analyzed for the combined loading. The combination of results may be algebraic, SRSS, a combination of both algebraic and SRSS, or Absolute.

Note: The `LOAD COMBINATION` specification is not appropriate for obtaining secondary effects for combined loads. Refer to notes below.

General Format

```
LOAD COMBINATION ( { SRSS | ABS } ) ( GENERATE ) i a1
```

```
i1 f1 i2 f2 … (fSRSS)
```

Where:

i	Load combination number. This can be any integer smaller than 100,000 that is not the same as any previously defined primary load case or load combination number.
a1	Any title for the load combination.
***i1*, *i2*, …**	The load case or load combination numbers which are to be combined. For the SRSS option, a minus sign may be used to indicate that this load case should be combined algebraically rather than as an SRSS case.
***f1*, *f2*, …**	The corresponding factors to be applied to loadings. Values greater than or equal to 0.0 are allowed.
fSRSS	An optional factor to be applied as a multiplying factor on the combined result of the SRSS load combination (see examples below).
GENERATE	Optional command for `SRSS` or `ABS` load combinations which will generate load combinations representing all possible positive or negative actions in each load degree of freedom. When used, a single set of absolute value analysis results is replaced by these 64 load combination analysis results.

A hyphen may be used at the end of a line to continue this command onto the next line.

Description

If the load combination option is left out (i.e., neither ABS or SRSS is included), then the results from analyses will be combined algebraically.

```
LOAD COMBINATION 6 DL+LL+WL
1 0.75 2 0.75 3 1.33
```

If the ABS load combination method is included, then the absolute value of results from the analyses will be combined.

Note: If GEN is included this single set of absolute values is replaced by 64 sets of load combinations.

```
LOAD COMBINATION ABS 7 DL+LL+WL
1 0.85 2 0.65 3 2.12
```

If the SRSS load combination method is included, then the results from analyses may be combined both algebraically and using the SRSS (Square Root of Summation of Squares) method. The combination scheme may be mixed if required. For example, in the same load combination case, results from load cases may be combined in the SRSS manner and then combined algebraically with other load cases.

Note: The case factor is not squared.

Note: If GEN is included this single set of absolute values is replaced by 64 sets of load combinations

Notes

a. In the LOAD COMBINATION SRSS option, if the minus sign precedes any load case no., then that load case will be combined algebraically with the SRSS combination of the rest.

b. The LOAD COMBINATION command should *not* be used to obtain the secondary effects of combined load cases through a P-Delta, Member/Spring Tension/Compression, Multilinear Spring, or Nonlinear Analysis. See the REPEAT LOAD command (TR.32.11 Repeat Load Specification (on page 2595)) for details.

c. In a load combination specification, a value of 0 (zero) as a load factor is permitted. In other words, a specification such as

```
LOAD COMB 7
1 1.35 2 0.0 3 1.2 4 0.0 5 1.7
```

is permitted. This is the same as

```
LOAD COMB 7
1 1.35 3 1.2 5 1.7
```

d. All combination load cases must be provided immediately after the last primary load case.

e. The total number of primary and combination load cases combined cannot exceed the limit described in TR.2 Problem Initiation and Model Title (on page 2202).

f. A maximum of 550 load cases can be combined using a LOAD COMBINATION command.

g. Load combinations can refer to previously defined load combination numbers.

Generate Load Combinations

If the optional `GENERATE` command is included, this single set of absolute values is replaced by 64 sets of load combinations. Otherwise, the program will follow the usual method of `ABS` or `SRSS` load combination.

Note: The generate load combination feature is implemented in AISC 360 05/10 and IS800 2007 only. For other design codes, the program will not design for these 64 generated load cases.

For a particular model, all 13 section forces for each of the members for the internally generated 64 load combination cases can be printed in an external text file. To do this, use the following `SET` command in the input file before joint incidences are specified.

```
SET CG TXT
```

This command will instruct the program to print the section forces for each member for 1 to 64 generated load combinations to a file named *`filename`* `_CG.txt` located in the same location as the STAAD input file.

Caution: For models with significantly larger number of members or load combination cases generated, this file can be come extremely large. This output option should only be used when the individual cases require review and *not* used in normal circumstance.

Response Spectra in Load Combinations

The following steps are followed in order to derive member section forces for a response spectrum case.

a. Forces at start and end joints of a member are calculated for each mode.
b. Since masses are lumped at two member ends, it is assumed that the section forces due each of the modes are varying linearly between member ends. Thus at any section the section force is linearly interpolated for each mode.
c. The forces at each section for all modes are combined using modal combination method to arrive at the final result.

The section forces for each mode for any response spectrum load case can be printed in an external text file. To do this, use the following `SET` command in the input file before joint incidences are specified.

```
SET RS TXT
```

This command will instruct the program to print the section forces for each member to a file named *`filename`* `_RESP.txt` located in the same location as the STAAD input file.

Caution: For models with significantly larger number of members or load combination cases generated, this file can be come extremely large. This output option should only be used when the individual cases require review and *not* used in normal circumstance.

Once the section forces are available it can be combined with other static load cases using SRSS/ABS and GENERATE options.

Design for Load Combinations per ASME NF

Steel design is performed for active load cases that may include primary loads and load combinations. If any load combination is an internal load generation case, instead of designing for one particular load combination case, the design is performed for all 64 load combinations. Thus, the steel design results may vary from what if it had been designed for only one combination case. If any load combination generation case becomes a critical load case for design, it is noted as such in the design output.

All section forces for the 64 generated load cases –whose parent load combination case becomes the critical design load– can be printed in an external text file. To do this, use the following `SET` command in the input file before joint incidences are specified.

```
SET NF TXT
```

This command will instruct the program to print the section forces for each member to a file named *`filename`* `_RESP.txt` located in the same location as the STAAD input file.

Caution: For models with significantly larger number of members or load combination cases generated, this file can be come extremely large. This output option should only be used when the individual cases require review and *not* used in normal circumstance.

Example of Simple SRSS Combination

Several combination examples are provided to illustrate the possible combination schemes

```
LOAD COMBINATION SRSS 8 DL+SEISMIC
1 1.0 2 0.4 3 0.4
```

This (LOAD COMBINATION SRSS 8) illustrates a pure SRSS load combination with a default SRSS factor of one. The following combination scheme will be used:

$$v = 1.0 \cdot (1 \cdot L1^2 + 0.4 \cdot L2^2 + 0.4 \cdot L3^2)^{1/2}$$

where

v	=	the combined value
L1, L2, and L3	=	values from load cases 1, 2 and 3.

Since an SRSS factor is not provided, the default value of 1.0 is being used.

Examples of Algebraic & SRSS Combination in the Same Load Combination Case

Example 1

```
LOAD COMBINATION SRSS 9
-1 0.75 2 1.3 3 2.42 0.75
```

The combination formula will be as follows:

$$v = 0.75 \times L\ 1 + 0.75 \times \sqrt{1.3(L\ 2)^2 + 2.42(L\ 3)^2}$$

where

v	=	the combined value
L2 and L3	=	values from load cases 2 and 3

In the above specification, a minus sign precedes load case 1. Thus, Load 1 is combined algebraically with the result obtained from combining load cases 2 and 3 in the SRSS manner. The SRSS factor of 0.75 is applied on the SRSS combination of 2 and 3.

Example 2

```
LOAD COMBINATION SRSS 10
-1 0.75 -2 0.572 3 1.2 4 1.7 0.63
```

Here, both load cases 1 and 2 are combined algebraically with the SRSS combination of load cases 3 and 4. Note the SRSS factor of 0.63. The combination formula will be as follows:

$$v = 0.75 \times L\ 1 + + 0.572 \times L\ 2 + 0.63 \times \sqrt{1.2(L\ 3)^2 + 1.7(L\ 4)^2}$$

TR.36 Calculation of Problem Statistics

This item has been removed. Please contact the Bentley Technical Support Group for further details.

TR.37 Analysis Specification

STAAD analysis options include linear static analysis, P-Delta (or second order analysis), Nonlinear analysis, and several types of Dynamic analysis.

This command is used to specify the analysis request. In addition, this command may be used to request that various analysis related data, like load info, statics check info, etc. be printed.

Related Links

- *G.17.1 Stiffness Analysis* (on page 2138)

TR.37.1 Linear Elastic Analysis

Used to perform a static, linear elastic analysis on the structure.

General Format

```
PERFORM  ANALYSIS (PRINT { LOAD DATA | STATICS CHECK | STATICS LOAD | BOTH | ALL } )
```

Without one of these analysis commands, no analysis will be performed. These `ANALYSIS` commands can be repeated if multiple analyses are needed at different phases.

The following `PRINT` options are available:

- If the `PRINT LOAD DATA` command is specified, the program will print an interpretation of all the load data.
- `PRINT STATICS CHECK` will provide a summation of the applied loads and support reactions as well as a summation of moments of the loads and reactions taken around the origin.
- `PRINT STATICS LOAD` prints everything that `PRINT STATICS CHECK` does, plus it prints a summation of all internal and external forces at each joint. This option generates a large volume of output.

Note: Since `PRINT STATIC LOAD` generates voluminous output, the printing of summation of internal and external forces at each joint is done for structures which have less than 1,000 joints. If the structure has 1,000 joints or more, this printing will be skipped.

- `PRINT BOTH` is equivalent to `PRINT LOAD DATA` plus `PRINT STATICS CHECK`.
- `PRINT ALL` is equivalent to `PRINT LOAD DATA` plus `PRINT STATICS LOAD`.
- The `PRINT MODE SHAPES` command may be added separately after the Analysis command if mode shapes are desired. Refer to TR.42 Print Specifications (on page 2666) for using additional print specifications.

Notes

This command directs the program to perform the analysis that includes:

a. Checking whether all information is provided for the analysis;
b. Forming the joint stiffness matrix;
c. Checking the stability of the structure;
d. Solving simultaneous equations, and
e. Computing the member forces and displacements.
f. If a `RESPONSE SPECTRUM`, `TIME LOAD`, or `GROUND MOTION` is specified within a load case or the `MODAL CALCULATION` command is used, a dynamic analysis is performed.

Note: Due to the mechanisms used to include control/dependent systems, if the reactions on control nodes are not included in a statics check then an out of balance report may result. This can be avoided by adding a short stiff member from a control node to the support.

General Analysis Comments

STAAD.Pro allows multiple analyses in the same run. Multiple analyses may be used for the following purposes:

a. Successive analysis and design cycles in the same run result in optimized design. STAAD.Pro automatically updates changes in member cross-sectional sizes. Thus the entire process is automated.

Refer to Example 1 in the Getting Started & Examples manual for detailed illustration.

b. Multiple analyses may be used for load-dependent structures. For example, structures with bracing members are analyzed in several steps. The bracing members are assumed to take Tension load only. Thus, they need to be activated and inactivated based on the direction of lateral loading.

The entire process can be modeled in one STAAD.Pro run using multiple `PERFORM ANALYSIS` commands. STAAD.Pro is capable of performing a design based on the load combinations provided.

Refer to Example 4 in the Getting Started & Examples manual for detailed illustration.

c. You may also use Multiple Analyses to model change in other characteristics like supports, releases, section properties, etc.
d. Multiple Analyses may require use of additional commands like the `SET NL` command (TR.5 Set Command Specification (on page 2206)) and the `CHANGE` command.
e. Analysis and `CHANGE` are required after UBC cases if the case is subsequently referred to in a Repeat Load command or if the UBC case will be re-solved after a Select command or after a Multiple analysis.

- *G.17 Analysis Facilities* (on page 2138)

TR.37.2 P-Delta Analysis Options

Used to perform a second-order analysis, considering either large- or small-delta effects—or both—on the structure.

General Format

The following options are available in STAAD.Pro when performing a P-Delta analysis:

1. P-Delta analysis with Small & Large Delta effects or Large Delta effects only. With this option the global forces are adjusted with every iteration

   ```
   PDELTA (n) ANALYSIS ( { LARGEDELTA | SMALLDELTA } ) (PRINT  print-options)
   ```

   Where:

PDELTA *n*	no. of iterations desired (default value of n = 1).
LARGEDELTA | SMALLDELTA	`SMALLDELTA` is the default

2. P-Delta analysis including stress stiffening effect of the KG matrix. With this option the global stiffness is adjusted with every iteration

   ```
   PDELTA KG ANALYSIS (PRINT  print-options)
   ```

```
print-options = { LOAD DATA | STATICS CHECK | STATICS LOAD | BOTH | ALL }
```

See TR.37.1 Linear Elastic Analysis (on page 2620) for details.

Without one of these P-Delta analysis commands, no P-Delta analysis will be performed.

These `ANALYSIS` commands can be repeated if multiple analyses are needed at different phases.

A `PDELTA ANALYSIS` will correctly reflect the secondary effects of a combination of load cases only if they are defined using the `REPEAT LOAD` specification (TR.32.11 Repeat Load Specification (on page 2595)). Secondary effects will not be evaluated correctly for load combinations.

P-Delta effects are computed for frame members and plate elements only. They are not calculated for solid elements or curved beams.

Notes for Small or Large Delta (Option 1)

a. This command directs the program to perform the analysis that includes:
   a. Checking whether all information is provided for the analysis;
   b. Forming the joint stiffness matrix
   c. Checking the stability of the structure;
   d. Solving simultaneous equations, and
   e. Computing the member forces and displacements.
   f. For P-Delta analysis, forces and displacements are recalculated, taking into consideration the chosen P-Delta effect.
   g. If a `RESPONSE SPECTRUM`, `TIME LOAD`, or `GROUND MOTION` is specified within a load case or the `MODAL CALCULATION` command is used, a dynamic analysis is performed.

      Note: Computing P-Delta effects for dynamic load cases is not recommended since such effects are not considered.

   h. In each of the iterations of the `PDELTA ANALYSIS`, the load vector will be modified to include the secondary effect generated by the displacements caused by the previous iterations.
b. The default procedure of option 1 is based on “P-small & large Delta” effects.(sometimes referred to as P-δ & P-Δ). Enter the LargeDelta parameter to only include the “PlargeDelta” effects (P-Δ only). SmallDelta is recommended.

c. This `PDELTA (n) ANALYSIS` command (option 1) should specify 3 to 30 iterations to properly incorporate the P-Delta effect. With this many iterations, the `PDELTA (n) ANALYSIS SMALLDELTA` command results are as good as or better than the `PDELTA KG` (option 2) command results for static analysis. The advantage of this `PDELTA (n) ANALYSIS` command comes from not having to re-form and then triangular factorize the stiffness matrix for every iteration within every case. Also this command allows tension/compression.
d. Be aware that global buckling can occur in P-Delta analysis, resulting in large or infinite or NaN values for displacement. Do not use the results of such a case. Sometimes the loads from Repeat Load combination cases are too large; sometimes partial moment releases rather than the full release is needed, sometimes connectivity needs to be corrected. Always check the maximum displacements for P-Delta analyses.

Note: Due to the mechanisms used to include control/dependent systems, if the reactions on control nodes are not included in a statics check then an out of balance report may result. This can be avoided by adding a short stiff member from a control node to the support.

Example

Following are some examples on use of the command for P-Delta analysis as described in TR.37.2 P-Delta Analysis Options (on page 2621).

```
PDELTA ANALYSIS
PDELTA 5 ANALYSIS
PDELTA 20 ANALYSIS SMALLDELTA PRINT STATICS CHECK
```

STAAD.Pro allows multiple P-Delta analyses in the same run (see the General Comments section of TR.37.1 Linear Elastic Analysis (on page 2620) for details).

Notes for Stress Stiffening Matrix (Option 2)

The P-Delta analysis also provides the option of including the stress stiffening effect of the Kg matrix into the member / plate stiffness.

a. A regular STAAD P-Delta Analysis (option 1) performs a first order linear analysis and obtains a set of joint forces from member/plates based on both large and small P-Delta effects. In contrast, the P-Delta KG Analysis (that is, with the Kg option selected) includes the effect of the axial stress after the first analysis is used to modify the stiffness of the member/plates. A second analysis is then performed using the original load vector. Large & small P-Delta effects are always included in this KG option.
b. This command directs the program to perform the analysis that includes:
   a. Solving the static case.
   b. Reforming the global joint stiffness matrix to include the Kg matrix terms which are based on the computed tensile/compressive axial member forces.
   c. Solving simultaneous equations for displacements;
   d. If a `RESPONSE SPECTRUM`, `TIME LOAD`, or `GROUND MOTION` is specified within a load case or the `MODAL CALCULATION` command is used, a dynamic analysis is performed. The static cases solved for a `PDELTA KG` analysis command will be solved first then the dynamic analysis cases.

   Note: The stiffness matrix used in the dynamic analysis will be the K+Kg matrix used in the last iteration for the last static case. This is a stress stiffened dynamic analysis, sometimes known as a PDELTA Dynamic analysis.

c. A `PDELTA KG ANALYSIS` will correctly reflect the secondary effects of a combination of load cases only if they are defined using the `REPEAT LOAD` specification (TR.32.11 Repeat Load Specification (on page 2595)). Secondary effects will not be evaluated correctly for load combinations since only final results are combined.
d. P-Delta KG effects are computed for frame members and plate elements only. They are not calculated for solid elements. The results are based on “P-large & small Delta” effects.
e. For static analysis, the other P-Delta command [`PDELTA (n) ANALYSIS (SMALL)`] with 20 or more iterations (option 1) is preferred.
f. Tension/compression only members are *not* allowed with this `PDELTA KG` command. You must use the `PDELTA (n) ANALYSIS (SMALL)` command instead.
g. Be aware that global buckling can occur in a `PDELTA KG ANALYSIS`. This condition is usually detected by STAAD.Pro. A message is issued and the results for that case are set to zero. STAAD.Pro will continue with the next load case.
h. Global buckling may not be detected which could result in a solution with large or infinite or NaN values for displacement or negative L-matrix diagonals or stability errors. Do not use the results of such cases. This condition may require a nonlinear analysis. Sometimes the loads from Repeat Load combination cases are too large; sometimes partial moment releases rather than the full release is needed, sometimes connectivity needs to be corrected. Always check the maximum displacements for P-Delta analyses.

Example

```
PDELTA KG ANALYSIS PRINT BOTH
PDELTA KG 2 ANALYSIS
```

TR.37.3 Nonlinear Cable Analysis

General Format

For basic cable analysis:

```
PERFORM CABLE ANALYSIS BASIC (STEPS f1) (EQITERATIONS f2) (EQTOLERANCE f3) (SAGMINIMUM f4) (STABILITY f5 f6) (KSMALL f7) (PRINT print-options)
```

Note: Use of the Basic cable analysis requires including the `BASIC` option in the command.

For advanced cable analysis:

```
PERFORM CABLE ANALYSIS ( ADVANCED ) (STEPS f8) (EQITERATIONS f9) (EQTOLERANCE f10) (REFORM f11) (KGEOM f12) (PRINT print-options)
```

Note: Use of the Advanced Cable analysis feature requires the STAAD.Pro Advanced License. The `ADVANCED` option is the default if you have the license.

Where:

```
print-options = { LOAD DATA | STATICS CHECK | STATICS LOAD | BOTH | ALL }
```

See TR.37.1 Linear Elastic Analysis (on page 2620) for details.

See TR.42 Print Specifications (on page 2666) for details on including the cable sag in the output.

This command may be continued to the next line by ending with a hyphen.

Table 279: Parameters for basic cable analysis

Parameter	Default Value	Description
STEPS *f1*	145	The number of load steps for basic cable analysis. The applied loads will be applied gradually in this many steps. Each step will be iterated to convergence. If entered, the value should be in the range 5 to 145.
EQITERATIONS *f2*	300	Maximum number of iterations permitted in each load step. Should be in the range of 10 to 500.
EQTOLERANCE *f3*	0.0001	The convergence tolerance for the above iterations.
SAGMINIMUM *f4*	0.0	Cables (not trusses) may sag when tension is low. This is accounted for by reducing the E value. Sag minimum may be between 1.0 (no sag E reduction) and 0.0 (full sag E reduction). As soon as SAGMIN becomes less than 0.95, the possibility exists that a converged solution will not be achieved without increasing the steps to 145 or the pretension loads. The Eq iterations may need to be 300 or more. The Eq tolerance may need to be greater or smaller.

Parameter	Default Value	Description
STABILITY *f5*	1.0	A stiffness matrix value (f5) that is added to the global matrix at each translational direction for joints connected to cables and nonlinear trusses for the first f6 load steps. The amount added linearly decreases with each of the f6 load steps. If f5 is entered, use 0.0 to 1000.0. This parameter alters the stiffness of the structure.
f6	1	The number of load steps over which f_5 is gradually applied. The default is one step.
KSMALL *f7*	0.0	A stiffness matrix value that is added to the global matrix at each translational direction for joints connected to cables and nonlinear trusses for every load step. The range for f_7 is between 0.0 and 1.0. This parameter alters the stiffness of the structure.

Table 280: Parameters for advanced cable analysis

Parameter	Default Value	Description
STEPS *f8*	1	Used to divide the loading into small increments. Any positive integer is valid. Generally, a value larger than one (1) may be beneficial for solution convergence, because the loading is applied gradually. However, with cable elements having fixed prestressing, a single step typical converges faster.

Parameter	Default Value	Description
EQITERATIONS *f9*	300	Maximum number of iterations permitted in each load step. During each loading increment, the analysis will iterate to find the converging solution. Once the iteration number reaches the maximum value, the analysis will be stopped even though converged solution is not achieved. Any positive integer is valid. Values too small may prevent the solution to achieve convergence. However, excessively large values may cost unnecessary running time when the problem diverges.
EQTOLERANCE *f10*	1.0E-6	The convergence tolerance for the iterations specified in `EQITERATIONS`. The residual force norm is used for this convergence. This error threshold indicates when the nonlinear solver will stop iterating and consider the ongoing step as converged once the computed error is equal or smaller than this value. A value that is too small may prevent the solution to be considered as converged. However, value that is too larger may result in inaccurate results. The tolerance printed in the output file is the norm of the current out-of-balance forces, divided by the norm of all the externally applied forces. This calculated tolerance must be less than f_{10} for the current iteration to converge.
REFORM *f11*	1	Used to specify if full Newton-Raphson method or modified Newton- Raphson method will be used. Theoretically, the full Newton-Raphson method can approach converge with less iterations but may require more computation effort than modified Newton-Raphson method.

Parameter	Default Value	Description
KGEOM *f12*	0	Used to specify whether or not geometric stiffness will be used.

Notes

a. STAAD allows multiple analysis in the same run (see the General Comments in TR.37.1 Linear Elastic Analysis (on page 2620)).
b. Multiple analyses may require use of additional commands like the `SET NL` command and the `CHANGE` command.
c. Analysis and `CHANGE` are required between primary cases for `PERFORM CABLE ANALYSIS BASIC` or `PERFORM CABLE ANALYSIS ADVANCED`.
d. A cable element cannot be loaded with either a non-uniformly distributed load or a concentrated load (using a `MEMBER LOAD` command).

Note: Due to the mechanisms used to include control/dependent systems, if the reactions on control nodes are not included in a statics check then an out of balance report may result. This can be avoided by adding a short stiff member from a control node to the support.

TR.37.4 Buckling Analysis

General Format

```
PERFORM BUCKLING { ANALYSIS (MAXSTEPS f1) | EIGEN } (PRINT print-options)
```

```
print-options = { LOAD DATA | STATICS CHECK | STATICS LOAD | BOTH | ALL }
```

See TR.37.1 Linear Elastic Analysis (on page 2620) for details.

Without this command (or any of the analysis commands described earlier), no analysis will be performed. These `ANALYSIS` commands can be repeated if multiple analyses are needed at different phases.

Where:

EIGEN if specified the analysis will perform the eigen method, otherwise the iterative method will be used

Note: This requires a STAAD.Pro Advanced license.

MAXSTEPS *f1* the maximum no. of iterations desired (default value of n = 20). 15 is recommended. For use with the iterative (`ANALYSIS`) method only.

There are two procedures available:

i. the iterative method: `PERFORM BUCKLING ANALYSIS`
ii. the eigen method: `PERFORM BUCKLING EIGEN`

Note: Due to the mechanisms used to include control/dependent systems, if the reactions on control nodes are not included in a statics check then an out of balance report may result. This can be avoided by adding a short stiff member from a control node to the support.

Iterative Method

This command directs the program to perform an analysis that includes:

a. Solving the static case.
b. Re-forming the global joint stiffness matrix to include the Kg matrix terms which are based on the computed tensile/compressive axial member forces and inplane plate stresses..
c. Solving simultaneous equations for displacements;
d. Repeat b) and c) for the number of required additional iterations; either until convergence or until MAXSTEPS is reached.

If the loads must be in the opposite direction, STAAD.Pro will stop solving that case at 1 iteration. The results for the case will be outputted; then STAAD.Pro will continue with the next case.

Convergence occurs when two consecutive buckling factors in the iteration are within 0.1% of each other.

Results are based on the highest successful Buckling Factor estimate that was calculated; as if the original applied loads times the buckling factor had been entered.

Eigen Method

Note: `MAXSTEPS` input is ignored when using the eigen method.

This command directs the program to perform the analysis that includes:

a. Solving the static case.
b. Reforming the global joint stiffness matrix to include the Kg matrix terms which are based on the computed tensile/compressive axial member forces & inplane plate stresses..
c. Solving an eigenvalue problem for up to 4 buckling factors and buckling shapes

A Buckling Analysis will correctly reflect the secondary effects of a combination of load cases only if they are defined using the `REPEAT LOAD` specification (TR.32.11 Repeat Load Specification (on page 2595)). Buckling will not be performed for `LOAD COMBINATIONS` cases.

Buckling Kg matrices are computed for frame members and plate elements only. They are not calculated for solid elements or curved members. The results are based on “P-large & small Delta” effects (refer to Option 1 in TR.37.2 P-Delta Analysis Options (on page 2621)).

Buckling Analysis solves for Buckling Factors. These are the amounts by which the load case must be factored for the buckling shape to occur. Only the last buckling case will be presented in the post processing. However, the buckling factors of all buckling cases will be written to the output.

If the loads must be in the opposite direction, STAAD.Pro will compute negative buckling factors.

Results are for the normalized buckling shape not as if the original applied loads times the buckling factor had been entered.

Example with eigen method:

```
PERFORM BUCKLING  EIGEN
```

Related Links

- *G.17.2.2 Buckling Analysis* (on page 2145)
- *A. To specify buckling analysis* (on page 957)
- *G.17.2.2 Buckling Analysis* (on page 2145)

TR.37.5 Direct Analysis

General Format

```
PERFORM DIRECT ANALYSIS ( {LRFD | ASD} TAUTOL f1 DISPTOL f2 ITERDIRECT i3 (REDUCEDEI
i4) (PDITER i5) (TBITER) PRINT print-options )
```

```
print-options = { LOAD DATA | STATICS CHECK | STATICS LOAD | BOTH | ALL }
```

This command directs the program to perform the analysis that includes:

a. Reduce Axial & Flexure stiffness to 80% for members selected in the Define Direct input. The 80% applies only to analysis.
b. Solving the static case which has notional loads included.
c. Perform iterations of the iterative PDelta with SmallDelta analysis procedure (default 15 iterations).
d. Solving simultaneous equations for displacements;
e. Compute Tau-b of AISC 05 Direct Analysis Appendix 7 based on required strength versus yield strength.
f. Reforming the global joint stiffness matrix.
g. Solving simultaneous equations for displacements;
h. Repeat steps c) through g) until converged or `ITERDIRECT` iterations are reached.

A Direct Analysis will correctly reflect the secondary effects of a combination of load cases only if they are defined using the `REPEAT LOAD` specification (TR.32.11 Repeat Load Specification (on page 2595)) and/or `REFERENCE LOAD` specification (TR.33 Reference Load Cases - Application (on page 2613)). Direct analysis will not be performed for `LOAD COMBINATIONS` cases.

Notional loads must be defined using a `DEFINE NOTIONAL` table.

A list of members which will have their initial Tau-b value set and/or have their Axial stiffness reduced and/or their flexural stiffness reduced must be entered using a `DEFINE DIRECT` table.

For information on `NOTIONAL LOADS`, see sections TR.31.7 Definition of Direct Analysis Members (on page 2454) and TR.32.13 Notional Loads (on page 2610).

PDELTA iterative load adjustments are computed for frame members only. They are not calculated for plate or solid elements. The results are based on “P-large&small Delta” effects (refer to Option 1 in TR.37.2 P-Delta Analysis Options (on page 2621)).

Convergence occurs when 2 consecutive iterations have all member tau-b values the same within a tolerance, `TAUTOL`, and displacements & rotations the same within a tolerance, `DISPTOL`.

LRFD is the default (all generated loads are factored by 1.0). If ASD entered then loads are factored by 1.6 for the Pdelta and Tau-b calculations. ASD final results are based on the final displacements divided by 1.6

If resulting displacements are diverging, then the P-Delta iterations will be terminated and the current iteration results will be used as the final results for that load case.

Table 281: Direct analysis parameters

Parameter Name	Default Value	Description
TAUTOL *f1*	0.01	Tau-b tolerance *f1* is normally 0.001 to 1.0.
DISPTOL *f2*	0.01 inch (displacement) 0.01 radians (rotation)	Displacement tolerance *f2* should not be too tight. The value is in current length units.
ITERDIRECT *i3*	1	Limits the number of iterations. A value for *i3* between 1 to 10 is typically sufficient.
REDUCEDEI *i4*	1	Integer, *i4*, specifies whether to use the reduced EI (Tau-b × 0.8 × EI) for member section moment and section displacement. 1) uses the reduced EI (Tau-b × 0.8 × EI) for member section moment & section displacement calculations 2) uses the full EI for member section moment & section displacement calculations
PDiter *i5*	15	The number of iterations, *i5*, used in the iterative PDelta with SmallDelta analysis procedure within Direct Analysis; 5 to 25 iterations is the normal range. The default is recommended.
TBITER	-	If this command is present, then the analysis procedure will iterate Tau-b.

Note: You can use the `SET NOPRINT DIRECT` command to turn off the tau-b details in the output file when running a Direct Analysis. This can greatly reduce the volume of output content for models with many load cases.

Note: Due to the mechanisms used to include control/dependent systems, if the reactions on control nodes are not included in a statics check then an out of balance report may result. This can be avoided by adding a short stiff member from a control node to the support.

Example

```
PERFORM DIRECT ANALYSIS LRFD TAUTOL 0.01 -
DISPTOL 0.01 ITERDIRECT 2 TBITER -
PRINT LOAD DATA
```

TR.37.6 Steady State and Harmonic Analysis

This section describes how to define steady state analysis in STAAD.Pro.

Note: This requires a STAAD.Pro Advanced license.

Related Links

- *G.17.3.6 Steady State and Harmonic Response* (on page 2166)
- *G.17.3 Dynamic Analysis* (on page 2154)

TR.37.6.1 Purpose

This analysis type is used to model steady, harmonically varying load on a structure to solve for the steady harmonic response after the initial transient response has damped out to zero. STAAD.Pro Steady State analysis options include results for one forcing frequency or for a set of frequencies. You may specify ground motion or a distributed joint loading in one load case. Damping is required either in this input or from the Modal Damp input or from the Composite Damping input.

This command is used to specify the analysis request, specify that the load case with the `MODAL CALCULATION` command (which must be prior to this analysis command) be used as the definition of the mass distribution, and to begin a block of data input describing the steady state forcing functions, the output frequencies, and the printing of the joint responses.

All of the input and output frequencies are in Hertz (Hz or CPS).

Related topics can be found in the following sections:

G.17.3 Dynamic Analysis (on page 2154)
TR.30 Miscellaneous Settings for Dynamic Analysis (on page 2344)
TR.34 Frequency Calculation (on page 2614)
TR.26.4 Modal Damping Information (on page 2312)
TR.26.5 Composite Damping for Springs (on page 2313)
TR.37 Analysis Specification (on page 2620)
TR.34 Frequency Calculation (on page 2614)

Note: The Modal Calculation command is required in the weight/mass definition load case.

General Format

```
PERFORM STEADY STATE ANALYSIS
```

This command directs the program to perform the analysis that includes:

a. Checking whether all information is provided for the analysis;
b. Forming the joint stiffness matrix;
c. Solving simultaneous equations;
d. Solving for modes and frequencies;

e. Computing for the steady state joint displacements, velocities & accelerations and phase angles;
f. Computing the above quantities versus frequency and displaying the results graphically.
g. Member & element forces & stresses and support reactions are not currently computed.

The first input after the Perform Steady State Analysis command is:

```
BEGIN ( { STEADY | HARMONIC } ) ( { FORCE | GROUND } )
```

Steady or Harmonic Steady = the analysis is at one forcing frequency

Harmonic = the analysis is at several frequencies

Force or Ground Choose whether the loading is a distributed joint force load or a ground motion.

This command selects which of the 4 load/analysis types, that are available, will be used in this analysis. These four are described in sections TR.37.6.4 Steady Ground Motion Loading (on page 2634) through TR.37.6.7 Harmonic Force Loading (on page 2637).

This block of data should be terminated with the `END STEADY` command as mentioned in TR.37.6.9 Last Line of this Steady State/Harmonic Analysis (on page 2641).

The steady state/harmonic analysis will calculate the maximum displacement and the associated phase angle for each of 6 joint directions, relative to the ground motion, for each frequency defined in TR.37.6.2 Define Harmonic Output Frequencies (on page 2633).

In `PRINT JOINT DISP` and in Post processor displayed results, the load case displacement for a given joint and direction will be the maximum value over all of the frequencies (without the phase angles) for a Steady State load case.

In post-processing for harmonic analysis, Log-Log graphs of any joint's relative translational displacement or velocity or acceleration versus frequency may be selected.

See TR.37.6.8 Print Steady State/Harmonic Results (on page 2639) for printing displacements with phase angles by frequency.

TR.37.6.2 Define Harmonic Output Frequencies

If Harmonic is requested above, then optionally include the next input.

```
FREQUENCY (FLO f1 FHI f2 NPTS f3 ( MODAL ) FLIST freqs  )
```

Where:

FLO *f1* Lowest frequency to be included in Harmonic output. Default to half the first natural frequency.

FHI *f2* Highest frequency to be included in Harmonic output. Default to highest frequency plus largest difference between two consecutive natural frequencies.

NPTS *f3* Number of plot frequencies to be included between natural frequencies. Defaults to 5 (7 if fewer than 10 modes) (3 if more than 50 modes). These points are added to improve the graphic display of responses versus frequency.

The natural and forcing frequencies are automatically included in the plot frequencies.

MODAL This option causes the natural frequencies between `FLO` and `FHI` to be added to the list of forcing frequencies.

FLIST *freqs* List of forcing frequencies to be included in the Harmonic analysis. Continue *freqs* input to additional lines by ending each line except the last with a hyphen.

Only forcing frequencies will be used to create load case results and print results.

TR.37.6.3 Define Load Case Number

The load case which contains the `MODAL CALC` command is automatically used for the load case number.

TR.37.6.4 Steady Ground Motion Loading

This set of commands may be used to specify steady ground motion loading on the structure, the ground motion frequency, the modal damping, and the phase relationship of ground motions in each of the global directions.

General Format

This command specifies the ground motion frequency and damping.

```
STEADY GROUND FREQUENCY f1 { DAMP f2 | CDAMP | MDAMP } { ABSOLUTE | RELATIVE }
```

Where:

FREQ *f1* the steady state frequency in cycles/sec at which the joint loads below will oscillate.

DAMP *f2* Damping ratio for all modes when DAMP is selected. Default value is 0.05 (5% damping if 0 or blank entered).

DAMP, MDAMP, and CDAMP select source of damping input:

- DAMP indicates to use the *f2* value for all modes
- MDAMP indicates to use the damping entered or computed with the `DEFINE DAMP` command if entered, otherwise default value of 0.05 will be used
- CDAMP indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the `CONSTANT` specification

`ABSOLUTE` or `RELATIVE`. Ground motion results in output file will be relative to the ground unless `ABSOLUTE` is specified. Graphical results are relative. This option has no effect for the force loading cases.

General Format

Enter the direction of the ground motion, the acceleration magnitude, and the phase angle by which the motion in this direction lags (in degrees). One Ground Motion command can be entered for each global direction.

```
GROUND MOTION { X | Y | Z } { ACCELERATION | DISPLACEMENT } f3 ( PHASE f4 )
```

Where:

f3 Ground acceleration as multiple of ‘g’ (i.e. acceleration due to gravity 9.81 m/s^2 or 32.17 ft/s^2) *or* displacement in length units.

PHASE *f4* Phase angle in degrees. If not specified, this is take as zero (i.e., no shifting).

Related Links

- *G.17.3.3 Damping Modeling* (on page 2158)
- *G.17.3.3 Damping Modeling* (on page 2158)

TR.37.6.5 Steady Force Loading

This set of commands may be used to specify JOINT loads on the structure, the forcing frequency, the modal damping, and the phase relationship of loads in each of the global directions.

General Format

This command specifies the forcing frequency and damping for a case of steady forces.

```
STEADY FORCE FREQ f1 { DAMP f2 | CDAMP | MDAMP }
```

Where:

FREQ *f1* the steady state frequency in cycles/sec at which the joint loads below will oscillate.

DAMP *f2* Damping ratio for all modes when DAMP is selected. Default value is 0.05 (5% damping if 0 or blank entered).

DAMP, MDAMP, and CDAMP select source of damping input:

- DAMP indicates to use the *f2* value for all modes
- MDAMP indicates to use the damping entered or computed with the DEFINE DAMP command if entered, otherwise default value of 0.05 will be used
- CDAMP indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the CONSTANT specification

Joint Loads

Refer to TR.32.1 Joint Load Specification (on page 2462) for additional information on Joint Loads

```
JOINT LOAD ( [ PHASE *{ X | Y | Z } f7] )
```

Where:

PHASE *f7* Phase angle in degrees. One phase angle per global direction.

Bracketed data may be entered for each global direction on the same line. All moments specified below will be applied with a phase angle of 0.0. All forces specified below will be applied with the phase angle specified above, if any. Default is 0.0.

Next are the joint forces, if any. Repeat as many lines of joint force data as needed.

```
joint-list *{ FX f1 | FY f2 | FZ f3 | MX f4 | MY f5 | MZ f6 }
```

Where:

FX *f1*, FY *f3*, FZ *f3* specify a force in the corresponding global direction.

MX *f4*, MY *f4*, MZ *f6* specify a moment in the corresponding global direction.

Notes

a. Joint numbers may be repeated where loads are meant to be additive in the joint.
b. UNIT command may be on lines in between joint-list lines.
c. Forces applied at a dependent degree of freedom will be ignored.

Copy Loads

The next command, Copy Load, may optionally be placed here to use the equivalent joint loads from prior cases. This feature enables using the more complex loading commands like selfweight, floor load, wind load, etc. that are not directly available here.

```
COPY LOAD
```

```
i1, f1, i2, f2 ... in, fn
```

Where:

i_1, i_2 ... i_n	prior primary load case numbers that are in this analysis set.
f_1, f_2 ... f_n	corresponding factors

This command can be continued to additional lines by ending all but last with a hyphen. These cases must have been between the Perform Steady State Analysis command and the prior Analysis command (if any).

Related Links

- *G.17.3.3 Damping Modeling* (on page 2158)
- *G.17.3.3 Damping Modeling* (on page 2158)

TR.37.6.6 Harmonic Ground Motion Loading

This set of commands may be used to specify harmonic ground motion loading on the structure, the modal damping, and the phase relationship of ground motions in each of the global directions.

Response at all of the frequencies defined in TR.37.6.2 Define Harmonic Output Frequencies (on page 2633) will be calculated.

General Format

```
HARMONIC GROUND { DAMP f2 | CDAMP | MDAMP } { ABSOLUTE | RELATIVE }
```

Where:

DAMP *f2* Damping ratio for all modes when DAMP is selected. Default value is 0.05 (5% damping if 0 or blank entered).

This command specifies the damping. The steady state response will be calculated for each specified output frequency entered or generated, see TR.37.6.2 Define Harmonic Output Frequencies (on page 2633).

DAMP, MDAMP, and CDAMP select source of damping input:

- DAMP indicates to use the *f2* value for all modes
- MDAMP indicates to use the damping entered or computed with the DEFINE DAMP command if entered, otherwise default value of 0.05 will be used
- CDAMP indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the CONSTANT specification

ABSOLUTE or RELATIVE. Ground motion results in output file will be relative to the ground unless ABSOLUTE is specified. Graphical results are relative. This option has no effect for the force loading cases.

General Format

```
GROUND MOTION { X | Y | Z } { ACCELERATION | DISPLACEMEBNT } f3 ( PHASE f4 )
```

Enter the direction of the ground motion, the acceleration and the phase angle by which the motion in this direction lags (in degrees). One Ground Motion command can be entered for each global direction.

Where:

f3	Ground acceleration as multiple of 'g' (i.e. acceleration due to gravity 9.81 m/s^2 or 32.17 ft/s^2) *or* displacement in length units.
PHASE *f4*	Phase angle in degrees. If not specified, this is take as zero (i.e., no shifting).

Next is an optional amplitude versus frequency specification to be used when the ground motion acceleration is a function of frequency. For any forcing frequency an amplitude can be determined, from the data below, which will multiply the acceleration *f3* entered above. If no amplitude data is entered for a direction then the acceleration is *f3* for that direction.

```
AMPLITUDE ( A a B b C c )
```

where

Amplitude	=	$a \times \omega^2 + b \times \omega + c$
ω	=	forcing frequency in rad/sec.
a, b, c	=	Constants. a and b default to 0.0 and c defaults to 1.0.

Or

```
AMPLITUDE
```

```
(f1 a1  f2 a2  … fn an )
```

f1 a1 f2 a2* … *fn an	Frequency - Amplitude pairs are entered to describe the variation of acceleration with frequency. Continue this data onto as many lines as needed by ending each line except the last with a hyphen (-). These pairs must be in ascending order of frequency. Use up to 199 pairs. Linear interpolation is used.

One Ground Motion and Amplitude command set can be entered for each global direction.

Related Links

- *G.17.3.3 Damping Modeling* (on page 2158)
- *G.17.3.3 Damping Modeling* (on page 2158)

TR.37.6.7 Harmonic Force Loading

This set of commands may be used to specify `JOINT` loads on the structure, the modal damping, and the phase relationship of loads in each of the global directions.

Response at all of the frequencies defined in TR.37.6.2 Define Harmonic Output Frequencies (on page 2633) will be calculated.

General Format

```
HARMONIC FORCE { DAMP f2 | CDAMP | MDAMP }
```

Where:

DAMP *f2*	Damping ratio for all modes when `DAMP` is selected. Default value is 0.05 (5% damping if 0 or blank entered).

This command specifies the damping for a case of harmonic forces.

DAMP, MDAMP, and CDAMP select source of damping input:

- DAMP indicates to use the *f2* value for all modes
- MDAMP indicates to use the damping entered or computed with the DEFINE DAMP command if entered, otherwise default value of 0.05 will be used
- CDAMP indicates to use the composite damping of the structure calculated for each mode. You must specify damping for different materials under the CONSTANT specification

Joint Loads

Refer to TR.32.1 Joint Load Specification (on page 2462) for additional information on Joint Loads

```
JOINT LOAD ( [ PHASE *{ X | Y | Z } f7] )
```

Where:

PHASE *f7*	Phase angle in degrees. One phase angle per global direction.

Bracketed data may be entered for each global direction on the same line. All moments specified below will be applied with a phase angle of 0.0. All forces specified below will be applied with the phase angle specified above, if any. Default is 0.0.

Next are the joint forces, if any. Repeat as many lines of joint force data as needed.

```
joint-list *{ FX f1 | FY f2 | FZ f3 | MX f4 | MY f5 | MZ f6 }
```

Where:

FX *f1*, FY *f3*, FZ *f3*	specify a force in the corresponding global direction.
MX *f4*, MY *f4*, MZ *f6*	specify a moment in the corresponding global direction.

Notes

a. Joint numbers may be repeated where loads are meant to be additive in the joint.
b. UNIT command may be on lines in between joint-list lines.
c. Forces applied at a dependent degree of freedom will be ignored.

Copy Loads

The next command, Copy Load, may optionally be placed here to use the equivalent joint loads from prior cases. This feature enables using the more complex loading commands like selfweight, floor load, wind load, etc. that are not directly available here.

```
COPY LOAD
```

$i_1, f_1, i_2, f_2 \ldots i_n, f_n$

Where:

$i_1, i_2 \ldots i_n$	prior primary load case numbers that are in this analysis set.
$f_1, f_2 \ldots f_n$	corresponding factors

This command can be continued to additional lines by ending all but last with a hyphen. These cases must have been between the Perform Steady State Analysis command and the prior Analysis command (if any).

Next is an optional amplitude versus frequency specification to be used when the ground motion acceleration is a function of frequency. For any forcing frequency an amplitude can be determined, from the data below, which will multiply the acceleration *f3* entered above. If no amplitude data is entered for a direction then the acceleration is *f3* for that direction.

```
AMPLITUDE ( A a B b C c )
```

where

Amplitude	=	$a \times \omega^2 + b \times \omega + c$
ω	=	forcing frequency in rad/sec.
a, b, c	=	Constants. a and b default to 0.0 and c defaults to 1.0.

Or

```
AMPLITUDE
```

```
(f1 a1  f2 a2  … fn an )
```

f1 a1 f2 a2 … fn an	Frequency - Amplitude pairs are entered to describe the variation of acceleration with frequency. Continue this data onto as many lines as needed by ending each line except the last with a hyphen (-). These pairs must be in ascending order of frequency. Use up to 199 pairs. Linear interpolation is used.

Leaving the direction field blank or inserting `ALL` will use the same Frequency versus Amplitude for all 3 force directions.

Enter amplitudes for up to three directions. For directions without amplitude input, including moment directions, the amplitude will be set to 1.0.

The first form of the amplitude input is converted to the second form by creating 199 equally spaced frequencies, then computing the amplitude for each frequency.

TR.37.6.8 Print Steady State/Harmonic Results

General Format

```
PRINT HARMONIC DISPLACEMENTS list-spec
```

```
list-spec = { (ALL) | LIST list of items-joints }
```

This command must be after all steady state/harmonic loadings and before the `END STEADY` command. For each harmonic frequency of TR.37.6.2 Define Harmonic Output Frequencies (on page 2633) the following will be printed:

1. Modal responses.
2. Phase angles with 1 line per selected joint containing the phase angle for each of the 6 directions of motion.
3. Displacements table with 1 line per selected joint containing the maximum displacements for each of the 6 directions of motion.
4. Velocities.
5. Accelerations.

Steady State Notes

For members, the final results at the joints will be complete but the section results will be as if the member loads were applied as statically equivalent loads at the member ends.

Steady State Examples

Example 1

```
BEGIN STEADY GROUND
STEADY GROUND FREQ 22.4 DAMP .033 ABS

TR.37.7 Pushover Analysis

This section describes how to define a pushover analysis in STAAD.Pro.

Note: This requires a STAAD.Pro Advanced license.

Related Links

- *Perform Pushover Analysis tab* (on page 2926)
- *A. To specify a pushover analysis* (on page 957)

TR.37.7.1 Beginning of Pushover Data

All Pushover analysis related data are to be entered after entering this command.

General Format

```
DEFINE PUSHOVER DATA
```

TR.37.7.2 Define Input

The following sections describe the input parameters used for a pushover definition.

TR.37.7.2.1 Type of Frame

FEMA recognizes only three types of frames: concentric braced frame (CBF), eccentric braced frame (EBF), and moment frame. Only CBF and fully restrained (FR) moment frame are used in the program.

General Format

```
FRAME i1
```

where:

i1 Type of frame:

1. for a Concentric Braced frame
2. for a Moment frame (default)

Related Links

- *G.17.4.2.1.1 Define Steel Moment and Braced Frames* (on page 2178)
- *M. To define general pushover data* (on page 881)

TR.37.7.2.2 Expected Yield Stress

Expected yield stress may be specified.

General Format

```
FYE f1 MEMBER { <list>  | ALL }
```

where:

f1 User-defined expected yield stress (default = 50 ksi). Refer to Section 5.3.2.3 and Tables 5-1 and 5-2 of FEMA 356 for additional information on values used.

<list> List of members associated with the user defined yield stress

Related Links

- *M. To define member specific pushover data* (on page 882)

TR.37.7.2.3 Effective Length Factor of Member

The effective length factor of any member can be defined. This value is used in finding Euler Buckling load of a member. The minimum of these values two will be taken in calculation.

General Format

```
KY f2 MEMBER { <list>  | ALL }
```

```
KZ f3 MEMBER { <list>  | ALL }
```

where:

f2 User-defined K value in local y-axis (default = 1.0)

f3 User-defined K value in local z-axis (default = 1.0)

<list> List of members associated with the user-defined effective length factor

Related Links

- *M. To define member specific pushover data* (on page 882)

TR.37.7.2.4 Consideration of Geometric Nonlinearity Effect

The following command is used to optionally consider geometric nonlinear effects.

You may specify either (or both) the `DISPTOL` or `GEOCYCLE` commands to optionally check for convergence.

General Format

```
GNONL  i2
( DISPTOL f4  )
( GEOCYCLE i3  )
```

i2 Specifies if geometric nonlinear effects are to be considered

0. = Include the effect of large displacements (Default)
1. = Ignore the effect of large displacements

f4 Convergence displacement tolerance for convergence of Geometric Nonlinearity, in current units of length. The default value is the maximum span of the structure divided by 120.

See Note a below.

i3 Number of iterations to be performed for convergence of Geometric Nonlinearity. Default value is one.

See Note b below.

Notes

a. he member end forces are evaluated by performing a convergence check on the joint displacements. In each step, the displacements are compared with those of the previous iteration in order to check whether convergence is attained.

Refer `SET DISPLACEMENT` command in TR.5 Set Command Specification (on page 2206) for additional details. If any displacement on any iteration exceeds the `DISPTOL` limit, the solution is diverging and is terminated.

b. If the number of nonlinear iterations exceeds `GEOCYCLE` limit the analysis is terminated. Please refer `NONLINEAR ANALYSIS` in STAAD for more details. However, maximum allowable iteration is 50. If the number of iterations exceeds 50 the analysis is terminated.

Related Links

- *M. To define general pushover data* (on page 881)

TR.37.7.2.5 KG Matrix Iteration

Optional control to limit the number of iterations performed on the geometric stiffness, KG, matrix.

General Format

```
IKGITER i4
```

where:

i4 The number of iterations to be performed for KG matrix iterations. If no value is specified, the program will assume the value of TR.37.7.2.4 Consideration of Geometric Nonlinearity Effect (on page 2645).

If the value is one (1), the program will continue iteration until the solution converges. However, maximum allowable iteration is 50. If the number of iterations exceeds 50, the analysis is terminated.

Related Links

- *M. To define general pushover data* (on page 881)

TR.37.7.2.6 Maximum number of Analysis cycle

Used to specify a maximum number of cycles to be considered during the strain hardening stage for the load increment stage.

Whenever there is load increment on the structure, a new analysis cycle starts. This consists of one analysis cycle for gravity loading and the rest consists of the sum total of number of cycles required in the linear stage plus the number of cycles required to pass the structure from the linear to the nonlinear and strain hardening stage plus the number of cycles required in the strength degraded stage. The strength degraded stage consists of both analysis cycles during the load increment and load decrement stages. You can specify a lower number of analysis cycles to be considered during the strain hardening stage for the load increment stage only, which will be considered after pushover analysis enters into the nonlinear stage.

Note: The sum total of number of cycles specified by user plus number of analysis cycles required in load decrement stage plus number of cycles required in linear stage including analysis cycle for gravity loading will be limited to 10001 cycles.

General Format

```
MAXCYCLE i5
```

where:

i5 Number of analysis cycles.

Related Links

- *M. To define general pushover data* (on page 881)

TR.37.7.2.7 Print Output Result

Only the final state is saved for nonlinear static analysis. You may instruct the program to print analysis result (joint displacements, member end forces, and support reactions) for the final state of nonlinear static analysis in the output file.

General Format

```
PRINT RESULT ( OUTPUT f5  )
```

where:

f5 Optionally used to limit the output to displacements, member end forces, or reactions.

1. Joint displacements only
2. Member end forces only

3. Support reactions only

Related Links

- *M. To define general pushover data* (on page 881)

TR.37.7.2.8 Save Output Results for Multiple Steps

By default the intermediate analysis results are saved for positive increments only at 0.1-inch incremental value of displacement at roof or at control joint. However, you instruct the program to save results at specific intermediate steps. This will create binary post-processing files that include load step results at user-defined points.

General Format

```
SAVE LOADSTEP RESULT { DISP | BSHEAR } f6
```

f6 If `DISP` is defined, this is the incremental value of displacement at roof or at control joint in current units. If no value is given 0.1 inch is taken as default.

If `BSHEAR` is defined, this is the incremental value of base shear in current units. If no value is given, 5.0 kip is taken as default

If the value of base shear defined is B and incremental value of `BSHEAR` is f, the number of intermediate results that can be saved in B / f. The maximum allowable value is 500. Similarly, if the value of allowable displacement at control joint is D and incremental value of `DISP` is n, the number of intermediate results that can be saved in D / n. The maximum allowable value is 500.

Besides saving user-defined intermediate results, the other cases where intermediate results will be saved are as follows:

- A frame hinge is formed
- A frame hinge is trying to unload
- A frame hinge has failed

Related Links

- *M. To define general pushover data* (on page 881)

TR.37.7.3 Define Loading Pattern

The pattern of the push load distribution on the nodes of the structure to be entered.

General Format

```
LOADING PATTERN i1
```

where:

i1 Method of loading pattern used:

0. = STAAD calculates internally the push load based on the specific gravity load and the first modal displacement in the direction of push load (Default)
1. = user-defined push load pattern

Note: You can define the Push load pattern explicitly when the `LOADING PATTERN` command value is one. The external push load is defined as primary load case. See TR.37.7.8 Pushover Loading Input (on page 2653).

Related Links

- *G.17.4.2.1.3 Define Lateral (Push) Loading* (on page 2179)
- *G.17.4.1.8 Lateral Load Distribution* (on page 2177)
- *M. To add a pushover loading* (on page 884)

TR.37.7.3.1 Program Defined Push Load Distribution Pattern

If `LOADING PATTERN` is 0 (i.e., STAAD.Pro internally calculates the lateral push load), you are required to define following two inputs.

For all analyses, at least two vertical distributions of lateral load shall be applied. One pattern shall be selected from each of the following two groups. Therefore, two different input files are to be generated. One analysis is to be performed by selecting any one method from Group 1. Another separate analysis is to be performed by selecting Method 3 from Group 2.

Group 1

Method 1 A vertical distribution proportional to the value of C_{vx} given in Equation (3-12) of FEMA 356 : 2000 is performed. Use of this distribution shall be permitted only when more than 75% of the total mass participates in the fundamental mode in the direction under consideration, and the uniform distribution is also used.

Method 2 A vertical distribution proportional to the shape of the fundamental mode in the direction under consideration is performed. Use of this distribution shall be permitted only when more than 75% of the total mass participates in the fundamental mode in the direction under consideration, and the uniform distribution is also used.

Group 2

Method 3 A vertical distribution is performed consisting of lateral forces at each level proportional to the total mass at each level.

General Format

```
VDB i2
```

i2 Method used for load distribution pattern:

1. Method 1
2. Method 2
3. Method 3

Related Links

- *M. To add a pushover loading* (on page 884)

TR.37.7.3.2 Total Base Shear to be Distributed

Optionally used to define base shear that will be distributed vertically along the height of the structure at each floor level.

Note: If base shear to be distributed is not defined, the program distributes 10 percent of gravity loading as lateral load.

General Format

```
DISTRIBUTE BASE SHEAR { X | Z } f1
```

where:

f1 Total base shear to be distributed in current units of force.

Related Links

- *M. To add a pushover loading* (on page 884)

TR.37.7.3.3 Number of Push Load Steps

This command is used to specify number of steps for the push load.

The lateral load at each floor divided by the number of load steps gives the push load increment at that floor level.

General Format

```
LDSTEP i3
```

i3 Number of load steps. Default is 100.

Related Links

- *M. To add a pushover loading* (on page 884)

TR.37.7.4 Define Solution Control

One of the two following methods must be specified to define the limit of the pushover analysis.

Note: Both method may be specified in the same input file. Upon exceeding either of the limits, the analysis will stop.

Related Links

- *G.17.4.2.1.6 Define Pushover Analysis Solution Control* (on page 2182)
- *M. To define solution control* (on page 884)

TR.37.7.4.1 Push Up to Defined Base Shear

The pushover analysis will continue until the cumulative base shear is less than or equal to the base shear specified by this command or the structure has additional strength.

General Format

```
BASE SHEAR { X | Z } DEFINED f1
```

f1 Explicitly defined base shear in current units of force.

TR.37.7.4.2 Push Up to Defined Displacement at Control Joint

The pushover analysis will continue until the displacement at the specified joint at the specified direction exceeds specified displacement.

General Format

```
DISP { X | Z } f2 JOINT i1
```

f2 Explicitly defined joint displacement value in current units of length.

i1 Node number of control joint.

TR.37.7.5 Define Hinge Property

If the automatic hinge calculation per FEMA 356 is not used, then the hinge properties must be defined and these hinges must be assigned to members.

TR.37.7.5.1 User-Defined Hinge Property

Several hinge property may be specified with specific type identifier. User may later refer this type identifier while assigning specific hinge properties to members (See "TR.37.7.9 Validation of Commands other than Input Parameters (on page 2654)"). If hinge property is not specified, STAAD assumes the FEMA specified hinge properties.

To specify uncoupled moment hinge property of the member following input is required.

General Format

```
HINGE PROPERTY MOMENT
TYPE n1
A xa1 ya1 B xb1 yb1 C xc1 yc1 D xd1 yd1 E xe1 ye1 YM f11 YR f21
IO f31 LS f41 CP f51
...
TYPE ni
A xai yai B xbi ybi C xci yci D xdi ydi E xei yei YM f1i YR f2i
IO f3i LS f4i CP f5i
```

n1,..., ni	Type identifier (Hinge property number)
A, B, C, D, E	Points on the load deformation curve at points A, B, C, D, and E as specified in FEMA
xa1 ya1 ... xe1 ye1,..., xai yai ... xei yei	Coordinates of A, B, C, D, E respectively

xa1, ..., xe1, ..., xai, ..., xei	Deformation Ratio, θ/θ_y
ya1 ..., ye1, ..., yai, ...,yei	Moment Ratio, Q/Q_y
f11,...,f1i	Yield moment in current force units
f21,...,f2i	Yield rotation in radians
f31,...,f3i	Immediate occupancy in deformation ratio
f41,...,f4i	Life safety in deformation ratio
f51,...,f5i	Collapse prevention in deformation ratio

The coordinates of point A should be always (0, 0) and that of point B is (1.0, 1.0). Both the coordinates of point C must be greater than 1.0. The X coordinate of point D must be same as that of point C and Y coordinate must be less than 1.0. The X coordinate of point E must be greater than that of point D and Y coordinate should be same as that of point D.

Note: The hinge property will be applied to hinge formed due to moment about local z-axis for beam. For column, hinge formation will be considered either about local y-axis or about local z-axis depending upon whichever moment is dominating and also the orientation of the column with respect to the push load direction. The hinge property will be applied to the hinge formed due to this moment.

See "TR.37.7.5.2 Assignment of Hinge Property to the Members (on page 2651)" for example input.

Related Links

- *G.17.4.2.1.5 Define Pushover Hinges Properties and Acceptance Criteria* (on page 2180)
- *G.17.4.1.4 Types of Nonlinearity* (on page 2173)
- *G.17.4.1.6 Frame element hinge properties* (on page 2174)
- *M. To manually define and assign hinges* (on page 882)

TR.37.7.5.2 Assignment of Hinge Property to the Members

This command is used to define the method by which the plastic hinges are formed. If no assignment of hinge property is done, the program will assign built-in FEMA 356 hinge property to the members.

```
HINGE { TYPE n1  | FEMA | IGNORE } { MEMBER <list>  | ALL }
```

n1	Hinge type identifier
<list>	List of members associated the current hinge command

Notes

a. Once `HINGE PROPERTIES` are specified (See "TR.37.7.5.1 User-Defined Hinge Property (on page 2650)"), you can assign these to the members using the `HINGE TYPE` command.

Note: Hinge properties must be defined prior to assigning them to members in the input file.

b. If a user-defined hinge property (i.e., the `HINGE TYPE` command) is assigned to some members, the program will consider hinge formation in these members only. The `HINGE FEMA` hinge property must be assigned to other members. Thus, you must take care to assign hinge property to all members if hinge formation is to be considered in all members.

In this case, the `HINGE FEMA` command must follow after the `HINGE TYPE` command in the input.

c. The `HINGE IGNORE` command can be used to ignore hinge formation in some members.

Note: The ALL option should not be used with HINGE IGNORE as this will prevent a successful pushover analysis.

Example

```
DEFINE PUSHOVER DATA
HINGE PROPERTY MOMENT
TYPE 1
A 0.0 0.0 B 1.0 1.0 C 10.0 1.2 D 10.0 0.6 E 12.0 0.6 YM 3325 YR 0.00899
IO 1.001 LS 6.0 CP 8.0
…
HINGE IGNORE MEMBER 16
HINGE TYPE 1 MEMBER 1 3 17
HINGE FEMA MEMBER 2 4 to 15 18 to 20
…
END PUSHOVER DATA
```

TR.37.7.6 Define Spectral Parameters

The parameters of this section are used to construct the response spectrum according to FEMA 356:2000.

General Format

```
SPECTRUM PARAMETERS
DAMPING f1  ( f2 f3 f4  )
SC f5
SS f6
S1 f7
```

f1 Percentage of critical damping for the 1st response spectrum (Default 5%)

f2 Optional percentage of critical damping for the 2nd response spectrum (Default is zero)

f3 Optional percentage of critical damping for the 3rd response spectrum (Default is zero)

f4 Optional percentage of critical damping for the 4th response spectrum (Default is zero)

f5 An integer corresponding to the site class as described in the following table. The default value is 4 (i.e., site class D):

Site Class	Value of f_5
A	1
B	2

Site Class	Value of f_5
C	3
D	4
E	5

f6 Spectral acceleration at short-period, S_S

f7 Spectral acceleration at one-second period, S_1

Related Links

- *G.17.4.2.1.7 Define Input for Demand Spectrum* (on page 2182)
- *M. To define pushover spectral data* (on page 883)

TR.37.7.7 End Pushover Data

All Pushover data are to be entered before this command.

General Format

```
END PUSHOVER DATA
```

Tip: This command is added automatically when the `DEFINE PUSHOVER DATA` command is added through the **Create New Definitions / Load Cases / Load Items** dialog in the graphical environment.

Related Links

- *M. To define general pushover data* (on page 881)

TR.37.7.8 Pushover Loading Input

Only two types of loading are accepted in pushover analysis.

Refer to TR.32 Loading Specifications (on page 2461) for additional information on primary load types.

Gravity Load

Syntax for gravity loading is as follows:

```
LOAD i1 LOADTYPE GRAVITY ( TITLE any_load_title  )
...
```

i1	gravity loading number

Push Load

Syntax for push loading (user-defined external incremental push loading pattern on the structure) is as follows:

```
LOAD i2 LOADTYPE PUSH  ( TITLE any_load_title  )
...
```

`i2` user-defined push loading number

Note: For user-defined incremental push load, the loading has to be applied only in global X or Z directions. Combinations of X and Z directions is not accepted. Also, the lateral load in either global X or Z directions is to be applied in form of joint loads.

Related Links

- *G.17.4.2.1.3 Define Lateral (Push) Loading* (on page 2179)
- *G.17.4.1.8 Lateral Load Distribution* (on page 2177)
- *M. To add a pushover loading* (on page 884)

TR.37.7.9 Validation of Commands other than Input Parameters

1. The `LOADTYPE` is required and must be either `GRAVITY` or `PUSH`. See "TR.37.7.8 Pushover Loading Input (on page 2653)"
2. There can be more than one gravity load case. STAAD internally combines all gravity load cases into one. Analysis uses this combined gravity loading only.
3. A mass vector for eigen solution is formed from this combined gravity loading. There is no need to provide mass modeling.
4. Only one push load case (either in the form of user defined external push load or generated by the program) is allowed. The direction of loading is either global X or global Z. Combination of these directions are not allowed. For user defined incremental push load pattern, only `JOINT LOAD`s in `FX` or `FZ` directions may be specified.

Limitations on Pushover Analysis Input

The following inputs are not allowed in Pushover Analysis:

- `PERFORM PUSHOVER ANALYSIS` cannot be repeated more than once.
- `PERFORM PUSHOVER ANALYSIS PRINT` is not accepted.
- `CHANGE` command is not accepted.
- `LOAD COMBINATION` command is not accepted.
- `SET Z UP` command is not accepted.
- `SET RESTART 1` command will not work (i.e., *<filename>* `.L17` file will not be created).
- `SURFACE` element is not accepted.
- Material concrete is not considered.
- Non-prismatic section is not considered.
- Curved beam is not considered.
- Cable member is not considered.
- Plate and solid elements is not considered.
- Beta angle other than 0 and 90 degree is not accepted.

TR.37.8 Geometric Nonlinear Analysis

Note: This requires a STAAD.Pro Advanced license.

General Format

```
PERFORM NONLINEAR ANALYSIS (ARC f1) (ITERATION i1) (TOLERANCE f2) (STEPS i2) (REBUILD
i3) (KG (i4)) (JOINT_TARGET  i5 (i6) DISPL_TARGET f3) (PRINT print-specs)
```

The first analysis step must be stable, otherwise use ARC control to prevent instability. The procedure does not use follower loads. Loads are evaluated at the joints before the first step; then those loads translate with the joint but do not rotate with the joint. Equilibrium is computed in the displaced position.

The following table describes the parameters available for nonlinear analysis:

Table 282: Geometric Nonlinear Analysis parameters

Parameter	Value	Default Value	Description
ARC	f_1	0.0	Displacement control. Value is the absolute displacement limit for the first analysis step. If max. displacement is greater than this limit, ARC will calculate a new step size for the first step and a new value for STEPS. Value should be in current length units. ARC = 0 indicates no displacement control.
ITERATION	i_1	100	Max. Number of iterations to achieve equilibrium in the deformed position to the tolerance specified.
TOLERANCE	f_2	0.0001 inch	For convergence, two successive iteration results must have all displacements the same within this tolerance. Value entered is in current units.
STEPS	i_2	1	Number of load steps. Load is applied in stages if entered. One means that all of the load is applied in the first step.
REBUILD	i_3	1	Frequency of rebuilds of the tangent K matrix per load step & iteration.
KG	i_4	0	This parameter controls whether the geometric stiffness, KG, is added to the stiffness matrix, K. • `KG` or `KG 1` Use K+KG for the stiffness matrix. (Default) • `KG 0` (or KG omitted) Do not use KG.
JOINT_TARGET	i_5	none	Joint being monitored in a displacement target analysis.

Parameter	Value	Default Value	Description
	i_6	1	Global degree of freedom (1 through 6): **1.** Global X **2.** Global Y **3.** Global Z **4.** Moment about Global X **5.** Moment about Global Y **6.** Moment about Global Z
DISPL_TARGET	f_3	none	Displacement target value in current length units.
print-spec		none	Standard STAAD analysis print options. See TR.37.1 Linear Elastic Analysis (on page 2620) for details.

If a target displacement is used, then *both* the `JOINT_TARGET` and `DISPL_TARGET` must be defined. If the degree of freedom is not specified, then the Global X direction is assumed.

If Joint target and Displacement target are entered and the `STEPS` parameter is greater than two; then the analysis will proceed step by step until the targeted joint degree of freedom has displaced `DISPL_TARGET` length units or more.

Nonlinear entities such as tension/compression members, multilinear springs, gaps, etc. are not supported when using a nonlinear analysis. Additionally, nonlinear analysis does not account for post-buckling stiffness of members.

Caution: The deprecated `NONLINEAR n ANALYSIS` command will adopt the new procedure (unless a `SET NONLINEAR OLD` command is entered before the joint coordinates to invoke the old procedure for backward compatibility). This uses *n* iterations. It is strongly recommended to use the new procedure.

Note: Due to the mechanisms used to include control/dependent systems, if the reactions on control nodes are not included in a statics check then an out of balance report may result. This can be avoided by adding a short stiff member from a control node to the support.

Temperature loads are *not* supported for geometric nonlinear analysis.

Example

```
PERFORM NONLINEAR ANALYSIS ARC 0.01 ITER 200 STEPS 100 TOL 0.00001 -
REBUILD 1 KG joint 11 2 DISPL_TARGET 0.5
```

TR.37.9 Imperfection Analysis

This performs a modified linear elastic analysis using Member Imperfection Specifications (See TR.26.6 Member Imperfection Information (on page 2313)) defined on beam and column members.

An Imperfection analysis will reflect the secondary effects only if the camber and/or drift is specified in a `DEFINE IMPERFECTIONS` specification (TR.26.6 Member Imperfection Information (on page 2313)). For combination of load cases, with imperfection, use the Repeat Load specification rather than the Load Combination.

General Format

```
PERFORM IMPERFECTION ANALYSIS (PRINT { LOAD DATA | STATICS CHECK | STATICS LOAD | BOTH
| ALL } )
```

See TR.37.1 Linear Elastic Analysis (on page 2620) for details.

Without one of these analysis commands, no analysis will be performed. These `ANALYSIS` commands can be repeated if multiple analyses are needed at different phases.

Note: Due to the mechanisms used to include control/dependent systems, if the reactions on control nodes are not included in a statics check then an out of balance report may result. This can be avoided by adding a short stiff member from a control node to the support.

TR.37.10 Floor Spectrum Command

This command is used to specify the calculation of floor spectra from time history acceleration results. The Floor Response Spectrum command must immediately follow an analysis command associated with the time history load case. The acceleration used may be either the absolute acceleration or the relative to ground acceleration.

Note: This data should only be entered if there is a time history case being solved.

Note: This requires a STAAD.Pro Advanced license.

General Format

First line of this Floor Spectrum Data.

```
GENERATE FLOOR SPECTRUM
```

Specify Floor Groups

Each new floor definition starts with the next command:

```
BEGIN  FLOOR  DIRECTION   { GX | GY | GZ }* {  TITLE  }
```

GX, GY, and GZ specify up to 3 global directions for which acceleration vs frequency spectra will be generated for this floor. Optionally enter a Title/Description (up to 50 characters) for this floor that will be displayed on the graphs in post processing.

The next one or more lines will identify the floors which will have spectrum curves generated either by referencing a NODE GROUP (see TR.16.1 Listing of Entities by Specifying Groups (on page 2235)) or explicitly listing the joints that constitute the floor. For multiple groups, enter each on a separate line.

```
{ _jointgroup | jointlist }
```

Enter as many lines as necessary to specify all of the groups needed to define this floor.

If more floors are to be defined, then repeat the `BEGIN FLOOR DIRECTION` command followed by the *_jointgroup_* name data. Enter as many floors as desired.

After the last floor definition, enter the following parameters that will be used in all of the Floor Spectrum calculations.

```
OPTIONS ( { FLOW f1 | FHIGH f2 | FDELTA f3 | DAMP f4 (… fn)| RELATIVE } ) print-options
```

This command may be continued to the next line by ending the line with a hyphen.

Where:

FLOW *f1*	Lowest frequency to be in the calculated spectrum. The value for FLOW should be at least 0.01 Hz.
FHIGH *f2*	Highest frequency to be in the calculated spectrum.
FDELTA *f3*	The spectrum will be calculated at *f3* intervals from the `FLOW` value (*f1*) to `FHIGH` (*f2*).
DAMP *f4* ... *fn*	Up to 10 damping values may be entered. One spectrum will be generated for each damping value for each global direction requested for each floor defined. The spectrum will be based on these modal damping ratios.
RELATIVE	If there is ground motion defined and you want the spectra to be based on the relative acceleration of the floor to the ground acceleration, then enter the relative parameter. Default is absolute.

The *print-options* are:

THPRINT *i1*	Option to print the time history acceleration being used in each spectrum calculation. 0 - No print 2 - Print the time history accelerations.
SPRINT	Include this parameter to print the calculated spectrum.

Tip: Omitting these options is recommended for most analysis runs.

Last line of the floor spectrum data:

```
END FLOOR SPECTRUM
```

Example 1

This partial input utilizes direct input data from a forcing function.

TR.38 Change Specification

This command is used to reset the stiffness matrix. Typically, this command is used when multiple analyses are required in the same run.

General Format

```
CHANGE
```

This command indicates that input, which will change the stiffness matrix, will follow. This command should only be used when an analysis has already been performed. The `CHANGE` command does or requires the following:

- sets the stiffness matrix to zero
- makes members active if they had been made inactive by a previous `INACTIVE` command
- allows the re-specification of the supports with another `SUPPORT` command that causes the old supports to be ignored. The `SUPPORT` specification must be such that the number of joint directions that are free to move (DOF or "releases") before the `CHANGE` must be *greater than or equal to* the number of "releases" after the `CHANGE`.
- the supports must be specified in the same order before and after the `CHANGE` command. To accomplish this when some cases have more supports than others do, you can enter unrestrained joints into the `SUPPORT` command list using `FIXED BUT FX FY FZ MX MY MZ`. It is best to put every joint that will be supported in any case into every `SUPPORT` list.
- `CHANGE`, if used, should be after `PERFORM ANALYSIS` and *before* the next set of `SUPPORT` or `LOADS`.
- Only active cases are solved after the `CHANGE` command.
- Analysis and `CHANGE` are required between primary cases for `PERFORM CABLE ANALYSIS`.
- Analysis and `CHANGE` are required after UBC cases if the case is subsequently referred to in a Repeat Load command or if the UBC case will be re-solved after a Select command or after a Multiple analysis.

Example

Before `CHANGE` is specified:

```
1 PINNED
2 FIXED BUT FX MY MZ
3 FIXED BUT FX MX MY MZ
```

After `CHANGE`is specified:

```
1 PINNED
2 FIXED
3 FIXED BUT FX MZ
```

The `CHANGE` command is not necessary when only member properties are revised to perform a new analysis. This is typically the case in which the user has asked for a member selection and then uses the PERFORM ANALYSIS command to reanalyze the structure based on the new member properties.

Notes

a. If new load cases are specified after the CHANGE command such as in a structure where the INACTIVE MEMBER command is used, the user needs to define the total number of primary load cases using the SET NL option (see TR.5 Set Command Specification (on page 2206) and Example 4).

b. Multiple Analyses using the CHANGE command should not be performed if the input file contains load cases involving dynamic analysis or Moving Load Generation.

c. Section forces and moments, stress and other results for postprocessing will use the last entered data for supports and member properties regardless of what was used to compute the displacements, end forces and reactions. So beware of changing member properties and releases after a CHANGE command.

Related Links

- *G.19 Multiple Analyses* (on page 2194)
- *A. To add a change command* (on page 958)

TR.39 Load List Specification

This command allows specification of a set of active load cases. All load cases made active by this command remain active until a new load list is specified.

This command is used to activate the load cases listed in this command and, in a sense, deactivate all other load cases not listed in this command. In other words, the loads listed are used for printing output and in design for performing the specified calculations. When the `PERFORM ANALYSIS` command is used, the program internally uses all load cases, regardless of `LOAD LIST` command, except after a `CHANGE` command. In these two cases, the `LOAD LIST` command allows the program to perform analysis only on those loads in the list. If the `LOAD LIST` command is never used, the program will assume all load cases to be active.

General Format

```
LOAD LIST { load-list | ALL }
```

Example

```
LOAD LIST ALL
PRINT MEMBER FORCES
LOAD LIST 1 3
PRINT SUPPORT REACTIONS
CHECK CODE ALL
```

In this example, member forces will be printed for all load cases, whereas loading 1 and 3 will be used for printing support reactions and code-checking of all members.

Notes

a. The `LOAD LIST` command may be used for multiple analyses situations when an analysis needs to be performed with a selected set of load cases only. All load cases are automatically active before a first `CHANGE` command is used.

b. After a `CHANGE` command has been used anywhere in the data, it is good practice to specify the `LOAD LIST` command after an `ANALYSIS` command and before the next command; otherwise only the last case analyzed may be used in the design.

c. Do not enter this command within the loads data (from the first Load command in an analysis set to the associated Analysis command).

d. Additionally, load cases can also be short-listed using load envelopes. This may be needed when operations such as steel design need to distinguish between service load combinations and factored load combination cases.

Related Links

- *A. To create a load list* (on page 961)

TR.40 Load Envelope

Load Envelopes are a means for clustering a set of load cases under a single moniker (number). If one or more tasks have to be performed for a set of load cases, such as, serviceability checks under steel design for one set of load cases, strength checks under steel design for another set of cases, etc., this feature is convenient.

It is an alternative to the `LOAD LIST` command described in TR.39 Load List Specification (on page 2662).

General Format

Load envelopes are defined within a definition block. Each envelope can be assigned an optional type to specify the qualitative nature of the load or load combination cases in the envelope definition.

```
DEFINE ENVELOPE
load-list ENVELOPE i  ( TYPE { STRESS | SERVICEABILITY | COLUMN | CONNECTION |
 STRENGTH | TEMPORARY} )
...
END DEFINE ENVELOPE
```

Where:

i = the load envelope number.

Two of the load envelope types —`SERVICEABILITY` and `STRENGTH`— have specific meaning from the standpoint of steel design to certain codes. See Using Load Envelopes in Designing Steel Members for Strength and Serviceability (on page 2664). Other types are used for annotating the load envelope use in reports and post-processing.

A load case or combination may only be included in *one* load envelope. If a load case or combination is included in more than one load envelope, that case or combination will only be included in the last load envelope that includes it.

Example

The first line within the `DEFINE ENVELOPE` command means that load cases numbered 1 to 8 make up the `CONNECTION` type load envelope 1. Similarly load case 9 to 15 define the `SERVICEABILITY` type load envelope 2.

```
DEFINE ENVELOPE
1 TO 8 ENVELOPE 1 TYPE CONNECTION
9 TO 15 ENVELOPE 2 TYPE SERVICEABILITY
16 TO 28 ENVELOPE 4 TYPE STRESS
END DEFINE ENVELOPE
```

Load Lists for Envelopes

For operations and calculations which are going to be based on the load cases contained in the envelopes, the command

```
LOAD LIST ENVELOPE load-env-list
```

must be specified *prior* to those commands.

For example, to print out the support reactions corresponding to load envelope 1, the following commands should be provided in the input file

```
LOAD LIST ENV 1
PRINT SUPPORT REACTIONS
```

Using Load Envelopes in Designing Steel Members for Strength and Serviceability

Most design codes require two types of checks to be performed

a. deflection
b. strength (capacity)

In codes that are based on the strength design method —like the AISC 360-16 / 10 / 05, AISI 2016, IS 800 2007 / 1984, Canadian S16-14 / S16-09 / S16-01, NZS3404 1997, and Eurocode 3— deflection checks are normally required to be done on the serviceability load cases and strength checks on a different set of load cases which are the factored load cases.

Hence, it is necessary to convey to the program which load cases are to be considered for the deflection checks, and which ones for the strength related checks.

Using Load Envelopes, you can convey to the program this information using the type keywords `SERVICEABILITY` and `STRENGTH`. Additionally, prior to the design command, you must also specify the command `LOAD LIST ENV` *`load-env-list`* .

```
DEFINE ENVELOPE
101 TO 110 ENVELOPE 1 TYPE SERVICEABILITY
201 to 225 ENVELOPE 2 TYPE STRENGTH
END DEFINE ENVELOPE

LOAD LIST ENVELOPE 1 2

PARAMETER 1
CODE AISC UNIFIED
METHOD LRFD
FYLD 46 MEMB 27 37 67 TO 89
DFF 240 ALL
DJ1 …
DJ2 …
…
…
CHECK CODE ALL
```

Note that if only one type of check is required —say for example, strength only— then the separation of load cases into the different categories is not needed which means these envelopes do not have to be created. In that event, the simple `LOAD LIST` command described in TR.39 Load List Specification (on page 2662) will suffice instead of `LOAD LIST ENV` *`load-env-list`* .

- *G.18.1.3 Member Stresses at Specified Sections* (on page 2193)

TR.41 Section Specification

This command is used to specify sections along the length of frame member for which forces and moments are required.

This command specifies the sections, in terms of fractional member lengths, at which the forces and moments are considered for further processing.

General Format

```
SECTION f1( f2) ( f3) { MEMBER memb-list | (ALL) }
```

Where:

f1, f2 , f3 Section (in terms of the fraction of the member length) provided for the members. The maximum number of sections is three, and only values between 0.0 and 1.0 will be considered. In other words, no more than three intermediate sections are permissible per `SECTION` command.

Example

```
SECTION 0.17 0.48 0.72 MEMB 1 2
SECTION 0.25 0.75 MEMB 3 TO 7
SECTION 0.6 MEMB 8
```

In the above example, first, section locations of 0.17, 0.48, and 0.72 are set for members 1 and 2. In the next `SECTION` command, sections 0.25 and 0.75 are set for members 3 to 7. In the third `SECTION` command, member 8 has its section specified at 0.6. The remainder of the members will have no sections provided for them. As mentioned earlier, no more than three intermediate sections are allowed per `SECTION` command. However, if more than three intermediate sections are desired, they can be examined by repeating the `SECTION` command after completing the required calculations. The following example will clarify.

Example

```
SECTION  0.2  0.4  0.5  ALL
PRINT  SECTION  FORCES
SECTION  0.6  0.75  0.9  ALL
PRINT  SECTION  FORCES
```

In this example, forces at three intermediate sections (namely 0.2, 0.4 and 0.5) are printed. Then forces at an additional 3 sections (namely 0.6, 0.75 and 0.9) are printed. This gives the user the ability to obtain section forces at more than three intermediate sections.

Notes

a. The `SECTION` command just specifies the sections. Use the `PRINT SECTION FORCES` command after this command to print out the forces and moments at the specified sections.
b. This is a secondary analysis command. The analysis must be performed before this command may be used.
c. To obtain values at member ends (`START` and `END`), use the `PRINT MEMBER FORCES` command.
d. If this command is specified before a steel design operation *and* if the `BEAM` parameter is set to zero, the section locations specified by this command will also be designed for, in addition to the `BEAM` ends. This can be used to specify three locations along the beam for design when the default sections are not sufficient. See D1.A.6 Design Parameters (on page 1100).

Print the deflected (sag) shape of a cable after an advanced cable analysis:

```
PRINT CABLE SAG
```

Description

The list of items is not applicable for `PRINT ANALYSIS RESULTS` and `PRINT MODE SHAPES` commands.

The `PRINT JOINT COORDINATES` command prints all interpreted coordinates of joints.

The `PRINT MEMBER INFORMATION` command prints all member information, including member length, member incidences, beta angles, whether or not a member is a truss member and the member release conditions at start and end of the member (1 = released, 0 = not released).

The `PRINT ELEMENT INFORMATION` command prints all incident joints, element thicknesses, and Poisson ratios for Plate/Shell elements. The `PRINT ELEMENT INFORMATION SOLID` command prints similar information for Solid elements.

The `PRINT MEMBER PROPERTIES` command prints all member properties including cross sectional area, moments of inertia, and section moduli in both axes. Units for the properties are always INCH or CM (depending on FPS or METRIC) regardless of the unit specified in UNIT command.

The following designation is used for member property names:

AX Cross section area

AY Area used to adjust shear/bending stiffness in local Y axis to account for pure shear in addition to the classical bending stiffness

AZ Area used to adjust shear/bending stiffness in local Z axis to account for pure shear in addition to the classical bending stiffness.

IZ Moment of Inertia about the local Z-axis

IY Moment of Inertia about the local Y-axis

IX Torsional constant

SY Smallest section modulus about the local Y-axis

SZ Smallest section modulus about the local Z-axis

The `PRINT MATERIAL PROPERTIES` command prints all material properties for the members, including E (modulus of elasticity), G (shear modulus), weight density and coefficient of thermal expansion (alpha) for frame members. This command is available for members only. G may be listed as zero if command is before load cases and Poisson ratio was entered but G was not entered.

The `PRINT SUPPORT INFORMATION` command prints all support information regarding their fixity, releases and spring constant values, if any. The `LIST` option is not available for this command.

The `PRINT ALL` command is equivalent to last five print commands combined. This command prints joint coordinates, member information, member properties, material properties and support information, in that order.

The `PRINT CG` command prints out the coordinates of the center of gravity and the total weight of the structure or of a single group of member/elements. If the CG of a portion of the structure is desired, the members and elements of that portion must be assigned using a group name (see TR.16 Entities as Single Objects (on page 2235) for details on using group-names). Only the selfweight of the structure is used to calculate the C.G. User defined joint loads, member loads etc. are not considered in the calculation of C.G.

The `PRINT (JOINT) DISPLACEMENTS` command prints joint displacements in a tabulated form. The displacements for all six directions will be printed for all specified load cases. The length unit for the displacements is always INCH or CM (depending on FPS or METRIC unit) regardless of the unit specified in `UNIT` command.

The `PRINT (MEMBER) FORCES` command prints member forces (i.e., Axial force (AXIAL), Shear force in local Y and Z axes (SHEAR-Y and SHEAR-Z), Torsional Moment (TORSION), Moments about local Y and Z axes (MOM-Y and MOM-Z)) in a tabulated form for the listed members, for all specified load cases. The `GLOBAL` option will output forces in the global coordinate system rather than the member local coordinate system for each member.

The `PRINT SUPPORT REACTIONS` command prints global support reactions in a tabulated form, by support, for all specified load cases. Use LIST option for selected joints.

The `PRINT ANALYSIS RESULTS` command is equivalent to the above three commands combined. With this command, the joint displacements, support reactions and member forces, in that order, are printed.

The `PRINT (MEMBER) SECTION FORCES` command prints axial force, shear forces, & bending moments at the intermediate sections specified with a previously input TR.41 Section Specification (on page 2665) The printing is done in a tabulated form for all specified cases for the first requested member, then for the next member, etc.

Note: An asterisk following a critical load case number within `PRINT JOINT DISPLACEMENT`, `PRINT MEMBER FORCES`, `PRINT SECTION FORCES`, `PRINT MEMBER STRESS`, or `PRINT SUPPORT REACTION` outputs indicates that this load case is a generated load combination. See TR.35 Load Combination Specification (on page 2616) for additional information.

The `PRINT (MEMBER) STRESSES` command tabulates member stresses at the start joint, end joint and all specified intermediate sections. These stresses include axial (i.e., axial force over the area), bending-y (i.e., moment-y over section modulus in local y-axis), bending-z (i.e., moment-z over section modulus in local z-axis), shear stresses in both local y and z directions (shear flow, q, over the shear area), and combined (absolute combination of axial, bending-y and bending-z) stresses.

- For `PRISMATIC` sections, if AY and/or AZ is not provided, the full cross-sectional area (AX) will be used.
- For `TAPERED` sections, the values of AY and AZ are those for the location where the stress is printed. Hence at the location 0.0, the AY and AZ are based on the dimensions of the member at the start node.

The `PRINT ELEMENT STRESSES` command must be used to print plate stresses (SX, SY, SXY, SQX, SQY), moments per unit width (MX, MY, MXY) and principal stresses (SMAX, SMIN, TMAX) for plate/shell elements. Typically, the stresses and moments per unit width at the centroid will be printed. The Von Mises stresses (VONT, VONB) as well as the angle (ANGLE) defining the orientation of the principal planes are also printed.

The variables that appear in the output are the following. Refer to G.5.1 Plate and Shell Elements (on page 2099) for more information regarding these variables.

SQX	Shear stress on the local X face in the Z direction
SQY	Shear stress on the local Y face in the Z direction
MX	Moment per unit width about the local X face
MY	Moment per unit width about the local Y face
MXY	Torsional Moment per unit width in the local X-Y plane
SX	Axial stress in the local X direction
SY	Axial stress in the local Y direction
SXY	Shear stress in the local XY plane
VONT	Von Mises stress on the top surface of the element
VONB	Von Mises stress on the bottom surface of the element
TrescaT	Tresca stress on the top surface of the element
TrescaB	Tresca stress on the bottom surface of the element
SMAX	Maximum in-plane Principal stress
SMIN	Minimum in-plane Principal stress
TMAX	Maximum in-plane Shear stress
ANGLE	Angle which determines direction of maximum principal stress with respect to local X axis

Note: If the `JOINT` option is used, forces and moments at the nodal points are also printed out in addition to the centroid of the element.

The `AT` option may be used to print element forces at any specified point within the element. The AT option must be accompanied by f_1 and f_2. f_1 and f_2 are local X and Y coordinates (in current units) of the point where the stresses and moments are required. For detailed description of the local coordinate system of the elements, refer to G.5 Finite Element Information (on page 2099).

The `PRINT ELEMENT FORCES` command enables printing of plate "corner forces" *[$Fp = Kp \bullet Dp$]* in global axis directions.

The `PRINT ELEMENT (JOINT) STRESS SOLID` command enables printing of stresses at the center of the SOLID elements. The variables that appear in the output are the following.

Normal Stresses	SXX, SYY and SZZ
Shear Stresses	SXY, SYZ and SZX
Principal Stresses	S1, S2 and S3.
Von Mises Stresses	SE
Direction cosines	Six direction cosines are printed following the expression DC, corresponding to the first two principal stress directions.

Note: The `JOINT` option will print out the stresses at the nodes of the solid elements.

The `PRINT MODE SHAPES` command prints the relative joint motions of each of the modes that were calculated. The maximum motion is arbitrary and has no significance. Dynamic analysis will scale and combine the mode shapes to achieve the final dynamic results.

Example

```
PERFORM ANALYSIS
PRINT ELEMENT JOINT STRESS
PRINT ELEMENT STRESS AT 0.5 0.5 LIST 1 TO 10
PRINT SUPPORT REACTIONS
PRINT JOINT DISPLACEMENTS LIST 1 TO 50
PRINT MEMBER FORCES LIST 101 TO 124
```

Example

Printing the Center of Gravity (CG)

```
PRINT CG
PRINT CG _RAFTERBEAMS
PRINT CG _RIDGEBEAMS
```

Notes

1. The output generated by these commands is based on the current unit system. The user may wish to verify the current unit system and change it if necessary.
2. Results may be printed for all joints/members/elements or based on a specified list.

Printing the Story Drift and Stiffness

The `PRINT STORY DRIFT` command may be used to obtain a print-out of the average lateral displacement of all joints at each horizontal level along the height of the structure.

The procedure used in STAAD.Pro for calculating story drift is independent of any code. For example, the story drift determination as explained in section 12.8.6 of the ASCE 7-05 code is *not* implemented in STAAD.Pro.

The method implemented in STAAD.Pro involves:

a. Find all the distinct Y coordinates in the model. Those are what STAAD.Pro calls as stories.
b. For each of those distinct stories, find all the nodes at that story elevation.
c. For each story, find the average displacement along the horizontal directions (X and Z) by adding up corresponding displacement for all the nodes at that story, and dividing by the number of nodes for that story. Thus, even if there is only a single node representing a story, a drift is calculated for that story too.

In STAAD.Pro if `PRINT STORY DRIFT` command is issued, the program prints the average of horizontal displacements of all the joints present at the particular floor level.

However, to check inter-story drift, the following commands needs to be issued after the `PERFORM ANALYSIS` command.

```
LOAD LIST i1
```

```
PRINT STORY DRIFT f3
```

Where:

i_1 = the primary load number for which inter-story drift check is required
f_3 = The allowable drift factor, as per the code provision

The program will calculate the relative horizontal displacement between two adjacent floors. This calculated value is checked against the allowable limit. The result is reported as either "PASS" or "FAIL" in the output.

Note:

There is only one exception to this format. For IS 1893: 2002 static seismic load case, even if this factor is not provided the program internally checks if the loading is IS 1893 static seismic loading or not. If yes, it automatically calculates the inter-story drift and checks against the code provisions.

For dynamic IS 1893: 2002 response spectrum analysis the above format for inter-story drift check does not hold true. The reason is that in response spectrum analysis the joint displacements represents the maximum magnitude of the response quantity that is likely to occur during seismic loading. Any response quantity like story drift should be calculated from actual displacements of each mode considered during analysis. The inter-story drift from each mode is combined using modal combination to get the maximum magnitude of this response quantity. In order to compute story drift for IS 1893 response spectrum the load case command format described in TR.32.10.1.7 Response Spectrum Specification per IS: 1893 (Part 1)-2002 (on page 2534) must be used..

The `PRINT STORY STIFFNESS` command may be used to include the calculated lateral stiffness of each story used in determining the drift. In STAAD.Pro lateral stiffness is calculated only when the floor is modeled as rigid floor diaphragm since it functions as transferring story shears and torsional moments to lateral force-resisting members during earthquake.

Printing the Center of Rigidity & Center of Mass

The `PRINT DIAPHRAGM CR` command may be used to obtain a print-out of the center of rigidity and center of mass at each rigid diaphragm in the model. The lateral force at each floor, as generated by earthquake and wind loading, acts at the center of rigidity of each floor which is modeled as rigid floor diaphragm. The center of mass of each floor is defined as the mean location of the mass system of each floor. The mass of the floor is assumed to be concentrated at this point when the floor is modeled as rigid diaphragm. The distance between these two is the lever arm for the natural torsion moment for seismic loads when that option is used.

TR.44 Printing Section Displacements for Members

This command is used to calculate and print displacements at sections (intermediate points) of frame members. This provides the user with deflection data between the joints.

General Format

```
PRINT SECTION (MAX) DISPLACEMENTS (NSECT i) (SAVE a) { NOPRINT | ALL | LIST memb-list }
```

Where:

i = number of sections to be taken. Defaults to 12 if NSECT is not used and also if SAVE is used (max=24, min=2).
a = File name where displacement values can be stored and used by the STAADPL graphics program. If the NOPRINT command is used in conjunction with the SAVE command, the program writes the data to file only and does not print them in the output.
This option is not necessary in STAAD.Pro.

Description

This command prints displacements at intermediate points between two joints of a member. These displacements are in global coordinate directions (see figure). If the MAX command is used, the program prints only the maximum local displacements among all load cases.

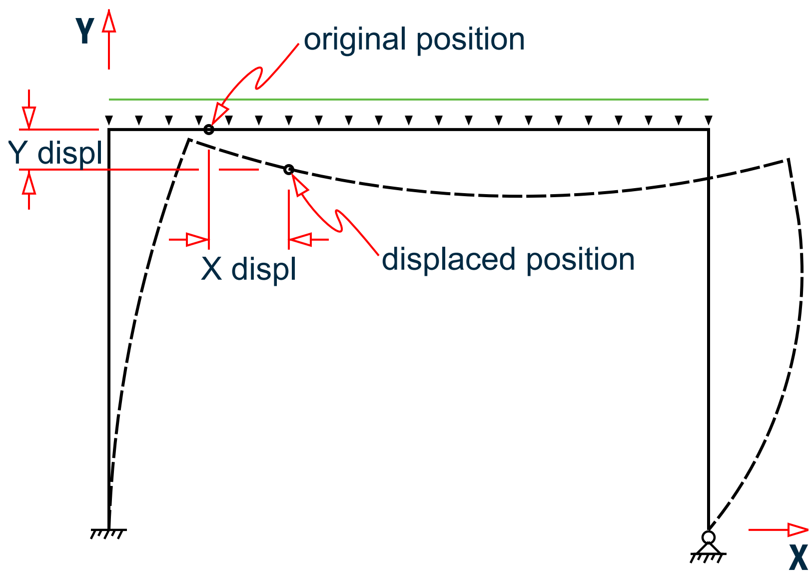

Figure 335: Displacements in the global coordinate directions

Example

```
PRINT SECTION DISPL SAVE
PRINT SECTION MAX DISP
```

`SECTION DISPLACEMENTS` are measured in `GLOBAL COORDINATES`. The values are measured from the original (undeflected) position to the deflected position. See figure above.

The maximum local displacement is also printed. First, the location is determined and then the value is measured from this location to the line joining start and end joints of the deflected member.

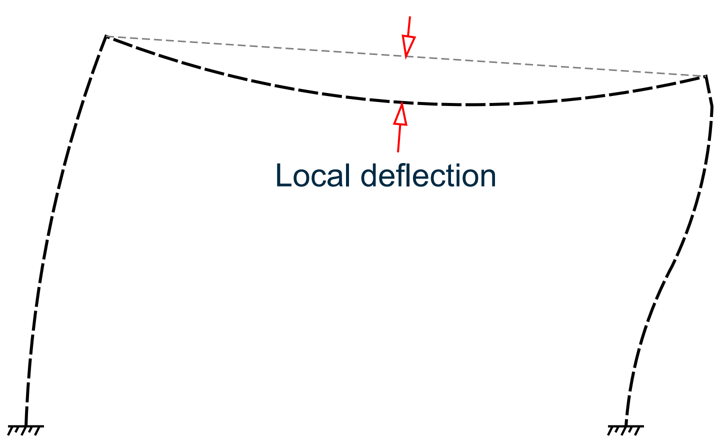

Figure 336: Local deflection

Notes

a. The section displacement values are available in Global Coordinates. The undeflected position is used as the datum for calculating the deflections.
b. This is a secondary analysis command. An analysis must be performed before this command may be used.

TR.45 Printing the Force Envelope

This command is used to calculate and print force/moment envelopes for frame members. This command is not available for finite elements.

General Format

```
PRINT { FORCE | MAXFORCE } ENVELOPE (NSECTION i) list-spec
```

```
list-spec = { LIST memb-list | (ALL) }
```

Description

Where:

NSECTION *i*	the number of equally spaced sections to be considered in printing maximum and minimum force envelopes. i is an integer up to 96, though not recommended to be less than 12. If the NSECTION i command is omitted, i defaults to 12.

MAXFORCE command produces maximum/minimum force values only of all sections, whereas the FORCE command prints maximum/minimum force values at every section as well as the max/min force values of all sections. The force components include FY, MZ, FZ, and MY. The SECTION command (as described in TR.40 Load Envelope (on page 2663)) does not define the number of sections for force envelopes. For the sign convention of force values, refer to G.18 Member End Forces (on page 2187)

Note: This is a secondary analysis command and should be used after analysis specification.

Example

```
PRINT FORCE ENV
PRINT MAXF ENV NSE 24
PRINT FORCE ENV NSE 24 LIST 3 TO 15
```

TR.47 Size Specification

This feature has been deprecated.

TR.48 Steel and Aluminum Design Specifications

This section describes the specifications necessary for structural steel & aluminum design.

The specific details of the implementation of these codes may be found in:

- D. Available Steel Design Codes (on page 969)
- D. Available Aluminum Design Codes (on page 1081)

Additional related information:

- TR.48.1 Parameter Specifications (on page 2676) discusses specification of the parameters that may be used to control the design.
- TR.49 Code Checking Specification (on page 2677) and TR.49.1 Member Selection Specification (on page 2678) describe the `CODE CHECKING` and `MEMBER SELECTION` options respectively.
- TR.49.2 Member Selection by Optimization (on page 2679) discusses member selection by optimization.

Shortlisting Load Cases Used for Design

There are two options available to instruct STAAD.Pro to use only specific load cases for design:

1. The `LOAD LIST` command.
2. The `LOAD LIST ENVELOPE` command, which can only be used if load envelopes have been created (using the `DEFINE ENVELOPE` command). Once envelopes have been created, this command must be used or the design will be based on all active load cases or those specified in a `LOAD LIST` command, rather than only the envelopes.

TR.48.1 Parameter Specifications

This set of commands may be used to specify the parameters required for steel and aluminum design.

Each design code supported by STAAD.Pro has an associated list of control parameters that allow the attributes associated with the members to be defined. The default values for the parameters associated with a design code are documented in the section associated with that code. Refer to D. Available Steel Design Codes (on page 969) for the list of available steel design codes. The section for each design code contains a titled "Design Parameters" which documents the available parameters and the default values that will be used unless alternatives are specified.

Parameters are defined in a collection that is initiated with the command PARAMETER and followed by a design code. This collection of parameters is referred to as a "parameter block."

Note: The code specified in the parameter block will determine the design code that will be used in any subsequent design command (e.g., CHECK CODE or SELECT).

General Format

```
PARAMETER (i)
```

```
CODE design-code
```

```
parameter-name f1  { MEMBER memb-list  | member-group-name  | ALL| PMEMBER psychical-member-list }
```

where:

PARAMETER (*i*)	Optional value used to identify the parameter block.
CODE *design-code*	The CODE parameter is used to specify the steel or aluminum design code and code edition to be checked for design. The default code is AISC ASD. Refer to D. Available Steel Design Codes (on page 969) and D. Available Aluminum Design Codes (on page 1081) for the lists of available steel and aluminum design codes, respectively.
***parameter-name* f1**	refers to the Parameter Names listed in the parameter table contained in the Steel Design and Aluminum Design sections. f1 refers to the value of the parameter. The details of the parameters available for specific codes may be found in D. Design Codes (on page 1086). You can control the design through specification of proper parameters.
MEMBER *memb-list*	a list of member numbers that the parameter value applies to. This can be a simple list of member numbers or can include a range defined by two numbers separated by the keyword TO.
member-group-name	Refer to TR.16 Entities as Single Objects (on page 2235) for the definition of member group names.
ALL	Indicates that the assigned value of the given parameter is assigned to all the members in the model.

PMEMBER ***psychical-member-list***	This is used only with parameters associated with a physical member and lists the physical members to which the parameter value applies.

Example

```
PARAMETERS
CODE AISC
KY 1.5 MEMB 3 7 TO 11
NSF 0.75 ALL
RATIO 0.9 ALL
```

Notes

- All unit-sensitive values should be the current input unit system.
- For default values of parameters, refer to the appropriate parameter table.
- Where a parameter is assigned to a member multiple times, the *last* value given before a design command is used.

Related Links

TR.49 Code Checking Specification

Used to perform the `CODE CHECKING` operation for steel and aluminum members.

This command checks the specified members against the specification of the desired code. Refer to D. Steel Design (on page 969) for detailed information.

General Format

```
CHECK CODE { MEMBER memb-list | ALL | member-group-name  | deck-name | PMEMB pmember-list }
```

Example

```
CHECK CODE MEMB 22 TO 35
CHECK CODE PMEMB 1 3
CHECK CODE MEMB _BEAMS
CHECK CODE ALL
CHECK CODE PMEMB ALL
```

Notes

a. The output of this command may be controlled using the TRACK parameter. Various codes support various levels of details. Refer to the appropriate section of the documentation, as explained in the table in TR.48.1 Parameter Specifications (on page 2676) for more information on the TRACK parameter.

b. Member group names and deck names are explained in TR.16 Entities as Single Objects (on page 2235) and TR.20.7 Composite Decks (on page 2270) respectively.

c. The PMEMB list is explained in TR.16.2 Physical Members (on page 2238).

Related Links

- *D. To specify steel design commands* (on page 977)

- *D1.B.1.3 Code Checking* (on page 1141)
- *D1.C.7 Code Checking and Member Selection* (on page 1171)

TR.49.1 Member Selection Specification

This command may be used to perform the MEMBER SELECTION operation.

This command instructs STAAD.Pro to select specified members based on the parameter value restrictions and specified code. The selection is done using the results from the most recent analysis and iterating on sections until a least weight size is obtained. Refer to D. Steel Design (on page 969) for more details.

The section selected will be of the same type section as originally designated for the member being designed. A wide flange will be selected to replace a wide flange, etc. Several parameters are available to guide this selection. If the PROFILE parameter is provided, the search for the lightest section is restricted to that profile. Up to three (3) profiles may be provided for any member with a section being selected from each one. Member selection can also be constrained by the parameters DMAX and DMIN which limit the maximum and minimum depth of the members. If the PROFILE parameter is provided for specified members, DMAX or DMIN parameters will be ignored by the program in selecting these members.

Member selection can be performed with all the types of steel sections listed in D1.A.4 Built-in Steel Section Library (on page 1088). Note that for beams with cover plates, the sizes of the cover plate are kept constant while the beam section is iterated.

Selection of members, whose properties are originally input from a user created table, will be limited to sections in that table.

Member selection *cannot* be performed on members whose section properties are input as prismatic.

General Format

```
SELECT { MEMBER memb-list | ALL | member-group-name  | deck-name | PMEMB pmember-list }
```

It is important that the keywords MEMBER, ALL, or PMEMB be provided. Thus, the keyword SELECT by itself is not sufficient.

Example

```
SELECT MEMB 22 TO 35
SELECT PMEMB 1 3
SELECT _COLUMNS
SELECT ALL
SELECT PMEMB ALL
```

Notes

a. The output of this command may be controlled using the TRACK parameter. Various codes support various levels of details. Refer to the appropriate section of the documentation, as explained in the table in TR.48.1 Parameter Specifications (on page 2676) for more information on the TRACK parameter.
b. Member selection can be done only after an analysis has been performed. Consequently, the command to perform the analysis has to be specified before the SELECT MEMBER command can be specified.
c. This command does not cause the program to re-analyze for results based on the selected member sizes. However, to maintain compatibility of analysis results with the final member sizes, you should enter a subsequent PERFORM ANALYSIS command. Otherwise the post processor will display the prior results with the revised member sizes.
d. Member group names and deck names are explained in TR.16 Entities as Single Objects (on page 2235) and TR.20.7 Composite Decks (on page 2270) respectively.
e. The PMEMB list is explained in TR.16.2 Physical Members (on page 2238).

Related Links

- *D. To specify aluminum design commands* (on page 1083)
- *D1.B.1.4 Member Selection* (on page 1142)
- *D1.B.1.3 Code Checking* (on page 1141)
- *D1.C.7 Code Checking and Member Selection* (on page 1171)

TR.49.2 Member Selection by Optimization

This command performs member selection using an optimization technique based on multiple analysis/design iterations.

The program selects all members based on an optimization technique. This method performs 2 analyses as well as iteration of sizes to reduce the overall structure weight. This command should be used with caution since it will require longer processing time.

The section selected will be of the same type section as originally designated for the member being designed. A wide flange will be selected to replace a wide flange, etc. Several parameters are available to guide this selection. If the PROFILE parameter is provided, the search for the lightest section is restricted to that profile. Up to three (3) profiles may be provided for any member with a section being selected from each one. Member selection can also be constrained by the parameters DMAX and DMIN which limit the maximum and minimum depth of the members. If the PROFILE parameter is provided for specified members, DMAX or DMIN parameters will be ignored by the program in selecting these members.

Member selection can be performed with all the types of steel sections listed in D1.A.4 Built-in Steel Section Library (on page 1088). Note that for beams with cover plates, the sizes of the cover plate are kept constant while the beam section is iterated.

Selection of members, whose properties are originally input from a user created table, will be limited to sections in that table.

Member selection *cannot* be performed on members whose section properties are input as prismatic.

General Format

```
SELECT OPTIMIZED
```

Notes

a. The output of this command may be controlled using the TRACK parameter. Various codes support various levels of details. Refer to the appropriate section of the documentation, as explained in the table in TR.48.1 Parameter Specifications (on page 2676) for more information on the TRACK parameter.

b. This command will perform one additional analysis and design cycle and therefore may be time consuming. Steps taken are: CHECK CODE ALL; then modify ratios; then SELECT ALL; then PERFORM ANALYSIS; then SELECT ALL. See TR.50 Group Specification (on page 2680) for other options used with this command. You may want to repeat this command for further optimization.

c. This command does not cause the program to re-analyze for results based on the selected member sizes. However, to maintain compatibility of analysis results with the final member sizes, you should enter a subsequent PERFORM ANALYSIS command. Otherwise the post processor will display the prior results with the revised member sizes.

- *D1.C.7 Code Checking and Member Selection* (on page 1171)

TR.50 Group Specification

This command may be used to group members together for analysis and steel design.

General Format

```
(FIXED GROUP)
```

```
GROUP (prop-spec) MEMBER memb-list (SAME AS i1)
```

```
prop-spec = { AX | SY | SZ }
```

Where:

SAME AS *i1* member number used in the `SAME AS` command. If provided, the program will group the members based on the properties of *i1*.

Description

This command enables the program to group specified members together for analysis based on their largest property specification.

When `FIXED GROUP` is omitted, the `GROUP` command is usually entered after the member selection command, and the selected members will be grouped immediately and the new member properties will be used in any further operations. After the grouping is completed, the `GROUP` commands are discarded and will not be used again. Further grouping will be done only if a new `GROUP` command is encountered later.

If the `FIXED GROUP` option precedes the group data, the specified grouping will be retained in memory by the program and will be used in subsequent `SELECT` commands. No grouping will occur unless a `SELECT` (MEMBER or ALL or OPTIMIZED) command is performed. However, grouping will be performed with every subsequent `SELECT` command.

Example 1

```
SELECT ALL
GROUP SZ MEMB 1 3 7 TO 12 15
GROUP MEMB 17 TO 23 27 SAME AS 30
```

In this example, the members 1, 3, 7 to 12, and 15 are assigned the same properties based on which of these members has the largest section modulus. Members 17 to 23 and 27 are assigned the same properties as member 30, regardless of whether member 30 has a smaller or larger cross-sectional area. AX is the default property upon which grouping is based.

Example 2

```
FIXED GROUP
GROUP MEMB 1 TO 5
SELECT OPTIMIZED
```

In the above example, the usage of the `FIXED GROUP` command is illustrated. In this example, the `SELECT OPTIMIZED` command involves the six stage process of

1. CHECK CODE ALL followed by modification of RATIO
2. SELECT ALL
3. GROUPING MEMBERS 1 TO 5
4. PERFORM ANALYSIS
5. SELECT ALL
6. GROUPING MEMBERS 1 TO 5

The `FIXED GROUP` command (and the `GROUP` commands that follow it) is required for execution of steps 3 and 6 in the cycle. You may want to repeat this data for further optimization.

Notes

The `FIXED GROUP` + `GROUP` commands are typically entered before the member selection for further analysis and design. This facility may be effectively utilized to develop a practically oriented design where several members need to be of the same size.

All the members in a list for a specific `GROUP` command should have the same cross section type. Thus, if the command reads

```
GROUP MEMB 1 TO 10
```

and member 3 is a W shape and member 7 is a Channel, grouping will not be done. The 10 members must be either all W shapes or all channels.

Also, refer to Note 'C' in TR.49.1 Member Selection Specification (on page 2678).

- *D. To design steel members in groups* (on page 977)

TR.51 Steel and Aluminum Take Off Specification

This command may be used to obtain a summary of all steel sections and aluminum sections being used along with their lengths and weights (quantity estimates).

This command provides a listing of the different steel and aluminum table sections used in the members selected. For each section name, the total length and total weight of all members which have been assigned that section will be listed in a tabular form. This can be helpful in estimating steel and aluminum quantities.

General Format

```
{ STEEL | ALUMINUM } (MEMBER) TAKE (OFF) ( { LIST memb-list | LIST membergroupname |
ALL } )
```

If the `MEMBER` option is specified, the length and weight of each member and the section name it is assigned will be reported.

Example

```
STEEL TAKE OFF LIST 71 TO 85
ALUMINUM TAKE OFF LIST PLGNO3
```

TR.52.1 Timber Design Parameter Specifications

This set of commands may be used for specification of parameters for timber design.

General Format

```
PARAMETER
CODE design-code
parameter-name f1 { MEMBER member-list | ALL }
```

Where:

parameter-name f1 = the name and corresponding value of the parameter.

Code	*design-code* Value	Parameters List
AITC 1994	AITC 1994 or AITC	D1.G.5 Design Parameters (on page 1254)
AITC 1984	AITC 1984 or TIMBER	D1.G.5 Design Parameters (on page 1254)
CAN/CSA -086-01	TIMBER CANADIAN	D4.D.6 Design Parameters (on page 1444)
EC 5: Part 1-1	TIMBER EC5	D5.E.3 Design Parameters (on page 1589)

Note: All values must be provided in the current unit system.

TR.52.2 Code Checking Specification

This command performs code checking operation on specified members based on the American Institute of Timber Construction (AITC), Canadian Standards Agency (CSA), or Eurocode (EC5) codes.

The results of the code checking are summarized in a tabular format. Examples and detailed explanations of the tabular format are available in D1.G. American Codes - Timber Design per AITC Code (on page 1248).

General Format

```
CHECK CODE { MEMBER member-list | ALL }
```

Note: For the EC5 code, the output of this command may be controlled by the TRACK parameter.

Related Links

- *D1.G.6 Member Design Capabilities* (on page 1259)

TR.52.3 Member Selection Specification

This command performs member selection operation on specified members based on the American Institute of Timber Construction (AITC 1984) code.

This command may be used to perform member selection according to the AITC 1984 code. The selection is based on the results of the latest analysis and iterations are performed until the least weight member satisfying all the applicable code requirements is obtained. Parameters may be used to control the design and the results are available in a tabular format. Detailed explanations of the selection process and the output are available in D1.G. American Codes - Timber Design per AITC Code (on page 1248).

General Format

```
SELECT { MEMBER memb-list | ALL }
```

TR.53 Concrete Design Specifications

This section describes the specifications for concrete design for beams, columns and individual plate elements. The concrete design procedure implemented in STAAD consists of the following steps:

TR.53.1 Design Initiation

This command is used to initiate concrete design for beams, columns and individual plate elements.

This command initiates the concrete design specification. Without this command, none of the following concrete design commands will be recognized.

Note: This command must be present before any concrete design command is used.

General Format

```
START CONCRETE DESIGN
```

Related Links

- *D. To specify concrete design code and parameters* (on page 1069)

TR.53.2 Concrete Design-Parameter Specification

This set of commands may be used to specify parameters to control concrete design for beams, columns and individual plate elements.

General Format

```
CODE design-code
```

```
parameter-name f1 { MEMBER member-list | ALL }
```

Where:

design-code = the concrete design code name, which is described in the concrete chapters of the D. Design Codes (on page 1086).

parameter-name f1 = is the concrete design parameter and corresponding value. Wherever applicable, this value is input in the current units. The UNIT command is also accepted during any phase of concrete design.

parameter-name = refers to the concrete parameters described in D1.F.3 Design Parameters (on page 1201) for the ACI code and in various corresponding concrete chapters of the D. Design Codes (on page 1086) for all other codes.

Note: All values must be provided in the current unit system.

Related Links

- *D. To specify concrete design code and parameters* (on page 1069)
- *D1.F.3 Design Parameters* (on page 1201)

TR.53.3 Concrete Design Command

This command may be used to specify the type of design required. Members may be designed as BEAM, COLUMN or ELEMENT.

Members to be designed must be specified as BEAM, COLUMN, or ELEMENT. Members, once designed as a beam, cannot be redesigned as a column again, or vice versa.

General Format

```
DESIGN { BEAM | COLUMN | ELEMENT } { memb-list | (ALL) }
```

Notes

a. Only plate elements may be designed as ELEMENT.
b. Enter this command after the parameters needed for this command have been entered.
c. The DESIGN ELEMENT command designs individual plate elements using the procedure explained in D1.F.6 Slab Design (on page 1243) for the ACI code. For theoretical information on designing individual plate elements per other design codes, please refer to D. Design Codes (on page 1086).

Related Links

- *D. To specify concrete beam design command* (on page 1070)

TR.53.4 Concrete Take Off Command

This command may be used to obtain an estimate of the total volume of the concrete, reinforcement bars used and their respective weights.

This command can be issued to print the total volume of concrete and the bar numbers and their respective weight for the members designed.

Tip: This command may be used effectively for quick quantity estimates.

General Format

```
CONCRETE TAKE OFF
```

Sample Output

```
          **************  CONCRETE  TAKE OFF  **************
                (FOR BEAMS, COLUMNS AND PLATES DESIGNED ABOVE)
     NOTE: CONCRETE QUANTITY REPRESENTS VOLUME OF CONCRETE IN BEAMS, COLUMNS,
AND PLATES DESIGNED ABOVE.
           REINFORCING STEEL QUANTITY REPRESENTS REINFORCING STEEL IN BEAMS
AND COLUMNS DESIGNED ABOVE.
           REINFORCING STEEL IN PLATES IS NOT INCLUDED IN THE REPORTED
QUANTITY.

          TOTAL VOLUME OF CONCRETE =         4.4 CU. YARD

           BAR SIZE         WEIGHT
            NUMBER         (in lbs)
           --------        --------
               4               261
               5                87
               6                99
               8               161
               9               272
                       ------------
             *** TOTAL=        880
```

Related Links

- *D. To generate concrete take off* (on page 1071)

TR.53.5 Concrete Design Terminator

This command must be used to terminate the concrete design.

This command terminates the concrete design, after which normal STAAD commands resume.

Note: Without this command, further STAAD commands will not be recognized.

General Format

```
END CONCRETE DESIGN
```

Example

```
START CONCRETE DESIGN
CODE ACI
FYMAIN 40.0 ALL
FC 3.0 ALL
DESIGN BEAM 1 TO 4 7
DESIGN COLUMN 9 12 TO 16
DESIGN ELEMENT 20 TO 30
END
```

TR.54 Footing Design Specifications

This feature has been removed from batch mode design. Please contact the Technical Support department for further information.

Footing design may be performed using STAAD Foundation Advanced through the D. Foundation Design (on page 1078) in the graphical interface.

TR.55 Shear Wall Design

Note: Shearwall design has been deprecated in STAAD.Pro CONNECT Edition. The analysis and design engine will allow it but its use is not recommended.

TR.56 End Run Specification

This command must be used to terminate the STAAD run.

This command should be provided as the last input command. This terminates a STAAD run.

General Format

```
FINISH
```

Index of Commands

The following is an alphabetic list of all STAAD.Pro commands in the STAAD Command Reference.

A
Ribbon Control Reference

This section describes the tools found in the ribbon toolbars.

Note: The ribbon toolbar dynamically updates for the current workflow selection.

File tab

The **File** tab opens the STAAD.Pro Backstage view, which is used for file operations.

Info tab

Used to specify general information about the structure, including a job description, job number, persons responsible for creating, checking, and approving the structure, etc. This page also provides general information about the structure such as the total numbers of nodes, members, elements as well as the STAAD commands present in the structure file.

Job Information

Job Name	Type a short description of the job. This description appears in the reports.
Client	Type the client name, if any.
Job Number / Revision / Part / Reference	Type the job, part and reference numbers, if any.
Engineer / Checker / Approved	These items are used to track modifications in the structure file. The names and dates of the changes may be entered.
Last Review	Type the date of the last review provided by respective engineer, checker, or approver.

CONNECT Project Information	When your STAAD.Pro model has a CONNECTED Project associated with it, the CONNECTED Project is displayed here. Click **[...]** to open the **CONNECTED Project Information** dialog which contains CONNECTED Project details and can be used to change the associated CONNECTED Project.

File Information

This group contains several items for information only. These items include the Filename, Directory, Date / Time of first creation, and the **File size**.

Model Information

Displays the total numbers of nodes, beams, and plates present in the structure. The Highest # column shows the highest Node / Beam / Plate numbers in the structure. In case the structure has discontinuous Node/Member/ Element number, the Highest # value will be different from the Count value.

The **Commands in File** group shows the STAAD commands which have been used in the structure.

New tab

Used to create a new STAAD project. Options are available to start with an analytical model, a physical model, or in STAAD Building Planner.

The **Additional License** options are available here to allow you to select which license options you want to use before creating a file.

Open tab

Used to open an existing STAAD input file or Archive. You can also open STAAD projects from a ProjectWise data source.

Select the **Recent** tab to view recent files by type. Hover your mouse pointer over any file to display the file and CONNECT Project properties.

The **Additional License** options are available here to allow you to select which license options you want to use before opening a file.

Save / Save As tabs

Used to save changes to the current model or to save the current model as a different file.

Save

Click this entry to save any changes made to the current STAAD input file.

Save As

This tab allows you to enter a new **File Name** and **Location** to save the current input file as a different file. Click **Browse** to open a Windows open dialog to select a folder.

Click **Save** to save the new file.

Backup/Restore tab

Used to create a backup of your STAAD project or to restore a STAAD project to a previously created restore point.

Menu item	Description
Restore Model	Used to restore the open STAAD project to a previously created restore point. Select a restore point in the list and then click the **Restore file** tool that appears when hovering over the right-hand side of an entry.
Compare Models	Used to compare two STAAD project versions. When one restore point is selected, you can compare this input file with the current model state. Selecting to compare points (by holding the **<Ctrl>** key and clicking the restore point labels) can be used to compare any two points. Click Compare Models or Compare with Current Model and a window opens with the input files compared.
Create Restore Point	Used to create a restore point for your entire STAAD project. Type an optional Name and Description for the resotre point (a generated name will be created for the restore point if you don't). You can also select the option to **Include Analysis Data** to the restore point as well.

Related Links

- *I. To create a restore point* (on page 2065)
- *I. To restore a model from a backup* (on page 2066)
- *I. To compare backups* (on page 2066)

Print tab

Used to print input, output, and reports for the current STAAD project.

Tip: Press **<Ctrl+P>** to open this **File** menu tab.

Tool name	Description
Input Command File	Used to print the contents of the STAAD input file (file extension .std) from the STAAD Editor.
Output File	Used to print the contents of the STAAD output file (file extension .anl) from the STAAD Output Viewer.
Report	Used to print the report for the STAAD input file. **Note:** You can set up the report contents in the **Postprocessing** workflow.
Error Report	Print error file, if any.

Report tab

Used to configure, review, and export STAAD reports.

Tool name	Description
Setup	Opens the **Report Setup** dialog, which is used to specify the contents of the customized report.
Preview Report	Opens the **Report Print Preview** window, which is used to review your project report before creating a hard copy. **Note:** You can also preview the report in the **Report** page in the **Postprocessing** worfklow.
Export to Text File	Opens a **Save As** dialog, which is used to save the current report to a plain text file (`.txt` file extension).
Export to MS Word File	Opens a **Save As** dialog, which is used to save the current report to a Microsoft Office Word document (`.doc` file extension).

Report Setup dialog

Used to specify the contents of the customized report

Opens when either:

- the **Setup** tool is selected from the **Report** tab on the **File** ribbon tab, or
- **Setup Report** is clicked on the **Reports** page in the **Postprocessing** workflow

Items tab

The *Items* tab is used for specifying the items to be included in the report.

Available list Displays items that may be included in the report. The Available list is divided into the following categories using the drop-down list:

- **Input -** lists all input related data that may be included in a report.
- **Output -** lists all output related data that may be included in a report.
- **Pictures -** lists all the pictures included in the **Picture Album** tab.
- **Reports -** lists all reports that have been previously created and saved. Thus, reports may contain sub-reports.
- **Saved Views -** lists all of the named (i.e., saved) views from the **View Management** dialog
- **RAM Connection Summary Report -** lists the “RCNX Report” after steel Connection Design has been performed on one or more joints.
- **Earthquake Check Reports -** lists the reports for a Eurocode 8 response spectrum check after these have been performed in the Earthequake workflow.

Selected list Displays items that have been selected for the report. Items in the **Available** list may be mixed and matched in any order or category within the **Selected** list. When this dialog box opens, a default item, “Job Information” appears in the **Selected** list.

Click this button…	to…
>	Add the currently selected item or items in the **Available** list to the **Selected** list. **Tip:** Double-clicking an item in the **Available** list has the same effect.
>>	Add all items from the current drop-down list category to the **Selected** list.
<	Remove the currently selected item or items the **Selected** list from that list. **Tip:** Double-clicking an item in the **Selected** list has the same effect.
<<	Remove all items from the **Selected** list.

Tip: To select multiple items in a list, hold down the **<Ctrl>** key while selecting items.

Items in the **Selected** list can be rearranged in any desired order by selecting an item and then using the up or down arrow to the right of the **Selected** list.

Report Details Increments — Used to specify the number of segments into which a member would be broken up for printing section forces.

Load Cases tab

Used specify which load case for which results are to be included in the report.

The results can be grouped by node and beam numbers or by load case. Specify the method of *Grouping* using the radio buttons. Load cases are moved to and from the *Available* and *Selected* lists as described before under the *Items* tab.

Available list	Displays all avaialble load cases that may be included in the report which have not already been included.
Selected list	Displays load cases that have been selected for the report.
Grouping for Load Tables	Check the option to group load tables either **by Load Type** or **by Load Case**.
Grouping for Result Tables	Check the option to group results either **by Node/Beam** or **by Load Case**.

Modes tab

Used to select mode shape numbers for which the results will be included for dynamic analyses (modal calculation, response spectrum, time history, etc.).

Note: A successful dynamic analysis must first be performed for mode shapes to be made available.

Grouping — Select to group modal results either **by Node** number or **by Mode** number.

Available list Displays available modes in the mode.

Selected list Displays all modes in the model. All mode shapes will be added to the **Selected** list by default.

Ranges tab

Used to select the members and elements to be included in the report. By default, the report includes all members, elements, and nodes.

All Select this option to include all model entities in the report (default).

View Select this option to select a previously saved view in the drop-down list. Only model entities included in the selected view will be included in the report.

Group Select this option to select a previously defined group name in the drop-down list. Only model entities included in the selected group will be included in the report.

Property Select this option to select a property tag in the drop-down list. Only model entities included in the selected property will be included in the report.

Ranges Select this option to specify a range of **Nodes** (by node number) and/or **Beams/Plates/Solids** (by entity number). Separate individual entries in either list using a comma. Ranges of values can be represented using a dash (e.g., 5-10).

Steel Design tab

Used to format the steel design results included in the report when steel design detail output has been added to the report on the **Items** tab.

Check Results Options for results generated by the code check facility. Use the radio buttons to specify whether to include no results, all results, the results of the first check or the results of the final check.

Select Results Options for results generated by the member selection facility. Use the radio buttons to specify whether to include no results, all results, the results of the first select or the results of the final check.

Summary Only (Track 0) Set this option to include a brief design summary for a BS 5950 steel design. Otherwise, the specified level of details (`TRACK` command option) is used.

Print Failed checks Only Set this option to include only steel design results for members which have failed one or more checks. Otherwise, the specified level of details (`TRACK` command option) is used for both passing and failing members.

Font Opens an Font dialog, which is used to change the typeface parameters used for steel design results. The current font settings are displayed adjacent to this button.

Picture Album tab

Used to control the display of pictures of the structure that have been taken using the **Take Picture** tool.

Note: To include pictures in the report, they must be added in the **Selected** list on the **Items** tab. Pictures are available in the Pictures category.

Name	A list of all available pictures appears in the drop down list.
Delete Picture	Removes the currently selected picture from the picture album. **Caution:** This action cannot be undone.
Preview	radio buttons allow the selection of results generated by the code check facility. Use the radio buttons to specify whether to include no results, all results, the results of the first check or the results of the final check.
Caption	Type or edit the caption to be included with the drawing in the report. **Tip:** If the model has changed since the picture was taken, a note is appended to the caption letting you know that changes have been made.
Full Page	Set this option to specify values of Height and Width equal to the full size of the default paper size. The picture will then take up an entire page of the report.
Height / Width	Specify printed dimensions for the selected picture. The aspect ration of the picture will remain constant, so updating one dimension will update the other. Click **in/mm** beside either dimension to toggle between the two units of length.
Width	Opens an Font dialog, which is used to change the typeface parameters used for steel design results. The current font settings are displayed adjacent to this button.

Options tab

Used for setting various report display options.

Header	Set this option to include the header on each page of the report. This includes custom name and logo, sheet numbering, job information, file name, and file modification information.
Page Outline	Set this option to add a solid, black border around the extents of the page content.
Footer	Set this option to include a footer on each page of the report. The footer contains a print time stamp, program version information, and print run information.
Prefix / Suffix	Specify optional sheet number prefix or suffix content in the respective field. This is useful if the STAAD.Pro report is to be included in an appendix or some other format where a special numbering format is used.
No. pages from	Specify the initial page number used for the report. This is useful if you have other content to include in a larger report before the STAAD.Pro output.
Reverse page order	Set this option to reverse the order in which pages are sent to the printer. The contents of the report, including sheet number, are *not* affected by this option.
Grid	Set this option to include grid lines around and between table elements.
Start each table on a new page	Set this option to add a page break after each table, even when a table does not fill an entire page alone.

Font	Opens a Font dialog, which is used to select the type face properties for the **Column Heading** or **Table** contents. The current font face and size are displayed for each setting.

Name and Logo tab

Used to add the your company name and/or logo to the report. This tab contains a viewing area to preview how the company name and logo will appear on the report.

Note: The **Remove Bentley (B) logo from Report** must be set on the **Configure** dialog File Options tab to remove the Bentley logo from the report heading.

Preview area	To use a text header, simply type in the preview area. Use the **Font** and **Alignment** controls to edit the appearance of the text. To use a graphic logo, use the **File** and **Position** controls.
File	Opens a Windows file open dialog, which is used to select a Windows Bitmap image (file extension `.bmp`) to use graphic for inclusion in report headings.
Paste	Adds an image file from the Windows clipboard.
Delete	Removes the graphic file from the report header.
Position	Select the horizontal position in the company identification portion of the report header.
Font	Opens a Font dialog, which is used to select the type face properties for the logo. **Tip:** In order to prevent clipping of the text block, a 14 point font size is the largest size for two lines and a 9 point font size is the largest size for three lines.

Load / Save tab

Used to save the contents of the customized report and to load previously saved reports.

Report	Previously saved reports are available in the drop-down list. Select one to load the report details for editing, printing, or deletion.
Save As	Opens the **Save Report** dialog, which is used to provide a name for the current report settings. Click **OK** in this dialog to save the named report in the **Report** list.
Delete	Removes the selected report name in the **Report** list. **Caution:** This action cannot be undone.

OK	Saves any changes to the Report setup and closes the dialog.
Cancel	Closes the dialog with out saving any changes.
Print	Prints the report with the current settings.
Help	Opens the STAAD.Pro Help window.

ISM tab

Contains tools for working with Integrated Structural Modeling repositories.

Note: ISM has some limited functionality when working with analytical models. It is recommended to use the Physical Modeling workflow in order to exchange physical model data with an ISM repository through the STAAD.Pro Physical Modeler.

Menu item	Description
 **Create Repository**	Transfers the current model opened in STAAD.Pro and generates a new ISM Repository. This is the most common way in which an ISM Repository is initially created.
 **New from Repository**	Creates a new STAAD.Pro input file from an existing ISM Repository. This is used to transfer model data into other tools used for your workflow.
 **Update Repository**	Coordinates changes made to the model in the client application and coordinate some or all of those changes with an existing ISM Repository.
 **Update from Repository**	Updates the current STAAD.Pro input file with some or all of the changes which have been made to the ISM Repository.

Related Links

- *I. ISM Sync Tools Overview* (on page 2063)

Import/Export tab

Import

Used to import data from other formats. Opens a Windows Open dialog, which is used to select a file name and location for importing the selected file format.

DXF (*.dxf)	Used to import an Autodesk AutoCAD® 3D DXF file.
QSE ASA (*.asa)	Import an ASA format file.
CIS/2 (*.stp)	Options are provided for creating new models (from Start page only) or updating the current model (when a STAAD project is open) from a CIS/2 model.

Export

Used to export data to other formats, such as DXF, the CIMsteel STEP format, etc.

3D DXF (*.dxf)	Exports the entire model into a 3D DXF file.
2D DXF (*.dxf)	Exports a selected plane of the model into a 2D DXF file. This option opens the Export 2D DXF dialog. **Note:** The Export 2D DXF dialog is used to indicate the section of the model to use to generate a plan as well as the model objects to include in the drawing.
QSE ASA (*.asa)	Export to an ASA format file.
CIS/2 (*.stp)	Exports the entire model into an analysis model CIS/2 file through the **Cis2Link** dialog.

DXF Import dialog

Used to specify the vertical axis for data imported from a DXF file into a STAAD input file.

Opens when a DXF file is selected from the **Import** dialog.

Structure Convention	Select an option for defining the global vertical ("up") axis for the structure. • **No Change -** Use the vertical axis as defined in the 3D DXF file. • **Y Up -** Adds a `SET Y UP` command to the STAAD input file. • **Z Up -** Adds a `SET Z UP` command to the STAAD input file.
OK	Imports the selected DXF file contents into the current STAAD input file.
Cancel	Closes the dialog without importing any model information.
Help	Opens the STAAD.Pro help window.

Cloud Services tab

Contains tools for using Bentley Cloud Services.

Menu item	Description
Access CONNECTION Center Port	Opens the CONNECT Personal Portal in your web browser.
ProjectWise Projects	Opens the Project Portal for your ProjectWise Project.

Menu item	Description
Download Results	Click to download the cloud analysis results for the current project.

The **CONNECT Project Information** associated with the current model is displayed here. If the model is not associated with a ProjectWise project, then you can click **Associate Project** to do so (required for a Cloud Analysis). If you want to disassociate the current ProjectWise project, then click **Disassociate Project.**

Settings tab

Used to control some of the application settings.

Tool name	Description
 **Display Options**	Opens the **Options** dialog, which is used to change the length and force units for various values which can be displayed in the graphics window, such as member properties, material constants, load magnitudes, plate stresses, etc.
 **Set Structure Colors**	Opens the **Color Manager** dialog, which is used to set colors for highlight, entities, and results..
 **Structural Tooltip Options**	Opens the **Tool Tip Options** dialog, which is used to set tooltip options for structural elements.

Help tab

Contains links for getting additional assistance and information about STAAD.Pro.

Table 284: Help menu items

Tool name	Description
Contents	Opens the online help in your web browser.
OpenSTAAD Help	Opens the online help in your web browser to the OpenSTAAD reference section.
Technical Support	Opens the Worldwide Technical Support Resources dialog, which offers a map of worldwide technical support contacts for STAAD.Pro.

Tool name	Description
ReadMe	Opens the STAAD.Pro Read Me file in your web browser.
Knowledge Base and FAQs	Opens the STAAD.Pro Support Solutions page on Bentley Communities in your web browser.
Discussion Group	Opens the RAM | STAAD Forum on Bentley Communities in your web browser.
Tutorials	Opens the Bentley LEARNserver in your web browser. Here you can access training and learning paths for STAAD.Pro and other Bentley products.

Table 285: About menu items

Tool name	Description
About STAAD.Pro	Opens the About STAAD.Pro CONNECT Edtion dialog, which contains version, licensing, and legal information about the product. Any Technical Preview items contained in the current version will also be listed here.
Product News	Opens the STAAD.Pro product page at Bentley.com in your web browser.
Home Page	Opens the Bentley.com home page in your web browser.
Ideas	Provide feedback with any ideas you have to improve STAAD.Pro.

Geometry tab

Table 287: Clipboard group

Tool name	Description	Shortcut
Undo	Negates the last operation. **Note:** You cannot undo settings changes. After you undo an operation, the operation previous to the negated operation can be undone. You can, therefore, undo a series of previous operations by repeatedly choosing Undo. There is no limit to the number of undos that can be performed. **Note:** Only geometry, property, support and member/plate specification operations support Undo/Redo.	**<Ctrl+Z>**
Redo	Negates the last undo operation. You can redo a series of negated operations by repeatedly choosing Redo. Each undo operation is a single re-doable operation regardless of the number of negated operations.	**<Ctrl+Y>**
Delete	Used to delete selected object(s).	**<Del(ete)>**
Cut	Used to cut selected object(s) (delete and copy to clipboard). The deleted objects may then be pasted. The object(s) remain on the Clipboard until another Cut or Copy is performed.	**<Ctrl+X>**

Tool name	Description	Shortcut
 **Copy**	Used to copy selected object(s) to clipboard for subsequent pasting. The element(s) remain on the Clipboard until another Copy or Cut is performed.	**<Ctrl+C>**
 **Paste**	Opens the Paste with Move dialog (on page 2715), which is used to specify the insertion point for pasting clipboard elements into the model. Because the elements remain on the Clipboard after pasting, you can paste repeatedly.	**<Ctrl+V>**

Table 288: Structure group

<table>
<tr><th colspan="2">Tool name</th><th>Description</th></tr>
<tr><td rowspan="4">Grids ></td><td>Beam Grid</td><td>Opens the Snap Node/Beam dialog, which is used to specify the grid and snap settings as well as to create members and nodes automatically by snapping to grid points.</td></tr>
<tr><td>
Triangular Plate Grid</td><td rowspan="2">Opens the Snap Node/Plate dialog, which is used to specify the grid and snap settings as well as to create plates and nodes automatically by snapping to grid points.</td></tr>
<tr><td>
Quad Plate Grid</td></tr>
<tr><td>Solid Grid</td><td>Opens the Snap Node/Solid dialog, which is used to specify the grid and snap settings as well as to create solids and notes automatically by snapping to grid points.</td></tr>
</table>

Tool name	Description
 **Structure Wizard**	Opens the M. Structure Wizard (on page 695), which offers a library of pre-defined structure prototypes, such as Pratt Truss, Northlight Truss, Cylindrical Frame, etc. The **Structure Wizard** may parametrically generate a structural model, and then transfer and superimpose it on the current structure.
 **Translational Repeat**	Opens the **Translational Repeat** dialog, which is used to make copies of portions of the structure at intervals along a linear path.
 **Circular Repeat**	Opens the **3D Circular** dialog, which is used to make copies of portions of the structure at intervals along a circular path.
 **Rotate**	Opens the **Rotate** dialog, which is used to rotate the selected portions of the structure about the specified axis through a specified angle. The selected portions may be copied or moved.
 **Mirror**	Opens the **Mirror** dialog, which is used to copy or move the selected portions of the structure by “mirroring” about any plane parallel to one of the three global Cartesian coordinates.
 **Wall/Slab Connection**	Used to select a wall which will have a common boundary with a slab consisting of a previously generated finite element mesh. This tool allows the consideration of boundary conditions at the interface of the panel and any other panel on whose surface one of its edge lies.
 **Input Units**	Opens a drop-down list used to set the current input units for length and force. Click **Apply** to set the unit selection.

Table 289: Node group

Tool name		Description
 **Move Node >**	**Move Joint**	Opens the **Move Entities** dialog, which is used to specify the translational offset for moving a selection of nodes.
	Move Origin	Opens the **Move Origin** dialog, which is used to specify the translational offset for moving a the model origin. All model geometry is updated relative to the new origin location.
 **Merge Selected Nodes**		Opens the **Select Node** dialog, which is used to select a node number you want to keep in the model. Other selected nodes will be merged to this node number.
 **Renumber Nodes**		Opens the **Renumber** dialog, which is used to renumber selected nodes starting with a specified number. The numbering sequence can be in an ascending or descending order and the order can be sorted by some criteria if needed.

Table 290: Beam group

Tool name		Description
 **Add Beam >**	 **Add Beam**	Used to add beam by clicking start and end nodes.
	 **Add Beam Between Midpoints**	Used to add a new beam connecting the midpoints of two existing beams. New nodes will be created at the exiting beam midpoints.

Tool name	Description
 **Add Beam by Perpindicular Intersection**	Used to add a beam from an existing node perpendicular to an existing beam. A new node will be created on the existing beam.
 **Add Curve Beam**	Used to define curved members. The curve must be a segment of a circle and the internal angle subtended by the arc must be less than 180 degrees.
Create Colinear Beams	Used to create beams between selected nodes which lie along a straight path (i.e., colinear).
Set New Beam Attributes	Opens the **Define Member Attributes** dialog, which is used to predefine member attributes such as properties, materials, beta angles, or release specifications for member attribute sets. Members which are then added to the model will have these properties by default.
 **Beam Layout**	Opens the **Beams** table.
 **Insert Node**	Opens the **Insert Node into Beam #** dialog, which is used to insert one or more nodes at specified distances along selected members.
 **Stretch Members**	Opens the **Stretch Member(s)** dialog, which is used to increase the length of a member in various ways.

Tool name		Description
Connect Beams	**Connect Beams Along X | Y | Z axis**	Used for automatically creating beams connected between points which lie along an imaginary straight line parallel to the selected global axis. Members will only be created from selected nodes. The program will automatically detect which nodes are collinear and lie along the global axis selected. Beams will be generated along the nodes that satisfy those requirements. The following figure shows a group of nodes selected for this particular operation.
Move Beam		Opens the **Move Selected Beams** dialog, which is used to specify the translational offset for moving a selection of beams.
Intersect Beams >	**Highlight Intersect Beams**	Used to scan the model and locate members which cross each other in space, but are not necessarily connected to each other at the intersection point.
	Intersect Selected Beams	Splits members at detected intersection points and creates an addition node at this intersection point such that the members are now connected.
Merge Selected Beams		Opens the **Merge Selected Beams** dialog, which is used to join two collinear beams and replace them with one beam.
Renumber Beams		Opens the **Renumber** dialog, which is used to renumber selected beams starting with a specified number. The numbering sequence can be in an ascending or descending order and the order can be sorted by some criteria if needed.
Break Beams at Selected Nodes		Splits a beam into separate beams at any selected node(s) which are located along that beam. This is useful when some new nodes are created on the line of the member and you want to split the beams at these newly created nodes.

Table 291: Plate group

Tool name		Description
Add Plate >	 **Add Quad Plate**	Used to add Quadrilateral plates. To create new elements, simply click on the existing nodes in the right sequence. A rubber-banded area shows the boundary of the plate being generated.
	 **Add Triangle Plate**	Used to add triangular plates. To create new elements, simply click on the existing nodes in the right sequence. A rubber-banded area shows the boundary of the plate being generated.
	 **Create Infill Plates**	Used to automatically generate plates from a selection of beams bounding panels. Panels bounded by beams on all sides are filled with plates. Typically used for floor slabs, this method significantly reduces the modeling time for generation of floor slabs in multi-storied framed structures. If no closed polygon can be found of the enclosed shape is not planar, then an error message will be displayed. **Note:** Depending on the node order, some or several plates may be facing opposite directions. The **Plate Reference Point** dialog can be used to remedy this. This will orient all the plates in the same direction. Also, check for plates, whose boundary nodes do not align themselves with other connecting plates. The **Structure Tools** > **Check Beam/Plate Connectivity** on the **Utilities** ribbon tab can help identify these problems.
	Set New Plate Attributes	Opens the **Define Plate Object Property** dialog, which is used to define the property, material and releases to each new plate element as it is created.
 **Plate Layout**		Opens the **Plates** table.
 **Parametric Models**		Opens the **Parametric Models** dialog, which is used to create and edit wall, slab, and panel meshes.

Tool name		Description
Generate Mesh	 **Create Mesh**	Used to create a collection of plates by selecting node points and then defining mesh parameters.
	 **Plate Mesh**	Used to generate a finite element mesh for an existing plate element. The polygon can be meshed into quadrilateral or triangular elements. You have control over parameters like number of divisions along each side of the polygon. Polygonal holes can also be defined within the surface during the meshing process for polygonal meshing.
 **Move Plate**		Opens the **Move Selected Plates** dialog, which is used to specify the translational offset for moving a selection of plates.
 **Renumber Plates**		Opens the **Renumber** dialog, which is used to renumber selected plates starting with a specified number. The numbering sequence can be in an ascending or descending order and the order can be sorted by some criteria if needed.

</table>

Table 293: Physical Member group

Tool name	Description
 **Physical Member Layout**	Opens the **Physical Members** table.
 **Toggle Physical Member Mode**	Sets the analytical modeling mode to assign sections, properties, and design parameters to physical members.
 **Form Members**	Used to manually form a physical structural member from a selection of one or more connected analytical beam segments.
 **AutoForm Members**	Used to automatically generate multiple physical members from a group of selected analytical beams.

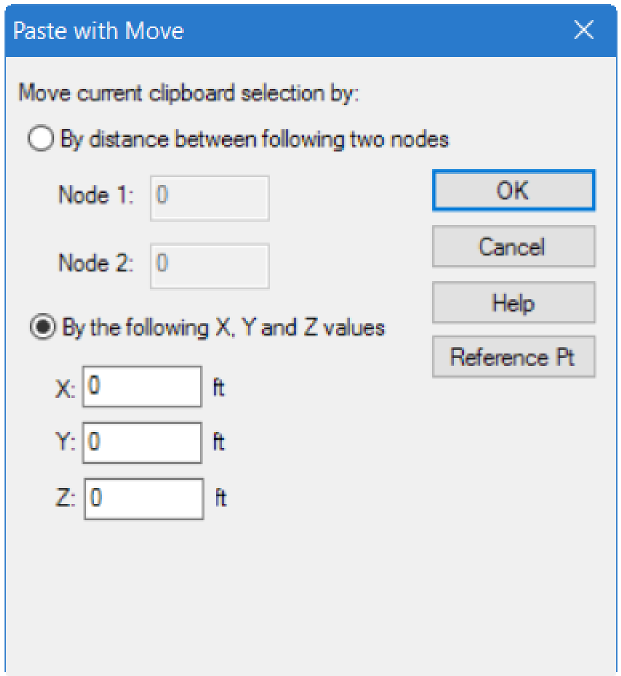
Table 294: Composite Deck group

Tool name	Description
 **Composite Deck Layout**	Opens the **Composite Deck** dialog, which is used to define and assign composite floor deck systems.

Paste with Move dialog

Used to specify the insertion point for pasting clipboard elements into the model.

Opens when the **Paste** tool is selected with one or more objects on the clipboard.

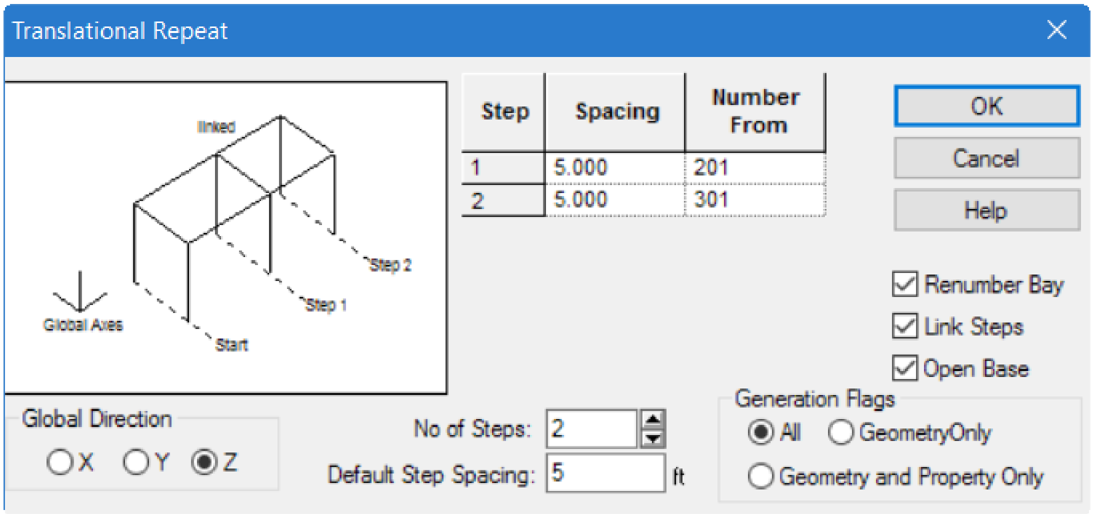


By distance between following two nodes	Specify two existing nodes. The vector distance between these two nodes will be used to insert a copy with respect to the original.
By the following X, Y, and Z values	Specify global axis distances to insert a copy to, with respect to the original.
OK	Accepts the paste settings and inserts a copy into the model.
Cancel	Closes the Paste with Move dialog without inserting a copy.
Help	Opens the Help window.
Reference Pt	Opens the Specify Reference Point dialog, which is used to select the insertion point which the paste command will be executed.

Translational Repeat dialog

Used to make copies of portions of the structure at intervals along a linear path

Opens when the **Repeat > Translational** tool is selected from the **Beam** group on the **Geometry** ribbon tab.



Global Direction — Choose any one of the three possible global directions along which the selected structural entities should be copied.

No of Steps — Specify the number of copies you want.

Default Step Spacing — Type the default spacing between steps (or copies) in the edit box in current length units. You can change the spacing between copies individually using the step table.

Step Spacing table — You can manually type the **Spacing** to each step as well as type the **Number From** to use when the **Renumber Bay** option is selected.

Renumber Bay — Instructs the program to use a user-specified starting number for the members generated in each step of the repeat.

Link Steps — Instructs the program to generate new members between each step in the direction of the repeat.

Open Base — This option instructs the program to *not* generate linking members at the base of the structure (i.e., the lowest nodes in the selection).

Generation Flags — Select the structural data that you want copied to the newly generated elements:

- **All** — Uses all properties assigned to the selected object (e.g., loads, properties, design parameters, member releases, etc.) are copied
- **Geometry Only** — Only geometry data is copied. That is, nodes, member and element incidences are generated but no properties, loads, etc. will be assigned to the new objects.
- **Geometry and Property Only** — Only geometry data and property assignments are copied. All other assignments (e.g., loads and design parameters) are not copied.

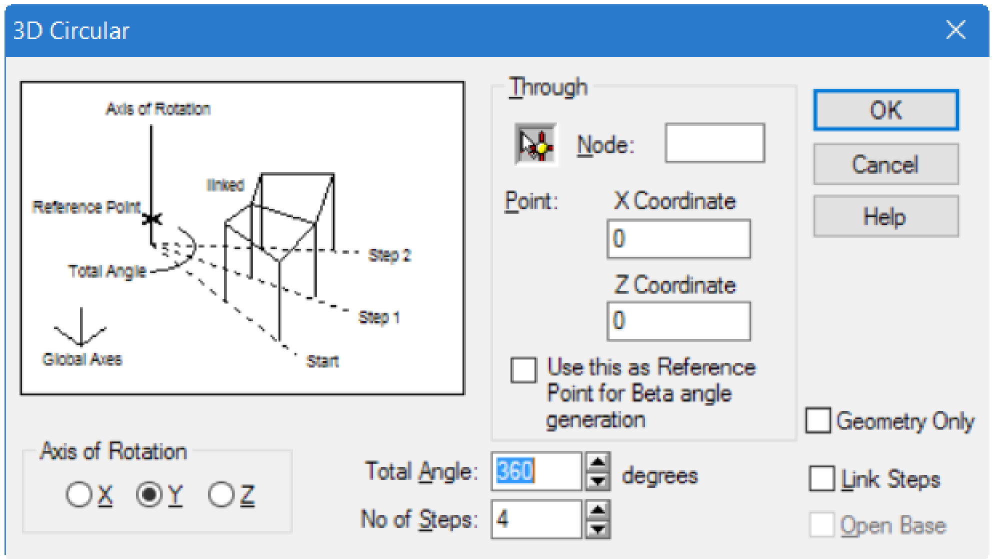
Related Links

- *M. To generate copies of geometry along a line* (on page 687)

3D Circular dialog

Used to make copies of portions of the structure at intervals along a circular path.

Opens when the **Repeat > Circular** tool is selected from the **Structure** group on the **Geometry** ribbon tab.



Axis of Rotation Select the global axis of rotation about which the selected components are repeated.

Through group

- **Node** The reference point through which the axis for circular repeat operation passes.

  Click the node selection tool and then click on a node in the view window to select a node in lieu of typing the node number.

- **Point** Type the X Coordinate and Y Coordinate of a an arbitrary reference point (i.e., when you want to use a axis of rotation that does not pass through an existing node).

- **Use this as Reference Point for Beta angle generation** The reference point used for the circular repeat will also be used as the reference point for the beta angle for each member. This allows you to orient all the members towards the central axis of rotation.

Total Angle Type he total sweep angle of rotation between the original structure and the last copied structure.

No of Steps Type the number of copies you want to generate over the specified angle.

Geometry Only Only geometry data is copied. That is, nodes, member and element incidences are generated but no properties, loads, etc. will be assigned to the new objects.

Link Steps Instructs the program to generate new members between each step in the direction of the repeat.

Open Base This option instructs the program to *not* generate linking members at the base of the structure (i.e., the lowest nodes in the selection).

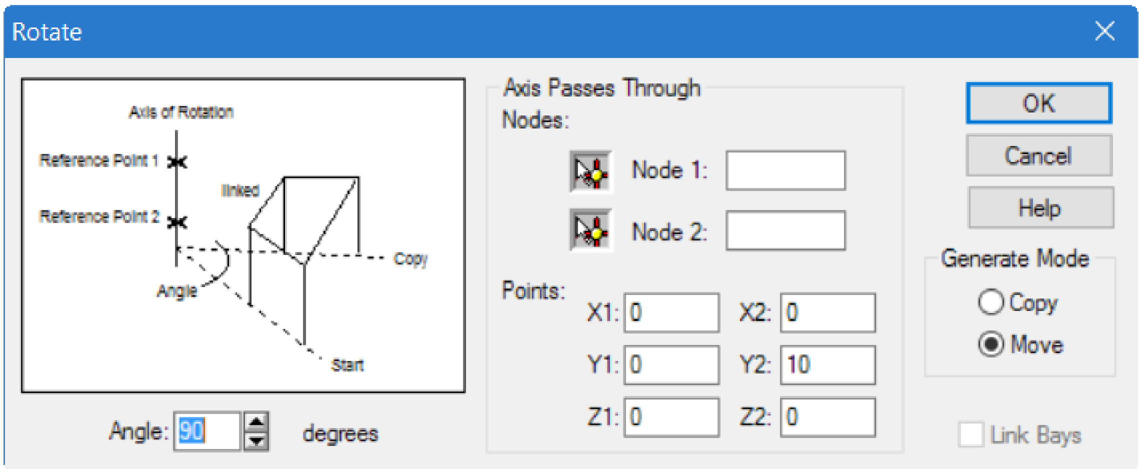
Related Links

- *M. To generate copies of geometry along an arc* (on page 688)

Rotate dialog

Used to rotate the selected portions of the structure about the specified axis through a specified distance. The selected portions may be copied or moved.

Opens when the **Rotate** tool is selected in the **Structure** group on the **Geometry** ribbon tab.



Note: Unlike the **Repeat** > **Circular** tool, the **Rotate** tool allows you to generate copies about any arbitrary axis instead of only one parallel to the global axes.

Angle	Type the angle of sweep.
Axis Passes Through	Define the axis of rotation by either a pair of existing nodes or two arbitrary points.
Generate Mode	The **Copy** option generates new structural elements. The **Move** option changes the coordinates of the selected structural elements.
Link Bays	(Available only for **Copy** option) This option connects the copy with the original geometry by creating new linking members between them.

Related Links

- *M. To rotate selected entities* (on page 687)

Snap Node-Beam dialog

Used to provide a construction grid which can then be used to easily draw beams, plates, or solid elements. Multiple grids may be created. Additionally, this dialog can be used to import a DXF file and use it as a template for a grid or import grid files created in another STAAD.Pro model.

Note: In STAAD.Pro 2007 (and later), grids are saved as separate files (with a `.grd`. file extension) for re-use in other models.

Opens when the **Grids** > **Snap Grid Beam** tool is selected in the **Structure** group on the **Geometry** ribbon tab.

Grid list	Lists all grid definitions in the current STAAD.Pro project.

The grid which is set to active has a check before its name. Only one grid may be active at a time.

Create Opens the **Grid Creation Method** pop-up dialog, which can be used to define either a Linear (on page 2721), Radial grid dialog (on page 2721), or Irregular grid dialog (on page 2722) grid pattern.

Edit When a grid definition is selected in the list, clicking this button opens the **Grid Creation Method** pop-up dialog for editing the definition.

Delete Delete a selected grid definition.

Copy Opens the **Provide Modified Grid Name** dialog, which is used to create a duplicate of the selected grid. Type the new grid name and Click **OK**. Click Cancel to close the dialog without creating a grid copy.

Rename Opens the **Provide Modified Grid** Name dialog, which is used to rename the selected grid. Type the new grid name and Click **OK**. Click Cancel to close the dialog without renaming the grid.

Import Opens the Import Options dialog, which is used to specify the imported grid file type. DXF files or STAAD.Pro Grid files (file extension `.grd`.) may be used.

- **DXF** — This option opens the DXF Import dialog (on page 2723), which is used to select elements from a `.DXF`. file for use as a construction grid in STAAD.Pro. Placement of an imported grid in the view window is controlled using the Imported Grid dialog (on page 2724) pattern.
- **STAAD Grid (.grd)** — Used to Import Grids previously defined in another STAAD.Pro model. Selecting this option opens a browse dialog box to identify a .GRD file created by the Snap Node Grid tool.

Active Grid Labels Setup Local Coordinate **-** this option allows us to view the grid line setting in the local coordinate mode. In this case, the construction grid lines intersecting the origin will be displayed as number zero construction lines and the other construction lines numbered accordingly irrespective of what was set in the global coordinate system.

Roaming grid labels help to identify the relative and exact gridline coordinates for the construction grid lines. This is an invaluable tool especially when the gridlines are skewed about a plane and the coordinates for the gridlines need to be displayed. These grid lines are used when adding nodes, beams, plates or solids by simply snapping on the intersection of gridlines.

Checking the **Rel Coords** box displays how far (either positive or negative) the grid line is from the origin. A “+” or “-” label will be drawn next to the gridline. By checking the **Axis Ids** box, the global axis id (X, Y or Z) which is parallel to the grid line being labeled will be drawn. The display font (size, color and type) can be changed through the **Font** button.

To display the actual coordinates for each grid lines in reference to the origin, choose which ends (Start, End or Both) of the grid line are to be labeled. Since the construction grid lines are only drawn in a plane, there will be a maximum of two directional gridline vectors that can be labeled (XY, XZ, or YZ). The frequency at which the grid labels are drawn can be controlled through the **Freq** spin button. If the frequency is set to 3, the grid labels will only be drawn at every third gridline. The coordinate values in the X, Y and Z directions can be displayed by pressing the appropriate coordinate labels next to the frequency spin button.

Snap to existing nodes too Select this option to select existing nodes for creating the members. If the mouse is clicked close to an existing node, the existing node is selected instead of creating a new node at that location.

Snap Node/ Beam Click to create members by snapping to grid and/or existing nodes. The button is depressed when this function is active. Click again to stop adding beams.

Related Links

- *M. To add a grid for drawing objects* (on page 653)

Linear

The *Linear* tab is meant for placing the construction lines perpendicular to one another along a “left to right - top to bottom” pattern, as in the lines of a chess board.

Related Links

- *M. To add a grid for drawing objects* (on page 653)

Radial grid dialog

Used to generate construction lines in transformed radial coordinates. This is used to create circular type models where members are modeled as piece-wise linear straight line segments.

Note: Though the parameters are entered in radial coordinate notation, the result coordinate values are in Cartesian coordinates. The grid is drawn with straight lines between points along an arc as well. Members drawn between two points on an arc will be straight line . Refer to the Curved Beam tool to add a beam with a radial curve.

Opens when Radial is selected as the type of new grid or an existing radial grid is edited in a Snap Node/<entity> dialog.

Name (Optional) Specify a name by which you can identify the grid in the Snap Node/<entity> dialog.

Plane Used when the grid is to be placed in a global plane. Select the global plane in which the gridlines will lie.

Angle of Plane Choose one of the three options (**X-X**, **Y-Y**, or **Z-Z**) and provide the angle of rotation (in degrees) of the grid plane about that axis.

Origin The (0,0) position on the grid in the grid coordinate system. Usually, the grid origin coincides with the structure origin.

Type in the location of the origin of gridlines in global coordinate system, in the current length units, or click the  tool to change the location of the grid origin by graphically selecting a existing node.

Construction Lines Start Angle, is the angle in degrees about the orthogonal axis to the plane from the axis first referred to in the definition of the plane. E.g. if the selected plane is X-Y, then the angle is measured about the Z axis (using the right hand rule) from the axis parallel to the X axis.

Sweep is the angle in degrees measured from the start angle which is divided into the selected number of Bays, thus

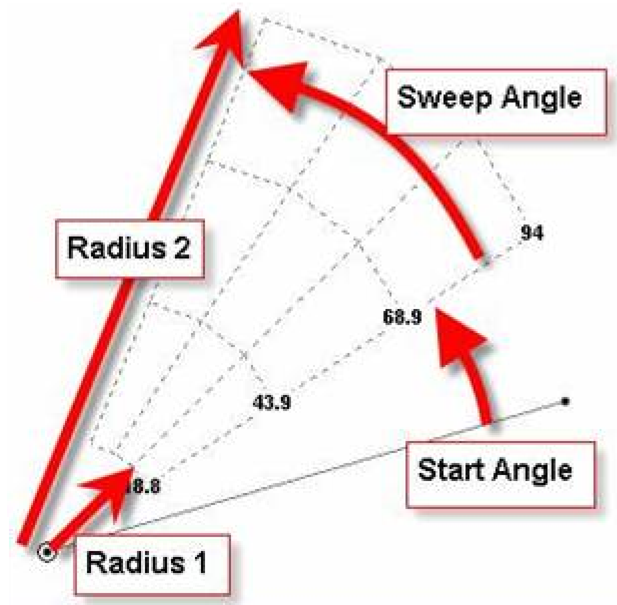


Figure 337: The nomenclature used for Radial grid construction lines

Related Links

- *M. To add a grid for drawing objects* (on page 653)

Irregular grid dialog

Used to create gridlines with unequal spacing that lie on the global planes or on an inclined plane.

Opens when Irregular is selected as the type of new grid or an existing irregular grid is edited in a **Snap Node/<entity>** dialog.

Name	(Optional) Specify a name by which you can identify the grid in the **Snap Node/<entity>** dialog.
Origin	The (0,0) position on the grid in the grid coordinate system. Usually, the grid origin coincides with the structure origin. Type in the location of the origin of gridlines in global coordinate system, in the current length units, or click the  tool to change the location of the grid origin by graphically selecting a existing node.
Use Arbitrary Plane	This option is used when the grid is to be placed in any arbitrary plane determined by a pair of vectors, which are specified by provided a pair of coordinates entered in global X, Y, and Z values. The vectors are then taken from the origin to each of nodes to define the plane's X and Y axis. **Tip:** These coordinates *do not* need to be existing nodes. Any arbitrary point may be type in.
Plane	Used when the grid is to be placed in a global plane. Select the global plane in which the gridlines will lie.

Angle of Plane	Choose one of the three options (**X-X**, **Y-Y**, or **Z-Z**) and provide the angle of rotation (in degrees) of the grid plane about that axis.

Relative gridline distances	Specify the distances between gridlines, with each distance separated by a space. Values are in the current input units of length. A gridline is always placed at zero in each direction, so there is no need to enter that value. Tabbing (or clicking) between fields updates the grids (if this is the active grid).
	For example, the following X and Y distances provide a grid for drawing `US.1. Plane Frame with Steel Design.std` (in units of feet, with zero angle and origin = 0,0,0).
	`5 2.5 2.5 5 5 2.5 2.5 5`
	`20 15 3 3 3`

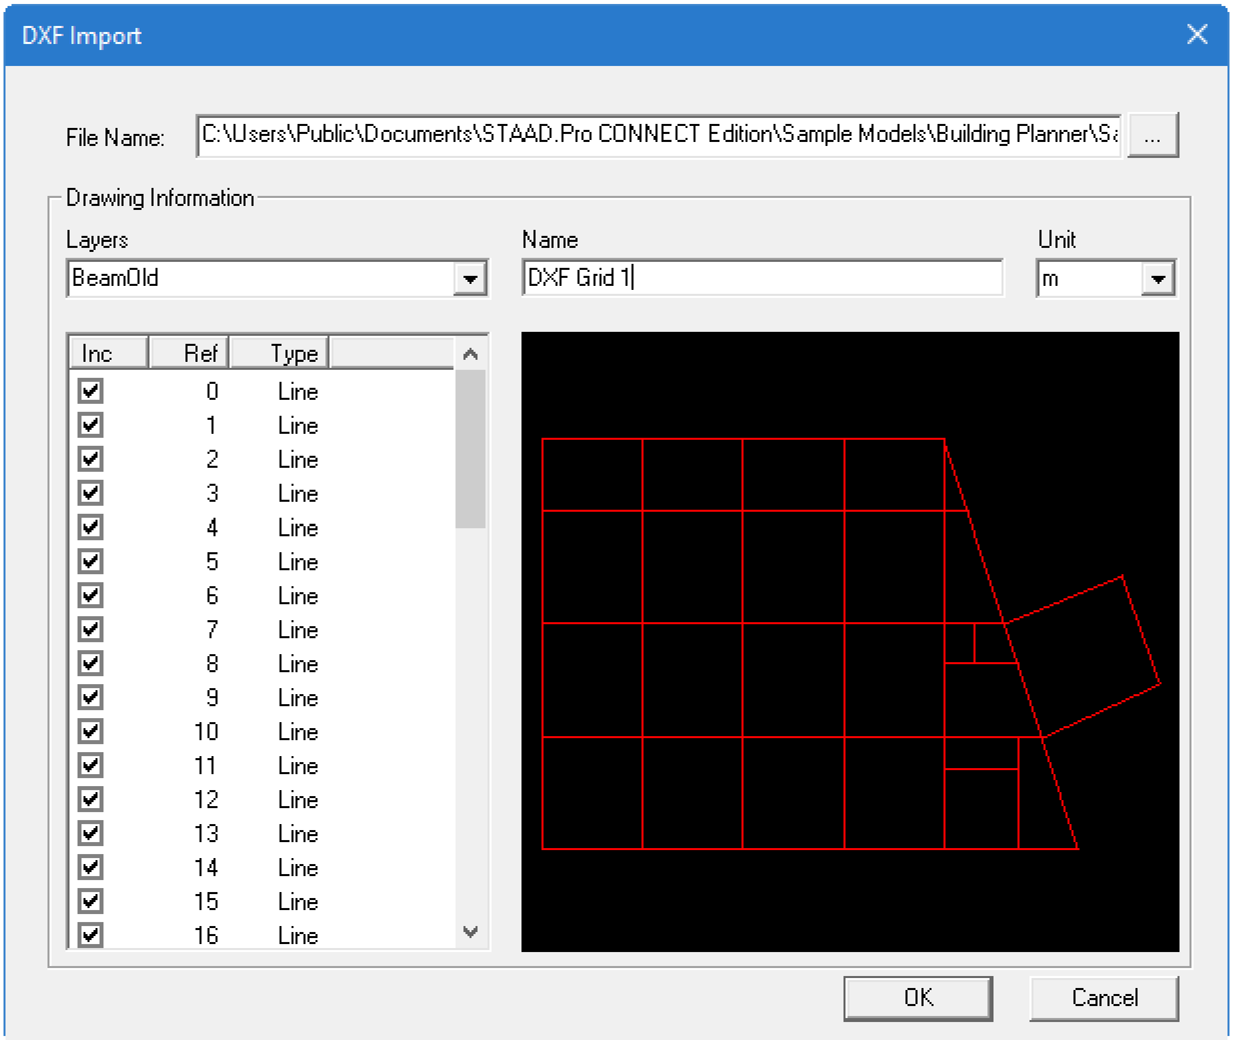
Related Links

- *M. To add a grid for drawing objects* (on page 653)

DXF Import dialog

Used to select drawing elements from a .DXF file for use as construction grids in STAAD.Pro.

Opens when the .DXF option is selected in the **Import Options** dialog.



To select a DXF file click on the **[...]** button and navigate to the required file.

The file will be opened and displayed in the preview window. Individual layers can be turned on and off from the Layers droplist. The individual entities in the selected layers are displayed and can be toggled on or off for import.

By clicking on an entity in the graphical window, the entity is highlighted in the table so that it can be turned off if required.

With the required entities selected, a suitable reference name supplied and unit selected, click on the [Import] button.

Related Links

- *M. To import a DXF file as a grid* (on page 655)

Imported Grid dialog

The data will be imported in the plane in which it was defined in the original DXF. However, if required this can be rotated about any of the global axes. Also, the origin of the grid can be located at any 3D coordinate.

The DXF grid is used just as a manually generated grid. Nodes can be created at the ends and intersections of grid lines.

Note: Curved lines are *not* imported.

Angle of Plane Choose one of the three options (**X-X, Y-Y, or Z-Z**) and provide the angle of rotation (in degrees) of the grid plane about that axis.

Grid Origin Provide the location of the origin of gridlines in global coordinate system in the current length units. One may do this by typing in the coordinates of the origin in the windows provided for the purpose.

The grid origin is the (0,0) position on the grid in the grid coordinate system. Usually, the grid origin coincides with the structure origin.

Click the  tool to change the location of the grid origin by graphically selecting a existing node.

Hide DXF text Select this option to toggle the display of grid labels if they start clashing with the rest of the model.

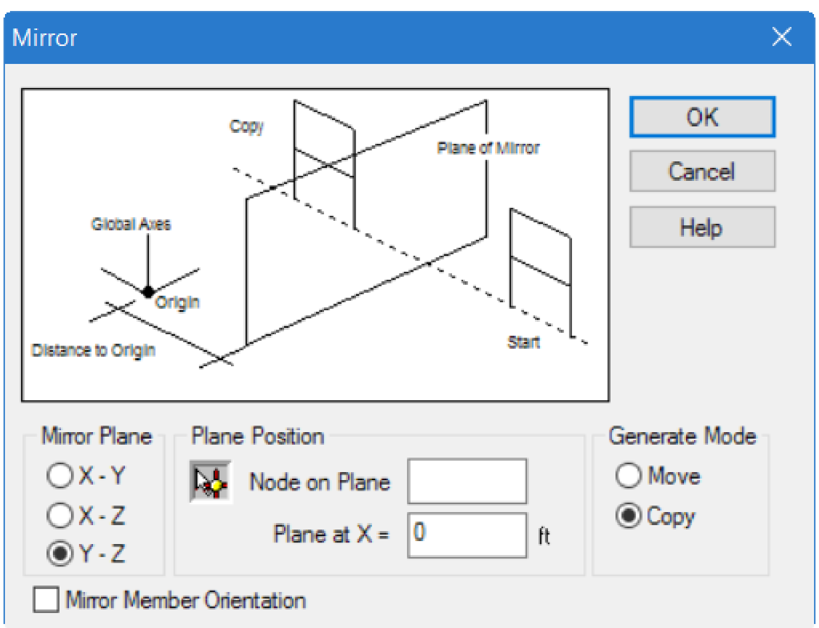
Related Links

- *M. To import a DXF file as a grid* (on page 655)

Mirror dialog

Used to copy or move the selected portions of the structure by “mirroring” about any plane parallel to one of the three global Cartesian coordinates.

Opens when the **Mirror** tool is selected in the **Structure** group on the **Geometry** ribbon tab.



Mirror Plane Choose one of the three global planes to mirror the selected geometry about.

Plane Position
: Used to establish the mirror plane position relative to the selected geometry. Select or type a **Node on Plane** to use an existing node to define the mirror plane.

  Alternately, type a distance from the global origin to the plane along the axis perpendicular to the selected Mirror Plane in the **Plane at X/Y/Z** field.

Mirror Member Orientation
: Select this option to consider the member orientation (Beta angle or member reference point) during mirroring. When this option is selected, the program will attempt to mirror the member orientation also, in addition to the member geometry.

Generate Mode
: The **Copy** option generates new structural elements. The **Move** option changes the coordinates of the selected structural elements.

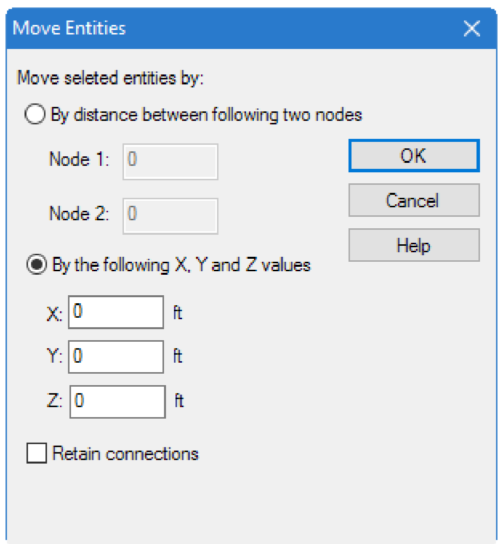
Related Links

- *M. To generate mirror copies of model entities* (on page 689)

Move Entities dialog

Used to specify the translational offset for moving a selection of model objects.

Opens when the **Move Node** tool is selected in the **Node** group on the **Geometry** ribbon tab.



Note: The controls in this dialog are analogous to the **Move Beams Selection** dialog (opens with the **Move Beam** tool is selected), the **Move Plates Selection** dialog, and the **Move Solids Selection** dialog.

By distance between following nodes
: uses two node numbers and determines the vector between them. The selected entities are moved along a parallel vector of the same distance

By following X, Y and Z values
: uses the Cartesian coordinates specified to create a vector

Retain connections
: Set this option to retain the connectivity between objects. The connection objects will distort by the resulting translation vector.

> **Note:** The model geometry will be adjusted to some degree, even if this is not selected, when nodes are the entities being moved as they member, plate, surface, and solid geometry is defined by node location. However, if you are moving a member, plate, surface, or solid, then selecting this option will move the associated nodes and thus retain the connection with adjacent entities (though their geometry will stretch, warp, or shift as a result of the move).

Related Links

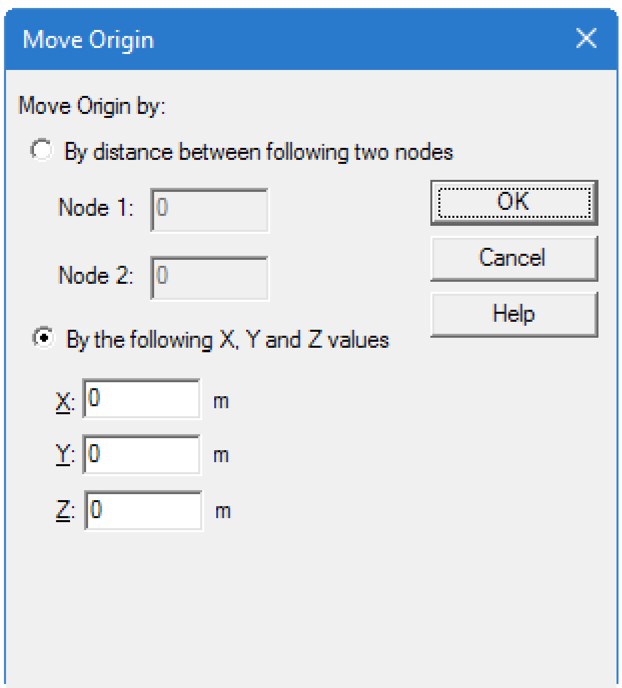
- *M. To move selected objects* (on page 685)

Move Origin dialog

Used to specify the translational offset for moving a the model origin.

Opens when the **Move Origin** tool is selected in the **Node** group on the **Geometry** ribbon tab.

> **Note:** All model geometry is updated relative to the new origin location.



> **Note:** The controls in this dialog are analogous to the **Move Beams Selection** dialog (opens with the **Move Beam** tool is selected), the **Move Plates Selection** dialog, and the **Move Solids Selection** dialog.

By distance between following nodes	Uses two node numbers and determines the vector between them. The origin is shifted along a parallel vector of the same distance.
By following X, Y and Z values	uses the Cartesian coordinates specified to create a vector

Related Links

- *M. To move the model origin* (on page 686)

Select Node dialog

Used to select a node number you want to keep in the model. .

Opens when the **Merge Nodes** tool is selected in the **Nodes** group on the **Geometry** ribbon tab.

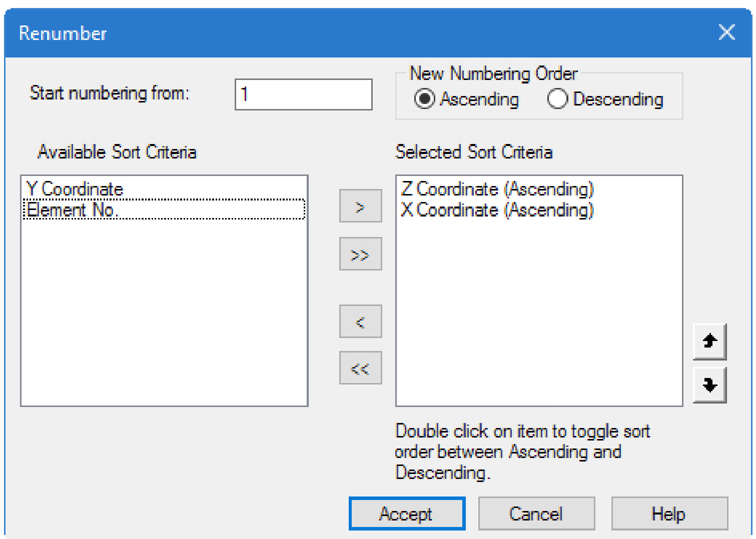
Node To Keep	The nodes in the selection set are listed. Select the node number you want to keep. Other selected nodes will be merged to this node number

Renumber dialog

Used to renumber selected entities starting with a specified number. The numbering sequence can be in an ascending or descending order and the order can be sorted by some criteria if needed.

Opens when one of the following tools is selected on the **Geometry** ribbon tab:

- the **Renumber Nodes** tool in the **Node** group
- the **Renumber Beams** tool in the **Structure** group
- the **Renumber Plates** tool in the **Plate** group
- the **Renumber Solids** tool in the **Solid** group



Start number from	Specify the starting number of the renumbered entities. Depending on the **New Numbering Order** option selected, the new entity numbers will ascend or descend from this number.
New Numbering Order	Select either an **Ascending** or **Descending** order to control the subsequent entity numbers.
Available Sort Criteria	Sort criteria can be used to control the order in which selected entities will be numbered once the procedure is complete.

List Operators

Click this button…	to…
>	Add the selected sort criteria to the Selected Sort Criteria list
>>	Add all sort criteria to the Selected Sort Criteria list.
<<	Remove all entries in the Selected Sort Criteria list.
<	Remove the selected entry from the Selected Sort Criteria list.

Selected Sort Criteria Items added to this list will be used as criteria for sorting the numbered items. The order of operations is that the entities are renumbered starting with the lowest criteria on the list. Once this is complete for a criteria, the next higher criteria in the list will be used.

Use the Move Up or Move Down buttons to change the order of the items in the list.

Note: You can change the numbering order (ascending or descending) of individual sort criteria by double-clicking its entry in this list.

Accept Renumbers the selected model entities based on the specified parameters.

Caution: This operation cannot be undone.

Cancel Closes the dialog without renumbering any model entities.

Help Opens the STAAD.Pro help window.

Related Links

- *M. To renumber selected beams* (on page 663)

Define Member Attributes dialog

Used to pre-define member attributes such as properties, materials, beta angles, or release specifications for member attribute sets. Members which are then added to the model will have these properties by default.

Opens when the **Set New Member Attributes** tool is selected from the **Add Beam** drop-down in the **Beam** group on the **Geometry** ribbon tab.

Select Template Contains a list of named templates, included user-defined templates created by clicking **New**.

New Click to create a new template. Type a name and click OK.

Save Save changes made to the currently selected template.

Rename Click to rename the currently selected template.

Delete Click to delete the currently selected template. You will be prompted to confirm this action.

Attributes group

Member Property
Select the Use Property option to predefine a Member profile. The Select Property: drop down list contains all the profiles currently being used in the STAAD.Pro command input file.

Beta Angle
Select the Use Beta Angle option to predefine a angle of rotation about the member's longitudinal axis. Options are available to use the Angle, the RAngle, or enter an Angle in Degrees.

Member Release
Select the Use Release at Start and/or Use Release at End options to predefine a member end release specification for either the start or end of the member(s). The Release at Start and Release at End drop-down lists contain all the member end releases currently being used at the respective member ends in the STAAD.Pro command input file.

Assign these attributes while creating new members
Select this option to ensure that these attributes will be assigned to any members which are created henceforth.

Related Links

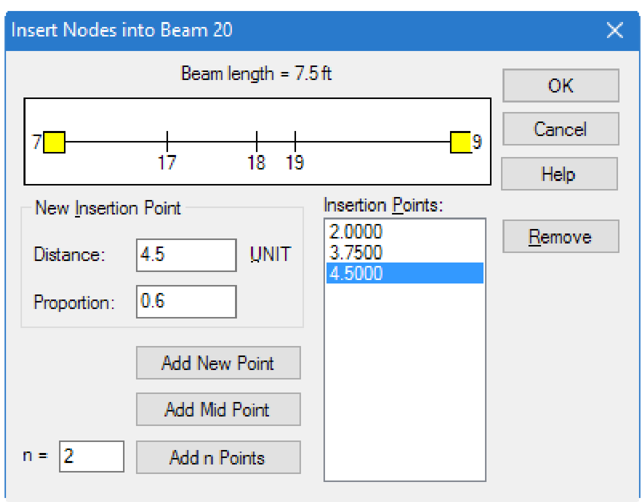
- *M. To set attributes for new beams* (on page 657)

Insert Nodes into Beam # dialog

Used to insert one or more nodes at specified distances along selected members.

Opens when the **Insert Node** tool is selected in the **Structure** group on the **Geometry** ribbon tab.

One or more beams must be selected for this tool be active.



Beam Length
Lists the distance from node A to node B along the beam to be split.

New Insertion Point
Provide the **Distance** from the start node (as shown in the associated graphics) of the member in current length units. Alternatively, provide the **Proportion** of the total length of the member to position the new node. Click **Add New Point** to add the node.

Add New Point	Adds the node indicated by the **Distance** or **Proportion** value.
Add Mid Point	Splits the member into two equal segments.
Add n Points	To divide the beam in a number of equal segments, provide the number of intermediate points in the **n =** field and click **Add n Points**. **Note:** This value should be an integer.
Insertion Points	A list of the locations of the newly created points is displayed here, shown as the distance from the start node of the member.
OK	Accept the added nodes and closed the dialog.
Cancel	Close the dialog without adding nodes.
Help	Opens the Help window.
Remove	To remove a node from the list of inserted nodes, highlight the desired node and click on this button.

Related Links

- *M. To insert a node in a single member* (on page 682)

Insert Node / Nodes dialog

Used to insert node(s) into multiple members simultaneously following the same prescribed method.

Opens when the **Insert Node** tool is selected in the Beam group on the Geometry ribbon tab (with multiple beams already selected).

New point by distance	Specify the distance in current length units at which the beam is to be split. The value for the distance is entered in the Distance edit box and is measured from the start node of the beam.
New point by proportion	This option allows the users to specify the distance in terms of a ratio. For example, to split a beam at the midpoint, enter 0.5 as the proportion. To split the beam at quarter points, use a proportion value of 0.25.
Add mid point	Splits the beams at their midpoints.
Add 'n' points	To split a beam by inserting **n** number of points, use this option. The beams are split up into n + 1 segments.
OK	Accept the added nodes and closed the dialog.
Cancel	Close the dialog without adding nodes.
Help	Opens the Help window.

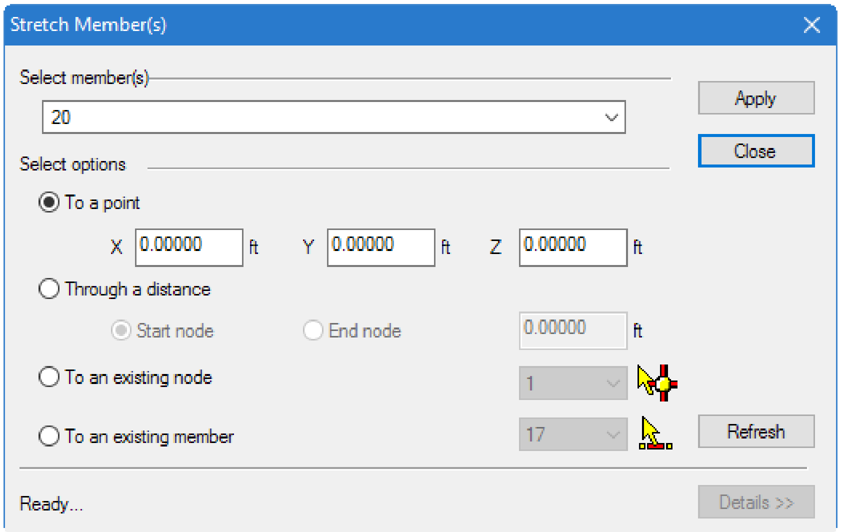
Related Links

- *M. To insert a node in multiple members* (on page 683)

Stretch Member(s) dialog

Used to increase the length of a member in various ways.

Opens when the **Stretch Members** tool is selected in the **Beams** group on the **Geometry** ribbon tab.



Select member(s)

Multiple members can be selected simultaneously for stretching. However, whether they will get stretched or not depends upon the type of method used in stretching as described later. If you wish to remove one or more members from the list, uncheck the corresponding boxes within the Select member(s) drop-down list.

Select options

Select the method to use for stretching the selected members:

To a point

Specify the coordinates in current length units of the point to which one of the ends of the member are to be moved. The point must lie on the axis of the member being stretched, or else, the stretching will not be performed. The program automatically determines which of the two ends of the member is to be moved. So, this method involves

- **i.** determining if the point lies on the axis of the member(s) being stretched
- **ii.** determining which end to move for the member(s) which satisfy criteria (i)
- **iii.** replacing the corresponding nodal coordinates with those of the desired point

Through a distance

Specify whether the start or end node will be stretched and the distance by which to stretch this end. In this method, all members selected for this operation will see the change in length.

You must create a node a resulting intersection point separately using the **Intersect Beams** tool.

To an existing node	This is very similar to the **To a point** method. The only difference is that instead of explicitly specifying the coordinates of the desired point, that point is already available for identification through its node number. A list of all nodes in the model is available in the drop-down list. Alternately, click the Node selection tool to select a node graphically.
To an existing member	If two members lie within a plane, this method may be used to stretch the first member to meet the second member. The second member will be automatically split at the intersection point into two segments. A list of all members in the model is available in the drop-down list. Alternately, click the Member selection tool to select a member graphically.

Details This button toggles the display of the detailed actions taken during the stretch operation.

Tip: If this button is disabled, then the selected stretch operation is invalid.

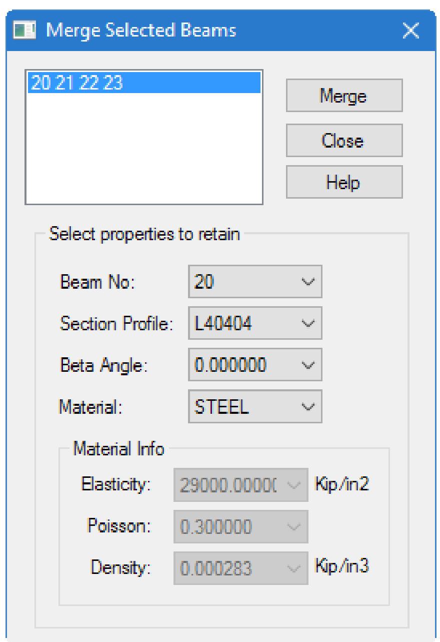
Related Links

- *M. To stretch a member* (on page 662)

Merge Selected Beams dialog

Used to join two collinear beams and replace them with one beam. The intermediate node(s) (common node) is removed from selected members and the incidences are redefined.

Opens when the **Merge Selected Beams** tool is selected in the **Beam** group on the **Geometry** ribbon tab.



Beam No Select the beam no to use for the merged beam.

Section Profile Select the section property to use for the merged beam.

Beta Angle	Select the local x axis rotation value to use for the merged beam.
Material	Select the material definition to use for the merged beam. Material data is listed below. **Note:** If the members are defined using material constants instead of material definitions, then the individual constants will be available to select for the merged beam instead.

Related Links

- *M. To merge two or more members* (on page 662)

Parametric Models dialog

Used to automatically generate finite element meshing for defined boundary areas.

Opens when the **Parametric Models** tool is selected in the **Plate** group on the **Geometry** ribbon tab.

Preview Models list

A list of mesh prototypes are listed here. Multiple settings may be experimented with here to obtain the desired surface mesh before merging with the base model. Selecting the meshed surface name displays the overall model parameters. Selecting a “child” item in the list (e.g., boundary, openings, etc.) displays the parameters for that item.

- model name

  Selecting the name of the model displays the overall model parameters, which were initially set in the **Add Parametric Model**
  dialog.

  - **Boundary Connectivity -** Two methods are available for parametric model boundaries:

    B - User Defined - this method uses the defined number of segments per boundary, which can be specified for each Boundary Point/Edge as needed
    C - Automatic - this method optimizes the boundary segmentation
  - **Target Element Size -** the target element size to use for meshing, in the given units of length
  - **Mesh the selected plate element -** the shape of the element used, which is restricted by the selected meshing method
  - **Meshing Method -**

    Standard - uses quadrilateral elements
    Basic - uses triangular elements
- **Boundary**

  Selecting a Boundary Point/Edge displays the points' 3D coordinates (which cannot be modified) and two additional parameters which can be edited:

  - **Division -** When a Mesh Type B) has been selected, this value is used to identify the number of divisions along the boundary edge from the selected node to the next defined point on the boundary.
  - **Density -** When a Mesh Type C) has been selected, this value is used as a biasing parameter. The larger the value, the denser the mesh around the boundary point.

- **Openings**

  Openings can be added by selecting the Openings heading and clicking the **Add** button. Either polygonal or circular openings can be added as described above. Both opening types have options that can be edited.

  - **Polygonal**

    Selecting a Polygonal opening definition in the dialog displays the control point coordinates that form the opening (which cannot be edited). Each point includes two additional parameters which can be edited:

    Division - When a Mesh Type B) has been selected, this value is used to identify the number of divisions along the boundary edge from the selected node to the next defined point on the boundary.

    Density - When a Mesh Type C) has been selected, this value is used as a biasing parameter. The larger the value, the denser the mesh around the opening point.
  - **Circular**

    Selecting a Circular opening definition in the dialog displays the circle center coordinates that form the opening (which cannot be edited). Each point includes three additional parameters which can be edited:

    Radius - This defines the size of the opening. This value is used by all Mesh Types.

    Division - This is used to define the number of segments that form the circle and is used by all Mesh Types.

    Density - When a Mesh Type C) has been selected, this value is used as a biasing parameter. The larger the value, the denser the mesh around each point that forms the opening.
- **Regions**

  Selecting a Region definition in the dialog displays the control point coordinates that form the region (which cannot be edited). Each point includes two additional parameters which can be edited:

  - **Division -** When a Mesh Type B) has been selected, this value is used to identify the number of divisions along the boundary edge from the selected node to the next defined point on the boundary.
  - **Density -** When a Mesh Type C) has been selected, this value is used as a biasing parameter. The larger the value, the denser the mesh around the point on the region.

  Note: The control points for an `OPENING` or `REGION` cannot lie on the surface boundary.
- **Density Points**

  Selecting a Density Point definition in the dialog displays the coordinate of that point, which cannot be edited and a single parameters which can be edited:

  - **Density -** When a Mesh Type C) has been selected, this value is used as a biasing parameter. The larger the value, the denser the mesh around the density point.
- **Density Lines**

Density lines are defined by two points. Selecting a Density Line definition in the dialog displays the two coordinates of the line which cannot be edited and two additional parameters which can:

- **Division -** This is displayed on the first point that defines the density line, but applies to the line between both points. This value is used to identify the number of divisions along the density line and is used by *all* mesh types.
- **Density -** When a Mesh Type C) has been selected, this value is used as a biasing parameter. The larger the value, the denser the mesh around the point on the density line.

Parameters table	Displays the parameters for the selected mesh model, Opening, Region, Density Point, or Density Line. Changes made here can be saved using the **Apply** button.
Add...	Used to add a new mesh model to the list or to add a new Opening, Region, Density Point, or Density Line to the current mesh model.
Delete	Removes the selected mesh model from the Preview Models list or removes the selected Opening, Region, Density Point, or Density Line from the current mesh model. **Caution:** No confirmation is used to delete mesh models or their sub-components. This action cannot be undone.
Apply	Updates the selected mesh model with any changes made to the settings.
Merge Mesh	Commits the selected mesh model to the STAAD.Pro input file base model. **Caution:** Until this button has been clicked for one or more mesh models, no data from this page will be saved.

- *TR.14.1 Parametric Mesh Models* (on page 2227)
- *M. To create a parametric surface model* (on page 671)

New Mesh Model dialog

Used to name a new mesh model.

Opens when **Add** is clicked to create a new mesh model in the Parametric Models dialog (on page 2734).

Name	Enter a unique name here to identify the mesh model in the Parametric Models dialog Preview Models list.
Use nodes and beams that occur on or inside the outer boundary as additional density points and lines?	Select this option to have the program auto-detect points on the outer boundary not explicitly clicked when defining the edge of the mesh boundary. The program will also used any beams and nodes inside the boundary as density lines and points, respectively.
OK	Closes the dialog and allows you to begin defining points around the mesh boundary.
Cancel	Closes the dialog without creating a new mesh model.

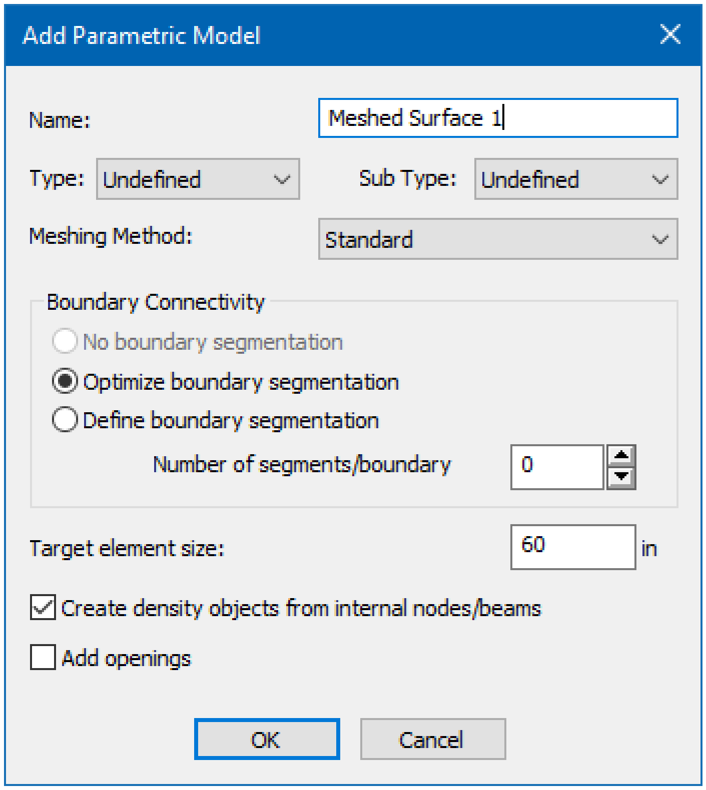
Related Links

- *M. To create a parametric surface model* (on page 671)

Add Parametric Model dialog

Used to specify the parameters used for automatically generating a finite element mesh over boundary area.

Opens when a new mesh boundary has been defined from the Parametric Models dialog (on page 2734).



Name	Type a string used to identify the meshed surface.
Type	Select an optional description for the surface type: • Undefined • Wall • Slab
Sub Type	Select an optional description for the selected **Type**: • Wall_Tank (Wall only) • Slab_Tank (Slab only)
Meshing Method	Select one of the following mesh methods: • **Basic -** Can make use of any of the three **Boundary Connectivity** options and uses triangular elements.

- **Standard -** Can use type either optimized or defined **Boundary Connectivity** options and uses quadrilateral elements.

Boundary Connectivity

Select how the program should sub-divide the boundary edges between the selected nodes:

No boundary segmentation - Meshing will be done without creating any nodes along the edges of the boundary we defined. Thus, the entire distance between two sequential nodes will form the side of one element. In most cases, this can lead to poor quality elements, and is best avoided.	 No divisions
Optimize boundary segmentation - (Default, recommended) Automatic boundary divisions to the target element size.	 Optimized
Define boundary segmentation - Each boundary between the selected nodes will be sub-divided into the specified number of segments given in **Number of segments/ boundary**.	 Equal number of divisions

Target element size

Specify a target dimension to use as a guideline when automatically generating the mesh. This value is nominally used when dividing the boundary region into finite elements, but the element size is also determined by other factors such as the distance between boundary and other density points..

Create density objects from internal nodes/ beams

Check this option to have additional nodes created along any members or defined nodes that lie in the defined surface area.

Add openings

Check this option to specify openings within the surface after you click **OK**.

OK

Closes the dialog and generates the mesh.

Cancel

Closes the dialog without generating a meshed surface.

Define Meshing Region dialog

Used to specify data such as the number of divisions along each side of the polygon, and whether any cutouts or holes are to be specified in the polygon.

Opens when a polygonal meshing is being defined.

Polygonal Plate tree

Entries in the tree represent the Boundary (polygonal surface edges) and the included Holes, if any.

Selecting the HOLES entry allows you to add holes or delete all holes either from the right-click pop-up menu or using the HOLES tools:

Table 295: HOLES tools in the Define Meshing Region dialog

Tool	Description
 Add New Hole	Adds a new hole for the current boundary region. Coordinates for the hole corners must be defined.
 Delete All Holes	Deletes all holes currently added in the boundary region.

Table

Each row in the table represents a corner node of the selected Boundary or Hole, along with the number of edge divisions and bias for the edge between the node on this row and the previous row.

- X / Y / Z — Global coordinates of the Boundary or Hole corner.
- Div. — Number of elements will be created between the current node represented by the current row and that of the previous row (division).
- Bias — Used to control the variation in division length along the edge. Represents the ratio of length of the last element to the first element along a side. That is, the last element will be (bias value) times the length of the first element. A value of unity (1) results in equal divisions along a side.

Table 296: Table tools in the Define Meshing Region dialog

Tool	Description
 Add New Row	Adds a new row to the bottom of the table with default values.

Tool	Description
 Delete Row	Removes the currently selected row from the table.
 Rename Hole	(When hole is selected) Used to provide a user-defined name for the hole.
 Delete Hole	(When hole is selected) Removes the current selected hole from the polgyonal plate tree.

OK Generates a meshed surface with the specified parameters.

Cancel Closes the dialog without generating a meshed surface.

Reset Undoes any changes made to the dialog.

Select Meshing Parameters dialog

Used to name and specify parameters for a quadrilateral plate super-element.

Opens when a quadrilateral meshing is selected.

Model Name Specify an optional, user-defined name for the quadrilateral super-element.

Corners The X, Y, and Z coordinates of each corner (the selected nodes) are labeled A through D.

Length, Bias & Division For each side connecting two Corners, the straight line distance is provided. You may also edit the Bias and Divn. values for each side to control the meshing.

- Div. — Number of elements will be created between the current node represented by the current row and that of the previous row (division).
- Bias — Used to control the variation in division length along the edge. Represents the ratio of length of the last element to the first element along a side. That is, the last element will be (bias value) times the length of the first element. A value of unity (1) results in equal divisions along a side.

Element Type Select either a Triangle or Quadrilateral element for the finite elements which compose the super-element mesh.

Apply Closes the dialog and generates a quadrilateral mesh with the specified parameters.

Cancel Closes the dialog without creating a quadrilateral mesh.

Define Plate Object Property dialog

Used to define various attributes of the plate to be pre-defined.

Opens when the **Add Plate > Set New Plate Attributes** tool is selected in the **Plate** group on the **Geometry** ribbon tab.

Use Property	Select the Use Property option to predefine a Plate thickness. The **Select Property** drop down list contains all the thicknesses currently being used in the STAAD.Pro command input file. Additional thicknesses can be added using the Create New Property button.
Create New Property	Opens the **Plate Element/ Surface Property** dialog to the Plate Element Thickness tab, which is used to define the thickness of the plate at each corner node.
Use Material	Select the Use Material option to predefine a plate Material. The **Select Material** drop down list contains all the materials currently being used in the STAAD.Pro command input file. Additional materials can be added using the using the Create New Material button.
Create New Material	Opens the **Isotropic Material** dialog, which is used to define Material properties for a new isotropic material type or select a predefined, common isotropic material.
Use Release	Select the Use Release option to predefine a set of plate releases. The **Plate Release** drop-down list contain all the plate releases currently being used in the STAAD.Pro command input file. Additional releases can be added using the Create New Releases button.
Create New Release	Opens the Plate Specs dialog, which is used to define the degrees of freedom to be released at each node of the plate as well as define the plate to e plane stress, no in-plane rotation, or no stiffness.
Assign these attributes while creating new plates	Select this option for the program to recognize the pre-defined attributes. Any new plate element created from here on (whether created individually, through a mesh or Structure Wizard) will now possess these attributes.

Related Links

- *M. To set new plate attributes* (on page 667)

Composite Deck dialog

Used to create and define composite decks.

Opens when the **Composite Deck Layout** tool is selected in the **Composite Deck** group on the **Geometry** ribbon tab.

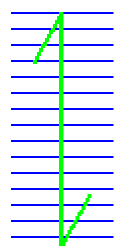
Composite Deck list	All composite deck groups and their constituent members are listed here.
New Deck options	• Clicking on Nodes - Used to define the deck by clicking on the nodal points that comprise the deck boundary. Click on the **Create New Deck** button to begin selecting the deck boundary using the composite boundary cursor . Once the deck is created, it will be shown with a hatch pattern. • Use Selected Beams - Used to define the deck by selecting the beams that comprise the deck boundary. Using the Beams cursor, select the beams which will define the outer boundary of the deck.

Create New Deck
Used to define the deck in by the selected method. Once the deck is identified by any one of the aforementioned methods, a dialog box as shown below will prompt for the deck name. Enter an appropriate deck name in the edit box provided.

The deck will then be defined and the deck name will appear in the **Composite Deck** box as shown below.

Select the deck in the tree control to define the properties of the deck. The various options in the **Composite Deck** box are explained as follows.

Create Direction
Used to define the deck direction (direction of the longitudinal flutes or ribs in the deck) by highlighting any two beams and clicking the **Create Direction** button. The deck direction will be defined to run perpendicular to the two beams that were selected. A symbol will appear to indicate the direction of the deck. This symbol will be placed at the centroid of the deck area.



Once the direction of the deck is specified, the beam numbers which comprise the deck will be displayed as child elements of the deck group.

Deck hash color
Click the color square (adjacent to the Create Direction button) to open a color picker dialog. Select a custom color to hash the selected deck or any newly created decks. Each deck can have a different color.

> **Tip:** Use different colors to quickly identify composite decks with different properties or directions.

Deck Properties

The following options appear in the Composite Deck dialog when a deck group is selected.

Update Deck Property
Synchronizes the graphical window and updates any changes made to the deck definition.

Concrete Properties
Specify the concrete thickness above the flutes, the unit weight of concrete and the grade of concrete in the respective edit boxes.

Rib Properties
Rib properties can now be defined either using the database or by entering the properties manually.

Use Database
A drop-down list of the various standards incorporated in STAAD.Pro. The program includes three standard catalogs: ASC™, Vulcraft™, and VERCO™. The rib properties will be used from the database provided.

Apart from using the available standards, you may also define custom rib properties by providing the **Rib Width** and **Rib Height**.

Rib Width
Width of the rib in this box. If a database deck is selected, this value is updated.

Rib Height The height of the rib in this box. If a database deck is selected, this value is updated.

Stud Diameter Specify a diameter for the Stud by choosing the **Custom** option or select from the three available diameters: 3/4", 5/8", 1/2".

Stud Length Specify the length (height above deck pan) of the stud in this box.

Shored Choose the appropriate radio button depending on whether or not shoring is to be used during construction.

Beam Properties

The following options appear in the Composite Deck dialog when a component beam is selected.

Current Property The current section and material of the selected beam is displayed.

Add / Change Property Opens the appropriate Section Profile Tables dialog (on page 2793) which is used to select a steel section and material.

Effective Width The effective width for each beam is automatically calculated by STAAD.Pro and is displayed in the **Effective Width** box. The user can modify the effective width for any individual beam by inputting the value in the **Effective Width** box and clicking on the update button.

View tab

Table 297: Labels group

Tool name	Description	Shortcut
 **Labels Settings**	Opens the **Diagrams** dialog to the **Labels** tab, which is used to customize the view of the structure by setting different view-related parameters.	

Tool name	Description	Shortcut
 **Node Labels**	Select any of the label types from the drop-down list to turn the display of that label on or off. **Tip:** Additional labels are controlled on the **Diagrams** dialog **Labels** tab.	**<Shift+N>**
 **Beam Labels**		**<Shift+B>**
 **Plate Labels**		**<Shift+P>**
 **Solid Labels**		**<Shift+C>**
 **Individual Node Labels**	When the object label type is activated, use these tools to show or hide the individual labels of objects. This can be useful for large models or views where you wish to display multiple types of labels simultaneously. **Note:** These tools require you to select the **Always Use Current Label Settings** option and then check the **Use Partial Labeling Mode** option on the **Diagrams** dialog **Labels** tab.	
 **Individual Beam Labels**		
 **Individual Plate Labels**		

Tool name	Description	Shortcut
Individual Solid Labels		

Table 298: Tools group

Tool name	Description	Shortcut
Zoom Window	Used to define the boundaries of a rectangular area of the active view to be displayed within the current view.	
Whole Structure	Fits the current view to display the entire structure limits. Resets view rotation to orthogonal.	
Zoom In	Zoom in the current view by a preset percentage magnification.	scroll wheel up
Zoom Out	Zoom out the current view by a preset percentage magnification.	scroll wheel down
Pan	Used to view a different part of the design without changing the view magnification. **Tip:** Press and hold the middle mouse button (typically the scroll wheel button) to quickly pan in the view window.	
Zoom Extents	Adjusts the view magnification so that the entire model is visible in the view.	

Tool name	Description	Shortcut
Zoom Factor	Opens the **Zoom Factor** dialog, which is used to zoom in or out of the structure by specifying a magnification factor. Factors less than one Zoom out.	
Zoom Previous	Undoes the last **Zoom Factor** or **Zoom Window** operation.	
Dynamic Zoom	Used to define the boundaries of a rectangular area of the active view to be displayed within a new view. The previous view window highlights the location of the zoomed portion.	
Magnifying Glass	Provides a magnified portion of the current view window when you click and drag the pointer.	
Isometric View	(Default view) View the model as an isometric projection.	
Front View	View the structure model from the positive Z axis.	
Left View	View the structure model from the negative X axis.	

Tool name	Description	Shortcut
 **Top View**	View the foundation mode in plan; from the positive Y axis.	
 **Back View**	View the structure model from the negative Z axis.	
 **Right View**	View the structure model from the positive X axis.	
 **Bottom View**	View the structure model from the negative Y axis.	
 **Rotate Up**	Rotate the structure model forward about the X axis.	**<↑>** (Up arrow key)
 **Rotate Left**	Rotate the structure model forward about the Y axis.	**<←>** (Left arrow key)
 **Spin Left**	Rotate the structure model forward about the Z axis.	**<Ctrl+←>** (Ctrl +Left arrow keys)

Tool name	Description	Shortcut
Rotate Down	Rotate the foundation mode backward about the X axis.	**<↓>** (Down arrow key)
Rotate Right	Rotate the structure model backward about the Y axis.	**<→>** (Right arrow key)
Spin Right	Rotate the structure model backward about the Z axis.	**<Ctrl+→>** (Ctrl +Right arrow keys)
Toggle View Rotation Mode	Used to select an node as the center of rotation. When toggled on, pressing **<Ctrl+Shift>** and clicking a node will set that node as the center of rotation.	
Orientation	Opens the **Orientation** dialog, which is used to modify the settings that define various view orientations of the structure, such as Plan view, Elevation view, Perspective view, etc.	**<F4>**
Always Fit in Current Window	Instructs the program on what guidelines to use when drawing a selected set of objects on the screen. It displays the selected portion of the model to a size governed by optimum usage of the dimensions of the current window. When you select various tools the program or switch workflows the size of the drawing window frequently changes. With this tool turned on, the model or selected portions of it, will be drawn in such a manner that all the entities will be drawn within the bounds of the drawing area. This means, the size to which the entities are drawn will correspondingly increase or decrease. With this tool turned off, the size of the entities will remain constant, but that means it may or may not fit within the bounds of the drawing window.	

Table 299: Views group

Tool name		Description
 **Open View**		Opens the **Open View** dialog, which is used to open a previously saved structural view window.
 **New View**		Opens the **New View** dialog, which is used to create a new view window for displaying the selected structural elements. You are prompted to indicate whether the selected view would be opened in a new (child) window or whether it would replace the current (parent) view. Any number of “child” view windows in this way. **Note:** This option becomes active only after you select one or more structural elements on screen.
 **Selected Objects**		Hides all objects that are not part of the current selection.
 **View Management >**	**Detach View**	Used to delete any saved or active view window.
	Add to View	Used to add geometry to any saved or active view window.
	Save View	Opens the **Save View As** dialog, which is used to save the current view of the structure with a name. Type a name for the view. This view may be opened later for performing verification/visualization operations.
	Rename View	Opens the **Rename View** dialog, which is used to rename an existing view. Type a **New Name** for the view. The old name is shown for reference.

Table 300: Options group

Tool name	Description
 **Display Options**	Opens the **Options** dialog, which is used to change the length and force units for various values which can be displayed in the graphics window, such as member properties, material constants, load magnitudes, plate stresses, etc.
 **Set Structure Colors**	Opens the **Color Manager** dialog, which is used to set colors for highlight, entities, and results..
 **Structural Tooltip Options**	Opens the **Tool Tip Options** dialog, which is used to set tooltip options for structural elements.

Table 301: Windows group

Tool name	Description	Shortcut
 **Cascade**	Stacks view windows in order with the active window entirely visible and the title bar of each remaining window visible.	**<Shift+F5>**
 **Tile Horizontal**	Tiles view windows vertically, with each window in a landscape (horizontal layout). This is a quick way to clean up the screen.	**<Shift+F4>**
 **Tile Vertical**	Tiles view windows horizontally, with each window in a portrait (vertical layout). This is a quick way to clean up the screen.	**<Ctrl+Shift+F4>**

Tool name	Description	Shortcut
 **Structure Only**	Closes all open view windows, non-modal dialogs, and tables and opens a View window of the full structure expanded to the full program window.	
 **Window**	A list of all open and saved Views is displayed here. Select any number to make this the active view.	
 **Tables**	Opens the **Tables** dialog, which is used to display and close different tables, such as Node coordinates, Beam incidences, Node displacements, etc. irrespective of the current page.	
 **3D Rendering**	Used to render the model using true lighting, reflection and shading in a separate window. It enables walk-through, dynamic zoom and panning capabilities in the 3D rendered view. Once the 3D Rendering option is chosen, a separate window opens displaying the rendered view. The structure can be dynamically rotated about all three axes by simply holding the left mouse button down and dragging the structure in the intended direction. Right-clicking the mouse button will display a myriad of viewing options. Depending on the material used (steel, concrete, etc.), an appropriate texture will be applied to the structure. A property or material must be assigned to the entities of the model before this feature can be used. This is for visual and presentation purposes only.	**<Ctrl+4>**

Diagrams dialog

Used to customize the view of the structure by setting different view-related parameters.

Opens when either:

- the **Labels** tool is selected in the **Labels** group on the **View** ribbon tab

- when either **Labels** or **Structure Diagrams** is selected from the right-click pop-up menu in the View area

Structure tab

Used to set up structural view parameters.

3D Sections The options in this group control how the members are displayed (only one may be selected).

- **None** - Displays the structure without displaying the cross-sectional properties of the members and elements.
- **Full Sections** - Displays the 3D cross-sections of members, depending on the member properties.
- **Sections Outline** - Displays only the outline of the cross-sections of members.

View The options in this group allow additional view-related operations on the structure.

Fill Plates/Solids/Surface	Fills up the plate and solid and surface elements, if present.
Hide Plates/Solids	Hides all plate and solid elements from the view.
Hide Structure	Hides the entire structure from view. This option may be used to switch off the original structure view while displaying the deflected shape of the structure or the mode shapes.
Show Center Lines	Displays the centerlines of the members.
Shrink	Displays the individual structural elements detached from each other and helps to view their connectivity. The individual members are not drawn to full length or full width but shrunk by a percentage provided in the associated edit box.
Perspective	Change current view to perspective.
Sort Geometry	Changes the display of plate and solid element results so that different elements are in front.
Sort Nodes	Changes the display of node results so that different nodes are in front.
Draw Deck Hatch	Hatches in composite deck areas.

Colors Allows you to display and change the color of beams, plates, solids, section outline and selected entities.

Beams	Click Default to select the color used for beams.
Plates	Click Default to select the color used for plates.

		Plate elements can be color coded to distinguish the directions of their local z-axes. The face of the element in the positive direction of the z-axis is referred to as the "front." The opposite side is referred to as the "back."
	Solids	Click Default to select the color used for solids.
	Section Outline	Click select the color for the **Sections Outline** option in the 3D Sections group.
	Selected Entities	Click to select the color of selected entities in the View area.
	Show Color Legend	Selecting this option will display a color legend on the screen.
Margin around Structure	Represents the blank margin around the structure in percentage of the total view window.	
Solid – Fill Face	Select a face of the solid to be filled with color. After checking this option and clicking **Apply**, the selected face of solids are filled with color.	

Load and Results tab

Used to specify the scales to which the different diagrams for viewing input and results should be plotted.

Scales tab

Used to specify the scales to which the different diagrams for viewing input and results should be plotted.

Tip: In general, a larger scale number causes the diagram to shrink and a smaller scale number enlarges the diagram.

Save as Default	If the scale, to which an input item or result item is drawn, has been modified, one may instruct the program to keep that setting as the default, in place of the previous setting or the built-in default.	
Reset to Default	Resets all scales to the installed default values.	
Apply Immediately	When checked scale values in the view window are updated immediately as you change the value.	
Icon Size	**Support Icon**	The size to which the fixed-but support icons are plotted can be increased or decreased using this option. This applies to fixed but support icons only.
	Control Block	Controls the size of the control node icon when the **Control/ Dependent** option has been checked on the **Labels** tab.

Labels tab

Used to select various display labels for different components of the structure.

Tip: You can use the **Label Settings** tool in the **Labels** group on the **View** ribbon tab to quickly access this dialog tab directly.

Nodes

Node Numbers	displays the node numbers on screen.
Node Points	identifies the nodes with a small circle.
Supports	displays the support icons at supported nodes.
Dimension	displays the member lengths in current units.

Properties

References	displays the Property Tag number of the member/element properties.
Sections	displays the section name (such as W12x26).
None	removes the display of property information.

Physical Members

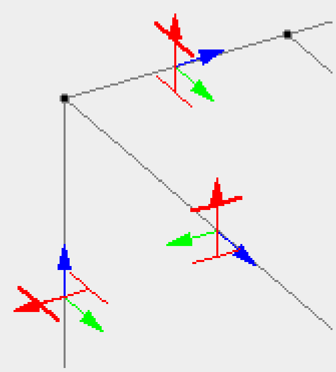
These options work only in the steel design mode. Please refer to the Miscellaneous section at the end of this manual for more details.

Beams

Beam Numbers displays the member numbers on the frame members.

Beam Orientation displays an icon showing the local axis of each member. The arrow indicates the positive direction of the local x-axis. The local y-axis is in the direction of the thicker flange. Please note that the I symbol is used regardless of the actual section type.

Note: The local x-axis is represented by the blue arrow. The local y-axis is represented by the red arrow. The local z-axis is represented by the green arrow.



Beam Spec option displays beam specifications which have been assigned, such as truss and tension only members.

Releases displays the member releases.

Beam Ends This switch, if turned on, paints the beams in the current view, with distinct colors to distinguish the start node of the member from its end node, thereby making it easy to identify the direction of the local X axis of the member.

	Start Color	Click on the little square adjacent to this option to set the color in which the zone of the member adjacent to its start node must be painted in.
	End Color	Click on the little square adjacent to this option to set the color in which the zone of the member adjacent to its end node must be painted in.
Plates	**Plate Numbers**	displays the plate element numbers.
	Plate Orientation	displays the local axis system for plates.
Solids	**Solid Numbers**	displays the solid element numbers.
Surfaces	**Surface Numbers**	displays the surface numbers
	Surface Orientation	displays the local axis system for surface object
Loading Display Options	**Load Values**	Check this box to display the intensity of the loads in the current unit system.
	Display Floor Loading	Check this box to enable/disable the display of the actual joint/ uniform load icons applied to the nodes or members.
	Display Floor Load Distribution	Check this box to display the tributary area diagrams for floor loads.
	Display Wind Load Contributory Area	Check this box to display the tributary area diagrams for wind loads.
	Display Wind Load	Check this box to enable/disable the display of the actual joint/ uniform load icons applied to the nodes or members.
General	**Show Axes Window**	Check this option to display a small icon at the bottom left corner of the drawing area which displays the directions of the global X, Y and Z axes are drawn with respect to the current view of the structure.
	Show Axes at Origin	Check this option to display an icon of the global axes system at the global X=0, Y=0, Z=0 position on the drawing. Axes are color-coded: X is blue, Y is red, and Z is green. 	Material	Displays the name of any material assigned.
	Show Diagram Info	Through the various pages of the post processing mode, the program provides the facility for plotting diagrams such as the Node displacements, beam moments, plate stress contours, etc. Along with these diagrams, a caption is displayed along the bottom right corner of the drawing window indicating the type of diagram, load case, degree of

		freedom, length and force units, etc. In order to bring up those captions, this switch must be turned on. If you do not want those captions to come up, switch off this label.
	Control/ Dependent	Set this option to display control joints as green cubes.

Always Use STAAD.Pro Default Label Settings	As you navigates the various pages of the program, certain labels –meant for easy identification of the assigned attributes– will become switched on by default. Keeping this setting on enables that.
Always Use Current Label Settings	Setting this option will save the current label settings for the current STAAD input file. The labels can be unique to each page within the GS. Workflows in STAAD.Pro (on page 36).

Use Partial Labeling Mode (use labeling cursors to turn ON/OFF individual labels)	If a label is toggled on (e.g, node numbers or beam numbers), by default, STAAD.Pro will display those numbers for *all* the nodes and beams which appear in the current view. On large models or if several types of labels are turned on, this can clutter the drawing making it difficult to distinguish the individual entities. The "Partial Labeling Mode" can be used to display labels for only a select few nodes, members, etc. This switch must be used in conjunction with the individual labeling cursors found in the **Labels** group on the **View** ribbon tab.

Force Limits tab

Used to identify the members having the force values lying inside or outside the specified ranges.

Load Case	Select the **Load Case** for which you want to display the diagram.
Forces	Select the force type from the list of available options, such as **Axial**, **Shear YY**, **Bending ZZ**, etc. Provide the range in the associated edit box under **Minimum** and **Maximum.**
View Limits	The buttons under this group determine which members are going to be highlighted. The **Exceed Either** option highlights any member whose forces exceed either the **Maximum** or the **Minimum** values. **Exceed Maximum** option highlights only the members whose forces exceed the **Maximum** values. **Exceed Minimum** option highlights only the members whose forces exceed the **Minimum** values.
Color Within Limit	Allows you to change the color and width of the force diagram when the forces fall within the view limits.
Color Outside Limit	Allows you to change the color and width of the force diagram when the forces fall outside the view limits.

Animation tab

Used to graphically view deflections, section displacements, mode shapes and stresses in an animated mode. It is a way of visualizing the stress build-up or attainment of peak displacement using animated views.

Diagram Type	**No Animation -** select this option to turn off any current animation

Deflections
Section Displacements
Mode
Stress

Animation Setup	**Full Screen**	displays the animation in the full monitor screen rather than in a window. This option may use less memory than displaying the animation in a large window.
	Extra Frames	Choose the number of **Extra Frames** above the minimum needed to enhance the animation if it appears choppy.
	Target FPS	Choose the **Target FPS** (frames per second) to control the animation speed. To speed up an animation, show more frames per second. To slow down an animation, show fewer frames per second.
	Use Metafiles for offscreen data	Click the **Use Metafiles for offscreen data** to save the animated screens as Windows Metafiles. Speed may be slower if this option is used.

Design Results tab

Used to display code check and steel design information on the structure.

Show Diagram options

- **None -** Do not display the design results graphically
- **Show Diagram (Based on Actual Ratio) -** Displays the design results diagram in the active view window. Values and colors displayed are based on the ratio of the demand to capacity ratio for the selected load case.
- **Show Diagram (Based on Normalized Ratio) -** Displays the design results diagram in the active view window.

Diagram detail options

- **Basic Diagram -** Members are displayed in four distinct colors which indicate Not Designed, Pass or Safe, Fail and Extreme Failure respectively. The default values define a member as Safe if the ratio is less than 1, Fail if the ratio is between 1 and 1.5, and Extreme Fail if the ratio is greater than 1.5.

  Note: It is important to understand that in this page, the definition of Pass and Fail can be set to have a different meaning than the one the calculation engine used during the steel design process. In the calculation engine, Fail means exceedance of the value set for the `RATIO` parameter (whose default value is 1.0 usually).

  Note: The utilization ratio plot that was available in previous versions of STAAD.Pro can also be accessed by choosing the **Basic Diagram** option.

- **Detailed Diagram -** The table on the right hand side of the box displays the index for the color plot. The first column indicates the lower limit and the second column represents the upper limit for the unity ratio. You can accept the default index settings or can choose to define your own settings by selecting the Use Custom Limits option. The upper and lower limit for the ratio can be provided in the Maximum and Minimum fields, respectively. Users can control the number of divisions between the maximum and minimum values for the index through the No of values option. The values for the divisions or ranges can also be set by the user by checking the Use Custom Divisions check box which will allow the user to edit the ranges displayed in the table on the right.

Show values Select this option to display the ratio values on the contour plot.

Actual Ratio ranges table Displays the From and To range used for a color to graphically represent the design results status of a member. By default, members passing all design checks performed will be shown in green, members failing design checks by 50% or less shown in blue, and those failing by greater than 50% shown in red.

Tip: Double click the colored index cell to open a **Color** dialog, which is used to set a custom color for the selected range.

Plate Stress Contour tab

Used to display stress contours for plates for different types of stresses.

Tip: This tab is only present when plate elements are in the model.

Load Case Select the Load Case for which the stress is to be displayed. You can also select **Envelope** (or a previously defined envelope name) to display an envelope of stress results.

If **Envelope** is selected, select either the **+ve** (maximum positive) or **-ve** (maximum negative) cases for dislay.

Stress Type Select the type of stress gradients to display on the elements:

Max Absolute
Max Top, Min Top, Max Bottom, Min Bottom (Principal Major and Minor Stresses)
Tau Max Top, Tau Max Bottom
Max Von Mis
Von Mis Top, Von Mis Bottom
Max Tresca
Tresca Top, Tresca Bottom
SX, SY, SXY, MX, MY, MXY, SQX, SQY (local)
Global Moment, Global Stress
Base Pressure
Top Combined SX, Top Combined SY, Top Combined SXY, Bottom Combined SX, Bottom Combined SY, Bottom Combined SXY (local)

Contour Type The **Normal Fill** option provides contours based on the values of centre stress and corner stress as described above.

The **Enhanced Fill** option will determine the contour using the centre and corner stresses as used in the Normal Fill option, and an additional set of interpolated control points along the edges of each plate that will tend to smooth out the contour lines on plates that have large changes of stress over their surface.

Absolute Values causes the stress values to be compared based on the absolute values, rather than algebraic values. If this option is checked, stress values of +10 units and -10 units will be in the same range.

Index Based on Center Stress	The Plate Stress Contour maps are based on values from the calculated analysis results of the centre stress/force of each plate and corner stresses (which are averaged from all plates that share the same node). There are two ways that the corner stresses/forces can be determined. This can be either directly from the analysis results or estimated by extrapolating the centre stresses to the corners of each plate. These method to use is specified with the option: • When checked, the contour map will be drawn using only the values of centre stresses/ forces calculated by the analysis. Values for corner stresses/forces will be determined from each centre stress by extrapolating them to the corner and then averaged for all plates that share the node. • When unchecked, the contour map will be based on both the centre stresses/forces AND the values of corner stress/force calculated by the analysis. Again the value is averaged for all plates that share the node.
View Stress Index	displays the legends of the colors with stress values at the side of the screen.
Re-Index for new view	When individual elements are isolated from the full model then the stress distribution for the entire element may be displayed in a single color . This is because the variation in stresses across the element may not have been appreciable with respect to the entire model and the entire stress range may have been represented by a single color in the full model. This may create problem because the users in such cases will not be able to view the stress variation across the element. To take care of this **The re-index stress range for new view** option has been included which automatically regenerates the stress index for any newly created view which will allow the users to view the stress variation in much more detail.
Show Displaced Shape	Displays the plate stresses on a displaced model.
Contour Base on Visible Entities Only	Limits the stress contour range to the stresses contained in only visible entities.
Use Custom Limits	By default, 15 contours are plotted with the maximum and minimum values determined by the program based on the results for the selected load case and stress type. Set the Use Custom Limits option to specify **Minimum** and **Maximum** values as well as **No. of values** to use for equal divisions.
Use Custom Divisions	By default, the values of the stresses used for color gradation are obtained by taking the **Maximum** and **Minimum** and dividing the difference equally into as many parts as is defined **No. of values**. Setting the Use Custom Divisions allows you to directly type the cut-off values for each color. **Tip:** Take care to ensure that they are in ascending order.
Directions for Global Stress	(Global Stress or Global Moment only) Select the **Result Dir** of interest and the vector direction for **Up**.

Solid Stress Contour tab

Used to display stress contours for solids for different types of stresses.

Tip: This tab is only present when solid elements are in the model.

To display the solid stresses on a displaced model, select the **Solid Stress Contour** tool in the **View Results** group on the **Results** ribbon tab in the **Postprocessing** workflow.

Load Case	Select the Load Case for which the stress is to be displayed.
Stress Type	Select the **Stress Type** from the drop down list. Once we select these, the **Maximum** and the **Minimum** values of that stress under the selected load case are displayed on the dialog box.
Contour Type	The **Normal** and **Enhanced** buttons indicate how the Stress Contour is drawn. The **Normal** contour option uses the stress points at each corner of the solid along with the center stress to calculate the contour. The **Enhanced** contour option uses the same points as the Normal contour plus the interpolated stress at the mid point of the edges. The second option takes more time to generate but is more accurate.
Absolute Values	causes the stress values to be compared based on the absolute values, rather than algebraic values. If this option is checked, stress values of +10 units and -10 units will be in the same range.
Index Based on Center Stress	the stress range of the index is based on the stress values obtained at the center of the elements.
View Stress Index	displays the legends of the colors with stress values at the side of the screen.
Use Custom Limits	By default, 15 contours are plotted with the maximum and minimum values determined by the program based on the results for the selected load case and stress type. Set the Use Custom Limits option to specify **Minimum** and **Maximum** values as well as **No. of values** to use for equal divisions.
Use Custom Divisions	By default, the values of the stresses used for color gradation are obtained by taking the **Maximum** and **Minimum** and dividing the difference equally into as many parts as is defined **No. of values**. Setting the Use Custom Divisions allows you to directly type the cut-off values for each color. **Tip:** Take care to ensure that they are in ascending order.
Re-Index stress range for new view	When individual elements are isolated from the full model then the stress distribution for the entire element may be displayed in a single color . This is because the variation in stresses across the element may not have been appreciable with respect to the entire model and the entire stress range may have been represented by a single color in the full model. This may create problem because the users in such cases will not be able to view the stress variation across the element. To take care of this **The re-index stress range for new view** option has been included which automatically regenerates the stress index for any newly created view which will allow the users to view the stress variation in much more detail.
Show Displaced Shape	Displays the solid stresses on a displaced model.

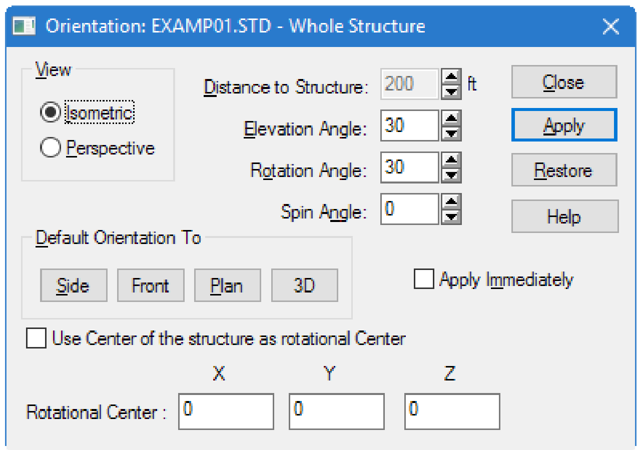
Orientation dialog

Used to modify the settings that define various view orientations of the structure, such as Plan view, Elevation view, Perspective view, etc.

Opens when the **Orientation** tool is selected in the **Rotation** group on the **View** ribbon tab.



View group

Isometric — This option will display the structure in default isometric view (with 70 degree Elevation angle and 330 degree Rotation Angle). An isometric view uses effectively an infinite distance to the structure.

Perspective — This option will display the perspective view of the structure. The viewing distance and angles can be changed by changing one of the three options: **Distance to Structure**, **Elevation Angle**, or **Rotation Angle**.

Distance to Structure

This value indicates the distance of the eye (or camera) from the structure in the perspective view. You may type this value or use the spin control to increase or decrease the current value.

Tip: This distance should be greater than the extents of a volume containing the structure in order to prevent distorting the view.

Elevation Angle

This value indicates the rotational angle of the eye about an axis which is lying horizontal (left to right) in the plane of the screen and passing through the center of the screen. You may type this value or use the spin control to increase or decrease the current value.

Rotation Angle

This value indicates the rotational angle of the eye about an axis which is lying horizontal (left to right) in the plane of the screen and passing through the center of the screen. You may type this value or use the spin control to increase or decrease the current value.

Spin Angle

This value indicates the rotational angle of the eye about an axis which is perpendicular to the plane of the screen (in to out) and passing through the center of the screen. You may type this value or use the spin control to increase or decrease the current value.

Default Orientation To

The orientation of the structure may be set to a view defined by one of the following options:

Side — View From + X (right)
Front — View From + Z (front)
Plan — View From + Y (top)
3D — isometric angle (default)

Apply Immediately Any change made through the **Orientation** dialog may be immediately reflected in the current view when this option is selected.

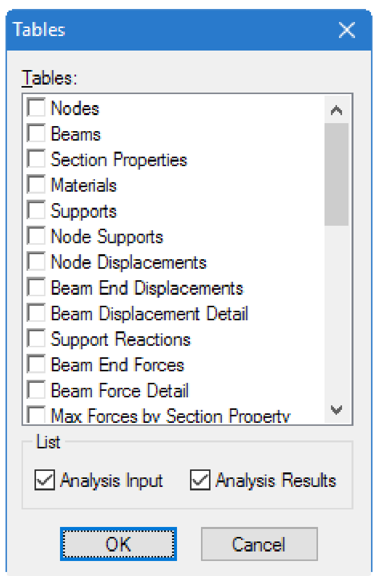
Use center of the structure as the rotational center When this options is selected, STAAD.Pro will consider the center of the structure as the rotational center. The axis of rotation can be manually input by clearing this box and then providing the **Rotational Center** values.

Rotational Center The axis of rotation can be manually input by checking this box and specifying the exact X, Y and Z coordinates in the Rotational Center boxes.

Tables dialog

Used to display and close different tables, such as Node coordinates, Beam incidences, Node displacements, etc. irrespective of the current page.

Opens when the **Tables** tool is selected in the **Windows** group on the **View** ribbon tab.



Tables Check the associated boxes for the tables you want to display. The boxes are automatically checked for the currently displayed tables. To close a table, leave the associated box blank.

List These check boxes control which tables are listed for selection from the **Tables** list. To display the list of available input related tables, set the **Analysis Input** option. To display the output related tables, set the **Analysis Results** option .

Open View dialog

Used to open a previously saved structural view window.

Opens when the **Open View** tool is selected in the **Views** group on the **View** ribbon tab.

Views list	A list of saved views is displayed here. Select the View you want to open.
Do you want to: options	Used to determine whether the selected view would be opened in a new window or whether it would replace the current view.
OK	Opens the selected view, using the selected option.
Cancel	Closes the Open View dialog without opening a view.
Help	Opens the Help window.

Options dialog

Used to control display items such as fonts, colors and styles for different labels, units, etc. The tabs of the dialog are explained in the following pages.

Opens when **Display options** is selected on the **Settings** tab in the Backstage view.

View Highlight tab

Controls the simultaneous display of several view windows on screen. STAAD allows us to create multiple "child" view windows from the default "Whole Structure" ("parent") view. Typically, the "parent" view would display the entire structure, while the "child" windows would display selected portions of the structure in various orientations.

When one or more "child" windows are displayed on screen along with the "parent" window, the parent window highlights the portion of the structure contained in a "child" window, whenever that child window is active (gets focus). The next figure shows that the *View 1* window is active and the portion of the structure contained in the *View 1* window is highlighted in the *Whole Structure* window.

The *View Highlight* tab controls how the Whole Structure window highlights the portion of the structure contained in a "child" window. In the above figure, the *Highlight View in Whole Structure Window* group is related to saved views, while the *Show Zoomed Area in Parent View* group is related to the view window created using the *Zoom Dynamic* option.

Highlight	When checked, the 'Parent" or Whole Structure window highlights the portion of the structure contained in the "child" window.
Width	Controls the width of the highlighted portion of the structure. The associated color button allows selection of the highlight color.

Tolerance tab

Tolerance	Controls the minimum allowable spacing between two adjacent nodes so that the program does not generate errors of duplicate or overlapping joints. Type a *Tolerance* in the associated edit box.
Split member if new node is added on the member	Among the various methods available for adding a beam in the Modeling mode, two of the methods are using **a.** The *Beam* sub-page of the *Geometry* page from the left side of the screen, and,

b. *Snap/Grid Node - Beam* option of the *Geometry* menu from the top of the screen.

In these methods, if the start or end point of a member being drawn (let us call this member B) happens to fall within the span point of an existing member (let us call this member A) , the setting chosen for this option will determine what happens to member A.

If the above option is switched on, the member A will be split into 2 members, and there will now be a total of 3 members incident from this common point.

If it is switched off, the member A will not be split, and the structure will be created as though the 2 members are NOT connected at the point in question.

One may test this by doing the following. Let us say that member A goes from (0,0,0) to (0,10,0), and that member B goes from (0,5,0) to (7,5,0).

If one were to use one of the methods (a) or (b) described above, it will be evident that leaving the option on will cause 3 members to be created, 5,5 and 6 units long. These 3 members will be connected at the common point (0,5,0).

Leaving the option off will cause only 2 members to be created, 10 and 7 units long respectively.

Here is another example of the relevance of this setting. Let us assume that a building is being assembled in two steps. First, the beam-column skeleton is created. Following that, the slabs and walls are created using the meshing capabilities of the *Geometry | Structure Wizard* option. If any of the nodes of the element mesh fall within the span lengths of the beams and columns, those beams and columns will either be split, or left unchanged, depending upon the settings here.

Tolerance for Warped Plate Element Detection

Used to so specify a tolerance for the plate warping check. By default, plate warping is reported when there is a 30 degree angle (or larger) between the normal to two triangles which are formed by splitting a quad element. This splitting can be done two ways so there are four triangles. If any have more than the tolerance angle (in degrees) between them, then an error is reported. M. To check for warped plates (on page 912) for how this value is used in the interface.

Set the **Save As Default** option to make this the default tolerance for warped plate checks.

> **Tip:** Alternatively, warped plates can be checked by the STAAD engine using the `SET PLATE FLATNESS TOLERANCE` command. See . However, checking for warped plates in the User Interface allows you to quickly correct any plates prior to running an analysis.

Tables tab

Used to choose the font used in various tables.

Sample Displays the current typeface settings used for Tables.

Font... Opens the Font (on page 2766), which is used to select font type, size, style, etc. used in tables.

Assign Dlgs tab

Used to control the display of labels for Property, Load, Support etc. while these are being assigned.

Show all labels when dialog is open	Displays labels for all assigned properties, loads, etc. when the corresponding dialog is opened.
Only show labels for selected items in dialog	Displays labels for only the selected items
Show all labels, with labels for selected items in the following color	Displays labels for the selected items in the specified color. Displays all other labels in default color.

Beam Labels/Plate Labels/Solid Labels/Load Labels/Load Icons/Annotation/Dimension tabs

These tabs offer options for labeling beams, plates, solids, etc. The *Beam Labels* tab controls how the labels for the beams (including the dimension of the members) appear on the screen, and is explained below.

Style	Select any of the pre-defined styles for displaying the beam numbers.
Separator, Reference	These options control how the property number reference is displayed with the member numbers.
Horizontal Alignment, Vertical Alignment	These items determine the relative position of the label with respect to the member.
Font...	Opens the Font (on page 2766), which is used to select font type, size, style etc. for the label.
Opaque	When checked, the labels behave as opaque objects, i.e. everything behind them become hidden.
Angle Text	When checked, displays the labels inclined along the members.

Structure Units/Section Units/Force Units tabs

The *Structure Units, Section Units* and *Force Units* tabs offer options for specifying units for the structure, sectional views, forces, etc. The *Section Units* tab is described below and is shown in the next figure.

Dimension

Used to set the length units in which dimension lines are drawn on the screen. This feature dictates the values that will be displayed for the *Dimension Beams* facility as well as the *Display Node to Node Dimension* facility of the *Tools* menu.

> **Note:** Changing units on these tabs does not change the input units in the Input Command File, the units are changed in the graphical display only. To change units in the Input Command File, see Tools | Set Current Input Unit...menu.

The *Section Units* tab allows you to specify the units to display different data items such as sectional Area, Moment of Inertia, etc. Select the appropriate units from the available drop down list and specify the number of digits to be displayed after the decimal point using the *Show* spin boxes.

Dimension

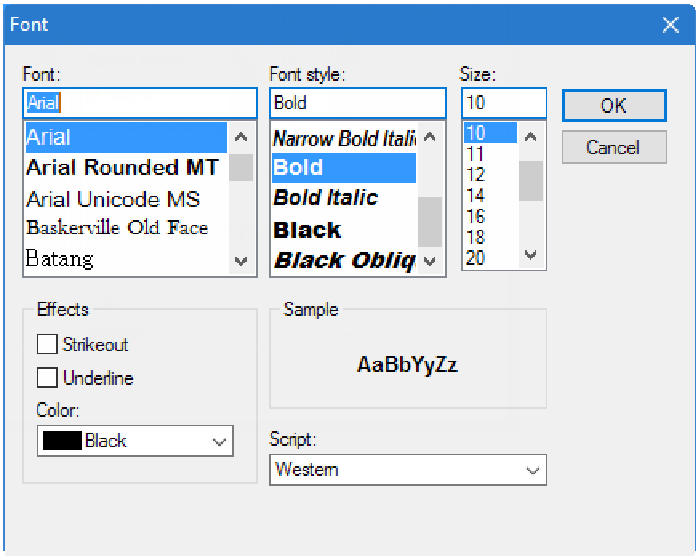
Used to set the length units in which certain property values are displayed on the screen. If you choose the *General* page followed by the *Property* page along the left side of the screen, a button called *Values* will be present along the right side of the screen. If properties have already been assigned to any members, you can examine the property values by clicking on the *Values* button. The terms *D, Bf, Tf* and *Tw* use the length settings of this facility. The same table may also be displayed by going to *View | Tables | Section Properties*.

OK	Applies all changes made and closes the dialog
Cancel	Closes the dialog without applying any changes.
Apply	Applies all changes made. Only active if changes have been made since the dialog was opened or the Apply button was last clicked.
Help	Opens the STAAD.Pro help window.

Font

Used to control the text display style.

Opens when the **Font** button is clicked in various dialogs.



Font	Sets the typeface. Select from the scroll list or simply type in the field to search for an installed font name.
Font style	Select font styles or combination of styles from the list.
Size	Sets the text size.
Effects	(Not available for all Font dialogs) Add **Strikeout** and **Underline** effects to the text.
Color	(Not available for all Font dialogs) Select a standard color to use for the font.
Script	Select the script set used.

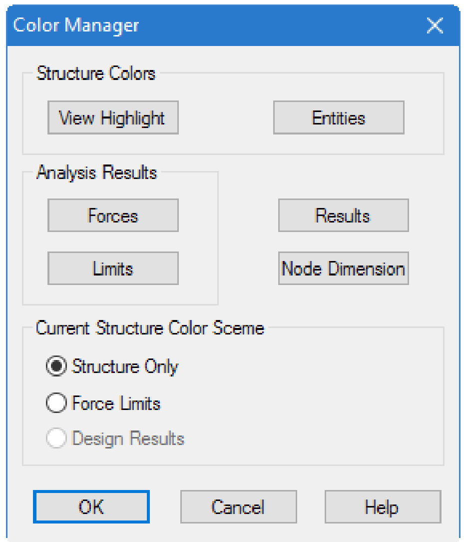
OK	Applies the font changes and closes the dialog.
Cancel	Closes the dialog without applying any changes.

Color Manager dialog

Used to specify colors of different items such as analysis results.

Opens when either:

- **Set Structure Colors** is selected on the **Settings** tab in the Backstage view, or
- the **Set Structure Colors** tool is selected in the **Options** group on the **View** ribbon tab.



View Highlights Opens a color selection dialog, which is used to specify a highlighting color for selected objects.

Entities Opens the **Define Colors** dialog, which is used to color code structural entities by specific attributes.

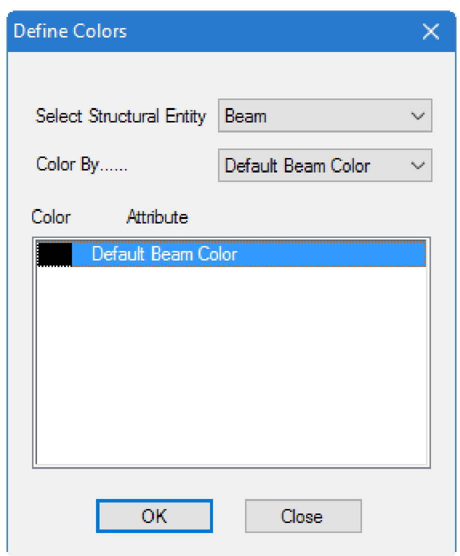


Figure 338: Define Colors dialog

	Specify the type of entity (Beam, Plate or Solid) whose colors are to be changed under the Select **Structural Entity** list box. Under the **Color By** option, select the type of attribute for which the colors will be arranged according to. To change the color of a particular attribute (for example, if Beam Properties option is selected, all the properties for that model will be listed), double-click on the color to bring up the color palette dialog box. Select a new color for that particular attribute. **Note:** The colors of the entities can also be changed through the Structure tab of the **Diagrams** dialog .
Forces	Opens a color selection dialog, which is used to specify a highlighting color for forces shown in analysis results.
Limits	Opens a color selection dialog, which is used to specify a highlighting color for limits in analysis results.
Results	Opens a color selection dialog, which is used to specify a highlighting color for results.
Node Dimension	Opens a color selection dialog, which is used to specify a highlighting color for node-to-node dimensions.
Current Structure Color Scheme	The following options are available for applying the selected color changes: Structure Only Force Limits Design Results

Tool Tip Options dialog

Used to display any customized input or output information about a node, beam, plate or solid element by simply placing the mouse over the structural entity.

The structural tool tips include the maximum and minimum nodal displacements and beam end forces out of all the load cases (envelope of displacements or forces). You can now place the mouse over a node or beam and have a tool tip report these values. Tool tips are similar to the information box displayed when the mouse hovers over a toolbar icon.

Opens when **Structural Tool Tip Options** is selected on the **Settings** page of the Backstage view.

Note: The tool tips automatically display the results for the active load case. All values are reported in the current display units.

Show Tool Tip	Turns the structural tool tips on or off.
Tip Delay	signifies the amount of time it takes from when the mouse hovers over an entity to when the tool tip actually pops up. This number is expressed in milliseconds (i.e., 1000 = 1 second).
Tool	Select the Node or Beam item from the left hand side On the right hand side, there will be new options to enable the display of the maximum and minimum nodal displacements or beam end forces out of all the load cases (i.e., an envelope).

Options

The options (items that can be displayed) for each entity are shown here. A check mark signifies that the particular data item will be displayed in the tool tip.

Note: An option with a “+” next to it signifies that further options can be enabled or disabled.

Note: A red “X” indicates the data will not be shown in the tool tip. Simply click on the check box to turn an option on or off.

The resulting tool tip for nodes with the Node Number, Displacement, and Support options set.

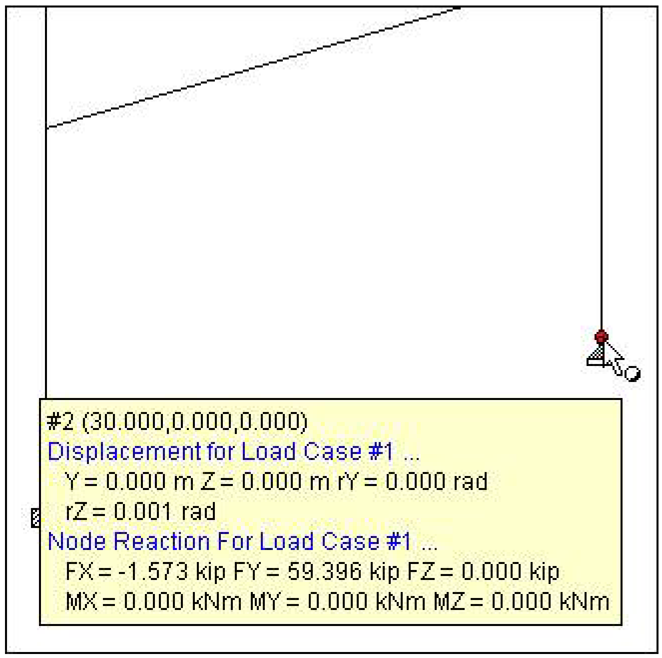

Figure 339: Example tool tip at a support

Select tab

Contains tools used for selecting objects in your analytical model.

Table 302: Cursors group

Tool name	Description
 **Nodes Cursor**	Used to graphically select nodes.

Tool name	Description
 **Beam Cursor**	Used to graphically select beams.
 **Plate Cursor**	Used to graphically select plates.
 **Solid Cursor**	Used to graphically select solids.
 **Geometry Cursor**	Used to graphically select nodes, members and elements of the structure simultaneously. To select nodes, members, or elements using the Geometry Cursor, simply click on the desired structural components. To select multiple nodes, members and elements, hold **<Ctrl>** while selecting. We may also select the structural components graphically by creating a window on screen with the cursor around these components.
 **Members Cursor**	Used in Steel Design or Concrete Design to graphically select all those beams defined as a same member in the member set up of member design, simultaneously. Members may be user defined or may be generated automatically using the Auto Form Member tool. To select all the beams defined as a same member using the Member Cursor, just click on one beam. The other beams having the same member name as the selected one will automatically be selected. To select multiple physical members, hold down **<Ctrl>** while selecting. You may also select the physical members graphically by dragging a fence area around these physical members using the cursor.
 **Plates & Solids Cursor**	Used to graphically select both plate and solid elements.

Tool name	Description
 **(Select) Text**	Used to add comments and titles to pictures and result diagrams. The added text can be plotted, too. The inserted text can be deleted, moved, and modified using the text cursor. Refer to the **Insert Text** on the **Utilities** ribbon for a detailed description on inserting text and modifying it using the text cursor.
 **Previous**	Selects the last objects selected if they have been deselected or if the selection set has changed.
 **Load**	Used to modify any load already applied on the model by double clicking it. When selected, the mouse pointer changes to the Load Edit Cursor.

Table 303: Geometry group

Tool name	Description
 **All**	Selects all nodes, members, elements, and solids in the model.
 **Inverse**	Used to select all objects but the ones which are currently selected.
 **List**	Opens the **Select Geometry** dialog, which is used to select one or more model entities (other than nodes) from a list of all entities in the model.

Tool name	Description
Parallel	Used to select all beams, elements, and surfaces which are parallel to a specified global axis. Select the desired global axis from the sub-menu. • **To XY** • **To YZ** • **To XZ**
Connected	Used to select all the entities that are connected to (i.e., have a common node with) any particular node, beam, plate, or solid. A dialog opens prompting you to select the node, beam, plate, or solid number. You can select to apply immediately or click **OK** to see all the model entities that are connected to the selection. • **To Node** • **To Beam** • **To Plate** • **To Solid** **Tip:** Options for geometry objects not contained in the current mode are disabled.
Highlight	Opens the **Visual Check** dialog, which is used to sequentially highlight a specific group of entities (beams, plates, or solids) in numerical order. Controls on the speed of the selection are also included.

Table 304: Nodes group

Tool name	Description
All	Selects all nodes in the model.
Inverse	All nodes in the selection set are deselected and any previously unselected nodes are added to the selection set.

Tool name	Description
 **List**	Opens the **Select Nodes** dialog, which is used to select one or more nodes from a list of all nodes in the model. A free list of node numbers may also be specified.
 **Supports**	Selects all supported nodes in the model.

Table 305: Beams group

Tool name	Description
 **All**	Used to select all beams.
 **Inverse**	All beams in the selection set are deselected and any previously unselected beams are added to the selection set.
 **List**	Opens the **Select Beams** dialog, which is used to select one or more beams from a list of all beams in the model.
 **Parallel**	Select beams that are parallel to the selected global axis. • **To XY** • **To YZ** • **To XZ**

Tool name	Description
 **Connected**	Select beams that connect to the selected object type. • **To Node** • **To Beam** • **To Plate** • **To Solid** **Tip:** Options for geometry objects not contained in the current mode are disabled.

Table 306: Plates group

Tool name	Description
 **All**	Selects all plates in the model.
 **Inverse**	All plates in the selection set are deselected and any previously unselected plates are added to the selection set.
 **List**	Opens the **Select Plates** dialog, which is used to select one or more plates from a list of all plates in the model.
 **Parallel**	Select plates that are parallel to the selected global axes plane. • **To XY** • **To YZ** • **To XZ**
 **Connected**	Select plates that connect to the selected object type. • **To Node** • **To Beam** • **To Plate** • **To Solid** **Tip:** Options for geometry objects not contained in the current mode are disabled.

Table 307: Solids group

Tool name	Description
 **All**	Selects all solids in the model.
 **Inverse**	All solids in the selection set are deselected and any previously unselected solids are added to the selection set.
 **List**	Opens the **Select Solids** dialog, which is used to select one or more solids from a list of all solids in the model.
 **Connected**	Select solids that connect to the selected object type. • **To Node** • **To Beam** • **To Plate** • **To Solid** **Tip:** Options for geometry objects not contained in the current mode are disabled.

Table 308: Filter group

Tool name	Description
 **Filter**	Used to select multiple types of geometric entities (nodes, beams, surfaces, etc.) with specific attributes in one pass. This will reduce the time required to create new views and help quickly identify the location of certain entities on your structure. **Note:** Before this cursor can be used, the actual filter parameters must be defined in advance in the **Selection Filters** dialog.

Table 309: Attributes group

Tool name	Description
 **Group**	Opens the **Select Groups** dialog, which is used to select objects in a named group.
 **Property Name**	Used to select nodes and members based on specifications associated with them. A number of specification types are included in the sub-menu list.
 **Missing Property**	Used to select beams, plates, or solids that lack critical input data (Property, Density, Elasticity, Poisson's ratio, and Alpha) in the active view.

Table 310: Modes group

Tool name	Description
 **Drag Box**	Click to activate the drag box selection mode.
 **Drag Line**	Click to activate the drag line selection mode.
 **Region**	Click to activate the region selection mode.

Visual Check dialog

Used to easily identify the location of entities in a certain section of the model. Many times, commands like assigning properties or releases are used for a certain set or range of entities which may be difficult to graphically observe because of their close proximity to each other. This feature may help alleviate difficulties in checking the properties of a concentrated group of entities.

Commands in the dialog to control the speed of the automatic selection process are described below.

Opens when the **Geometry** > **Highlight Entities Sequentially** tool is selected in the Selection group on the Geometry ribbon tab.

Start With list
Select the entity type to highlight.

Currently Selected
Displays the currently selected entity

>
Automatically selects the type of entity chosen in the Start With list in a sequential order (by entity number).

||
Pauses the sequential selection operation. Inactive when the automatic selection is not active.

>>
Increases the speed at which the automatic selection occurs. The selection process becomes faster with each press of this button.

<<
Decreases the speed at which the automatic selection occurs. Each time this button is pressed, the selection process becomes slower.

|<
Increments the selection manually one entity at a time. If this is not highlighted, the Pause button must be pressed to stop the automatic selection process.

>|
Decrements the selection process manually one entity at a time. If this is not highlighted, the Pause button must be pressed to stop the automatic selection process.

Stop
Stops the selection process.

Query
Opens the entity query dialog for the currently selected entity.

Exit
Closes the Visual Check dialog.

Select Nodes dialog

Used to select one or more nodes from a list of all nodes in the model. A free list of node numbers may also be specified.

list of nodes
Select the desired nodes by clicking on their number in the displayed list. To select sequential nodes, either click and hold the mouse button while dragging over the numbers or hold the SHIFT To select non-sequential nodes, hold down **<Ctrl >**while clicking.

Selection Type
To select nodes by numbers in the list, select the **Select from list by cursor** option. To select nodes with a typed list of node numbers, click the **Select using typed list** option then click **Select Listed Entities** .

Select Listed Entities
Click to select nodes listed in the **Enter list** box.

Enter list
Specify node numbers for selection. You may use `to` to represent a range of sequential node numbers. Separate values by either spaces or commas.

> **Tip:** Clicking in this box selects the Select using types list option for Selection Type automatically.

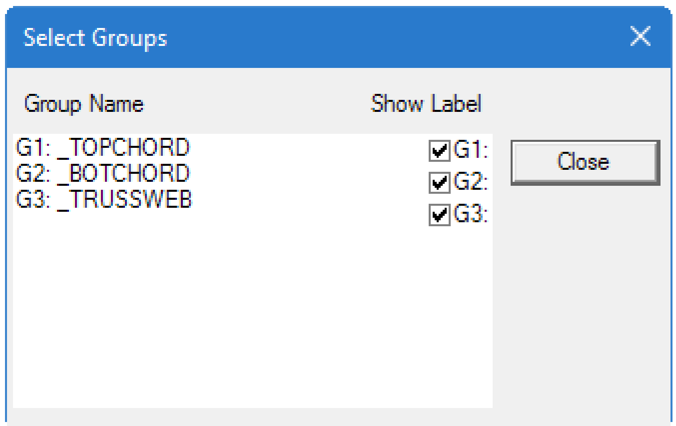
> **Note:** Similar features exist for selecting by lists of beams, plates, solids, surfaces, and geometry.

Opens when the **Nodes** > **Node List** tool is selected in the **Selection** group on the **Geometry** ribbon tab.

Select Groups dialog

Used to select members in a named group.

Opens when the **Group Selection** tool is selected in the **Selection** group on the **Selection** ribbon tab.



Group List Select a single group to highlight the component model elements in the View window. Multiple groups may be selected by pressing **<Ctrl>**.

Show Label If labels pertaining to certain entities are switched on (e.g., beam labels), the labels will be displayed only for members with a **Show Label** check box set. Clear the check box for any group for which you do not want labels displayed.

Close Closes the dialog.

Specification tab

Table 311: Beam Profiles group

Tool name	Description
 **Database**	Click the drop-down arrow to display a gallery list of all database section tables. Click a country name or material to open the corresponding section table dialog.

Tool name	Description
Prismatic	Opens the **Property** dialog, which is used to assign Circular, Rectangular, Tee, Trapezoidal, General(arbitrary), etc. cross sections to the members.
Tapered	Opens the Tapered I Property dialog, which is used to specify an I-section having a varying depth over the length of the member.
User Table > **User Table Manager**	Opens the **User Table Manager** dialog, which is used for adding and managing previously created user table sections to the structure.
User Table > **Assign from User Table**	Opens the User Property Table dialog, which is used to assign previously created user table sections to the structure. **Note:** If you have not created any user-provided tables, then you will asked if you would like to create one first.
Assign	Opens the **Assign Profile** dialog, which is used to select a section profile and optional material to a member for member selection during design.

Table 312: Plate Profiles group

Tool name	Description
Plate Thickness	Opens the **Plate Element/Surface Property** dialog, which is used to provide plate element properties (thickness) with or without the material specification. Plates can have a different thickness at each node. Surfaces have a constant thickness.

Table 313: Material Constants group

Tool name		Description
Constants >	**Young's Modulus**	Opens the **Material Constant - Elasticity** dialog, which is used to assign the modulus of elasticity, E, based on a predefined material value or a custom value.
	Shear Modulus	Opens the **Shear Modulus - G** dialog, which is used to assign the shear modulus, G, based on a predefined material value or a custom value.
	Poisson's Ratio	Opens the **Material Constant - Poisson's Ratio** dialog, which is used to assign Poisson's ratio, ν, based on a predefined material value or a custom value.
	Density	Opens the **Material Constant - Density** dialog, which is used to assign the material density, γ, based on a predefined material value or a custom value.
	Thermal Coefficient	Opens the **Material Constant - Alpha** dialog, which is used to assign the thermal coefficient, α, based on a predefined material value or a custom value.
	Damping Ratio	Opens the **Material Constant - Damping Ratio** dialog, which is used to assign the damping ratio, c, based on a predefined material value or a custom value.

Table 314: Specifications group

Tool name		Description
Node >	**Add Control/ Dependent Specification**	Opens the **Node Specification** dialog to the **Control/Dependent** tab, which is used to select a control node and the directions which other dependent nodes follow actions.
	Delete Control/ Dependent Specification	Used to delete a control/dependent specification.
Beam >	**Beta Angle**	Opens the **Beta Angle** dialog, which is used to specify the beta angle for members.
	Beam Reference Point	Opens the **Reference Point** dialog, which is used to specify a reference point for the members from which the program calculates the beta angle.
	Cable	Opens the **Member Specification** dialog to the **Cable** tab, which is used to assign standard cable and nonlinear cable specifications.
	Compression Only	Opens the **Member Specification** dialog to the **Compression** tab, which is used to define compression-only members. These members are capable of carrying compressive forces only.

Tool name		Description
	Tension Only	Opens the **Member Specification** dialog to the **Tension** tab, which is used to define tension-only members. These members are capable of carrying tensile forces only.
	Truss	Opens the **Member Specification** dialog to the **Truss** tab, which is used to specify truss members. These members are capable of carrying axial forces only.
	Imperfection	Opens the **Member Specification** dialog to the **Imperfection** tab, which is used to assign camber or drift values to members.
	Cracked Property	Opens the **Member Specification** dialog to the **Property Reduction Factors** tab, which is used to assign reduced (i.e., “cracked”) section property factors to members.
	Release	Opens the **Member Specification** dialog to the **Release** tab, which is used to assign releases, partial moment releases, or spring values to member ends.
	Offset	Opens the **Member Specification** dialog to the **Offset** tab, which is used to assign member end offset values to a member end.
	Inactive	Opens the **Member Specification** dialog to the **Inactive** tab, which is used to instruct the analysis and design engine to ignore a member for analysis.
	Fireproofing	Opens the **Member Specification** dialog to the **Fire Proofing** tab, which is used to assign block or contour fire proofing material to a member for weight calculations.
 **Plate >**	**Plate Reference Point**	Opens the **Plate Reference Point** dialog, which is used to specify options for determining the general direction of the local Z axis of elements,
	Release	Opens the **Plate Specs** dialog to the **Release** tab, which is used to assign released degrees of freedom at a plate node.
	Ignore Inplane Rotation	Opens the **Plate Specs** dialog to the **Ignore Inplane Rotation** tab, which is used to override the value that STAAD determines for the stiffness associated with the local axis Mz degree of freedom for plate elements
	Plane Stress	Opens the **Plate Specs** dialog to the **Plane Stress** tab, which is used to model plate elements as Plane Stress elements.
	Ignore Stiffness	Opens the **Plate Specs** dialog to the **Ignore Stiffness** tab, which is used to instruct the program to neglect the stiffness of the selected plates while assembling the stiffness matrix. Hence, the stiffness contribution of the selected plates is not considered. This is similar to the Inactive command for the members.

Table 315: Supports group

Tool name		Description
 **Fixed**		Opens the **Create Support** dialog **Fixed** tab, which is used to create a fixed support tag and (optionally) to assign that to selected nodes. A Fixed support is restrained in all 6 degrees of freedom.
 **Pinned**		Opens the **Create Support** dialog **Pinned** tab, which is used to create a pinned support tag and (optionally) to assign it to selected nodes. A Pinned support is restrained in all three translational degrees of freedom and free in the 3 rotational degrees of freedom.
 **Custom**		Opens the **Create Support** dialog **Fixed But** tab, which is used to create various types of roller, hinge and spring supports with specified restrained degrees of freedom and to assign them to selected nodes.
 **Foundation**		Opens the **Create Support** dialog **Foundations** tab, which is used to create spring supports for independent footings and mat foundations and to assign them to selected nodes.
 **One-way Spring**		Opens the **Create Support** dialog **Tension/Compression Only Spring** tab, which is used to designate certain support springs as Tension-only or Compression-only springs.
Other Supports >	**Inclined**	Opens the **Create Support** dialog **Inclined** tab, which is used to create supports that offer restraints in an axis system that is inclined with respect to the global axis system.
	Mulit-Linear Spring	Opens the **Create Support** dialog **Multilinear Spring** tab, which is used to enter displacement and spring stiffness data pairs for a multilinear spring definition, which is then used for a Fixed But support type.
	Enforced	Opens the **Create Support** dialog **Enforced** tab, which is used to create a fixed-condition support defined in terms of being stiff springs.
	Custom Enforced	Opens the **Create Support** dialog **Enforced But** tab, which is used to create a fixed-condition support defined in terms of being stiff springs with the option to release selected degrees of freedom.

Table 316: Tools group

Tool name	Description
 **Section Wizard**	Launches the **Section Wizard** application.
 **Section Database**	Launches the **Section Database Manager** application.

Specifications - Whole Structure dialog

Used for defining specifications and assigning them to nodes, members and elements.

Opens when either:

- the **Specifications** page is selected, or
- the **Specifications Layout** tool in the **Specifications** group on the **Specifications** ribbon tab is selected

Specification list
All Specifications that have been defined for the model are listed here.

Note: Physical Member specifications are designated with either PMEMBER or Physical tags.

Highlight Assigned Geometry
When this box is checked and you click on a specification in the **Specifications** dialog box, members that have been assigned the specification will appear highlighted in the structure window. For example in the previous figure, if you click on the MEMBER TRUSS specification, all truss members will be highlighted.

Edit/Delete
Used to modify a previously assigned attribute, or delete it altogether.

Node...
Opens the Node Specification dialog (on page 2784), which is used to specify rigid links or specialized linkages in the structure.

Beam...
Opens the Member Specification dialog (on page 2786), which is used for specifying frame member specifications.

Plate...
Opens the Plate Specs dialog (on page 2791), which is used to specify finite element specifications.

Toggle Specification
This is a switch setting which turns on what is called the toggle mode. In this mode, when an attribute is selected and assigned using the "Use Cursor to assign" method, the following happens.

- Click on the member or element once - the attribute gets assigned.
- Click on the same member or element a second time - the attribute gets de-assigned.

- Click on the same member or element again, - the attribute gets re-assigned.

Thus each click will result in an assign if the attribute was un-assigned, and a de-assign if the attribute was assigned.

Assignment Method

The options under the **Assignment Method** are used to assign specifications to joints, members and elements. The assignment method can be one of **Assign To Selected Beams, Assign To View, Use Cursor To Assign** or **Assign To Edit List**.

- Assign To Selected Beams **-** To assign a specification to selected nodes, members or elements, first select the specification from the **Specifications** dialog box. The specification selected is highlighted. Then select the nodes, members or elements to which this specification is to be assigned. This is done by going to the **Select** menu, then choosing the appropriate cursor option. Select the desired joints, members or elements using the cursor. When all desired nodes, members or elements are selected, click the **Assign To Selected Beams** radio button, then click the **Assign** button. Note that the label for this button changes depending on whether nodes, members or elements are selected.
- Assign To View **-** To assign a specification to all nodes, members or elements in a view, first select the specification from the **Specifications** dialog box. The selected specification is highlighted. Select the **Assign To View** radio button, then click the **Assign** button. All nodes, members or elements in the structure are assigned this specification.
- Use Cursor To Assign **-** To assign a specification to nodes, members or elements using the cursor, first select the specification from the **Specifications** dialog box. The selected specification is highlighted. Select the **Use Cursor To Assign** radio button, then click the **Assign** button. The button will appear depressed and the label will change to **Assigning**. Use the appropriate cursor (from the Select menu) to assign the selected specification to the individual nodes, members or elements. Click on the **Assign** button again to finish.
- Assign To Edit List **-** To assign a specification using a typed list of node, member or element numbers, first select the specification from the **Specifications** dialog box. The selected specification is highlighted. Select the **Assign To Edit List** radio button, then type the list of node, member or element numbers and click the **Assign** button.

Related Links

- *M. To add a member specification* (on page 802)

Node Specification dialog

Used to specify rigid links or specialized linkages in the structure. This facility can be used to model special structural elements such as ties or a floor diaphragm which makes the floor rigid for in-plane movements. The process is to select a node to act as the control and then degrees of freedom for which the dependent nodes are linked to the control.

Note: Refer to TR.28 Rigid Diaphragm Modeling (on page 2327) for additional details.

Opens when **Node** is clicked on the **Specifications - Whole Structure** dialog.

Note: STAAD.Pro is also capable of defining a rigid floor diaphragm without the need to specify a “control” node. This feature is only available by manually editing the STAAD input file. Refer to TR.28.2 Floor Diaphragm (on page 2328) for additional details

Control/Dependent tab

Note: Control / Dependent was formerly referred to as master / slave.

Control Node
It is called as such because the displacements of the dependent node will be based on the displacement of this “control” node. From the drop-down list, select the node which should serve as the control node.

Dependent Directions

- **Rigid -** This is a means of defining that the link which connects the control with the dependent has infinite stiffness for all the six degrees of freedom. In other words, if one were to consider an imaginary object that has infinite stiffness axially, for shear, torsion and bending, that would be the type of link which connects the control and the dependent.

  Note: By default, STAAD.Pro keeps this box checked. Un-check this box to activate the options described below.

- **XY**, **YZ**, and **ZX -** This is a way of specifying a type of connection where the rigidity is limited to in-plane directions.

  The plane of this link is defined in terms of the global planes XY, YZ, or ZX. For example, if you have a concrete slab in a building, and the slab can be assumed to be nearly inflexible for translations along global X and global Z, and the rotation about global Y, that type of link would be called a “diaphragm” in global XZ.

  XY is equivalent to a Control-Dependent relationship for the degrees of FX, FY and MZ. Similarly, YZ is equivalent to linking FY, FZ and MX, and, ZX is equivalent to linking FX, FZ and MY.
- **FX**, **FY**, **FZ**, **MX**, **MY**, and **MZ -** This provides a way for linking only the specific degrees of freedom you want.

Floor Diaphragm tab

Diaphragm group

No Select diaphragm number.

Type Select the diaphragm type from the drop-down list:

Rigid - a diaphragm that translates & rotates as a rigid body.

Floor Level group
Select one of the options as the method to define the floor level of the diaphragm.

Height Type the global coordinate value (elevation), in Y direction, to specify floor level.

YRange Select this option to define the floor level by upper and lower bounds of Y coordinates.

Note: A single diaphragm may be defined at a given level in STAAD.Pro.

YRange group
Used when the **YRange** option is selected.

	Minimum	The lower bound of Y coordinates for the Y range.
	Maximum	The upper bound of Y coordinates for the Y range.
Control Node Information group	Select the method used to define the Control node of the diaphragm.	
	Calculate	The diaphragm center of mass is determined and a node is created at that location to use as the Control node.
	Select Control Node	Select the existing node to use from the drop-down list.
Define Floor Range	Set this option to define the floor range as a XZ range of coordinates or by manually selecting coordinates.	

Related Links

- *G.14 Rigid Diaphragms* (on page 2128)
- *M. To assign a rigid link between nodes* (on page 817)

Member Specification dialog

Used to set and modify member (beam) specifications.

Opens when **Beam** is clicked on the **Specifications - Whole Structure** dialog.

This dialog contains multiple tabs, each of which is used to add a different member specification.

Release tab

Used to specify the end conditions of members by releasing specified degrees of freedom. Unless a release is specified, all members are rigidly connected the nodes (i.e., all degrees of freedom are restrained) except if the end is a cantilever end or supported.

Note: Refer to TR.22.1 Member Release Specification (on page 2286) for additional information.

Location	Specify either **Start** or **End** as the released joint **Member Incidence** of the member.
Release Type	Select either the **Partial Moment Release** or the **Release** option.
Partial Moment Release	Type a release **Factor** to define a partial release condition. The MP option is a means of specifying the same partial release for all the 3 moment degrees of freedom (MX, MY and MZ). Alternately, use the MPX, MPY or MPZ options to apply different release factors in each direction.
Release	Click the **Release** radio button and check the boxes for the **FX**, **FY**, **FZ**, **MX**, **MY** or **MZ** directions to define the member release condition. You may also specify a Spring Constant along the six degrees of freedom by using the **KFX, KFY, ... KMZ** edit boxes. For example, to define a Spring Constant in the local X direction, enter the Spring Constant in the **KFX** edit box.

Tension tab

Used to define tension-only members. These members are capable of carrying tensile forces only.

There are no additional parameters for this member specification.

Property Reduction Factors tab

Used to specify a set of reduction factors to be applied on the calculated section properties such as area, moments of inertia, and torsional constant.

Note: Refer to TR.20.10 Member Property Reduction Factors (on page 2282) for additional information.

Select the method of how to specify member property reduction factors:

- **Global** – specify the **Reduction Factors** to be used below, which will apply to any member regardless of material.
- **Code Specific** – select the building code to use reduction factors specific to load cases per that code which are only applied to concrete members:

  IS1893 2016

Reduction Factors

Provide a set of reduction factors between which will be used in the stiffness analysis. These factors are directly multiplied to the following section properties:

- Reduction Factor for Cross sectional Area (RAX)

  Note: For IS1893 2016 reduction factors, the **RAX** input field is inactive as this property reduction is not mandated by that code for concrete members.
- Reduction Factor for Torsion Constant (RIX)
- Reduction Factor for Moment of Inertia, major axis (RIY)
- Reduction Factor for Moment of Inertia, minor axis (RIZ)

Notes:

a. Reduction factors are considered for analysis only but not for design.
b. Results using the reduced section properties are not available when using the member query feature.

Note: Automated stiffness reduction requires a STAAD.Pro Advanced license.

Cable tab

Used to define cable members. Select either the Tension or Length option to specify a member tension. Tension-only springs are capable of carrying tensile forces only. Thus, they are automatically inactivated for load cases that create compression in them. Compression-only springs are capable of carrying compressive forces only. Thus, they are automatically inactivated for load cases that create tension in them.

Note: Refer to TR.23.2 Member Cable Specification (on page 2290) for more information.

Initial TENSION	Use this option to specify the initial tension in the cable as a force. **Average** The average tension in the cable is used (considered in advanced cable analysis only). **Start node** Tension is measured from the start node of the member (considered in advanced cable analysis only). **End node** Tension is measured from the end node of the member (considered in advanced cable analysis only).
Unstressed LENGTH	Use this option to specify the initial tension in the cable as a length for nonlinear cable analysis.
Factor in global X Fwx	Multiplying factors on self weight components applied in the global X direction.
Factor in global Y Fwy	Multiplying factors on self weight components applied in the global Y direction. **Tip:** When Y is up, use a negative value to act as gravity.
Factor in global Z Fwz	Multiplying factors on self weight components applied in the global Z direction. **Tip:** When Z is up, use a negative value to act as gravity.

Truss tab

Used to specify truss members. These members are capable of carrying axial forces only.

There are no additional parameters for this member specification.

Note: To specify tension in a truss member for a nonlinear cable analysis, you must edit the STAAD input file directly. Refer to TR.23.1 Member Truss Specification (on page 2289) for additional details.

Compression tab

Used to define compression-only members. These members are capable of carrying compressive forces only.

There are no additional parameters for this member specification.

Offset tab

Used to rigidly offset a frame member end from a joint to model the offset conditions existing at the ends of frame members.

The actual beams and columns of a physical structure are represented by lines in the mathematical (computer) model. In the actual structure, a beam spans a distance which in the clear span between the faces of columns. But in the model, the line for the beam spans between the centerlines of the column. The half-depth portion of either column is considerably stiffer than the beam itself from the standpoint of bending. To take advantage of this additional stiffness, you may specify that the start and end faces of the beam are offset from the node by a distance equal to the half-column-depths.

Member offsets can be specified in other situations too. For example, consider:

- when a bracing member does not meet the node which is defined in its incidence list
- a girder and top slab in a bridge where the centerline of the girder is several inches below the centerline of the slab.

This facility is useful when you want to design the structural parameters of a member by considering the clear distance of the member between the supports (e.g., in the case shear forces or bending moments).

Refer to TR.25.1 Member Offset Specification (on page 2296) for additional information on member offsets.

Location	Specify either **Start** or **End** as the joint at which to specify an offset.
Direction	Select either the **Local** or **Global** axis system for assigning offset distances.
Offsets	Enter the offset distance from the joint in the three axis directions.

Inactive tab

Used to temporarily inactivate members for a specific analysis cycle. Inactivated members may be re-activated later for further processing.

Information on using this is available in EX. US-4 Inactive Members in a Braced Frame (on page 6334) or EX. UK-4 Inactive Members in a Braced Frame (on page 6618). This option is also explained in TR.18 Inactive/ Delete Specification (on page 2240).

There are no additional parameters for this member specification.

Fire Proofing tab

Used to automatically consider the weight of fire proofing material applied to structural steel.

Refer to TR.20.9 Applying Fireproofing on members (on page 2279) for additional information on fireproofing.

Fire Proofing Type	Two types of fireproofing configurations are currently supported: • **BFP (Block Fireproofing):** The fire-protection material forms a rectangular block around the steel section. The thickness specified is the minimum thickness which defines the outer block dimensions.

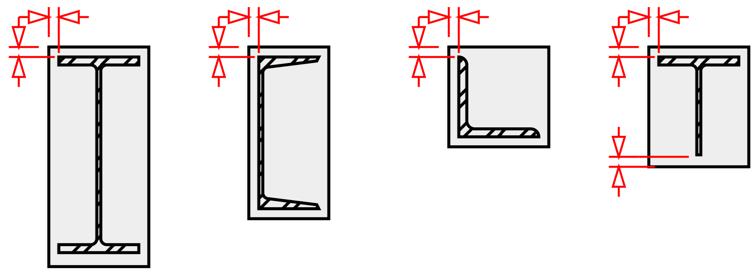

Figure 340: BFP: Block Fireproofing

- **CFP (Contour Fireproofing):**

  The fire-protection material forms a coating around the steel section. The thickness specified is a constant thickness around the section profile.

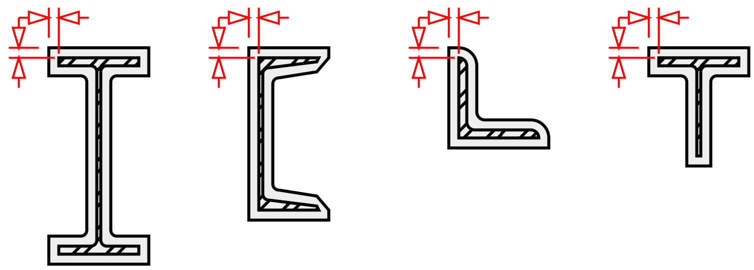

Figure 341: CFP Contour Fireproofing

Thickness	Thickness (dimension in the figures above) in length units
Density	Density of fireproofing material in (force / length^3) units

Imperfection tab

Used to define camber and drift specifications for selected members.

Note: Refer to TR.26.6 Member Imperfection Information (on page 2313) for additional details.

Imperfection type	Select if whether the imperfection is either **Camber** or **Drift**. Drift is usually for columns and camber for beams.
Local Direction	Specify if the camber or drift acts in either the member local **Y** or **Z** direction.
Value	Specify the value for the camber or drift, defined as a ratio of member length/offset. Default ratio value is 300.
Respect	(Camber option only) A dimensionless constant used to skip the camber imperfection calculation if the compressive load is small or EI is great or length is short. A combination of these terms, called ε, is calculated. If ε is less than the respect value given, then the imperfection calculation is skipped for that local direction, for that case, for that member. The imperfection calculation is also skipped for any member that is in tension.

$$\varepsilon_y = \text{Length} \times \sqrt{\frac{\left| \text{axial load} \right|}{EI_z}}$$

$$\varepsilon_z = \text{Length} \times \sqrt{\frac{\left| \text{axial load} \right|}{EI_y}}$$

Plate Specs dialog

Used to specify finite element specifications.

Opens when either:

- **Plate** is clicked on the **Specifications - Whole Structure** dialog, or
- the **Plate** tool in the **Specifications** group on the **Specifications** ribbon tab is selected

This dialog contains multiple tabs, each of which is used to add a different member specification.

Release tab

Used to release one or more degrees of freedom at the corner nodes of the elements. Unless a release is specified, elements are rigidly connected at the nodes (all six degrees of freedom are restrained) unless the node is a cantilever node or is supported.

Note: Refer to TR.22.2 Element Release Specification (on page 2287) for additional information on plate element releases.

Node — Select the node to be released. The node number depends on the Element Incidence for the element.

Release — Check the boxes for the **FX**, **FY**, **FZ**, **MX**, **MY**, or **MZ** directions to define the element release condition. These are based on the local coordinate system for the element.

Offset tab

Used to add rigid link offsets from element incident joints to the element corners.

Refer to TR.25.2 Element Offset Specification (on page 2298) for additional details.

Direction	Select one of the following direction options for assigning offsets: • **Local -** the nodal offsets at a specified joint are given in the element local axes. • **Global -** the nodal offsets at a specified joint are given in the global axes. • **Z Offset -** the offset is specified along the local z axis of the element (i.e., parallel offset to the plane of the element)
Local of Global Offsets	Select the incident node number of the element and type the offsets in the given units.
Z Offsets	Type the offset distance at each node. **Note:** By default, typing a distance for **Node 1** will populate the same value for the other nodes, thus indicating a parallel offset. You may override these values with different offsets but the offset element must remain coplanar.

Ignore Inplane Rotation tab

Used to override the value that STAAD determines for the stiffness associated with the local axis Mz degree of freedom for plate elements.

Refer to TR.24 Element Plane Stress and Ignore Inplane Rotation Specification (on page 2295) for additional information.

There are no additional parameters for this plate element specification.

Rigid Inplane Rotation tab

Used to program to connect the corner Mz "in-plane rotation" action to the other corner Mz rotations rigidly

Refer to TR.24 Element Plane Stress and Ignore Inplane Rotation Specification (on page 2295) for additional information.

There are no additional parameters for this plate element specification.

Plane Stress tab

Used to model plate elements as Plane Stress elements.

Refer to TR.24 Element Plane Stress and Ignore Inplane Rotation Specification (on page 2295) for additional information.

There are no additional parameters for this plate element specification.

Ignore Stiffness tab

Used to instruct the program to neglect the stiffness of the selected plates while assembling the stiffness matrix. Hence, the stiffness contribution of the selected plates is not considered. This is similar to the Inactive command for the members.

When modeling plate elements, often we come across situations where we want the plates to carry loads, but at the same time do not want the stiffness of the plates to be considered in the analysis. For example, structural units such as glass panels or corrugated sheet roofs are subjected to loads like wind pressures or snow loads. While these elements are designed to carry the loads and transmit the same to the other parts of the structure, they are not designed to provide any additional stiffness to the structure.

Note: Refer to TR.22.3 Element Ignore Stiffness (on page 2288) for additional information.

There are no additional parameters for this plate element specification.

Properties - Whole Strucutre dialog

Used to define and assign member, plate element and material properties.

Section tab

Used for defining member section properties and element thickness and assigning them to members and elements. Properties can be defined and assigned to members and elements using the options available on the **Section** tab. As property values are assigned, the Section Tab is updated with their tag number and property description. The items on the Section tab are described below.

Beta Angle tab

Used to define beta angles (rotation of the member about its local x-axis) and assign them to members.

- *M. To add a new table section property* (on page 715)

Section Profile Tables dialog

Used to assign catalog sections for steel, timber, and aluminum members. Sections or organized by material, country, and then profile.

Opens when **Section Database** is clicked on the **Properties - Whole Structure** dialog.

Tables list	Select the type of section by clicking on the appropriate tab and then select the specific section from the list box. Please note that depending on the type of section selected, additional properties may be specified.
View Table	This option displays all member properties for the aluminum table.
Material	Select this option to select the material from the drop down list if the new member property tag should include the material constants.
Type Specification	Refer to TR.20.1 Assigning Properties from Steel Tables (on page 2257) for details on type specifications for different table profiles.

Steel tab

Used to select hot-rolled and joint sections. Displays the contents of the various country steel tables in a series of tabs on the left hand side of the dialog.

Coldformed Steel tab

Used to select cold-formed steel sections.

Timber tab

Used to select standard species and size timbers as well as glue-laminated sections for American and Canadian standards.

Naming Convention	Click and hold to display a pop-up of the nomenclature conventions used for the currently selected catalog.

Aluminum tab

Used to assign aluminum sections to members from the built-in American aluminum table.

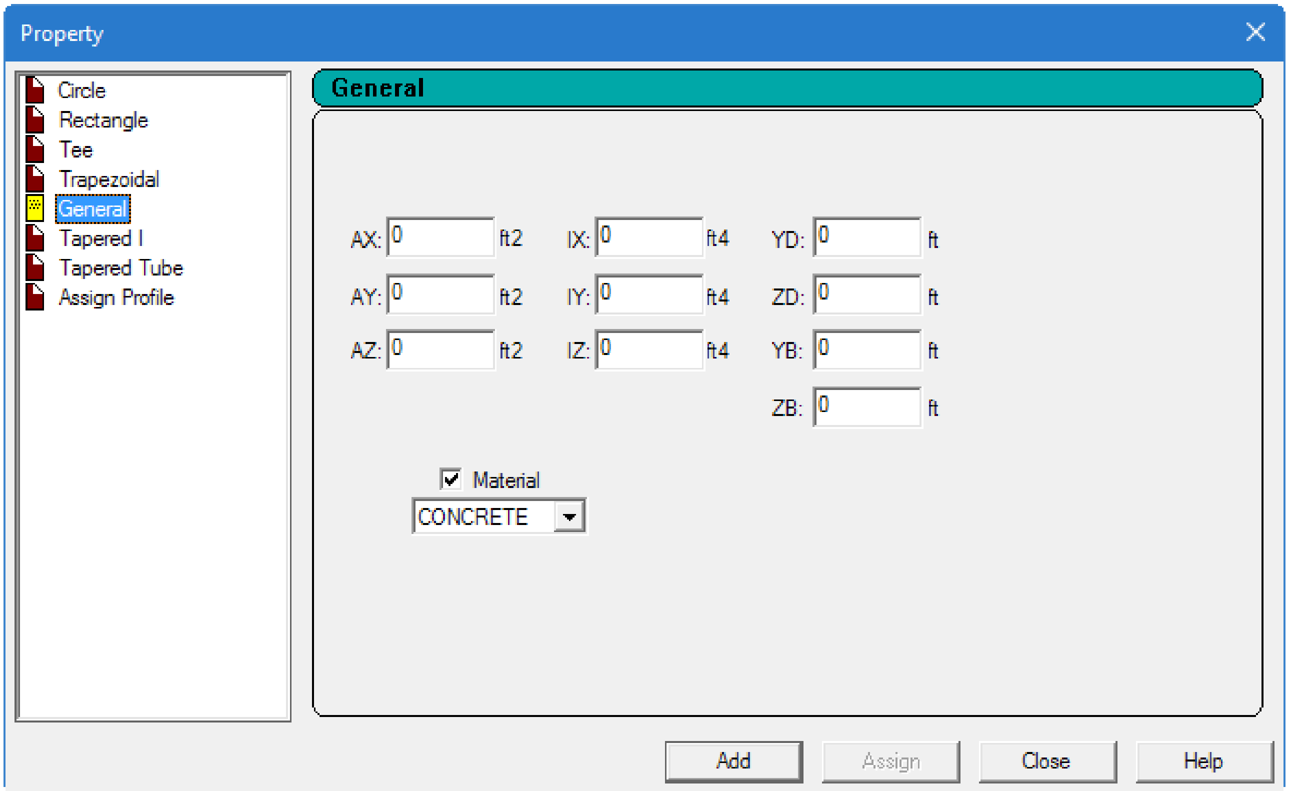
- *M. To add an American steel joist section* (on page 716)

Property dialog

Used to assign prismatic cross sections to members.

Opens when the **Beam Profiles > Prismatic Profiles** tool is selected in the **Specifications** group on the **Specification** ribbon tab.

Note: The **Properties - Whole Structure** dialog also opens simultaneously so that some of the other options available from that dialog may be utilized.



Circle tab

YD Section diameter.

Material Check this box and select the material from the drop down list if the new member property tag should include the material constants.

Rectangle tab

YD Depth of the member in local y direction.

ZD Width of the member in the local z direction.

Tee tab

YD Depth of the member in local y direction.

ZD Width of the flange.

YB Depth of the stem (web).

ZB Width of the stem (web).

Trapezoidal tab

YD Depth of the member in local y direction.

ZD Top width.

ZB Bottom width.

General tab

AX Cross sectional area of the member.

AY Effective shear area in local y-axis.

AZ Effective shear area in local z-axis.

IX Torsional constant.

IY Moment of inertia about local y-axis.

IZ Moment of inertia about local z-axis (usually major).

YD Depth of the member in local y direction. Used as the diameter of section for circular members.

ZD Depth of the member in local z direction. If ZD is not provided and YD is provided, the section will be assumed to be circular.

YB Depth of stem for T-section.

ZB Width of stem for Tee section or bottom width for trapezoidal section.

Tapered I tab

F1 Depth of section at start node.

F2 Thickness of web.

F3 Depth of section at end node.

> **Note:** F3 should be *less than* F1 (i.e., the section should decrease in depth from start to end). You must provide the member incidences accordingly.

F4 Width of top flange.

F5 Thickness of top flange.

F6 Width of bottom flange. Defaults to F4 is zero.

F7 Thickness of bottom flange. Defaults to F5 if zero.

Tapered Tube tab

Type of Section Select one of the profile shapes:

Round

Hexdecagonal – 16-sided
Dodecagonal – 12-sided
Octagonal – 8-sided
Hexagonal – 6-sided
Square – 4-sided

d1	Depth of section at start of member.
d2	Depth of section at end of member.
th	Thickness of section (constant throughout the member length).

Notes:

1. Section properties are calculated using the rules applicable for thin-walled sections.
2. Shear deformation is not considered for tapered I-Beams and tapered poles. This means that the `SET SHEAR` command has no effect on the deformation computed for members with these cross sections.

Assign Profile tab

Used to instruct the program to select a suitable steel section based on a profile classification, such as beam, column, double-angle, etc.

Select Profile Specification

Specify a profile by selecting one of the options:

Angle
Double Angle
Beam
Column
Channel

The program will then assign a section based on that profile from the relevant built-in Steel table.

Property: Tapered I dialog

Used to specify an I-section having a varying depth over the length of the member.

Opens when the **Beam Profiles > Tapered Profile** tool is selected in the **Specifications** group on the **Specification** ribbon tab.

Note: This dialog is identical to the **Tapered I** tab of the **Property** dialog.

F1 Depth of section at start node.

F2 Thickness of web.

F3 Depth of section at end node.

> **Note:** F3 should be *less than* F1 (i.e., the section should decrease in depth from start to end). You must provide the member incidences accordingly.

F4 Width of top flange.

F5 Thickness of top flange.

F6 Width of bottom flange. Defaults to F4 is zero.

F7 Thickness of bottom flange. Defaults to F5 if zero.

User Provided Table dialog

Used for adding and assigning previously created user table sections to the structure.

> **Note:** The Properties - Whole Strucutre dialog (on page 2793) also opens simultaneously so that some of the other options available from that dialog box may be utilized.

Opens when the **Beam Specifications** > **User Table Profile** tool is selected in the **Specifications** group on the **Specification** ribbon tab.

Select Existing Table	Select a previously created User Table number from the drop down list. User Tables are created using the User Table Manager dialog (on page 2798).
Section List	Select the specific section from the list.
Material	Check this box and select the material from the drop down list if the new member property tag should include the material constants.

Add	Click to add this property to the structure.
Assign	Click to assign the property to selected members as well as add this property to the structure.
Close	Closes the dialog without adding any properties.
Help	Opens the STAAD.Pro Help window.

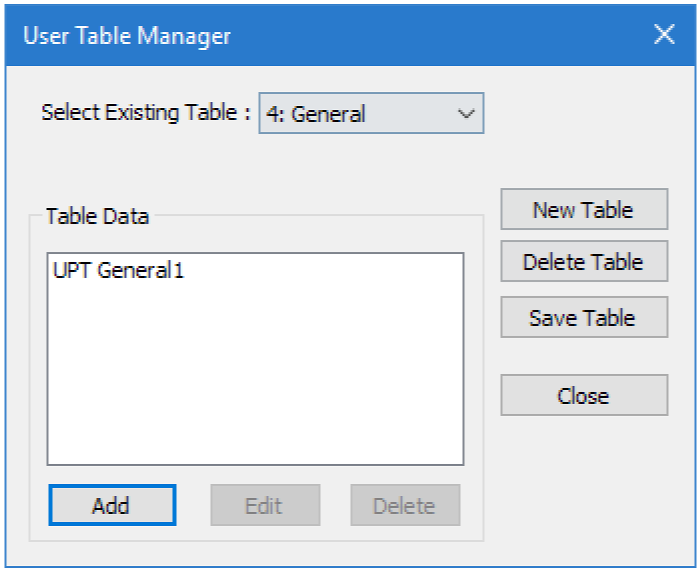
User Table Manager dialog

Used to add new or edit existing user provided section properties tables.

Opens when either:

- you select a section type and click **OK** in the **Select Section Type** dialog, or
- or when you select **Beam Profiles > User Table Profile** tool in the **Specifications** group on the **Specification** tab, but no user provided tables are present.



Select Existing Table If you have already created a user provided table, you may select it from this drop-down list box for further editing.

> **Note:** If you select an external table (indicated by "(EXT)"), then the file path and file name will be displayed below.

New Table Opens the **New User Table** dialog, which is used to select the section type for a user provided table and to optional specify an external table file.

Add Click this to specify a custom UPT section after creating a new table or selecting an existing table. A dialog opens for inputting property values applicable to the section type chosen for the current table.

Once the section is defined, it may be assigned from the **Properties - Whole Structure** dialog.

> **Note:** You may not add entries to external tables from this interface.

The following values are required for the various shapes. Additional values may be entered or you may click **Calculate** for some section types to have the program calculate derived section properties.

- Wide Flange Sections - D, TF, WF, TW are required (and optionally TW1 and WF1 if the flanges are of different sizes).

  Ax, Iz, Ix, Iy, Ay, and Az can be calculated
- Channel Sections - D, TF, WF, and TW are required

  Ax, Iz, Ix, Iy, Cz, Ay, and Az can be calculated
- Angle Sections - D, WF, and TF are required

R, At, and Az can be calculated

- Double Angle Sections - D, WF, TF, and SP are required

  Iz, Ix, Iy, Cy, Ay, and Az can be calculated (does not calculate RVV)
- Tube Sections - D, WF, and TF are required

  Ax, Iz, Ix, Iy, Ay, and Az can be calculated
- General Sections - The general polygon profile is required

  Ax, D, TD, B, TB, Iz, Ix, Iy, Sz, Sy, Ay, Az, Pz, Py, HSS, and DEE can be calculated

Other section types do not have the option to calculate section properties. Therefore, any value not to be assumed as zero is required.

Edit / View	Click to open the details of a selected table data entry for viewing or editing.
Delete	Click to delete the currently selected table data entry from the table.
Delete Table	Deletes the current user provided table.
Save Table	Saves changes made to the user provided table.
Close	Closes the dialog.
Section Wizard	(Displayed only for External tables) Click to open the Section Wizard interface.

Related Links

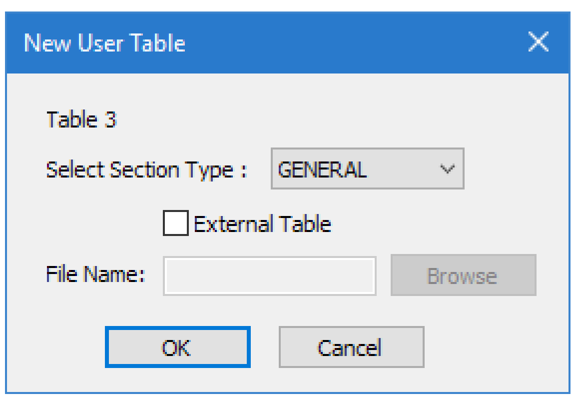
New User Table dialog

Used to select the section type for a User Provided Table and to optional specify an external table file.

Opens when **New Table** is selected in the **User Table Manager** dialog.



External Table	Set this option to load section data from an external file (e.g., a `.upt` file exported from Section Wizard). The File Name must be provided.
File Name	Type a name for the external table file. Click **Browse** to search for a location from which to load the table file.

Select Section Type	Select the type of cross section contain in the table. All sections within a table must be of the same type. • Wide Flange • Channel • Angle • Double Angle • Tee • Pipe • Tube • General • I Section • Prismatic **Note:** Refer to TR.19 User Steel Table Specification (on page 2241) for details on the property value requirements for various section types.
OK	Creates a new User Provided Table of the selected type.
Cancel	Closes the dialog without creating a new table.

Wide Flange dialog

Used to specify the section properties for a wide flange user defined table section.

Opens when you click **Add** in the **User Table Manager** dialog when a Wide Flange section table is selected.

Note: Refer to TR.19.1 Wide Flange (on page 2244) for detailed descriptions on properties of Wide Flange sections in User Steel tables.

Tip: To generate a tapered wide flange section, use an I Section dialog (on page 2808) instead.

Section Name	Type a section name used to identify the shape in the table.
D	Depth of the section
TF	Thickness of top flange (or both flanges when `WF1` is not specified)
WF	Width of the top flange (or both flanges when `WF1` is not specified)
TW	Thickness of web
TF1	Thickness of bottom flange
WF1	Width of the bottom flange
Cross Section Area (Ax)	Cross section area. Can be automatically calculated by clicking the **Calculate** button.
Inertia About Local z (Iz)	Moment of inertia about local z-axis (usually strong axis). Can be automatically calculated by clicking the **Calculate** button.
Inertia About Local y (Iy)	Moment of inertia about local y-axis. Can be automatically calculated by clicking the **Calculate** button.

Torsional Constant (Ix)	Moment of inertia about local x-axis. Can be automatically calculated by clicking the **Calculate** button.
Shear Area in Y (Ay)	Shear area in local y-axis. If zero, shear deformation is ignored in the analysis. Can be automatically calculated by clicking the **Calculate** button.
Shear Area in Z (Az)	Same as above except in local z-axis. Can be automatically calculated by clicking the **Calculate** button.
Additional Composite Flange	Set this option to add a composite concrete slab to the section. **B(left)** Width of the composite slab to the left of the web center line **B(right)** Width of the composite slab to the right of the web center line **Thickness** Thickness of the composite slab **Modular Ratio** The ratio of the modulus of elasticity of steel to concrete
Additional Bottom Steel Plate	Set this option to add a bottom cover plate to the wide flange section. This may only be included if the **Additional Composite Flange** option is selected. **B(left)** Width of the additional bottom flange plate to the left of the web center line **B(right)** Width of the additional bottom flange plate to the right of the web center line **Thickness** Thickness of the additional bottom flange plate

OK	Saves the UPT section and closes the dialog.
Cancel	Closes the dialog without creating a new section.
Calculate	Click to calculate the Ax, Iz, Iy, Ix, Ay, Az values from the provided section dimensions.

Related Links

- *M.To create a wide-flange user table section* (on page 731)

Channel dialog

Used to specify the section properties for a channel user defined table section.

Opens when you click **Add** in the **User Table Manager** dialog when a Channel section table is selected.

Section Name	Type a section name used to identify the shape in the table.
D	Depth of the section
TW	Thickness of web
WF	Width of flange
TF	Thickness of flange
Cross Section Area (Ax)	Cross section area. Can be automatically calculated by clicking the **Calculate** button.

Inertia About Local z (Iz)	Moment of inertia about local z-axis (usually strong axis). Can be automatically calculated by clicking the **Calculate** button.
Inertia About Local y (Iy)	Moment of inertia about local y-axis. Can be automatically calculated by clicking the **Calculate** button.
Torsional Constant (Ix)	Moment of inertia about local x-axis. Can be automatically calculated by clicking the **Calculate** button.
C.G. Along local Z (Cz)	Centroid of section along local z axis, measured from heal of channel. Can be automatically calculated by clicking the **Calculate** button.
Shear Area in Y (Ay)	Shear area in local y-axis. If zero, shear deformation is ignored in the analysis. Can be automatically calculated by clicking the **Calculate** button.
Shear Area in Z (Az)	Same as above except in local z-axis. Can be automatically calculated by clicking the **Calculate** button.

OK	Saves the UPT section and closes the dialog.
Cancel	Closes the dialog without creating a new section.
Calculate	Click to calculate the Ax, Iz, Iy, Ix, Cz, Ay, and Az values from the provided section dimensions.

Related Links

- *M.To create a channel user table section* (on page 733)

Angle dialog

Used to specify the section properties for a single angle user defined table section.

Opens when you click **Add** in the **User Table Manager** dialog when a Angle section table is selected.

Section Name	Type a section name used to identify the shape in the table.
D	Depth of angle (i.e., length of the leg along the local y-axis)
WF	Width of angle (i.e., length of the leg along the local z-axis)
TF	Thickness of angle leg
Rad. of Gyration about Principal Axis (R)	Radius of gyration about principal axis, shown as “r(Z-Z)” in the AISC manual (this must not be zero). Can be automatically calculated by clicking the **Calculate** button.
Shear Area in Y (Ay)	Shear area in local y-axis. If zero, shear deformation is ignored in the analysis. Can be automatically calculated by clicking the **Calculate** button.
Shear Area in Z (Az)	Same as above except in local z-axis. Can be automatically calculated by clicking the **Calculate** button.

OK	Saves the UPT section and closes the dialog.
Cancel	Closes the dialog without creating a new section.
Calculate	Click to calculate the R, Ay, and Az values from the provided section dimensions.

Related Links

- *M.To create an angle user table section* (on page 735)

Double Angle dialog

Used to specify the section properties for a double angle user defined table section.

Opens when you click **Add** in the **User Table Manager** dialog when a Double Angle section table is selected.

Section Name	Type a section name used to identify the shape in the table.
D	Depth of angle (i.e., length of the leg along the local y-axis)
WF	Width of angle (i.e., length of the leg along the local z-axis)
TF	Thickness of angle leg
SP	Space between angles.
Cross Section Area (Ax)	Cross section area. Can be automatically calculated by clicking the **Calculate** button.
Inertia About Local z (Iz)	Moment of inertia about local z-axis (usually strong axis). Can be automatically calculated by clicking the **Calculate** button.
Inertia About Local y (Iy)	Moment of inertia about local y-axis. Can be automatically calculated by clicking the **Calculate** button.
Torsional Constant (Ix)	Moment of inertia about local x-axis. Can be automatically calculated by clicking the **Calculate** button.
C.G. along local Y (Cy)	Distance from the face of angles to the center of gravity (C.G.) along the local y-axis. Can be automatically calculated by clicking the **Calculate** button.
Shear Area in Y (Ay)	Shear area in local y-axis. If zero, shear deformation is ignored in the analysis. Can be automatically calculated by clicking the **Calculate** button.
Shear Area in Z (Az)	Same as above except in local z-axis. Can be automatically calculated by clicking the **Calculate** button.
Single Angle (rvv)	The radius of gyration about the minor principal axis for single angles - z-z axis for `TA ST` angles, and y-y axis for `TA RA` angles.

OK	Saves the UPT section and closes the dialog.
Cancel	Closes the dialog without creating a new section.
Calculate	Click to calculate the Iz, Iy, Ix, Cy, Ay, and Az values from the provided section dimensions.

Related Links

- *M.To create a double angle user table section* (on page 737)

Tee dialog

Used to specify the section properties for a tee user defined table section.

Opens when you click **Add** in the **User Table Manager** dialog when a Tee section table is selected.

Section Name	Type a section name used to identify the shape in the table.
D	Depth of the section

TF	Thickness of flange
WF	Width of flange
TW	Thickness of web
Cross Section Area (Ax)	Cross section area.
Inertia about local z (Iz)	Moment of inertia about local z-axis (usually strong axis)
Inertia about local y (Iy)	Moment of inertia about local y-axis
IX	Torsional constant
C.G. along local Y (Cy)	Distance from back of web to center of gravity (C.G.) of the shape along the local y-axis.
Shear Area in Y (Ay)	Shear area in local y-axis. If zero, shear deformation is ignored in the analysis.
Shear Area in Z (Az)	Shear area in local z-axis. If zero, shear deformation is ignored in the analysis.

OK	Saves the UPT section and closes the dialog.
Cancel	Closes the dialog without creating a new section.

Pipe dialog

Used to specify the section properties for a pipe user defined table section.

Opens when you click **Add** in the **User Table Manager** dialog when a Pipe section table is selected.

Section Name	Type a section name used to identify the shape in the table.
OD	Outer diameter
ID	Inner diameter
Shear Area in Y (Ay)	Shear area in local y-axis. If zero, shear deformation is ignored in the analysis.
Shear Area in Z (Az)	Shear area in local z-axis. If zero, shear deformation is ignored in the analysis.

OK	Saves the UPT section and closes the dialog.
Cancel	Closes the dialog without creating a new section.

Tube dialog

Used to specify the section properties for a tube user defined table section.

Opens when you click **Add** in the **User Table Manager** dialog when a Tube section table is selected.

Section Name	Type a section name used to identify the shape in the table.
D	Depth of the section
WF	Width of flange
TF	Thickness of flange
Cross Section Area (Ax)	Cross section area. Can be automatically calculated by clicking the **Calculate** button.

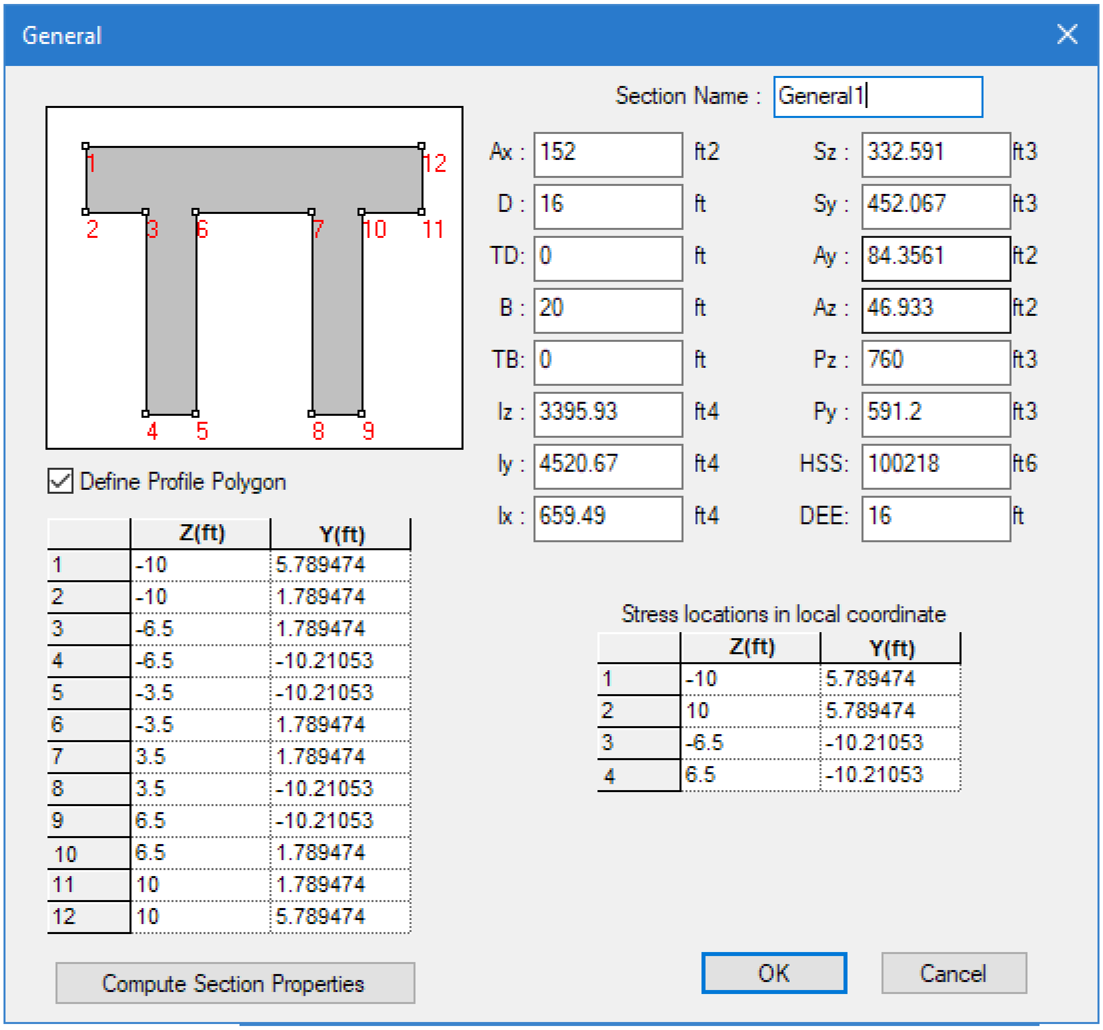
Inertia About Local z (Iz)	Moment of inertia about local z-axis (usually strong axis). Can be automatically calculated by clicking the **Calculate** button.
Inertia About Local y (Iy)	Moment of inertia about local y-axis. Can be automatically calculated by clicking the **Calculate** button.
Torsional Constant (Ix)	Moment of inertia about local x-axis. Can be automatically calculated by clicking the **Calculate** button.
Shear Area in Y (Ay)	Shear area in local y-axis. If zero, shear deformation is ignored in the analysis. Can be automatically calculated by clicking the **Calculate** button.
Shear Area in Z (Az)	Same as above except in local z-axis. Can be automatically calculated by clicking the **Calculate** button.

OK	Saves the UPT section and closes the dialog.
Cancel	Closes the dialog without creating a new section.
Calculate	Click to calculate the AX, IZ, IY, IX, AY, and AZ values from the provided section dimensions.

General dialog

Used to specify the section dimensions and properties for a general polygonal user defined table section.

Opens when you click **Add** in the **User Table Manager** dialog when a General section table is selected.



Section Name	Type a section name used to identify the shape in the table.
Define Profile Polygon	Check this option to define polygon vertices by Z and X coordinates in the following table.
	You also have the option compute the section properties for the shape automatically.
AX	Cross section area
D	Depth of the section
TD	Thickness associated with section element parallel to depth (usually web). To be used to check depth/thickness ratio
B	Width of the section
TB	Thickness associated with section element parallel to flange. To be used to check width/ thickness ratio
IZ	Moment of inertia about local z-axis (usually strong axis)
IY	Moment of inertia about local y-axis

IX	Torsional constant
SZ	Section modulus about local z-axis
SY	Section modulus about local y-axis
AY	Shear area in local y-axis.
AZ	Shear area in local z-axis.
PZ	Plastic modulus about local z-axis
PY	Plastic modulus about local y-axis
HSS	Warping constant for lateral torsional buckling calculations
DEE	Depth of web. For rolled sections, distance between fillets should be provided

Note: Properties PZ, PY, HSS, and DEE must be provided for code checking or member selection per plastic and limit state based codes (AISC LRFD, British, French, German and Scandinavian codes). For codes based on allowable stress design (AISC-ASD, AASHTO, Indian codes), zero values may be provided for these properties.

Compute Section Properties	Click to calculate the AX, D, B, IZ, IY, IX, SZ, SY, AY, AZ, PZ, PY, HSS, and DEE values from the provided polygon points.
OK	Saves the UPT section and closes the dialog.
Cancel	Closes the dialog without creating a new section.

I Section dialog

Used to specify the section properties for a I Section user defined table section.

Opens when you click **Add** in the **User Table Manager** dialog when an I Section table is selected.

This section can be of constant depth (effectively a TR.19.9 I Section (on page 2252)) or a tapered member.

DWW	Depth of section at start node
TWW	Thickness of web
TFF	Thickness of top flange
BFF	Width of top flange
TFF1	Thickness of bottom flange
BFF1	Width of bottom flange
Depth at Start Node	Depth of section at end node. This must be the larger depth of the two member nodes. You must provide member incidences accordingly.
Depth at End Node	Depth of section at end node. Must be less than the depth at the start node.
Torsional Constant (Ix)	Torsional constant (IX or J) (see note #2)
Shear Area in Y (Ay)	Shear area for shear parallel to Y-axis (see note #2)
Shear Area in Z (Az)	Shear area for shear parallel to Z-axis (see note #2)
Additional Composite Flange	Set this option to add a composite concrete slab to the section.

B(left)	Width of the composite slab to the left of the web center line
B(right)	Width of the composite slab to the right of the web center line
Thickness	Thickness of the composite slab
Modular Ratio	The ratio of the modulus of elasticity of steel to concrete

OK	Saves the UPT section and closes the dialog.
Cancel	Closes the dialog without creating a new section.

Related Links

- *M.To create an I shape user table section* (on page 739)

Prismatic dialog

Used to specify the section dimensions and properties for a general, prismatic user defined table section.

Opens when you click **Add** in the **User Table Manager** dialog when a Prismatic section table is selected.

Note: This is a *non*-parametric section. That is, you must specify the all cross-sectional properties rather than dimensional parameters.

Section Name	Type a section name used to identify the shape in the table.
YD	Depth of the section in the direction of the local y-axis.
ZD	Depth of the section in the direction of the local z-axis
Cross Section Area (Ax)	Cross-section area
Inertia about local z (Iz)	Moment of inertia about the local z-axis
Inertia about local y (Iy)	Moment of inertia about the local y-axis
Torsional Constant (Ix)	Torsional constant
Shear Area in Y (Ay)	Shear area for shear parallel to local y-axis.
Shear Area in Z (Az)	Shear area for shear parallel to local z-axis.

OK	Saves the UPT section and closes the dialog.
Cancel	Closes the dialog without creating a new section.

Related Links

- *M.To create an prismatic user table section* (on page 741)

Material Constant dialog

Used to specify individual material constants of the materials of which members and elements are comprised.

Opens when a constant name is selected from the **Constants** tool in the **Materials** group on the **Specifications** ribbon tab. A separate dialog is used to define each constant value.

The types of constants available to define are:

- **Young's Modulus** – the modulus of elasticity, E
- **Poisson's Ratio**, ν
- **Shear Modulus**, G
- **Density** , γ
- **Thermal Coefficient** , α
- **Damping Ratio** ,c

Material Constant Select the pre-defined materials Aluminum, Concrete, or Steel to use a built-in value. See below for the built-in material values

Alternately, select the **Enter Value** option to type in a custom constant value in the current units.

Assign Select the scope of members which the material constant is to be assigned.

- **To View** assigns the material constant to all members within the current view.
- **To Selection** assigns the material constant to only those members selected.

Built-In Material Constants

For E, G, POISSON, DENSITY, ALPHA, and CDAMP, built-in material names can be entered instead of a value for *f1*. The built-in names are `STEEL`, `CONCRETE`, & `ALUMINUM`. Appropriate values will be automatically assigned for the built-in names.

Table 317: Constants (in Kip, inch, Fahrenheit units)

Constant	Material			Units
	Steel	Concrete	Aluminum	
E (US)	29,000	3,150	10,000	Kip/in^2
Poisson's	0.30	.17	.33	(ratio)
Density	.000283	.0000868	.000098	Kip/in^3
Alpha	6.5E-6	5.5E-6	12.8E-6	L/L/° F
CDAMP	.03	.05	.03	(ratio)
E (nonUS)	29,732.736			Kip/in^2

Table 318: Constants (in MKS, Celsius units)

Constant	Material			Units
	Steel	Concrete	Aluminum	
E (US)	199, 947,960	21,718,455	68,947,573	kN/m^2
Poisson's	0.30	.17	.33	(ratio)

Constant	Material			Units
	Steel	Concrete	Aluminum	
Density	76.819 541	23.561612	26.601820	kN/m^3
Alpha	12.0E-6	10.0E-6	23.0E-6	L/L/° C
CDAMP	.03	.05	.03	(ratio)
E (nonUS)	205, 000,000			kN/m^2

Note: E (US) is used if US codes were installed or if Member Properties American is specified for an analysis; otherwise E (nonUS) is used.

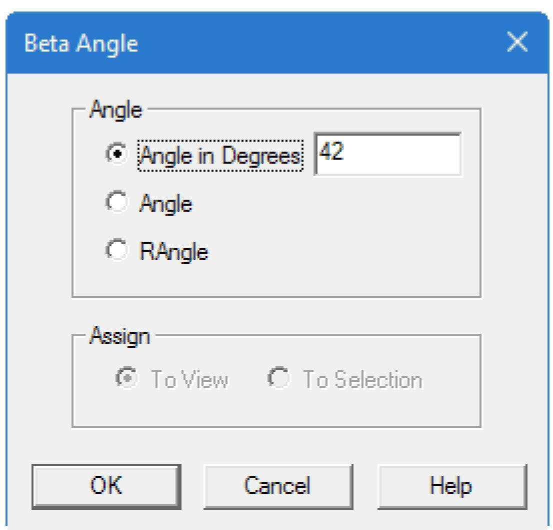
Beta Angle dialog

Used to specify the Beta angle for members.

Opens when:

- the **Beam >Beta Angle** tool is selected in the **Specifications** group on the **Specification** ribbon tab, or
- **Create Beta Angle** is clicked on the **Properties - Whole Structure** dialog **Beta Angle** tab



Angle Type the rotation about the longitudinal member axis (i.e., local x axis) in the **Angle in Degrees** field.

The **Angle** and **RAngle** options are for use only with single angle sections. These options are further described in G.4.3 Relationship Between Global and Local Coordinates (on page 2092).

Assign Select the scope of members which the geometric constant is to be assigned.

- **To View** assigns the geometric constant to all members within the current view.
- **To Selection** assigns the geometric constant to only those members selected.

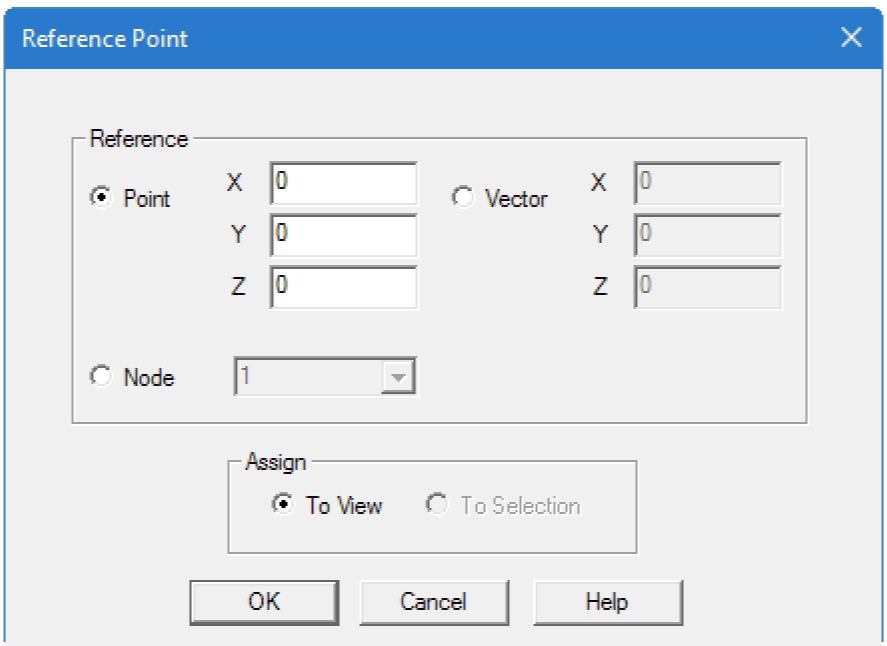
Related Links

- *G.4.3 Relationship Between Global and Local Coordinates* (on page 2092)
- *M. To assign a member rotation angle* (on page 799)
- *M. To align a single angle to its flanges* (on page 800)

Reference Point dialog

Used to specify a reference point for the members from which the program calculates the beta angle.

Opens when the **Beam Specifications > Beam Reference Point** tool is selected from the **Specifications** group on the **Specification** ribbon tab.



Point Provide the global coordinates of the point towards which the minor axis (local y axis) of the member should be directed. The point should not lie on the longitudinal axis (local x axis) of the member.

Vector A vector can be assigned with respect to the local coordinate system of the member. The local Y axis for the member is going to oriented along this vector.

This can be used to orient a member without the need to calculate a beta angle. For example, vector values of X = 0, Y = 2, and Z = 1 will create a vector at a slope of 1:2 from the member's axis. The resulting beta angle = $tan^{-1}(1/2) = 26.5651°$.

Refer to AD.2006.1.6 Specification of Member Orientation Using Reference Vector (on page 344) section for additional information on this feature.

> **Note:** The **Member Query** dialog **Geometry** tab will report the actual beta angle used.

Node An existing node in the structure can be set as the reference point for one or more members. This is the alternative to defining the coordinates of the reference point. When this button is turned on, the list of all nodes in the structure will appear in the drop-down list. Select the desired node number.

Assign Select the scope of members which the geometric constant is to be assigned.

- **To View** assigns the geometric constant to all members within the current view.
- **To Selection** assigns the geometric constant to only those members selected.

Related Links

- *G.4.3 Relationship Between Global and Local Coordinates* (on page 2092)
- *M. To align a member to a reference point* (on page 801)

Plate ElementProperty dialog

Used to provide plate element properties (thickness) with or without the material specification. Plates can have a different thickness at each node.

Opens when:

- the **Plate Thickness** tool is selected from the **Plate Profiles** group on the **Specification** ribbon tab, or

- **Thickness** is clicked on the **Properties - Whole Structure** dialog

Node 1, Node 2, etc. Enter the thickness at each of the nodes. For plates of uniform thickness, entering the thickness at Node 1 only will suffice. The other three values will default to that of Node 1 if no input is provided for them.

Material Check this box and select the material from the drop down list if the new element property tag should include the material constants. The specification of the standard materials (that is, Concrete, Steel, or Aluminum) can be added in this dialog box or can be done separately with other material specifications.

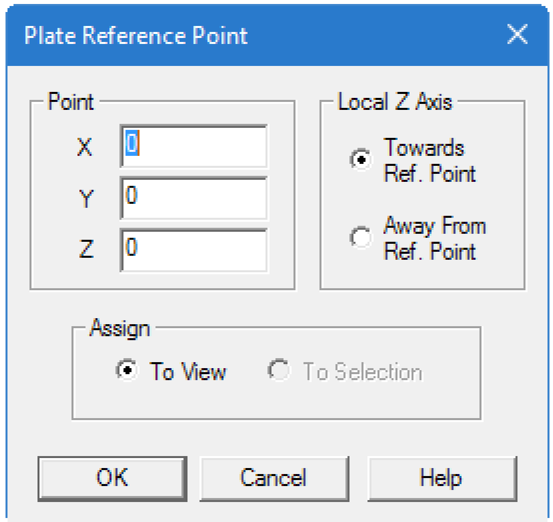
Related Links

- *G.5.1 Plate and Shell Elements* (on page 2099)
- *M. To specify plate thickness* (on page 811)

Plate Reference Point dialog

Used to specify options for determining the general direction of the local Z axis of elements.

Opens when the **Plate Specifications > Plate Reference Point** tool is selected from the **Specifications** group on the **Specification** ribbon tab.



Point Type the global coordinates of a point to use for orienting the local z axis of the plate elements.

> **Note:** The local coordinate system of the plate must still obey that the xy plane lie in the plane of the element itself. So the z axis won't necessarily point directly to this coordinate. Rather, the z axis will point away from the element to the side that the reference point is located.

Local Z Axis Select an option to define the direction of the local z axis of the plate element with reference to the **Point** provided.

Assign Select the scope of plates which the geometric constant is to be assigned:

To View – assigns the plate reference point to all plate elements within the current view.
To Selection – assigns the plate reference point to only those plate elements selected.

Supports - Whole Structure dialog

Used to define supports and assign them to nodes. All supports that have been defined for the model are listed here.

Edit Click to edit the parameters of the one of the following support types after it is created.

- Fixed But
- Enforced But
- Inclined
- Foundation

> **Note:** You cannot edit support types which are defined, such as fixed, pinned, or enforced.

Create Opens the **Create Support** dialog opens, which is used to create various support types.

Delete	Click to delete a previously assigned support.
Assignment Method	The options under the Assignment Method offer different choices for assigning supports to the structure.

Assign To Selected Nodes	To assign a support to selected nodes, first select the support from the Supports dialog box. The support selected is highlighted. Then select the nodes to which this support is to be assigned. When all desired nodes are selected, click the Assign To Selected Nodes radio button, then click the Assign button.
Assign To View	To assign a support to all free nodes in a view, first select the support from the Supports dialog box. The selected support is highlighted. Select the Assign To View radio button, then click the Assign button. All free nodes in the structure are assigned this support.
Use Cursor To Assign	To assign a support to nodes using the cursor, first select the support from the Supports dialog box. The selected support is highlighted. Select the Use Cursor To Assign radio button, then click the Assign button. The button will appear depressed and the label will change to Assigning. Make sure that the Nodes Cursor is selected so that we can select the nodes. Using the cursor, click on the nodes to which this support is to be assigned. Click on the Assign button again to finish.
Assign To Edit List	To assign a support using a typed list of node numbers, first select the support from the Supports dialog. The selected support is highlighted. Select the Assign To Edit List radio button, then type the list of node numbers and click the Assign button.

Related Links

Create Support dialog

Used to define support (boundary) conditions of the structure to nodes. The dialog consists of a series of tabs, each of which are used to assign a different support condition. Each tab includes options for the specified support condition.

Note: The **Supports - Whole Structure** dialog also opens simultaneously so that some of the other options available from that dialog box may be utilized.

If the support is not assigned as it is created, it can be assigned later from the **Support** dialog. However, note that if it is not assigned to at least one spring support when is closed, then the definition will not be saved in the STD file.

Fixed tab

Used to create a fixed support tag and (optionally) to assign that to selected nodes. A Fixed support is restrained in all six degrees of freedom.

Refer to TR.27.1 Global Support Specification (on page 2316) for additional information on global supports.

Opens when **Add Support > Fixed** is selected from the **Specification** ribbon tab **Supports** group.

There are no settings for assigning a Fixed support.

Pinned tab

Used to create a pinned support tag and (optionally) to assign it to selected nodes. A Pinned support is restrained in all three translational degrees of freedom and free in the 3 rotational degrees of freedom.

Refer to TR.27.1 Global Support Specification (on page 2316) for additional information on global supports.

Opens when **Add Support > Pinned** is selected from the **Specification** ribbon tab **Supports** group.

There are no settings for assigning a Pinned support.

Fixed But tab

Used to create various types of roller, hinge and spring supports with specified restrained degrees of freedom and to assign them to selected nodes.

Refer to TR.27.1 Global Support Specification (on page 2316) for additional information on global supports.

Opens when **Add Support** > **Fixed But/Spring** is selected from the **Specification** ribbon tab **Supports** group.

Release	Select the degrees of freedom you want to release.
Define Spring	To specify a spring support, the spring constant in the appropriate edit box.

Enforced tab

Used to create a fixed-condition support definition. The Enforced support is the same as a Fixed support except that the restrained degrees of freedom are defined in terms of being stiff springs. The real advantage of using the Enforced type lies in the fact that it enables STAAD.Pro to accept loads such as support displacement loads in the case of plates and solids. Support displacement loads are not permitted for plates and solids if the FIXED support type is used. So, for structures without these characteristics, the Fixed type of support offers the same level of functionality as the Enforced support type.

Refer to TR.27.1 Global Support Specification (on page 2316) for additional information on global supports.

There are no settings for assigning an Enforced support.

Enforced But tab

Used to create a fixed-condition support defined in terms of being stiff springs with the option to release selected degrees of freedom. The Enforced But support type is the same as the Enforced support except that we have a choice on the degrees of freedom we wish to restrain. For example, you can select Enforced But and restrain just the FX, FY, and FZ degrees of freedom, and let the remaining three free to deform.

Refer to TR.27.1 Global Support Specification (on page 2316) for additional information on global supports.

Release	Select the degrees of freedom you want to release.

Inclined tab

Used to create supports that offer restraints in an axis system that is inclined with respect to the global axis system.

Refer to TR.27.2 Inclined Support Specification (on page 2318) for additional details on specifying inclined supports.

Incline Reference Point	Specify a point in space to define the incline.
Support Type	Select to use one of the standard STAAD.Pro support types: Pinned, Fixed, Fixed But, Enforced, or Enforced But.
Release	(Fixed But or Enforced But options only) Select the forces and moments to release by checking the respective box.
Spring	(Fixed But option only) To specify a spring support, the spring constant in the appropriate edit box.

Foundation tab

Used to create spring supports for independent footings and mat foundations and to assign them to selected nodes.

Refer to TR.27.3 Automatic Spring Support Generator for Foundations (on page 2319) for additional details on Foundation supports.

Foundation

- Footing - Select this option to define a spring support for an isolated footing. Provide the Length (**L**) and Width (**W**) dimensions of the footing in current units.

  In generating spring supports for mat foundations, there are two methods available in STAAD.Pro. Both those options require the program to calculate the influence area of the nodes which define the surface, and then multiply that area by the subgrade modulus of the medium. The difference between these two options lies in the way the influence area is calculated.
- Elastic Mat - In this method, the area is calculated using a Delaunay triangle principle. Hence, the candidates for this option are the nodes which define the mat. To achieve best results, one needs to ensure that the contour formed by the nodes form a convex hull.
- Plate Mat - If the foundation slab is modeled using plate elements, the spring supports can be generated using an influence area calculated using the principles used in determining the tributary area of nodes from the finite element modeling standpoint. Hence, the candidates for this option are the plates which define the mat. When the mat is modeled using plates, this produces superior results than the ELASTIC MAT type.

Direction

The X,Y, Z, XONLY, YONLY, and ZONLY indicate the direction of resistance of the spring supports. If X ,Y or Z is selected, then a spring support is generated in that direction only whereas the associated rotational degree of freedom and the other two translational d.o.f receive a fixed support. For example, if Y is selected, then FY is supported by a spring support, where as MY, FX and FZ are fixed supports; and MX and MZ are free. If XONLY,

	YONLY, or ZONLY is selected, then a spring support in that direction alone is generated, and every other d.o.f is set to be free to deform.
Subgrade	Type a value for the subgrade modulus of the soil.
Print Influence Area of Each Joint	(For Mat footing options only) Select this option to have the influence area of each support included in the output. The are used in the calculation of the spring stiffness of each joint used when defining a Plate Mat or Elastic Mat command will be included.
Generate Compression Only/Multi-linear Spring	(For Mat footing options only) When the Compression Only option is set, then if after any of the cycles of analysis, the force at a node included in the command range (in the elastic mat range or used to define a plate in the plate mat range) is found to be tensile (i.e. negative reaction), then the load case is marked for a re-analysis with that support removed.

Multilinear Spring tab

Used to enter displacement and spring stiffness data pairs for a multilinear spring definition, which is then used for a Fixed But support type.

The Multi Linear support type allows the user to model the support type for which the resistance offered to external loads varies with the extent of deformation of the support node. For example, when its behavior in tension differs from its behavior in compression, as in the case of soil springs, this facility can be utilized. Another example is a partial roller support where translation can occur without any resistance for a certain amount of displacement, after which it becomes fully restrained. The problem is solved iteratively using cycles of analysis and convergence checks. Hence, only on static load case can be specified per analysis command. It cannot be used with dynamic load cases.

Refer to TR.27.4 Multilinear Spring Support Specification (on page 2322) manual for additional information.

Multilinear Spring table	Values are entered in order from least to greatest displacement (including negative displacements, which are then ordered first) and their corresponding spring stiffness values.

Tension/Compression Only Spring tab

Used for support types which are capable of unidirectional action only, such as soil under a foundation slab.

Refer to TR.27.5 Spring Tension/Compression Specification (on page 2324) for additional details on Tension/ Compression Only Spring supports.

Reaction Type

Select whether the support degree(s) of freedom (d.o.f) are tension only or compression only. Indicates that if, after any of the cycles of analysis, the direction of the force in the spring is of the wrong 'type', then the support will be removed from that direction and a new analysis performed.

Reaction Type	Support will be active if the reaction is…	Support will be made inactive and a new analysis will be performed if the reaction is…
Tension Only	- ve	+ ve

Reaction Type	Support will be active if the reaction is…	Support will be made inactive and a new analysis will be performed if the reaction is…
Compression Only	+ ve	- ve

Spring Direction Select the degree(s) of freedom to set as unidirectional. More than one d.o.f may be set at a time.

Material - Whole Structure dialog box

Used to define, manage, and assign materials used in the STAAD.Pro input file. The **Isotropic** tab is used for defining isotropic materials and assigning them to members and elements. The **Orthotropic 2D** tab is used for defining materials with different properties in two dimensions and assigning them to members and elements.

Material list All materials that have been defined for the model are listed here. Select the Isotropic or Orthotropic 2D tab to display materials which exhibit those directional properties.

We may specify Materials in two ways. We may first create a material tag and then select the members or elements to which this tag is applied. Alternatively, we may first select the members or elements and then specify a material to be assigned to the selected items. In the second case, a new material specification is created along with a material tag.Please note that the Assign button becomes active if you have already selected the members or elements to which the material tag is to be applied.

Highlight Assigned Geometry When this box is checked and we click on a material tag in the Material dialog box, members that have been assigned the material tag will appear highlighted in the structure window. For example in the previous figure, if we click on the STEEL material tag, all steel members will be highlighted.

Create When the Isotropic tab is selected, clicking **Create** opens the Isotropic Material dialog (on page 2821), which is used to add a new isotropic material and properties to the STAAD.Pro input file. When the Orthotropic2D tab is selected, this button opens the 2D Orthotropic Material Property dialog (on page 2822), which is used.

Edit Opens the Isotropic Material dialog (on page 2821) or the 2D Orthotropic Material Property dialog (on page 2822), which can be used to edit the properties for the currently selected material (the name field is inactive when editing).

Delete Deletes the currently selected material from the list.

Tip: If you accidentally delete one of the predefined materials, they can still be added using the Create button and selecting the predefined material name from the drop-down list.

Assignment Method The options under the Assignment Method are used to assign material tags to members and elements.First select a material tag from the Materials dialog box.Use one of the following assignment methods to apply this material: Assign To Selected Beams, Assign To View, Use Cursor To Assign or Assign To Edit List.

Option	Description
Assign To Selected Beams	To assign a material to selected members or elements, first select the material tag from the **Materials** dialog box. The selected material is highlighted.Then select the members or elements to which this material is to be assigned.This is done by going to the **Select** menu, then choosing the appropriate cursor option.Select the desired members or elements using the cursor.When all desired geometry is selected, click the **Assign To Selected Beams** radio button, then click the **Assign** button. Note that the label for this button changes depending on whether members or elements are selected.
Assign To View	To assign a material to all members or elements in a view, first select the material tag from the **Materials** dialog box.The selected material is highlighted.Select the **Assign To View** radio button, then click the **Assign** button.All members or elements in the structure are assigned this material.

Option	Description
Use Cursor To Assign	To assign a material to members or elements using the cursor, first select the material tag from the **Materials** dialog box.The selected material is highlighted.Select the **Use Cursor To Assign** radio button, then click the Assign button. The button will appear depressed and the label will change to Assigning. Use the appropriate cursor (from the Select menu) to assign the selected material to the individual members or elements. Click on the Assign button again to finish.
Assign To Edit List	To assign a material using a typed list of member or element numbers, first select the material tag from the **Materials** dialog box.The selected material is highlighted.Select the **Assign To Edit List** radio button, then type the list of member or element numbers and click the **Assign** button.

Assign Assigns the material per the selected assignment method.

Close Closes the dialog.

Isotropic Material dialog

Used to add a new isotropic material and properties to the STAAD.Pro input file.

Note: Steel, Concrete, Stainless Steel, and Aluminum are default materials in the program and are always included.

Title Enter a unique name to use for a new material. The drop-down list provides the predefined materials available in STAAD.Pro.

Material Properties Define each of the material properties:

- Young's Modulus (E)
- Poisson's Raio (nu)
- Density
- Thermal Coeff (a)
- Critical Damping
- Shear Modulus (G)

Type of Material Select a predefined material type for associating Design Properties with the material. If one of the predefined materials is not appropriate, select Not Specified and no Design Properties will be assigned.

Yield Stress (Fy)	(Steel only)
Tensile Strength (Fu)	(Steel only)
Yield Strength Ratio (Ry)	(Steel only)
Tensile Strength Ratio (Rt)	(Steel only)
Compressive strength (Fcu)	(Concrete only)

Related Links

- *M. To create a material definition* (on page 792)

2D Orthotropic Material Property dialog

Used to add a new orthotropic material and properties to the STAAD.Pro input file.

Refer to TR.26.1 Define Material (on page 2303) for additional information.

Title	Enter a unique name to use for a new material. The drop-down list provides the predefined materials available in STAAD.Pro.
Material Properties	Define each of the material properties for the local X and Y directions: • **Young's Modulus** (E) – modulus of elasticity • **Thermal Coefficient** (a) The general properties are not orthotropic: • **Density** • **Critical Damping** • **Poisson's Ratio** (ν) The **Shear Modulus** (G) property is defined as follows: • **Gxy** – in-plane shear • **Gyz** – shear transverse to the local yz plane • **Gxz** – shear transverse to the local xz plane

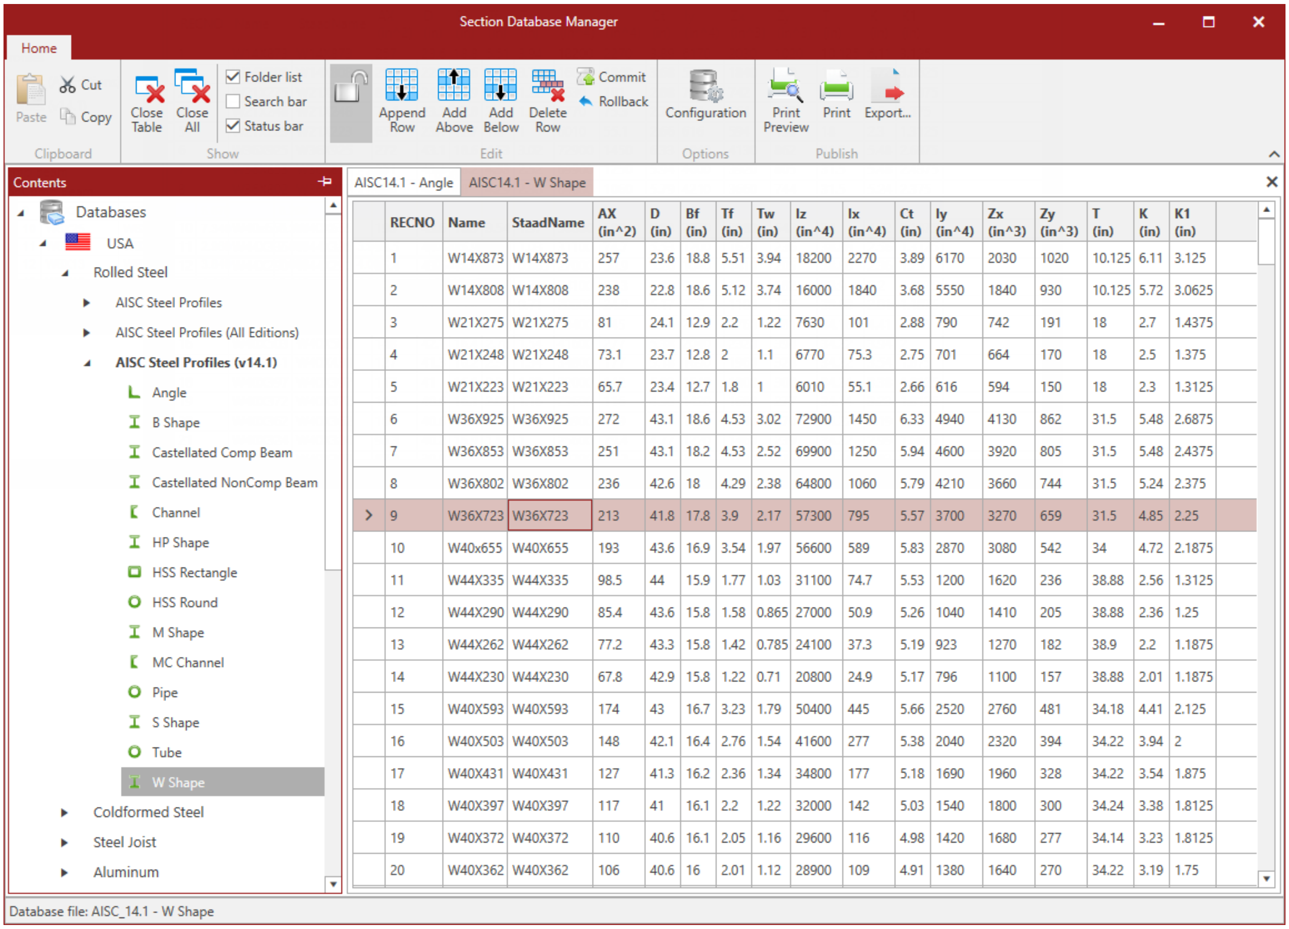
Section Database Manager window

Used to view or edit the existing steel databases by country code and section type. On selection of the section type, the adjacent list box displays the available sections defined in the database. Selection of section in the list box enables the buttons for operating on the database.

In the Analytical Modeling workflow, this window opens when the **Section** > **Section Database** tool is selected in the **Specifications** group on the **Specification** ribbon tab.

In the Physical Modeling workflow, this window opens when the **Section Database** tool is selected in **Sections And Materials** group on the **Catalog** ribbon tab.



Double-clicking on a section opens a new dialog where there are buttons for operating on the database.

Table 319: SectionDBMAnager Home ribbon tab

Tool	What it Does
Close Table	Closes the currently selected table.
Close All	Closes all open tables.
Print	Click to open the currently displayed table in a Print Preview window, where you can print the contents to a Windows printer.
Export	Click to export the currently displayed table as a Microsoft® Office Excel® spreadsheet (file extension `.xslx`).

Tool	What it Does
Lock / Unlock	Click to unlock the table for editing. Editing-related tools (e.g., **Append Row**) are made active when unlocked. Click again to lock the table against further editing.
Append Row	Adds a new section to the database under the selected country and section type. It displays the following dialog box for the input of section properties.
Add Above	Click to add a new record befor the currently selected row.
Add Below	Click to a new record after to the currently selected row.
Delete Row	Deletes the selected section in the list box from the database under the selected country and section type.
Commit	Saves changes made to the current table.
Rollback	Undoes the any changes made to the current table.
Font controls	Use to change the display font of tables.
Search	Use to filter the table for the typed string. Click the "X" to clear the filter and display the entire table again.

Loading tab

Table 320: Loading Specifications group

Tool name	Description
 **Primary Load Cases**	Opens the **Create Primary Load Case** dialog, which is used to create new primary load cases.
 **Combination Load Case**	Opens the **Define Load Combinations** dialog, which is used to specify a load case that combines results of analysis performed for different primary load cases. **Note:** That this option combines the results of the analysis in the specified manner. It does *not* analyze the structure for the combined loading.

Tool name	Description
Reference Load Case	Opens the **Create Primary Load Case** dialog, which is used to create new reference load definition.
Load Items	Opens the **Create New Load Items** dialog, which is used to

Table 321: Loading group

Tool name		Description
Vehicle Load Generator		Opens the **Create New Load Generation** dialog, which is used to create a primary load case using the data of a pre-defined vehicle.
Wind Load Generator >	**IS 875 (Part 3) : 2015**	Opens the **Wind Load Generation - IS 875 (Part 3) : 2015** dialog, which is used to specify wind load definition data as well as generate wind load cases for the Indian IS-875 (Part 3): 2015 code.
Mass Model Generator		Opens the **Create Mass Model** dialog, which is used to generate a mass model for dynamic load cases based on a selected set of load cases.
Primary Load Type		Opens the **Define Load Type** dialog, which is used to define load types for multiple primary load cases in a single dialog.
	Add Auto Load Combintions	Opens the **Auto Load Combination** dialog, which is used to automatically create load combinations based on code-specified combination rules and primary load type selections.

Tool name		Description
Automatic Combinations >	**Edit Load Combination Rules**	Opens the **Edit Load Rules for Auto Load Combination Generator** dialog, which is used to edit load combination rules for the automatic generation of load combination cases.

Table 322: Define Load Systems group

Tool name	Description
Wind	Opens the **Create New Wind Type Definition** dialog, which is used to add a new wind load definition.
Direct Analysis	Opens the **Add New Direction Analysis Definition** dialog, which is used to define parameters used in the direct analysis method described in AISC 360-05 Appendix 7.
Snow	Opens the **Add New Snow Definition** dialog, which is used to define parameters used for generating snow loading on a structure per the ASCE 7-02 code.
Vehicle	Opens the **Add New Vehicle Definitions** dialog, which is used to define different types of moving loads. Several load cases can be generated by applying these types of loads.
Seismic > <country list>	Opens the **Add New Seismic Definitions** dialog, which is used to define the parameters for performing a dynamic analysis using the static equivalent approach as outlined in the various seismic codes supported by STAAD.Pro.
Pushover	Opens the **Add New: Pushover** dialog, which is used to define structural parameters for a pushover analysis.

Table 323: Dynamic Specifications group

Tool name		Description
 **Time History >**	**Forcing Function**	Opens the **Add New Time History Definitions** dialog, which is used to define the Forcing Function of a time varying load.
	Parameters	Opens the **Define (Time History) Parameters** dialog, which is used to define time step, damping, and arrival times for time history loads.
 **Modal Damping**		Opens the **Modal Damping** dialog, which is used to define unique damping ratios for the individual modes used in a dynamic analysis.

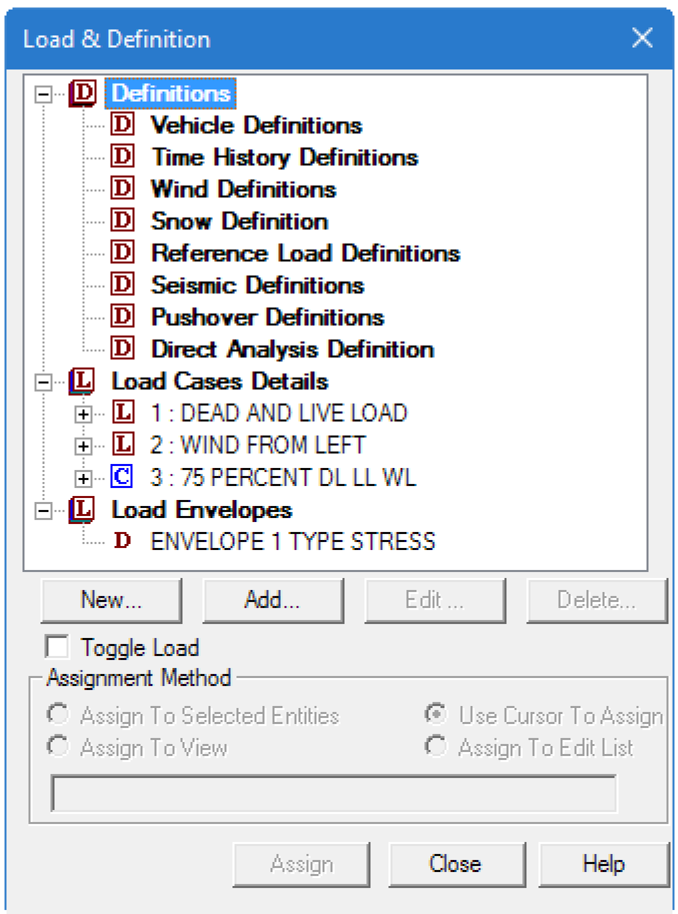
Table 324: Display group

Tool name	Description
Load	Select the active load case, load combination, or load envelope from the pop-up dialog.
 **View Loading Diagram**	Click to toggle the display of the current load case on the structure.

Load & Definition dialog

Used to create and assign load types to the structure.

Opens when the **Loading** page is selected in the **Analtyical Modeling** workflow.



Load & Definitions list	• **Definitions -** contains the options through which you create the `DEFINE` block of data required to create wind load cases, seismic load cases like IBC and UBC, moving load cases and time history load cases. • **Load Cases Details -** contains the dialog boxes through which load cases can be created and loading data added to such cases. • **Load Envelopes -** Lists all load envelopes contained in the model. Selecting the Load Envelopes and click the Add button to open the Add New Load Envelopes dialog.
New	Opens the Create New Definitions/Load Cases/Load Items dialog, which is used to define new Primary Load Cases.
Add	Click to add the newly created load under the current load case in the Load dialog box.
Edit	Used to modify a previously assigned load component. When clicked, the corresponding load dialog is opened with additional controls for editing the load and structural objects to which the load is applied.
Delete	Removes a previously assigned load case or load component.
Toggle Load	Select this option to enable what is called the toggle mode. In this mode, when an attribute is selected and assigned using the **Use Cursor to assign** method, the following happens. • Click on the member or element once - the attribute gets assigned. • Click on the same member or element a second time - the attribute gets de-assigned. • Click on the same member or element again, - the attribute gets re-assigned.
Assignment Method	These options are used to assign predefined loads to nodes, members, and elements. First select a predefined load specification from the Loads & Definitions list. Use one of the following assignment methods to apply this load: Assign To Selected Beams, Assign To View, Use Cursor To Assign or Assign To Edit List. • **Assign To Selected Beams -** To assign a load to selected nodes, members or elements, first select the load from the Loads dialog box. The selected load is highlighted. Then select the nodes, members or elements to which this load is to be assigned. This is done by going to the Select menu, then choosing the appropriate cursor option. Select the desired nodes, members or elements using the cursor. When all desired geometry is selected, click the Assign To Selected Beams radio button, then click the Assign button. Note that the label for this button changes depending on whether nodes, members or elements are selected. • **Assign To View -** To assign a load to all nodes, members or elements in a view, first select the load from the Loads dialog box. The selected load is highlighted. Select the Assign To View radio button, then click the Assign button. All nodes, members or elements in the structure are assigned this load. • **Use Cursor To Assign -** To assign a load to nodes, members or elements using the cursor, first select the load from the Loads dialog box. The selected load is highlighted. Select the Use Cursor To Assign radio button, then click the Assign button. The button will appear depressed and the label will change to Assigning. Use the appropriate cursor (from the Select menu) to assign the selected load to the individual nodes, members or elements. Click on the Assign button again to finish. • **Assign To Edit List -** To assign a load using a typed list of node, member or element numbers, first select the load from the Loads dialog box. The selected load is highlighted. Select the Assign To Edit List radio button, then type the list of node, member or element numbers and click the Assign button.

Load Case tab

Used to generate new load cases (primary and load combination) as well as moving load generations.

Tab name		Dialog Contained
Primary		Create Primary Load Case dialog (on page 2835)
Moving	Load Generation	Load Generation dialog (on page 2866)
	Load Generation Type	(Moving) Load Generation Type dialog (on page 2832)
Combination	Define Combination	Define Load Combinations dialog (on page 2836)
	Auto Load Combination	Auto Load Combination dialog (on page 2872)

Load Items tab

Load Items contains the dialog boxes through which loading data can be added to load cases.

This tab contains the Add New Load Items dialog (on page 2839).

Load Envelopes tab

This tab contains the Add New Load Envelopes dialog (on page 2833).

Add Adds the specified load data to the model.

Close Closes the dialog without adding any load data.

Help Opens the STAAD.Pro Help window.

(Moving) Load Generation Type dialog

Used to specify direction on plane on the structure to simulate the movement of a predefined vehicle for a moving load definition.

Note: If a moving load generation command has not yet been defined for the model, a warning message is displayed in the dialog and the controls are inactive. Refer to the Load Generation dialog (on page 2866) to learn more about defining a moving load.

Opens when **Add** is clicked from the **Load & Definition** dialog when **Vehicle Definitions** is selected.

Note: Refer to TR.31.1 Definition of Moving Load System (on page 2346) for additional information.

Type Reference a previously defined moving load (e.g., vehicle definition) in the input file. Vehicles definitions are created using the Add New Vehicle Definitions dialog (on page 2899).

Range (Optional) defines section of the structure along global vertical direction to carry moving load. This r value is added and subtracted to the reference vertical coordinate (y1 or z1)in the global vertical direction to form a range. The moving load will be externally distributed among

	all members within the vertical range thus generated. r always should be a positive number. In other words, the program always looks for members lying in the range Y 1 and Y1+ABS(r) or Z1 and Z1+ABS(r). The default r value is very small, so entering r is recommended.
Initial Position of Load	Global X, Y, and Z coordinates of the initial position of the reference load.
Load Increment	Incremental values of position of load system coordinates (in global axes) to be used for generation of subsequent load cases. **Note:** The defined vertical direction (e.g., either Y-up or Z-up) is not available to incremental placement of the moving load.

Add New Define Starting Mass Load dialog

Used to explicitly define the starting load vector for use with Ritz vector analysis.

The direction selected will extract a single set of Ritz vectors. This is thus best suited when the structural response is predominant in one translation direction. If responses in multiple translational degrees of freedom are predominant, then it is recommended that the program generated starting load vector is used (i.e., do not define a starting mass load with the load dependent Ritz vector eigen solution method for this case).

For each direction selected, enter the number of vectors to generate in that direction.

Tip: The number of vectors should typically be between 10 and 35, inclusive. If this number of vectors fails to achieve 90% mass participation in the direction of interest, then it is recommended to use full Ritz vector or Eigen solution instead.

X Direction Only
Y Direction Only
Z Direction Only
X and Y Directions
Y and Z Directions
Z and X Directions

Related Links

- *M. To use starting vectors with load-dependent Ritz vectors* (on page 885)

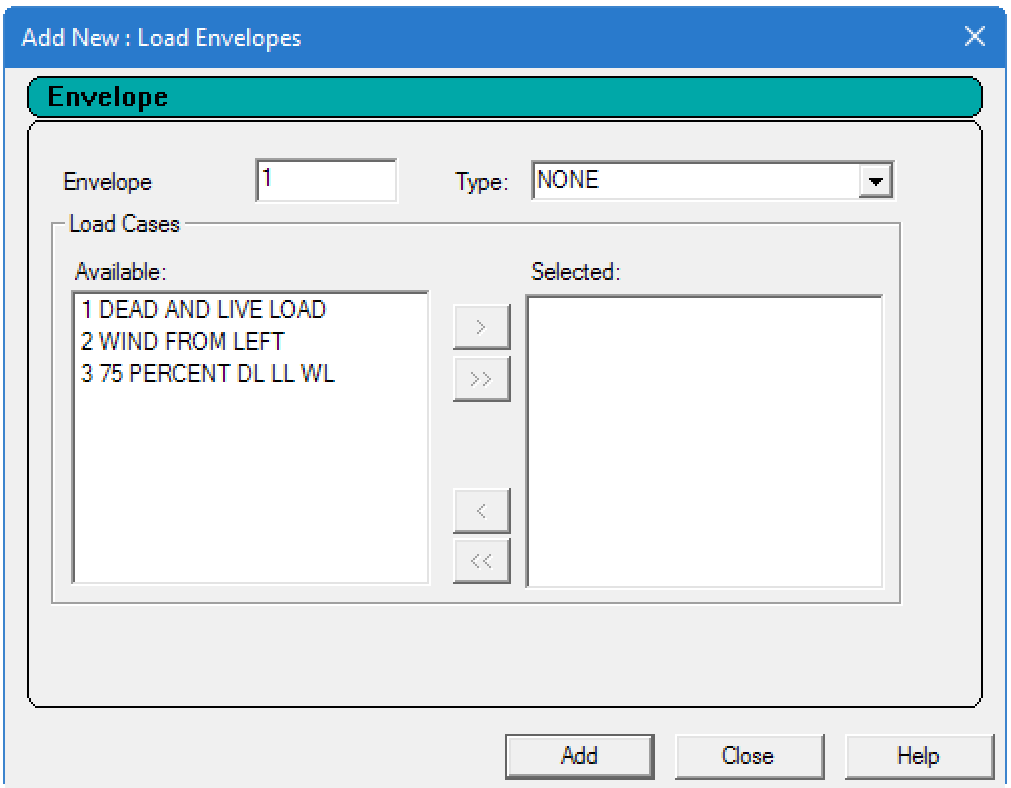
Add New Load Envelopes dialog

Used to create load envelopes, which are used to group results set under a single id and can later be used in post processing. If one or more tasks have to be performed for a set of load cases, such as, serviceability checks under steel design for one set of load cases, strength checks under steel design for another set of cases, etc., this feature is convenient.

Note: Load Envelopes are an alternative to using Load Lists. These commands are treated the same by the STAAD engine.

Once load envelopes have been defined, you can select a Load Envelope for reporting results or design in the **Result Setup dialog**or the appropriate design setup dialog.

Opens when **Add** is clicked on the **Load & Definition dialog** with the **Load Envelopes** entry selected.



Envelope Specify a unique ID number for the load envelope.

Type The envelope can be tagged with optional key words to specify qualitative nature of the load or load combination cases included in the envelop definition. Based on the nature of the load cases in the envelope, you can define appropriate design parameters for each envelope.

For example, for design under wind load condition, most of the design codes allow increase of allowable stresses. Design routine can increase the allowable stress used in interaction equation, when it does the design for the envelope. Another application of this feature can be to specify separate load groups for serviceability check, working stress and limit state checks.

Available list All primary load and load combinations cases are listed here.

List Operators

Click this button…	to…
>	Add the selected load case to the Selected list

Click this button…	to…
>>	Add all load cases to the Selected list.
<<	Remove all entries in the Selected list, load combination is placed back in the Available list.
<	Remove the selected entry from the Selected list.

Selected list Loads to be considered in this Load Envelope.

Related Links

- *M. To create a load envelope* (on page 901)

Create Primary Load Case dialog

Used to create new primary load cases.

Opens when the **Primary Load Case** tool is selected from the **Loading Specifications** group on the **Loading** ribbon tab.

Number

Specify a the load case Number the program recommends, or specify one of our own.

Note: If the load case number has been previously used in this input file, a warning message will be displayed.

Loading Type

Used to associate the load case we are creating with any of the ACI, AISC, or IBC definitions of Dead, Live, Ice, etc. This type of association needs to be done in order to make use the program's facility for automatically generating load combinations in accordance with those codes.

The available load types are the following:

Dead	Soil	Ice
Live	Rain Water/ Ice	Wind on Ice
Roof Live	Ponding	Crane Hook
Wind	Dust	Mass (Notes (on page 2461))
Seismic-H (horizontal, Notes (on page 2461))	Traffic	Gravity

Seismic-V (vertical, Notes (on page 2461))	Temperature	Push
Snow	Accidental	None
Fluids	Flood	

Reducible per UBC/IBC (for Loading Type = Live only) Select this option if the load will be a reducible load per building code.

The UBC 1997, IBC 2000, and IBC 2003 codes permit reduction of floor live loads under certain situations. Please refer to TR.32.4 Area, One-way, and Floor Load Specifications (on page 2475) for details of this feature.

Title Type an optional title which is used to describe the load for identification in modeling and in reports.

Define Load Combinations dialog

Used to specify a load case that combines results of analysis performed for different primary load cases.

Opens when the **Combination Load Case** tool is selected from the **Loading Specifications** group on the **Loading** ribbon tab.

Tip: To automatically generate multiple combinations, use the **Edit Load Rules for Auto Load Combination Generator** dialog.

For more information about Load Combinations, refer to TR.35 Load Combination Specification (on page 2616).

Load No. Specify an integer value to define a new load case combination. This number is automatically incremented.

Name Specify a *Name* for the load case combination.

Type There are three types of combinations possible:

- **Normal -** A pure algebraic load combination in which the results of all constituent cases will be algebraically added. To accomplish this, select each case individually from the left pane, specify the value by wish we see its results factored, and move it over to the right pane by clicking on the > arrow. Do not check any of the boxes Combine Algebraically, SRSS or ABS.
- **SRSS -** The square root of the sum of the squares method of combination.

This enables one to achieve a combination such as L1 * f1 + r1 * [√(f2*L2^2 + f3*L3^2)]. The sequence of operations will be,

1. Select the **SRSS** check box. The *Combine Algebraically* check box will become active.
2. Select *L1*. In the box above Combine Algebraically, specify a *Factor*, (term f1 in the equation above), place a check against the *Combine Algebraically* check box, click on the > arrow.
3. Select *L2*. In the box above Combine Algebraically, specify a *Factor*, (term f2 in the equation above), un-check the *Combine Algebraically* check box, click on the > arrow.
4. Select *L3*. In the box above Combine Algebraically, specify a *Factor*, (term f3 in the equation above), keep the *Combine Algebraically* box un-checked, click on the > arrow.
5. In the box called *Factor* which appears to the right of the expression SRSS, specify the value for *r1*.

- **ABS -** Algebraic combination of absolute values.

  This enables one to achieve a combination such as f1*ABS(L1) + f2*ABS(L2). The sequence of operations will be,

  1. Switch on the *ABS* check box.
  2. Select *L1*. In the box above Combine Algebraically, specify a *Factor*, (term f1 in the equation above), click on the > arrow.
  3. Select *L2*. In the box above Combine Algebraically, specify a *Factor*, (term f2 in the equation above), click on the > arrow.

Factor The load factor coefficient, b, used for the square root value of the sum of the squares.

Default Indicates the default value of the load factor, a (or c, in the case of a SRSS combination), for any load case moved from the Available Load Cases to the Load Combination Definition.

Load factors may be changed from the current default by selecting the entry in the Load Combination Definition.

SRSS Component (Active only when the **SRSS** type is selected) The SRSS load combination type allows a mixture of algebraic combination with an SRSS combination. Select this option to for the load to include it as a SRSS in lieu algebraic addition.

Generate Combination (Active only when either the **SRSS** or **ABS** type is selected) Se this option to generate 1 - 64 load combinations for each combination of degrees of freedom at member ends to create load envelopes for positive and negative analysis results for SRSS and Absolute load combinations.

Available Load Cases list Lists all of the previously created Primary Load Cases or Load Combinations in the current input file.

Tip: Double clicking any load case or combination will add it to the Load Combination Definition list.

Load Combination Definition list Entries here represent the Primary Load Case, load factors, and SRSS component (if any) which will make up the Load Combination.

List Operators

Click this button…	to…
>	Add the selected load case or combination to the Load Combination Definition list
>>	Add all load cases and combinations to the Load Combination Definition list.
<<	Remove all entries in the Load Combination Definition list.
<	Remove the selected entry from the Load Combination Definition list.

Example

Thus, for example, if you want to create a combination case called 101, which combines the absolute values of the results of cases 7 and 15, factored by 1.5 and 1.64 respectively, the command would be

```
LOAD COMBINATION ABS 101
7 1.5 15 1.64
```

From the Create New Load Combination dialog:

1. Select the **ABS** option.
2. Select load case 7 in the Available Load Case list.
3. Specify a **Default** factor of 1.5 and move it to the right pane by clicking on the **>** button.
4. Repeat this process for case 15 with a factor of 1.64.
5. Click **Add**.

The table shown below illustrates the Load Combination logic for Algebraic and SRSS types assuming that the Primary Load Cases are L1, L2, and L3.

Primary Load Case	Factor	Combine Algebraically?	SRSS?	SRSS Factor	Resulting Combination Formula
L1	0.75	Yes	No	n/a	$0.75(L1) + 0.75(L2)+1.33(L3)$
L2	0.73	Yes	No	n/a	
L3	1.33	Yes	No	n/a	
L1	1.0	No	Yes	1.2	$1.2\sqrt{1(L1)^2 + 0.4(L2)^2 + 0.4(L3)^2}$
L2	0.4	No	Yes	1.2	

Primary Load Case	Factor	Combine Algebraically?	SRSS?	SRSS Factor	Resulting Combination Formula
L3	0.4	No	Yes	1.2

- *M. To define a new load combination* (on page 886)

Add New Reference Load Definitions dialog

Used to add a reference load case to the input file.

Opens when the **Reference Load Case** tool is selected in the **Loading Specifications** group on the **Loading** ribbon tab.

Note: See GS. Load Types in STAAD.Pro (on page 51) for additional information on when different load types are used in STAAD.Pro.

The parameters in this dialog are analogous to the Create Primary Load Case dialog (on page 2835).

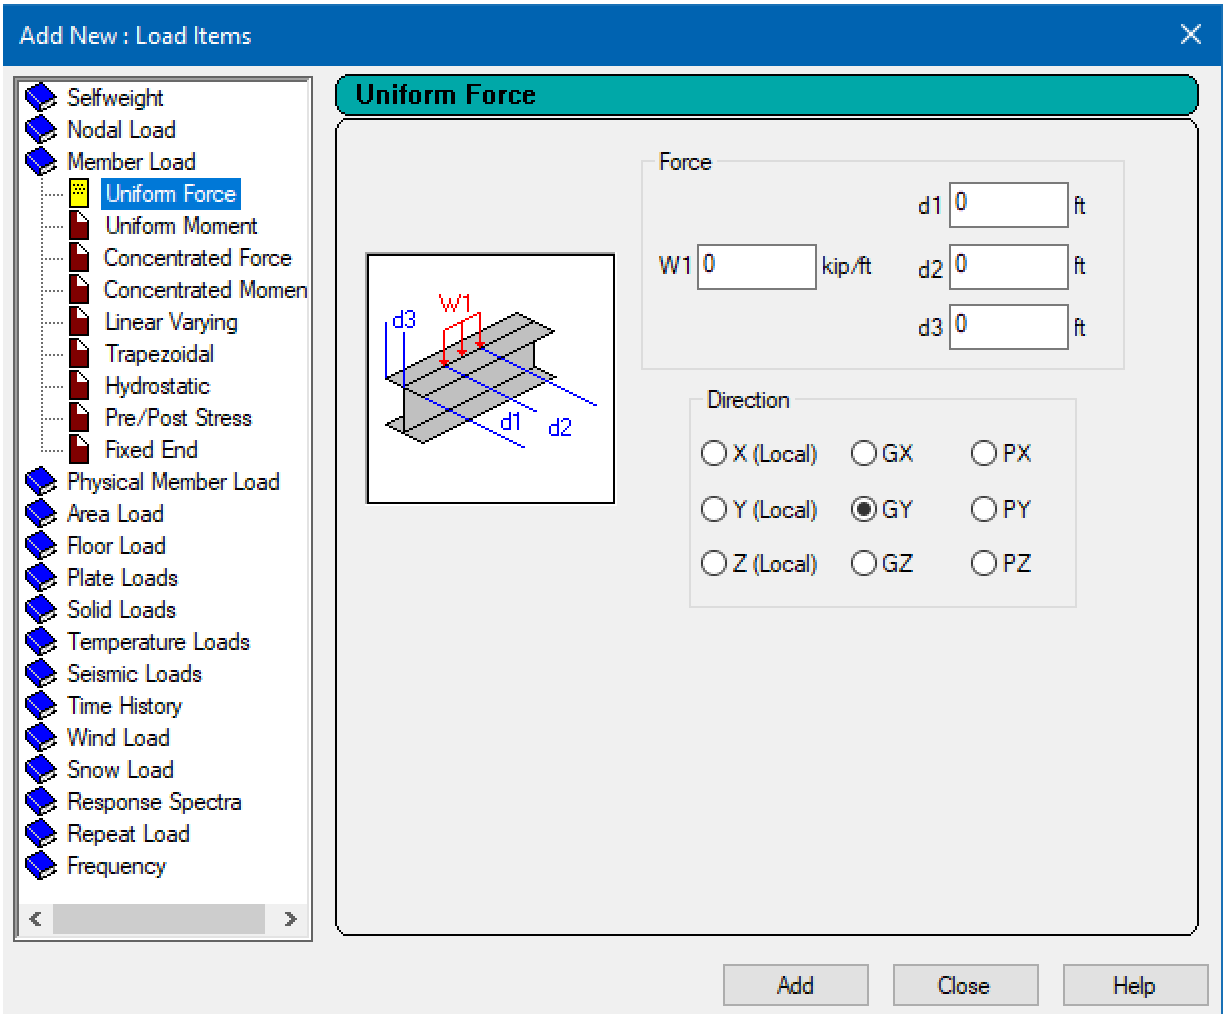
Note: In STAAD.Pro V8i (SELECTseries 3) and higher, the Loading Type Mass can be used to generate a single mass model for re-use in dynamic loads. Refer to TR.31.6 Defining Reference Load Types (on page 2453) for additional details.

Add New Load Items dialog

Used to define and assign loads to the structure.

Opens when the **Load Items** tool is selected in the **Loading Specifications** group on the **Loading** ribbon tab.

Load Item types are grouped into tabs on the right side of the dialog, with parameters for each type in the main dialog.



Note: If the current active load case is not a Primary Load, then many of the tabs will display an error message and the controls will be inactive.

Load Specifications list	Lists the categories into which load specifications are grouped. Selecting a load specification type causes the appropriate dialog controls to be displayed to the right of the list.
Add	Adds the load case on the current tab to the input file. The new load appears in the **Load & Definition** dialog under the currently selected load case.
Close	Closes the dialog. Any load data entered without clicking the Add button will be lost.
Help	Opens the STAAD.Pro help window.

Related Links

- *M. To edit a previously assigned load* (on page 901)

Selfweight tab

Used to apply the selfweight of the structure as a load. Selfweight of all active components of the structure are calculated and applied as a uniformly distributed load.

Note: The material (or the density parameter) of the members must be defined before this command is used.

Direction Specify the direction in which the selfweight load is to be applied by clicking on the X, Y, or Z buttons.

Factor Specify the factor with which the calculated selfweights are to be multiplied. A negative value indicates that the load is applied along the negative direction of the chosen axis.

Related Links

- *M. To add selfweight load* (on page 831)

Nodal Load tab

Used to apply nodal loads.

The following options are available under this tab:

Node

Fx/Fx', Fy/Fy', Fz/Fz' Type values of the forces in corresponding global directions or inclined axis (') directions when the **Inclined Load?** option is checked. A negative sign (-) may be used.

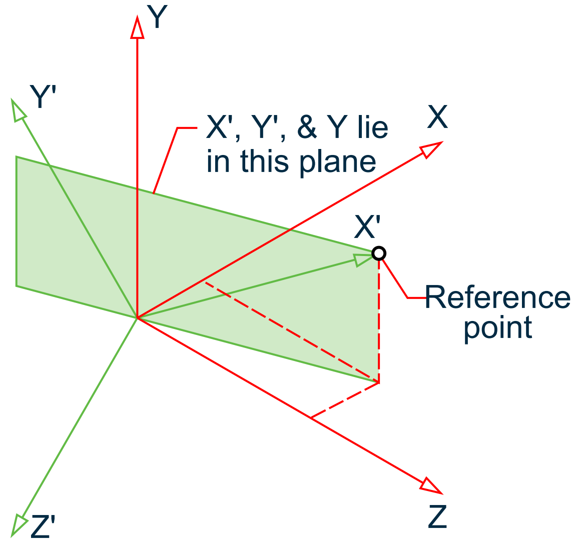
Mx/Mx', My/My', Mz/Mz' Type values of the moments about the corresponding global directions or inclined axis (') directions when the **Inclined Load?** option is checked. A negative sign (-) may be used.

Inclined Load? Check this option to specify the load along an inclined coordinate system. An inclined coordinate system is defined by an X' axis that pass from the loaded joint through a reference point. That reference point can be defined either a reference node, a set of absolute (global) coordinates, or a set of relative distances from the loaded joint.

Note: When this option is checked, the load vector labels are updated to reflect the inclined (') vector.

Inclination Select the option used to define the inclined coordinate system.

- **Reference Node -** select an existing node number from the model. The global coordinates of that node are displayed as read-only.
- **Absolute -** type the global coordinates of an arbitrary point to use as the reference.
- **Relative -** type relative distances from the loaded joint to the reference point. These distances are measured along the global axes.



The reference point –whether it is specified using absolute coordinates, relative distances, or a reference joint– defines the direction of the x' axes from the loaded node to the reference point. The direction of the Y' axes is then defined as the direction perpendicular to x' that lies in the plane of X' and Y. In the special case of when X' is in the direction of Y, Y' is taken to be the direction of Z. The direction of Z' is then defined as the direction perpendicular to the plane X' and Y' and follows the right-hand rule as for all other axes systems used in STAAD.Pro.

Support Displacement

Used to specify a support displacement. Multiple support displacements may be used for a single load case, but each support value and direction must be entered independently.

Displacement	Specify the value of the displacement. A negative sign (-) may be used.
Direction	Select the direction of the displacement as **Fx**, **Fy**, or **Fz** (translational), or **Mx**, **My**, or **Mz** (rotational).

Member Load tab

Used to apply loads on the span of frame members or physical members (select the appropriate parent tab).

These following options are available:

Uniform Force / Moment

Used to specify a Uniformly Distributed Force or Uniformly Distributed Moment along a member.

W1 Value of the load in currently selected units.

d1, d2 Distance of starting and ending points of the load from the starting node (Node A) of the member. If these values are zero, then the load is applied over the entire length of the member.

d3 Perpendicular distance from the member's shear center to the plane of loading.

Direction Click on the appropriate radio button to specify the direction of the load. **X**, **Y**, **Z** indicate the direction in local coordinates; **GX**, **GY**, **GZ** indicate the loads in global coordinates; **PX**, **PY**, **PZ** indicate the loads along the projected length of the member in the corresponding global direction. However, d1, d2 and d3 are still measured along the length of the member and not along the projected length.

The projected load direction, PY, uses the component length in the XZ plane for the load effect.

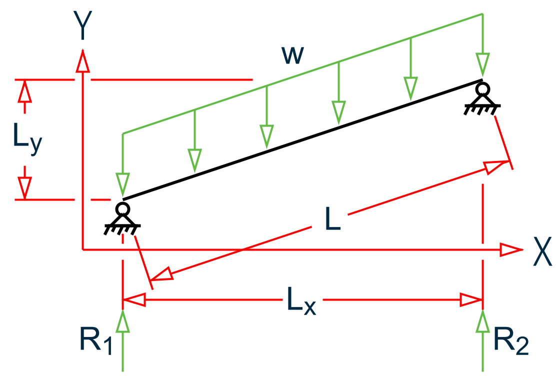

Figure 343: Example inclined beam parallel to the XY plane

Concentrated Force / Moment

Used to specify a concentrated force or moment load on a member.

P Value of the load in currently selected units.

d1 Distance of the load from the starting node (Node A) of the member. If this value is not specified, then the load is applied at the midpoint of the member.

d2 Perpendicular distance from the member's shear center to the plane of loading.

Direction Click on the appropriate radio button to specify the direction of the load. **X**, **Y**, **Z** indicate the direction in local coordinates; **GX**, **GY**, **GZ** indicate the loads in global coordinates; **PX**, **PY**, **PZ** indicate the loads along the projected length of the member in the corresponding global direction. However, d1 and d2 are still measured along the length of the member and not along the projected length.

Linear Varying

Used to specify a linearly varying load on a member. The load is applied over the entire length of the member.

W1, W2	For a linearly increasing or decreasing load, enter the values of force **W1** at the start of the beam and **W2** at the end of the beam in currently selected units.
W3	For a triangular load distribution, enter the value **W3** of the force in the middle of the beam.
Direction	Select the direction of the force in local coordinates from the radio buttons **X**, **Y** or **Z**.

Trapezoidal

Used to specify a trapezoidal load on a member.

W1, W2	Starting and ending load values in currently selected units.
d1, d2	Distance of starting and ending points of the load from the starting node (Node A) of the member. If these values are zero, the load is applied over the entire length of the member.
Direction	Click on the appropriate radio button to specify the direction of the load. **X**, **Y**, **Z** indicate the direction in local coordinates; **GX**, **GY**, **GZ** indicate the loads in global coordinates; **PX**, **PY**, **PZ** indicate the loads along the projected length of the member in the corresponding global direction. However, d1 and d2 are still measured along the length of the member and not along the projected length.

Hydrostatic

Used to specify loads due to hydrostatic pressure on one or more adjacent beams. The Hydrostatic load is converted to Trapezoidal loads on the beams. The load is applied over the entire length of the members.

W1, W2	Type the value of the load at the minimum and maximum global axis in currently selected units. For example, to model a retaining wall with soil pressure, **W1** is the force at the bottom of the wall and **W2** is the force at the top of the wall.
Direction	Select the direction in which the force is applied by clicking on the appropriate radio button. **X**, **Y**, **Z** indicate the direction in local coordinates; **GX**, **GY**, **GZ** indicate the loads in global coordinates; **PX**, **PY**, **PZ** indicate the loads along the projected length of the member in the corresponding global direction.
Interpolate along Global Axis	Specify the global axis along which the load would vary from **W1** to **W2**. For example, the load would vary along the Y axis on a vertical retaining wall.
Select Member	Opens a **Selected Item(s)** dialog, which is used to generate a list of selected members. The Create Loads dialog is dismissed until all loads are added using the Beams Cursor tool in the View Window. Once the **Done** button is clicked, the Create Loads dialog re-opens with the member table populated. Unlike other load definition options, we must select members for this option to become active.

Pre/Post Stress

Used to apply Poststress and Prestress loads on members.

Type	Select either the **Prestress** or **Poststress** radio button.
Load	Type the **Force** as a positive value in current units.
Eccentricity Distances	If applicable, specify the Eccentricity of the cable with respect to the center of gravity of the cross section at the **Start**, **Middle** and **End** of the member.

Note: Please refer to TR.32.5 Prestress Load Specification (on page 2489) for more detailed information on these options.

Fixed End

If a load acts at an intermediate point along the span of a frame member, there are two ways of assigning the load. a) It could be specified using the member load option. In this case, the magnitude and position along span are specified. b) It could be converted to fixed end actions and defined as a FIXED END load as shown below.

Start / End Node	Type values for FX, FY, FZ, MX, MY and MZ (axial, shear-y, shear-z, torsion, moment-y, and moment-z) in the local coordinates for the Start node and /or the End node.

Area Load tab

Used to apply area (panel) load which will be distributed on surrounding beams based on a one way distribution.

Pressure	This load is a one-way distributed pressure load on members that circumscribe a panel. Enter the value of the area load (force per unit area) in the current units. This load always acts along the positive local y-axis on the two longest members in each panel.
Direction	Select the direction in which the force is applied. **Local Z** indicates the direction in local coordinates, perpendicular to the panel; **GX**, **GY**, **GZ** indicate the loads in global coordinates.

Related Links

- *G.15.3 Area, One-way, and Floor Loads* (on page 2130)
- *M. To add an area load* (on page 839)

Floor Load tab

Used to apply a panel load which will be distributed on surrounding beams based on a two way distribution.

This load is a two-way distributed pressure load on members that circumscribe a panel.

Load	Floor load value (force per unit area) in the current units. This load will act parallel to the global vertical axis.

XRANGE / ZRANGE / YRANGE options
Select one of these options to specify a floor load by range of global coordinates

Group option
Select this option to apply a floor load on a previously added member group or composite deck definition.

Pressure
Specify the pressure of the floor load in the current force per square length units.

Direction
The floor load may be considered as acting perpendicular to the plane of the panel on which it is defined. This is the normal static load condition. However, for the purposes of generating the mass matrix for dynamic analysis, it may also be considered as weights lumped at the nodes of its panels and acting (vibrating) parallel to the plane of the panel. Hence, the user has the choice of specifying it in one of the 3 global directions.

Note: Refer TR.32.4.3 Floor Load Specification (on page 2483) for more information.

Define X Range / Y Range / Define Z Range
Specify the location of the floor using the *Define X Range* option. The load will be calculated for all members lying between this range.

Corner points of the area on which the floor load acts, in global X and Z directions. If omitted, the floor load is assumed to be acting for all members located within the Y range specified.

One Way Distribution
Select this option to use one way distribution to get a one way type distribution of the pressure. In such cases the program finds out the shorter side of the panel. It then divides the load in between the long direction beams . No load is generated by this option if the panel is square in shape.

To specify a floor load with the Z-axis vertical, select the *Floor With Z Range* menu option. The data items are the same as the Floor load with Y axis vertical except that the Y and Z axes are interchanged.

Towards
(One Way Distribution) Used to define the direction in which the load is spanning by selecting a member in the loaded zone onto which the load is to be directed. The default is for the load to resolve toward the longer span of supporting beams framing the Floor load. However, you can select a beam number to direct the load to that beam.

Panel Information Output group

Print to output file
Includes the floor panel information in the output file (`.ANL`).

Print Options (output file):

- **Print -** The total number of panels identified, total area of all panels and total load generated will be printed in the output file.
- **Panel with member list -** This option is used to print panel member numbers on which loads are generated in addition to the **Print** option output.
- **Panel with member load -** This option is used to print panel loading information in addition to the **Print with member list** option output..

Print to external text file
This option will output the panel information in an external text file named `(filename) _FLD.TXT`.

Print Options (external text file):

- **Panel with member list -** This option is used to print panel member numbers on which loads are generated. Additionally, the total number of panels identified, total area of all panels and total load generated will be printed in the text file.
- **Panel with member load -** This option is used to print panel loading information in addition to the **Print with member list** option output..

Related Links

- *G.15.3 Area, One-way, and Floor Loads* (on page 2130)
- *M. To add a floor load or one-way load* (on page 840)

Plate Loads tab

Used to apply loads to elements.

Pressure on Full Plate

Used to define a pressure load that acts on the full surface of an element. (To define a pressure load that acts on a small part of an element, see the Partial Plate Pressure tab that is described in the coming pages).

Load W1 is the pressure magnitude, in the current units.

Direction The load may be applied along:

- the local X, Y, or Z axis,

> **Tip:** Loads in the **Local X** or **Local Y** directions can be used to represent in-plane friction loads.

- one of the global X, Y or Z axes (**GX**, **GY**, or **GZ**)
- projected area of the plate (**PX**, **PY**, or **PZ**)

Concentrated Load

Use this option to define a concentrated load that acts at a specific point within the boundary of an element. If a load acts at a node point of an element, it is advisable to apply it using the Nodal Load option described in earlier pages.

Load **Force** is the magnitude of the load.

Direction The load may be applied along the local Z axis, or along one of the global X, Y or Z axes (GX, GY, GZ).

Partial Plate Pressure Load

Used to specify a uniform pressure load on the entire element or on a user specified portion of the element.

Load The element pressure (force per unit area) or concentrated load (force unit). For concentrated load, the values of **X2** and **Y2** must be omitted, while **X1** and **Y1** must be specified.

X1, Y1, X2, Y2 For element pressure (force per unit area), these values represent the coordinates of the rectangular boundary on which the pressure is applied. If **X1**, **Y1**, **X2**, and **Y2** are all zero,the pressure is applied over the entire element. If **X1** and **Y1** are specified but **X2** and **Y2** are omitted, then **W1** is treated as a concentrated load.

Direction	**GX**, **GY**, and **GZ** represent the global X, Y, and Z directions along which the pressure may be applied. **Local Z** indicates that the pressure is applied normal to the element in the local Z direction.

Note: For more information, please refer to TR.32.3 Element Load Specifications (on page 2468) .

Trapezoidal

Used to specify a trapezoidally varying pressure load on a plate. The load is applied over the entire element in the local Z direction, varying along the positive local X or Y direction.

Direction of Pressure	**GX**, **GY**, and **GZ** represent the global X, Y, and Z directions along which the pressure may be applied. **Local Z** indicates that the pressure is applied normal to the element in the local Z direction.
Variation along element	Define the direction in which the pressure varies as either the local **X** or **Y** direction or choose the joint option which is discussed next. The Joint option is used to apply different values of pressure at different nodes of the plate element. When checked, the dialog updates to allow a different pressure value for each of the four plate corner nodes.

Hydrostatic

Used to model loads due to hydrostatic pressure on one or more adjacent elements. The Hydrostatic load is converted to Trapezoidal loads on the elements. The load is applied over the entire area of the element.

Force	Enter value of the load at the minimum and maximum global axis in current units. For example, to model a retaining wall with soil pressure, **W1** is the force at the bottom of the wall and **W2** is the force at the top of the wall.
Interpolate along Global Axis	Specify the global axis (**X**, **Y**, or **Z**) along which the load should vary from **W1** to **W2**. For example, the load would vary along the Y axis on a vertical retaining wall.
Direction of pressure	Specify the direction of design pressure as **Local Z** axis or global axes (**GX, GY** or **GZ**) and click on **Add.** This will assign the linearly varying hydrostatic load on all the selected elements.
Select Plate(s)	Opens a **Selected Item(s)** dialog, which is used to generate a list of selected plates. The **Create Load Items** dialog is dismissed until all loads are added using the Plates Cursor tool in the View Window. Once **Done** is clicked, the **Create Load Items** dialog re-opens with the Plate table populated. Unlike other load definition options, we must select plates for this option to become active.

Element Joint Load

To specify a varying pressure at each joint on a plate, select the **Element Joint Load** option. This load item can be applied on joints directly whether they are plate corner nodes or not.

Joint Load Data	Choose Three Noded Facet / Four Noded Facet, depending on whether the plate element is 3 noded or 4 noded.

Pressure Table	Specify the corner node number and corresponding pressure load, in the current units (displayed).
Direction	The load may be applied along the local Z axis, or along one of the global X, Y or Z axes (GX, GY, GZ).

- *M. To add a concentrated load on a plate* (on page 838)

Solid Loads tab

Used to apply uniform pressure and uniformly varying pressure on the faces of the solid element.

Face Number	Select the face on which we want to apply the load.
Node 1.... Node 4	Specify the pressure at each node on the selected face of the solid element. For example, if the pressure is uniform, the same value ought to be entered in all four columns.
Direction	Specify the direction of design pressure as *Local Z* axis or global axes (*GX, GY* or *GZ*) and click on *Add.* By doing this, the solid pressure load is added to that particular load case.

Temperature Loads tab

Used to apply Strain and Temperature loads on members.

Temperature

Used to specify a temperature load

Temperature Change for Axial Elongation	The change in temperature that will cause axial elongation in members or uniform volume expansion in elements.
Temperature Differential from Top to Bottom	Temperature differential of the member or element (T top surface – T bottom surface). **Note:** The top surface is in the positive local Y direction for members, and the positive local Z direction for elements. If the **Temperature Differential from Top to Bottom** is omitted, bending is not considered.
Temperature Differential from side to side (Local Z)	Accounted for when the temperature difference is not the same across the sides of the member from left to right.

Strain

Used to specify a strain load.

Initial Axial Elongation or Shrinkage	Enter the initial elongation or shrinkage in the member in current units. A positive value indicates elongation, a negative value indicates shrinkage.

Seismic Loads tab

Used to apply previously defined UBC loads on the structure.

Note: If a seismic load definition has not yet been added to the model, a warning message is displayed in the dialog and the controls are inactive. Refer to the Add New Seismic Definitions dialog (on page 2895) to learn more about defining a seismic load.

Direction group	Specify the global direction in which the seismic load is to be generated by selecting the **X Direction**, **Y Direction**, or **Z Direction** radio button. **Factor** Specify a multiplying factor, if applicable. The default factor is 1.0.
Multiplying factor for Accidental Torsion Moment	Set this option to include the accidental torsion load per the UBC, IBC, 1893, etc. code. Type the **Factor** in the associated field (may be a negative value).
Multiplying factor for Natural Torsion Moment	Set this option to include the torsion arising due to static eccentricity which is the difference between center of mass and center of rigidity of a rigid floor diaphragm. Type the **Factor** in the associated field (must be greater than or equal to zero).

Time History tab

Used to apply previously defined time history loads on the structure.

Note: If a time history load has not yet been defined for the model, a warning message is displayed in the dialog and the controls are inactive. Refer to the Add New Time History Definitions dialog (on page 2907) or Define (Time History) Parameters dialog (on page 2909) to learn more about defining a time history load.

Loading Type	Select **Time Load** to apply the Time History load to joints in the structure or **Ground Motion** to apply the load at the structure's base.
Arrival Time	Select a previously defined Arrival Time to define the time at which the load begins to act.
Direction	Select the global direction in which to apply the Time History load.
Defined Types	Select a previously defined Type number.
Force Amplitude Factor	Specify a factor to multiply the values of force or acceleration which were input while defining the Time History loading.

Related Links

- *G.17.3.5 Response Time History* (on page 2165)
- *M. To add a time history load* (on page 880)

Wind Load tab

Used to apply previously created wind load types on the structure through the means of a load case.

Note: If a wind load has not yet been defined for the model, a warning message is displayed in the dialog and the controls are inactive. Refer to the Create Wind Type Definition dialog (on page 2880) to learn more about defining a wind load.

Wind Load tab

Used to add static wind forces per ASCE 7 and other codes.

Select Type
Choose a previously defined wind load type from the drop down list.

Exposed Surface and Direction
Specify the global direction in which the wind load is to be generated by clicking the **X**, **Z**, **-X**, or **-Z** option. When wind is generated in X direction ,the wind load is applied on the near side and when -X is chosen the load is applied on the far side as explained in the following figures. Generation in Z or -Z is similar.

	Wind in X	Wind in -X

Figure 344: Wind in positive and negative directions

Table 325: Wind direction explanation

If the direction is set to…	and f is…	Then the load is applied to surfaces facing…	and the load will be directed toward…	This can be though of as…
X or Z	Positive	Negative X or Z	Positive X or Z	Windward load for wind in the positive X or Z direction
	Negative	Positive X or Z	Negative X or Z	Windward load for wind in the negative X or Z direction

If the direction is set to…	and f is…	Then the load is applied to surfaces facing…	and the load will be directed toward…	This can be though of as…
-X or -Z	Positive	Positive X or Z	Positive X or Z	Leeward load for wind in the positive X or Z direction
	Negative	Negative X or Z	Negative X or Z	Leeward load for wind in the negative X or Z direction

Factor Specify the factor by which the calculated wind loads will be multiplied.

Open Structure Select this option to generate loads on open structures like highway signs or transmission towers. By default, the load generation is based on the assumption that the region between members is covered by panels (i.e., cladding). Setting this option will apply load to only the members (i.e., no cladding).

Tip: The term used here is not the same as the ASCE 7 definition of "open structure." Please use the ASCE 7 Wind Load dialog box (on page 2882) to generate describe the enclosure classification per this code.

SNiP Parameters The following parameters are used for wind loads generated per the Russian code (SNiP).

Apply Wind Load at the Corner Select this option for wind loads to be applied at 45°.

Note: This parameter is only applicable for rectangular buildings.

Select Configuration The building configuration as defined in SNiP 2.01.07–85 "Loads and Actions":

0. Prismatic building structure - Rectangular building- Outstanding architectural details on the left façade.
1. Prismatic building structure - Rectangular building- Both side façades are smooth
2. Prismatic building structure - Rectangular building- Outstanding architectural details on the right façade
3. Prismatic building structure - Rectangular building- Outstanding architectural details on both side façades
4. Prismatic building structure - Rectangular building- Triangular building
5. Prismatic building structure - Rectangular building- Rhombic building

6. Prismatic building structure - Rectangular building- Number of vertices of polygonal building, not more than 12
7. Prismatic building structure - Less than 3 — rectangular building
8. Prismatic building structure - 3 — triangular
9. Prismatic building structure - 4 — rhombic
10. Prismatic building structure - More than 4 — polygonal
11. Framed RC structure
12. Lattice steel structure

Reynolds Number (NU)	Specify the wind pressure correlation coefficient. If parameter is omitted or is exactly 1, a computed value is used instead. For rectangular buildings, the correlation coefficient is always calculated automatically, thus any specified value will be ignored.

Note: The first load case which has a Russian Wind Load command added to it will consider all other loads defined in it as the masses to be considered for calculating the dynamic effect which is required by this command.

Wind Load - Dynamic tab

Used to specify dynamic wind forces per SP 20.13330.2016.

Wind Definition	Choose an SP 20.13330.2016 wind load definition from the drop down list.
Width of Building along wind dir	Effective length of the structure parallel to wind direction.
Wid of Building across wind dir	Effective projection of the structure facing the wind direction.
Ground Level	Select if the ground level is not considered (i.e., global Y = 0 is the ground level) or if it is to be specified at different Y coordinate.
Factor	Correction factor along specified direction.
Internal	Set this option to indicate an internal, or suction, wind force on the surfaces (i.e., the load direction is reversed).
Allow all Mode Shapes	Check this option to compute dynamic wind load vector for all mode shapes extracted from Modal Analysis provided it is within code stipulated frequency limit. When this check box is clear, the calculation takes only the first mode shape.
Include Orthogonal Load	Check this option to include orthogonal directions in the load case.
Static Wind Case	Select a previously defined primary load cases in the model.
Wind Direction	Select the plan direction to apply the wind force.

- *M. To add a SNiP wind load definition* (on page 847)

Snow Load tab

Used to generate snow loading on a structure in accordance with the provisions of the ASCE-7-02 code.

The feature is currently implemented for structures with flat or sloping roofs. Snow load generation for members of open lattice structures like electrical transmission towers is currently not part of this facility. Hence, the feature is based on panel areas, not the exposed width of individual members.

Note: If a snow load has not yet been defined for the model, a warning message is displayed in the dialog and the controls are inactive. Refer to the Add New Snow Definition dialog (on page 2894) to learn more about defining a snow load.

Floor Group	Select the floor group on which the snow load is to be applied.
Condition	Specify whether the load is “Balanced” or “Unbalanced.” These terms are described in section 7.6, and figures 7.3 and 7.5 of ASCE 7-02.
Define Snow Type	Select the snow load type number. This is the number specified against the *Type No.* field while creating the snow load definition in Part I described earlier in this section.
Roof Type	Specify the roof type from the available choices: • Default (if the roof type is not Mono, Hipped or Gable, it is referred to as Default) • Mono (see mono-sloped roof shown in figure 6-6 of the code) • Hipped (see figures 6-3 and 6-6 of the code) • Gable (see figures 6-3 and 6-6 of the code)
Roof Obstruction	Specify whether the roof is “obstructed” or “unobstructed.” This also is a term described in section Table 7-2 of ASCE 7-02.
Roof Slope Factor	For sloped roofs, the roof slope factor is described in section 7.4 of the SEI/ASCE-7-02. A value of 0 indicates that the roof is horizontal.

- *M. To add an ASCE 7-02 snow load* (on page 870)

Response Spectra tab

Used to apply response spectrum loads on the structure.

Note: The dialog updates dynamically to reflect the **Code** selection.

Common Parameters for all **Code** options

Combination Method	The various methods available in STAAD.Pro for combining the contribution from the individual modes is listed under this heading. The details of these methods are explained in TR.32.10.1 Response Spectrum Analysis (on page 2498). **Note:** Not all methods are available for all code options.

- **SRSS** is the square root of summation of squares method.
- **ABS** is the absolute sum method. This method is very conservative and represents a worst case combination.
- **CQC** is the complete quadratic combination method. This method is recommended for closely spaced modes instead of SRSS.
- **ASCE** is the NRC Regulatory Guide Rev. 2 (2006) Gupta method for modal combinations and Rigid/Periodic parts of modes are used. The ASCE4-98 definitions are used where there is no conflict. ASCE4-98 Eq. 3.2-21 (modified Rosenblueth) is used for close mode interaction of the damped periodic portion of the modes. This method should only be used for a general response spectrum.
- **TEN** is the Ten Percent Method of combining closely spaced modes as per the NRC guideline 1.92 (1976).
- **CSM** is the closely spaced modes method. The peak response quantities for closely spaced modes (considered to be within 10 percent of each other) are combined by Absolute method. This peak response quantity for closely spaced modes is then combined with those of widely spaced modes by SRSS method.
- **GRP** is the closely spaced modes grouping method where the peak response quantities for closely spaced modes (considered to be within 10 percent of each other) are combined using the absolute method. This peak response quantity for closely spaced modes is then combined with those of widely spaced modes by SRSS method. NRC Reg. Guide 1.92 (Rev. 1.2.1, 1976).

Save Select this option to generate a file (with `.acc`. extension) containing the joint accelerations in g's and radians/sec_2

Period vs. Acceleration table Provide the values of period (seconds) and corresponding acceleration (current length units/sec^2) or displacement (current length unit). Spectrum pairs should be provided in ascending value of period. As we provide the curve points, the program displays the curve at the bottom of the dialog box.

Spectrum Type Choose whether the response spectrum curve will be input as Period vs. Acceleration or Period vs. Displacement (Custom and IS 1394 only).

Interpolation Type From the spectrum data that are provided under the *Define Spectrum Pairs* tab of the dialog box shown above, STAAD fetches the spectral value for the actual modes of the structure using one of two interpolation methods – **Linear** and **Logarithmic**. Linear interpolation is the default method.

Since Spectra versus Period curves are often linear only on Log-Log scales, the logarithmic interpolation is recommended in such cases; especially if only a few points are entered in the spectra curve.

Damping Type

- **Damping -** This is to be used for specifying a single modal damping ratio which will be applied to all modes. The default value is 0.05.
- **CDAMP -** Select this option to use Composite Modal Damping. This evaluates the damping from that defined in the material or constant definitions. A Damping ratio is defined by the material definition or in the **Material Constants - Damping Ratios** dialog. If there is no damping information entered in the material or constant definitions, the behavior is the same as MDAMP.

- **MDAMP -** Selection this option to use Modal Damping, which is used for individual damping ratios for each mode. Individual mode damping ratios are defined using the Modal Damping dialog (on page 2910).

Scale	Linear scale factor by which the spectra data will be multiplied. Usually to factor g's to length/sec^2 units. This input is the appropriate value of acceleration due to gravity in the current unit system You may choose to provide the spectral acceleration or displacement data as a set of un-normalized values or as a set of normalized values. For normalized values, the normalization factor is specified through the means of the Scale factor. For example, if the curve is input in terms of "g" - the acceleration due to gravity - and the current length unit is feet, the *Scale* would be 32.2. For un-normalized values, the scale factor is provided as 1.0, which also happens to be the default. The spectra data will be multiplied by the scale factor during the analysis.
Missing Mass	Select this option to apply the Missing mass correction. The static effect of the masses not represented in the modes is included. If this option is selected on any spectrum case it will be used for all spectrum cases.
ZPA	Zero Period Acceleration: It is used only with the missing mass option. If no value is entered or a zero value is entered, the default considered by the program is 33 Hz. If an acceleration is entered corresponding to the Missing mass mode, then the ZPA value is ignored. If no acceleration value is entered for the missing mass mode, then spectral acceleration corresponding to the ZPA frequency is used.
Direction	Specify the global direction(s) in which the spectrum is to be applied. The response spectrum may be applied in one or more directions simultaneously. Directions not provided will default to zero.
Use Torsion	(IS 1893, IBC 2012, IBC 2018 and NRC only) **Dynamic Eccentricity (DEC)**: Factor to be multiplied with static eccentricity (i.e., eccentricity between center of mass and center of rigidity). If not specified (or zero), a value of 1.0 is assumed. **Accidental Eccentricity (ECC)**: Factor for accidental eccentricity. Positive values indicate clockwise torsion and negative values indicate counterclockwise torsion. If not specified (or zero), a value of 0.05 (5% of floor plan dimension perpendicular to force at a given level) is used.
Signed Response Spectrum Results Options	Two method are available for added mathematical signs to the spectrum response output: • **Dominant Mode No. -** Select this option and (optionally) specify a mode number to define as a dominant mode. The sign (sense) of this mode will be applied to other modes. • **Signed -** Select this option to create signed values for all results by comparing the sum of the squares values for positive and negative values to determine the governing sign.
Individual Modal Response Load Case Generation	Select this option to have the program automatically generate primary load cases from the mode shape scaled to the magnitude that the mode has in this spectrum analysis case before it is combined with other modes. A load case is generated for each of first number of modes specified, starting with the specified load case number.

> **Note:** The Individual Modal Response case generation is not available for SNiP II code response spectra.

Custom

Generate Spectrum Opens the Spectrum Parameters dialog (on page 2862), which is used to generate a response spectrum curve per the International Building Code.

> **Note:** This is the response spectrum type that is explained in Section TR.32.10.1.1 Response Spectrum Specification - Custom (on page 2499) l.

IS-1893 2002

Subsoil Class Select the soil type for the site (hard , medium, soft, or custom). Depending on the type of soil & time period, average response acceleration coefficient Sa/g is calculated.

> **Note:** This is the response spectrum type that is explained in Section TR.32.10.1.7 Response Spectrum Specification per IS: 1893 (Part 1)-2002 (on page 2534).

IS-1893 2016

Subsoil Class Select the soil type for the site (hard , medium, soft, or custom). Depending on the type of soil & time period, average response acceleration coefficient Sa/g is calculated.

> **Note:** This is the response spectrum type that is explained in Section TR.32.10.1.8 Response Spectrum Specification per IS: 1893 (Part 1)-2016 (on page 2544).

IS-1893(Part 4):2015

RSMIN Select a factor, given in percent, to multiply by the total seismic weight of the structure to obtain a minimum base shear value. This percentage is taken from Table 2 of IS:1839(Part 4)-2015. The default value is taken for a structure category 1 and zone 2.

If the minimum base shear value exceed the calculated response spectrum base shear, then all analysis results of the response spectrum load case are scaled by the ratio of the minimum base shear to the calculated response spectrum base shear. This multiplying factor will be noted in the output.

EURO (EC8) -1994

Load Type Select either a Elastic or Design response spectrum for the loading type.

Design Ground Acceleration Specify a design ground acceleration expressed in terms of acceleration due to gravity(g). For most of the application of Eurocode 8, the hazard is described in terms of a single parameter (i.e., the value of effective peak ground acceleration in rock or firm soil). This acceleration is termed as the design ground acceleration.

Behaviour Factor Specify the value used to reduce the elastic response spectra to the design response spectra. The behavior factor is an approximation of the ratio of the seismic forces, that the structure would experience, if its response was completely elastic with 5% viscous damping, to the minimum seismic forces that may be used in design- with a conventional linear model still ensuring a satisfactory response of the structure.

Subsoil Class

Used to define the subsoil conditions based on which the response spectra will be generated. Based on the subsoil conditions the soil types may be of three kinds

- Type **A**: for Rock or stiff deposits of sand
- Type **B**: for deep deposits of medium dense sand,gravel or medium stiff clays.
- Type **C**: Loose cohesionless soil deposits or deposits with soft to medium stiff cohesive soil.

Please refer section 3.2 of Eurocode8 for detailed guidelines regarding the choice of soil type.

Note: This is the response spectrum type that is explained in TR.32.10.1.4 Response Spectrum Specification per Eurocode 8 1994 (on page 2520) .

EURO (EC8) - 2004

Load Type

Select either a Elastic or Design response spectrum for the loading type.

Two types of response spectra curve can be generated based on either RS1 (for response spectra type 1 curve) or RS2 (for response spectra type 2 curve) f.

Design Ground Acceleration

Specify a design ground acceleration expressed in terms of acceleration due to gravity(g). For most of the application of Eurocode 8, the hazard is described in terms of a single parameter (i.e., the value of effective peak ground acceleration in rock or firm soil). This acceleration is termed as the design ground acceleration.

Behaviour Factor

Specify the value used to reduce the elastic response spectra to the design response spectra. The behavior factor is an approximation of the ratio of the seismic forces, that the structure would experience, if its response was completely elastic with 5% viscous damping, to the minimum seismic forces that may be used in design- with a conventional linear model still ensuring a satisfactory response of the structure.

Subsoil Class

Used to define the subsoil conditions based on which the response spectra will be generated. Based on the subsoil conditions the soil types may be of three kinds

- Type **A** : rock or other rock-like geographical formation.
- Type **B**: very dense sand, gravel or very stiff clay.
- Type **C**: Deep deposits of dense or medium dense sand, gravel or stiff clay.
- Type **D**: Deposits of loose-to-medium cohesionless soil or of predominantly soft to firm cohesive soil.
- Type **E**: Surface alluvium layer

Please refer section 3.2 of Eurocode 8 for detailed guidelines regarding the choice of soil type.

Note: This is the response spectrum type that is explained in TR.32.10.1.5 Response Spectrum Specification per Eurocode 8 2004 (on page 2525) .

IBC 2006

Zip	The zip code of the site location to determine the latitude and longitude and consequently the Ss and S1 factors.
Latitude / Longitude	The geographic coordinates of the site used to determine the Ss and S1 factors. This option may be used if no value is entered for **Zip**.
S1 / SS	Mapped MCE for 0.2s spectral response acceleration and spectral acceleration for a 1-second period, respectively. These values may be entered if not geographic coordinate or postal code is provided.
Long Period (TL)	Long-Period transition period in seconds.
Fa / Fv	Optional Short-Period site coefficient at 0.2s and Long-Period site coefficient at 1.0s, respectively. Values must be provided if the selected **Site Class (SCL)** is **F**.
Site Class (SCL)	Select A through F for the Site Class as defined in the IBC code.

Note: This is the response spectrum type that is explained in TR.32.10.1.10 Response Spectrum Specification per IBC 2006 (on page 2561) .

IBC 2012

Zip	The zip code of the site location to determine the latitude and longitude and consequently the Ss and S1 factors.
Latitude / Longitude	The geographic coordinates of the site used to determine the Ss and S1 factors. This option may be used if no value is entered for **Zip**.
S1 / SS	Mapped MCE for 0.2s spectral response acceleration and spectral acceleration for a 1-second period, respectively. These values may be entered if not geographic coordinate or postal code is provided.
Long Period (TL)	Long-Period transition period in seconds.
Fa / Fv	Optional Short-Period site coefficient at 0.2s and Long-Period site coefficient at 1.0s, respectively. Values must be provided if the selected **Site Class (SCL)** is **F**.
Site Class (SCL)	Select A through F for the Site Class as defined in the IBC code.

Note: This is the response spectrum type that is explained in TR.32.10.1.10 Response Spectrum Specification per IBC 2006 (on page 2561).

IBC 2015

Zip	The zip code of the site location to determine the latitude and longitude and consequently the Ss and S1 factors.
Latitude / Longitude	The geographic coordinates of the site used to determine the Ss and S1 factors. This option may be used if no value is entered for **Zip**.
S1 / SS	Mapped MCE for 0.2s spectral response acceleration and spectral acceleration for a 1-second period, respectively. These values may be entered if not geographic coordinate or postal code is provided.
Long Period (TL)	Long-Period transition period in seconds.

Fa / Fv Optional Short-Period site coefficient at 0.2s and Long-Period site coefficient at 1.0s, respectively. Values must be provided if the selected **Site Class (SCL)** is **F**.

Site Class (SCL) Select A through F for the Site Class as defined in the IBC code.

Note: TR.32.10.1.12 Response Spectrum Specification per IBC 2015 (on page 2573).

IBC 2018

Zip The zip code of the site location to determine the latitude and longitude and consequently the Ss and S1 factors.

Latitude / Longitude The geographic coordinates of the site used to determine the Ss and S1 factors. This option may be used if no value is entered for **Zip**.

S1 / SS Mapped MCE for 0.2s spectral response acceleration and spectral acceleration for a 1-second period, respectively. These values may be entered if not geographic coordinate or postal code is provided.

Long Period (TL) Long-Period transition period in seconds.

Fa / Fv Optional Short-Period site coefficient at 0.2s and Long-Period site coefficient at 1.0s, respectively. Values must be provided if the selected **Site Class (SCL)** is **F**.

Site Class (SCL) Select A through F for the Site Class as defined in the IBC code.

Note: TR.32.10.1.13 Response Spectrum Specification per IBC 2018 (on page 2578).

SNiP II-7-81

Note: Only the SRSS and ABS combination methods are valid for the SNiP code.

Zoning Factor Specify the zoning factor per SNiP II-7-81.

Subsoil Class Defines the subsoil conditions on which the response spectrum will be generated.

1. Non-weathered rock and rock-like geological formation or permafrost subsoil.
2. Weathered rock or deep deposits of medium dense sand, gravel or medium stiff clays.
3. Loose cohesion less soil deposits or deposits with soft to medium stiff cohesive soil.

Direction The SNiP code allows an alternate method of specifying directional factors. You may input individual parameters such as KWX, KX1 the product of which is used as the factor along that direction.

Note: This is the response spectrum type that is explained in TR.32.10.1.14 Response Spectrum Specification per SNiP II-7-81 (on page 2584) .

SP 14.13330.2011

Subsoil Class Defines the subsoil conditions on which the response spectrum will be generated.

1. Non-weathered rock and rock-like geological formation or permafrost subsoil.

2. Weathered rock or deep deposits of medium dense sand, gravel or medium stiff clays.
3. Loose cohesion less soil deposits or deposits with soft to medium stiff cohesive soil.

Direction The SNiP code allows an alternate method of specifying directional factors. You may input individual parameters such as KWX, KX1 the product of which is used as the factor along that direction.

Note: This is the response spectrum type that is explained in TR.32.10.1.14 Response Spectrum Specification per SNiP II-7-81 (on page 2584).

NRC 2005

The NRC 2005 response spectrum has no code-specific parameters.

Note: This is the response spectrum type that is explained in TR.32.10.1.2 Response Spectrum Specification per NRC 2005 (on page 2506) .

NRC 2010

The NRC 2010 response spectrum has no code-specific parameters.

Note: This is the response spectrum type that is explained in TR.32.10.1.3 Response Spectrum Specification per NRC 2010 (on page 2512).

Chinese GB 50012 - 2010

Note: The parameters **Save** and **Scale** do not apply to the GB 50012-2010 response spectra. Further, only the CQC and SRSS Combination Methods are available for this response spectra.

Fortification Intensity Fortification Intensity (ref. table 5.1.4-1). Selectable values are 6, 7, 7(0.15g), 8, 8(0.30g), or 9.

Seismic Frequency Frequency of seismic action (ref. table 5.1.4-1 and clause 3.10.3), as specified by:

Frequent
Fortified
Rare

Seismic Group Design Seismic Group (ref. table 5.1.4-2). Selectable values are 1st, 2nd, or 3rd

Site Class (SCL) Site class (ref. table 5.1.4-2). Selectable values are I0, I1, II, III, or IV

Max. Horizontal Influence Factor Max horizontal seismic influence factor (ref. table 5.1.4-1 and clause 3.10.3).

Period (Tg) Characteristic period of the structure (Tg) (ref. table 5.1.4-2).

Note: This is the response spectrum type that is explained in TR.32.10.1.6 Response Spectrum Specification per GB 50011 2010 (on page 2531).

- *V. NRC 2010 Response Spectrum* (on page 3604)

Generated Spectrum dialog

Displays the generated IBC response spectra data in tabular and graphical format.

Note: No data may be modified in this dialog.

Opens when **Generate Spectrum** is clicked on the Spectrum Parameters dialog (on page 2862) .

Spectra Table	Displays period values with the associated Acceleration, Velocity, or Displacement values for the generated spectra. The table updates based on the Graph Type selection.
Graph Paper Type	Select to display the response spectra period on a Linear or Logarithmic scale.
Draw Points	Select this option to display point markers at each period, displacement/velocity/ acceleration coordinate on the curve.
Show Peak Value	Displays the peak displacement/velocity/acceleration in the generated spectrum curve.
Graph Type	Select to display the period versus displacement, velocity, or acceleration on the graph and in the Spectra Table.
Close	Closes the dialog and returns focus to the **Create New Load Item** dialog.

Spectrum Parameters dialog

Used to generate a response spectrum curve per generates the spectrum based on the inputted data and as per section 11.4.5 of the ASCE-7-05 code (which is referenced by the International Building Code).

Opens when the **Generate Spectrum** button is clicked in the **Create New Load Item** dialog from the **Response Spectra** tab (with **Custom** selected for the code).

Select Zip	Type or select the Zip code (US Postal code) to look up the geographic location.
Find Lat/Long	Click to update the Latitude and Longitude values if the postal code value changes.
Latitude / Longitude	Type the geographic coordinates of the site here, if know. These fields will be populated if the Select Zip or Find Lat/Long options are used.
Calculate S1 / SS	Click this button to recalculated the seismic acceleration coefficients if the Latitude and/or Longitude values were manually entered.
S1	This is the mapped MCE spectral response acceleration at a period of 1 second, determined in accordance with section 11.4.1 of ASCE-7-05. It is calculated by setting the Zip code or by clicking the **Calculate S1/SS** button. Alternatively, you may specify this value directly.

SS	This is the mapped MCE spectral response acceleration at short period, determined in accordance with section 11.4.1 of ASCE-7-05. It is calculated by setting the Zip code or by clicking the **Calculate S1/SS** button. Alternatively, you may specify this value directly.
Site Class	This is the classification (A to F) assigned to a site based on the soil type as defined in chapter 20 of ASCE-7-05. Values of Fa and Fv from the IBC table are displayed for reference. If the classification is set to F, then you must specify the parameters Fa and Fv.
Fa	Short period site coefficient determined in accordance with table 11.4 -1 of ASCE-7-05. This is determined by the Site Class, but must be specified if the Site Class is set to F.
Fv	Long period (1 sec) site coefficient determined in accordance with table 11.4 -2 of ASCE-7-05. This is determined by the Site Class, but must specified if the Site Class is set to F.
Start / End	Specify the start and end times (T) to define the response time range.
Interval	Specify a time step interval for generating the curve.
Generate Spectrum	Closes the dialog and generates response spectrum curve data. The Generated Spectrum dialog (on page 2862) opens to review the IBC response spectrum data.
Cancel	Closes the dialog without generating response spectrum data.

Repeat Load tab

Used to add load combinations in STAAD.Pro which will be used directly by the analysis engine.

Refer to GS. Load Types in STAAD.Pro (on page 51) for additional information.

Repeat Load

Used to create a primary load case using combinations of previously defined primary load cases. A Repeat Load is treated as a new primary load. Therefore, a P-Delta analysis will reflect correct secondary effects. Load Combinations, on the other hand, algebraically combine the results such as displacements, member forces, reactions and stresses of previously defined primary loadings evaluated independently.

Available Load Cases All primary load cases that are defined for the structure are listed here.

Repeat Load Definition Loads included in this list make up the Repeat Load.

The *Factor* cell is used to specify a factor with which the selected primary load case is to be multiplied. The resulting values are utilized in the repeated load definition

Click this button…	to…
>	Include the selected Primary Load Case in the Repeat Load Definition list.

Click this button...	to...
>>	Include all Primary Load Cases in the Repeat Load Definition list.
<<	Remove all Primary Load Cases from the Repeat Load Definition list.
<	Remove the selected Primary Load Case from the Repeat Load Definition list.

Reference Load

Used to include Reference Loads in a Primary Load case here.

A reference load is defined using the Add New Reference Load Definitions dialog (on page 2839). Load specifications are then added to the Reference Load entry in the **Load & Definition** dialog for later reference.

Available Load Cases
All reference load cases that are defined for the structure are listed here.

Referenced Load list
Loads included in this list make up the Reference Load.

The *Factor*cell is used to specify a factor with which the selected reference load case is to be multiplied. The resulting values are utilized in the primary load definition

Click this button...	to...
>	Include the selected Reference Load Case in the Primary Load Definition list.
>>	Include all Reference Load Cases in the Primary Load Definition list.
<<	Remove all Reference Load Cases from the Primary Load Definition list.
<	Remove the selected Reference Load Case from the Primary Load Definition list.

Notional Load

Used to define a Notional Load from Primary Load Cases and / or Reference Load Cases. These are used for direct analysis.

Primary Load Cases
All primary load cases that are defined for the structure are listed here.

Reference Load Cases
All reference load cases that are defined for the structure are listed here.

Notional Load Definition

Loads included in this list make up the Notional Load.

The *Factor* cell is used to specify the factor with which the selected primary load case or reference load case is to be multiplied. The resulting values are utilized in the notional load definition

The **Direction** cell is used to select a global direction in which the (lateral) notional loads act for this case.

Click this button...	to...
>	Include the selected Primary Load Case or Reference Load Case, respectively, in the Notional Load Definition list.
>>	Include all Primary Load Cases or Reference Load Cases, respectively,in the Repeat Load Definition list.
<<	Remove all Primary Load Cases or Reference Load Case, respectively, from the Repeat Load Definition list.
<	Remove the selected Primary Load Case from the Repeat Load Definition list.

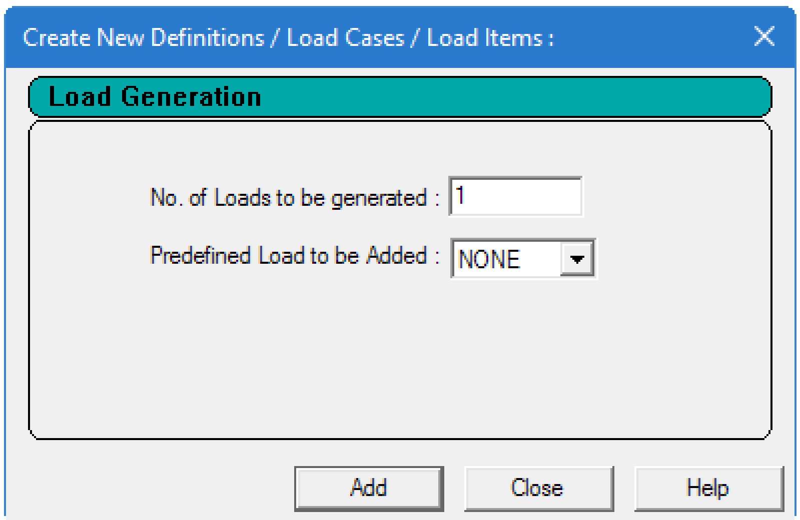
Load Generation dialog

Used to create a primary load case using the data of a pre-defined vehicle.

Opens when the **Load Generator** tool is selected in the **Load Generation** group on the **Loading** ribbon tab.

Vehicles definitions are created using the **Create New Moving Load Definitions** dialog.



Note: Once a load definition has been created, the **(Moving) Load Generation Type** dialog is used to specify the direction and path for the moving loads.

Refer to TR.32.12.1 Generation of Moving Loads (on page 2596) for additional details.

No. of loads to be generated

The moving load is discretized into a number of distinct positions of the vehicle along the direction of movement. Each position represents a distinct load case whose loads are derived from the corresponding position of the vehicle on the structure. The number of such positions hence has to be communicated in the form of the number of load cases to be generated.

For example, if a bridge is 200 ft long, the first axle to last axle distance of your design vehicle is 15 ft, and you want enough cases to be generated to account for the first axle entering the bridge up to and including the last axle leaving the bridge, that would account for a total distance of 230 ft. If you assume 2 ft increments, then the number of cases would be 230/2 + 1 = 116.

Predefined load to be added

With each generated load case, the program Used to include within that load case, other loads from a previous defined primary load case. Such a primary load case might be for example, the dead load case, which the user may defined as load case 1. So, if the user wishes to have each generated load case to consist of a) the selfweight and other dead loads of the structure b) loads resulting from the position occupied on the structure by the vehicle, then, he/she could specify load case 1 as the predefined load case to be added to each of the generated moving load cases.

Wind Load Generation - IS 875 (Part 3): 2015 dialog

Used to automatically generate both wind load definition and wind load cases per the IS 875 (Part 3) : 2015 code.

Opens when the **Wind Load Generator** > **IS 875 (Part 3) : 2015** tool is selected from the **Load Generation** group on the **Loading** ribbon tab.

Notes: The following limitations pertain to generation of IS 875 (Part 3) : 2015 wind loads:

- The wind profile for the loading is calculated based on Y ordinate set to 0 rather than lowest point of the building. Thus, the topographical factor (k3) may not be relevant and should be applied with caution.
- Only Y-up models may be used (that is, the `SET Z UP` command may not be used).
- The resulting wind load intensity vs. height values generated for IS 875 (Part 3) : 2015 are in metric, regardless of the current input units.
- The dynamic effect of wind load is not considered.
- Cl. 6.3.2.4 and Annex B for changes in terrain categories (Table 3 Fetch and Developed Height Relationships) are not considered.
- For rectangular buildings, the frictional drag per Cl. 7.4.1 is not considered.
- For free standing walls and hoarding type structures, the check for oblique wind loads per Cl. 7.4.2.3 is not considered.
- For lattice tower structures, the corner wind effect on square lattice towers with flat-sided members per Cl. 7.4.3.5(b) is not considered.

Wind Profile tab

The calculated wind intensity values (speeds and pressures) are tabulated and graphically plotted as the input parameters are updated. The calculated values are per Cl. 7.2 of IS 875 (Part 3) and the minimum pressure, $pd \geq 0.7 \times pz$, is also considered.

General Information	**Year of Publication**	Select the edition of the IS-875 code from the drop-down list. • 2015
	Structure Type	Select the type of structure from the drop-down list: • Rectangular Clad Building • Unclad Building

	Maximum Height	By default, this dimension is taken as the maximum Y coordinate of the structure. You may also type a **Height** value.
	Ground Level Elevation	(Read-only) Always assumed as zero.
	Height Interval for Intensity	The vertical interval (along the global Y axis) for calculating the wind intensity.
Wind Parameters	**Basic Wind Speed (Vb)**	Either select the name of the location from the drop-down list to use the mapped wind speed per Annex A of IS 875 (Part 3) : 2015 *or* check the **Custom** to type the wind speed directly in m/s.
	Risk Coefficient Factor (k1)	Select class of structure from drop-down option and corresponding k1 value will be automatically selected as per Table 1 of IS 875 (Part 3) : 2015. Alternatively, select **Custom** from the drop-down list to directly type the k1 value for use.
	Topography Factor (k3)	Type the topographic factor to use. The value should be between 1 to 1.36 as per clause 6.3.3.1 of IS 875 (Part3) : 2015.
	Importance Factor (k4)	Select the importance category of the structure from drop-down option and corresponding Importance Factor (k4) value will be selected as per Clause 6.3.4 of IS 875 (Part -3) : 2015. Alternatively, select **Custom** from the drop-down list to directly type the k4 value for use.
	Terrain Category	Select terrain category from drop-down option and corresponding height factor (k2) will be automatically calculated as per Table 2 of IS 875 (Part 3) : 2015 and corresponding Aerodynamic Roughness Height (z0i) value will be automatically selected as per clause 6.3.2.1 of IS 875 (Part 3) : 2015. The Aerodynamic Roughness Height is used for calculating hourly mean wind speed factor (k2,i) and determined mean hourly wind speed at different height as per clause 6.4 of IS 875 (Part 3) : 2015. Alternatively, select **Custom** from the drop-down list to directly type the k2,i and z0i values for use.
	Wind Directionality Factor (Kd)	Defaults to 1.0
	Area Averaging Factor (Ka)	Defaults to 1.0
	Combination Factor (Kc)	Defaults to 1.0

Wind Load Data tab - Rectangular Clad Building

Building Dimensions By default, the dimensions are calculated based on the minimum and maximum global coordinates of the structure along the X, Z, and Y global axes, respectively. You may also type the **Length Along X (Lx)**, **Length Along Z (Lz)**, and **Height (H)** dimension values.

Coefficients Select the option for evaluating the coefficient factor. The associated table with the selection is made active.

- **Pressure Coefficient -** select this option to specify parameters to calculate the pressure coefficients on building face per Cl. 7.3.2 and 7.3.3.
- **Force Coefficient -** select this option to directly specify the **Force Coefficient Factor (Cf)** on the building per Cl. 7.4.2.

External Pressure Coefficient (Cpe)

table	The calculated *Cpe* values for each direction and face are displayed in the table. Double-click to enter a custom value in any table cell. Custom values are highlighted. A **Reset** option is made active if any custom values are used in the table. **Tip:** A tool-tip will also display the calculated value for any cell.
Internal Pressure Coefficient (Cpi)	Check this option to include the Internal Pressure Coefficient (Cpi).
Building Permeability	Select the range of openings to overall building exterior from the drop-down list. This is used to select the Cpi and Cpnet values per Clause 7.3.2.1 of IS-875. Alternatively, select **Custom** from the drop-down list to type a value to use for Cpi
Use (-) Cpi	Check this option to use negative Internal Pressure Coefficient (Cpi) value to calculate Net Pressure Coefficient (Cpnet)

Force Coefficient (Cf)

table	Type a *Cf* value to use for each face (default is 1.0).

Assignments There are four method of assignments for the generated load cases:

- **Automatic -** The program will select faces A, B, C, and D. The list of members in this selection are displayed in the read-only **Member List** cell.
- **Group -** An existing group name is used to define the members which make up the building wind faces.
- **Member List -** Each face is defined by typing a list of members.
- **Range -** Type the minimum and maximum values for the global coordinates (in the units shown) for each face.

Check the **Exclude** option for an row to exclude assigning wind loads to this building face.

Wind Load Data - Unclad Frame Building

Number of Frames Select the number of frames in the structure along the wind direction.

Wind Direction Select the wind direction for this load definition and load case.

Frame Information Select the method for specifying the frame spacing:

- **Dimension -** the actual distance between each frame in the units shown is entered in the **Space Between Frames** cell.
- **Ratio -** the frame spacing ratio as indicated in Table 32 (Clause 7.4.3.4) of IS-875 is entered in the **Spacing Ratio** cell.

Member Profile Cross Section Select if the cross section profile of the frame(s) is **Flat Sided** or **Rounded.** For rounded members, you must also specify the **Diameter** of the members used at each height interval in the frame information table.

Width / Height Type the overall dimensions of the frame. The default values are used based on the detected dimensions of the structure.

Force Coefficient A separate table is listed for each frame in the structure. Select the frame number to display that table's values.

The intermediate values along with the calculated values are displayed in the table.

You must specify the **Solidity Ratio** (Φ) at each height interval of the structure in each frame table. For multiple frames, you must also specify the **Effective Solidity Ratio** (Φ_e) at each height interval for frames No. 2 and higher.

If the **Custom** option is selected, then you must specify the Force Coefficient (**Cf**) values at each height interval. For multiple frames in the Custom option, you must also specify the **Shielding Factor** at each height interval for frames No. 2 and higher.

Assignments There are three method of assignments for the generated load cases:

- **Group -** An existing group name is used to define the members which make up the frames.
- **Member List -** Each frame is defined by typing a list of members.
- **Range -** Type the minimum and maximum values for the global coordinates (in the units shown) for each frame.

Check the **Exclude** option for an row to exclude assigning wind loads to this frame.

Related Links

- *M. To add an IS-875 (Part 3): 2015 wind load* (on page 850)

Create Mass Model dialog

Used to generate a mass model for dynamic load cases based on a selected set of load cases.

Opens the **Mass Model Generator** tool is selected from the **Load Generation** group on the **Loading** ribbon tab.

Add or remove available primary and reference load cases to the selected load cases list using the **>** and **>>** buttons. These will be included with the current **Load Factor** value.

You can remove unwanted load cases from the selected list by using the **<** and **<<** buttons.

Generate Mass as
Select the load case in which the mass model will be generated:

- **New Reference Load Case**
- **Add into 1st Dynamic Load Case**

Load Factor
Type a load factor to use for the load cases to include. This will be applied to the load cases added but can be changed for subsequent load cases.

Available Primary Load Cases
A list of all primary load cases in the model. Only those of the appropriate load types for mass modeling are active for use.

Available Reference Load Cases
A list of all reference load cases in the model. Only those of the appropriate load types for mass modeling are active for use.

Selected Load Cases
This is the list of load cases that will be included in the generated mass model, along with their load type and load factor.

Related Links

- *Rules Used for Generation of Mass Models* (on page 897)
- *M. To generate a mass model* (on page 899)
- *G.17.3.2 Mass Modeling* (on page 2157)
- *M. To generate a mass model* (on page 899)

Define Load Type dialog

Used to define load types for multiple primary load cases in a single dialog. The load type definition is required if you want the program to automatically generate load combinations from the defined primary loads. Load type and reducible options may be set or editing for primary load cases individually when they are created, as well.

Opens when the **Primary Load Type** tool is selected in the **Load Generation** group on the **Loading** ribbon tab.

Load
The primary load case number.

Title
The name of the primary load case.

Type
Select the appropriate load type from the drop-down list in this cell. If the chosen load type is Live or Roof Live, the *Reducible* option is active.

Dead	Soil	Ice
Live	Rain Water/ Ice	Wind on Ice

Roof Live	Ponding	Crane Hook
Wind	Dust	Mass
Seismic-H (horizontal)	Traffic	Gravity
Seismic-V (vertical)	Temperature	Push
Snow	Accidental	None (default)
Fluids	Flood	

Note: If the load type was defined at the time of defining the primary load, the type of the defined load (dead, live, wind etc.) is shown here.

Reducible-IBC 2003 — Check this option if you want the live load to be reduced as per the provisions in IBC 2003.

Related Links

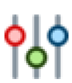
- *M. To define primary load type* (on page 886)

Auto Load Combination dialog

Used to automatically create load combinations based on code-specified combination rules and primary load type selections.

In order to use this feature, one or more primary load cases must be created with a load type defined. A load type can be assigned to a primary load case either at the time when the load is being created or later.

Opens when the **Automatic Combinations** > **Automatic Load Combinations** tool is selected in the **Load Generation** group on the **Loading** ribbon tab.



Note: If no load cases have yet been defined for the model, a warning message is displayed over the dialog and the parameters are inactive. Primary load cases are defined using the **Create Primary Load Case** dialog.

Select Load Combination Code — The load types available include the following:

ACI:318-2002
AISC 9th Ed
ASCE 7-10
BS:5950
BS:8110
GB:50009-2012
GB:55002-2021

IBC-2012
IBC-1997
NBCC-2005
NBCC-1995
IS:456 / IS:800
SNiP 2.01.07-85
UBC-1997
ASCE 7-16

Note: Any Load Rule sets you have added or edited in the **Edit Load Rules for Auto Load Combination Generator** dialog are also available here.

Select Load Combination Category Select the load combination category as specified in the selected load combination code. Refer to the selected code for details.

Select Starting Combination No Type an integer for the initial load combination number. This number should not be a current load case number.

Create Repeat Load Cases Select this option to create primary load cases for all the load case combinations in the Selected Load Combinations list using the Repeat Load Command, rather than combined results using Load Combinations.

See GS. Load Types in STAAD.Pro (on page 51) for additional information on using Repeat loads versus Load Combinations.

Include Notional Load Select this option to include Notional Load cases in the generated combinations when the **Create Repeat Load Cases** option is selected, if they are present in the input file.

Factor Type the notional load factor to use

Use Floor Count Optionally, you may select to use the floor count to determine the notional load factor by checking this option and typing the floor count value. This method is adapted from the Chinese GB50017-2017 code and uses the following formula modified from Cl. 5.2.1-2:

$$\text{factor} = \frac{A}{250}$$

where:

$$2/3 \leq A = \sqrt{0.2 + \frac{1}{n_s}} \leq 1.0$$

n_s = the number of stories

Direction Check the directions for which to generate notional loads: **X**, **-X**, **Z**, and **-Z**.

Generate Loads Click to create all the load combinations. The generated load combinations, with their associated load factors, are shown in the Selected Load Combinations list on the right-hand side.

Discarded Load Combinations Any load combinations which are generated can be removed from the final load combination. These will be listed here.

list operators

Click this button…	to…
>	Add the selected primary load case to the Selected Load Combinations list
>>	Add all primary load cases to the Selected Load Combinations list.
<<	Remove all entries in the Selected Load Combinations list, load combination is placed in the Discarded Load Combinations list.
<	Remove the selected entry from the Selected Load Combinations list.

Selected Load Combinations list All load combinations which will be added to the input file are listed here.

Automatically Generated Load Combinations in the STAAD input file

In the STAAD.Pro Input File, the generated load combinations look like the following:

```
UNIT FEET KIP
LOAD 1 DEAD + LIVE
MEMBER LOAD
2 UNI GY -2.5
LOAD 2 WIND FROM LEFT
JOINT LOAD
2 FX 10
LOAD COMB 3 Generated AISC 1
1 1.6
LOAD COMB 4 Generated AISC 2
1 1.4
LOAD COMB 5 Generated AISC 3
1 1.7 2 0.8
LOAD COMB 6 Manual
1 1.7 2 -1.2
PERFORM ANALYSIS
PRINT MEMBER FORCES
```

The syntax `Generated xxx n`, where *xxx* is the design code name (AISC, BOCA, etc.) and *n* is the index in the series of load combinations generated for a specific code, are interpreted by STAAD.Pro. Deleting any of the aforementioned keywords will break the program's ability to read back in the generated load combinations.

The following are some important caveats to keep in mind when using the automatic load combination generator:

- If the automatically generated load combinations are edited (or deleted) from the STAAD input file, they will be reflected in the graphical interface as well.
- The load combination numbers (i.e. `LOAD COMB` *n* `GENERATED AISC 1`) can also be edited from the input file.
- Deleting the keyword `GENERATED` code index will remove that particular load combination from the automatically generated list. It will not remove the load combination.
- The factors assigned to the primary load cases in a generated load combination *cannot* be changed in the graphical interface using the **Combine** button from the **Loads** dialog box.

Edit Load Rules for Auto Load Combination Generator dialog

STAAD.Pro includes a facility for the automatic generation of load combination cases. Using the rules described in ACI, AISC, UBC and IBC codes for combining standard load types, you can instruct the program to automatically generate load combination cases from primary load cases which have been assigned load types (i.e., DEAD, LIVE, FLOOD, SNOW, RAIN WATER/ICE, etc.).

You can also use the Edit Loading Rules facility to alter the definitions and factors which come included with the program for these codes or to add new codes containing their own definitions and factors.

Opens when the **Automatic Combinations** > **Edit Auto Combination Rules** tool is selected in the **Load Generation** group on the **Loading** ribbon tab.

Table 326: Automatic Load Combination Manager Home ribbon tab

Tool name	What it Does
 **Code**	Add a new code to the Codes and tables section of the Contents panel
 **Table**	Add a new table to the currently selected code
 **Unlock / Lock Table Updating**	Toggles the editable state of the current code table or configuration page

Tool name	What it Does
' **Append Row**	Adds a new row (load combination) at the end of the current table
Add Above	Adds a new row (load combination) before the currently selected row in the current table
Add Below	Adds a new row (load combination) after the currently selected row in the current table
Commit	Saves changes made to the current table or configuration page
Rollback	Undoes the any changes made to the current table or configuration page
Rename	Click to rename the currently selected table
Copy	Copies the current selection.

Tool name	What it Does
 **Paste**	Pastes the clipboard contents to the current selection.
 **Cut**	Copies and the deletes the current selection
 **Delete**	Deletes the current selection
 **Close Table**	Closes the active table or configuration page.
 **Close All**	Closes all open tables and configuration pages
 **Reset In-built Codes**	Used to reset all codes and tables to the default settings
 **Reset to Default**	Used to reset the currently selected code or table to the default settings

Tables

Displays the rules associated with the selected code and category.

Rows in the table typically represent a single load combination rule. Columns in the table represent load types.

Configurations

Contains instructions for how each load type for tables in this Code should be handled.

Notional Load Select this option for each load type to include Notional Load cases in the generated combinations, if they are present in the input file. These loads are used for Perform Direct Analysis tab (on page 2920).

Combination Type As some load types can result in different actions, a single rule may result in multiple load combinations (i.e., wind or seismic acting in positive or negative directions). The combination rule directs the program how to handle such cases:

- **Aggregate -** Combine all cases together: For each rule, a single combination will be created which will include all the load cases of that load category multiplied by the factor in the table.
- **Separate -** Separate combination for each case: For each rule, multiple combinations will be created, each will include one of the load cases of that load category multiplied by the factor in the table.
- **Matrix -** All possible combinations: For each rule, multiple combinations will be created which will include each of the load cases of that load category on their own and with each and every other load case of that category multiplied by the factor in the table.

Example 1: Combine All Load Cases

Consider both load categories are set with the option **Aggregate.** This will result in a single load combination:

[(LC1 + LC2 + LC3 + LC4) × 1.4] + [(LC5 + LC6) × 1.6]

The STAAD input command generated in the Analytical Workflow is then:

```
LOAD COMBINATION 7 Generated Code 1
1 1.4 2 1.4 3 1.4 4 1.4 5 1.6 6 1.6
```

Example 2: Separate Combinations for Each Case

Consider the DEAD category now is set to **Aggregate** and the LIVE category is set to **Separate.** For this single rule, this will result in two load combinations due to the two LIVE load cases which are to be considered separately, thus:

[(LC1 + LC2 + LC3 + LC4) × 1.4] + [(LC5) × 1.6]
[(LC1 + LC2 + LC3 + LC4) × 1.4] + [(LC6) × 1.6]

The STAAD input command generated in the Analytical Workflow is then:

```
LOAD COMBINATION 7 Generated Code 1
1 1.4 2 1.4 3 1.4 4 1.4 5 1.6
LOAD COMBINATION 8 Generated Code 2
1 1.4 2 1.4 3 1.4 4 1.4 6 1.6
```

Example 3: All Possible Combinations

Consider the DEAD category now is set to **Matrix** and the LIVE category is set to **Aggregate.** For this single rule, this will result in 15 load combinations due to the fourteen ways the four dead loads can be combined together and the two LIVE load cases which are to be considered together, thus:

[(LC1) × 1.4] + [(LC5 + LC6) × 1.6]
[(LC1 + LC2) × 1.4] + [(LC5 + LC6) × 1.6]
[(LC1 + LC2 + LC3) × 1.4] + [(LC5 + LC6) × 1.6]
[(LC1 + LC2 + LC3 + LC4) × 1.4] + [(LC5 + LC6) × 1.6]
[(LC1 + LC2 + LC4) × 1.4] + [(LC5 + LC6) × 1.6]
[(LC1 + LC3) × 1.4] + [(LC5 + LC6) × 1.6]
[(LC1 + LC3 + LC4) × 1.4] + [(LC5 + LC6) × 1.6]
[(LC1 + LC4) × 1.4] + [(LC5 + LC6) × 1.6]
[(LC2) × 1.4] + [(LC5 + LC6) × 1.6]
[(LC2 + LC3) × 1.4] + [(LC5 + LC6) × 1.6]
[(LC2 + LC3 + LC4) × 1.4] + [(LC5 + LC6) × 1.6]
[(LC2 + LC4) × 1.4] + [(LC5 + LC6) × 1.6]
[(LC3) × 1.4] + [(LC5 + LC6) × 1.6]
[(LC3 + LC4) × 1.4] + [(LC5 + LC6) × 1.6]
[(LC4) × 1.4] + [(LC5 + LC6) × 1.6]

The STAAD input command generated in the Analytical Workflow is then:

```
LOAD COMB 7 Generated Code1
1 1.4 5 1.6 6 1.6

Create Wind Type Definition dialog

Used to add a new wind load definition.

Opens when the **Wind** tool is selected in the **Define Load Systems** group on the **Loading** ribbon tab.

Type No.	Denotes a number by which the wind load type will be identified. Multiple wind types can be created in the same model.
Comments	An optional description used to help identify the load.
Code	Select the method or building code you want to use for wind load definitions: • Custom - enter a list of height vs wind pressure value pairs • ASCE 7: 1995 • ASCE 7: 2002 • ASCE 7: 2010 • ASCE 7: 2016 • GB 50009-2012 • IS 875 (Part 3): 2015 • SNiP 2.01.07-85 • SP 20.133330.2016

Add New Wind Definitions (data) dialog

Used to add wind pressure data or code-specific wind parameters.

Intensity tab

Select Type	Choose the method of specifying wind pressure values from the drop-down: • **ASCE 7**, **IS 875**, **GB 50009**, or **Custom** – Code generated or user-entered intensity values:

Intensity vs. Height table

Enter pairs of data for wind pressure at a given height (in the current units).

Int cells – wind intensities (pressures) in force/area. Up to 100 different intensities can be defined in the input file per type.

Height cells – corresponding heights in global vertical direction, measured in terms of actual Y (or Z for Z UP) coordinates up to which the corresponding intensities occur.

> **Note:** These values may be negative in the case of GB 50009-2012 wind loads. This indicates a ground level below the base of the building.
>
> In this case, the first row of the Intensity vs. Height is used to simply indicate the ground level.

Generate

Opens the code-specific wind load dialog, which is used to generate a wind load per the ASCE 7, IS 875, or GB 50009 specifications (depending on code selection). Input data on the type of structure, surrounding terrain, and wind.

- **SNiP 2.01.07-85** or **SP 20.13330.2016** – Russian wind load parameters:

Pressure the characteristic value of wind pressure, always positive

Terrain terrain roughness category:

A. Coastal Zone.
B. Urban Zone.
C. Large City.

Region Wind region as per clause 11.5 of SNiP 2.01.07-85* 2016. This is used to determine the wind pressure in determine the dynamic wind component.

Delta logarithmic decrement of oscillations, Delta (see table 11.5 - Section 11.1.8 for the definition). Typically values are:

0.15 for steel towers, masts, lined chimneys, column means including the ones on the reinforced concrete pedestals
0.3 for reinforced concrete and stone structures as well as for buildings with steel framework if there are walling structures

Exposures tab

Factor exposure factors. A value of 1.0 means that the wind force may be applied on the full influence area associated with the joint(s) if they are also exposed to the wind load direction. Limit: 99 factors.

> **Note:** Note any joint does not have an exposure assigned, the exposure will be taken as 1.0.

ASCE 7 Wind Load dialog box

Used to generate a wind load per the ASCE 7 specification. Input data on the type of structure, surrounding terrain, and wind.

Opens when **Generate** is clicked on the Wind Load tab (on page 2850) when an **ASCE 7** code edition is selected as the code.

Using this feature, you can define different intensity vs. height data for the windward side, leeward side and side walls for a structure. Each can be defined as a different load type and then applied in the relevant direction with appropriate direction factor. The defined wind loading can then be applied to the structure following the usual method.

Note: For details on generation of wind load and command syntax, refer to TR.32.12.3 Generation of Wind Loads (on page 2603) .

Common tab

ASCE -7

Displays the version of the ASCE 7 (ASCE 7 - *Minimum Design Loads for Buildings and Other Structures*) code selected in the **Add New: Wind Definition** dialog: **1995**, **2002**, **2010**, or **2016**.

Building classification category

Select the building classification category, based on the nature of occupancy, as obtained from Table 1-1 in ASCE 7-95 / 02 or from Table 1.5-1 in ASCE 7-10 / 16.

Category can be I, II, III or IV.

Basic Wind Speed

Specify a basic wind speed as described in Figure 6-1 in ASCE 7-95, section 6.5.4 of ASCE 7-02, or section 26.5.1 of ASCE 7-10 / 16, along with units.

Wind speed is assumed to be the plotted or tabulated 3-second gust wind speed.

Exposure Category

Select an exposure category as per section 6.5.3 in ASCE 7-95, section 6.5.6.3 of ASCE 7-02, or section 26.7.3 of ASCE 7-10 / 16.

Structure Type

Select the type or structure that best fits the model from the following:

- Building structures
- Chimneys, Tanks, and similar structures
- Solid Signs
- Open Signs
- Latticed Framework
- Trussed Tower

Note: The data input tab changes to the selected structure type once the **Apply** button is clicked.

Height Above Sea Level

(ASCE 7-16 only) Type the height above sea level for the base of the structure, z_g in Table 26.9-1, in the selected units. This is used to calculate the groud elevation factor, K_e.

Consider Wind speed-up over hill or escarpment	Select **Yes** to consider wind speed-up over a hill or an escarpment and **No** to ignore it. If there are isolated hills and escarpments that constitute abrupt changes in the general topography, the increase in speed can be considered as per clause 6.5.5 in ASCE 7-95, per section 6.5.7 in ASCE 7-02, or per section 26.8.1 of ASCE 7-10 / 16.

Type of Hill or Escarpment	Select the type of hill, ridge or escarpment on which the structure is located, based on Figure 6-2 of ASCE-7-95, Figure 6-4 of ASCE 7-02, or Figure 26.8-1 of ASCE 7-10 / 16. The options available are: • **2-D Ridge** • **2-D Escarpment** • **3-D Axisymmetrical Hill**
Height of Hill or Escarpment (H)	Specify the height of the hill or escarpment relative to the upwind terrain (H in Figure 6-2 of ASCE 7-95, Figure 6-4 ASCE 7-02, Figure 26.8-1 of ASCE 7-10 / 16).
Distance upwind of crest (L_h)	Specify the distance upwind of crest to where the difference in general elevation is half the height of the hill or escarpment (L_h in Figure 6-2 of ASCE 7-95, Figure 6-4 ASCE 7-02, Figure 26.8-1 of ASCE 7-10 / 16).
Distance from the crest to the building (x)	Specify the distance from the crest to the building site. A negative value signifies the distance is in the downwind direction (x in Figure 6-2 of ASCE 7-95, Figure 6-4 ASCE 7-02, or Figure 26.8-1 of ASCE 7-10 / 16).

<structure type> tab

When the structure type is changed on the Common tab, the list of parameters on the Main Building tab changes. The full list of parameters explained here is for the structure type of **Building Structures**. Those parameters that are different are explained below for each type of structure.

Structure Type: Building Structures

Building Height	Specify the height above ground to the highest point on the roof surface, along with units.
Building Length along the direction of Wind (L)	Length of building measured along the direction of wind.
Building Length Normal to the direction of Wind (B)	Length of building measured normal to the direction of wind.
Building Natural Frequency	Specify the natural frequency of the building to calculate Gust Effect Factor.
Building Damping Ratio	Specify the damping ratio to calculate Gust Effect Factor.

Enclosure Classification	Select the building classification as open, partially enclosed, partially open (ASCE 7-16 only), or enclosed per the provisions of section 6.2 of ASCE 7-02, section 26.10 of ASCE-7-10, or section 26.12 of ASCE 7-16. **Note:** Not applicable for ASCE 7-95.
Kz	Velocity Pressure exposure coefficient calculated as per Table 6-3 of ASCE 7-95, Table 6-3 of ASCE 7-02, or Table 26.10-1 of ASCE 7-16).
Use Kzt	Select this option to specify a topographic factor value for wind speedup. If not selected, the topographic factor is calculated and displayed. When wind speedup is considered, Kzt is calculated as per Eq 6-2 of ASCE 7-95, Eq 6-4 of ASCE 7-02, or section 26.8.2 of ASCE 7-16.
Use I	Select this option to specify an importance factor value. If not selected, the importance factor is calculated and displayed. The importance factor used is as per Table 6-2 of ASCE 7-95 or as per section 6.2 of ASCE 7-02.
Use Kd	Select this option to specify a wind directionality factor. If not selected, the wind directionality factor is calculated and displayed. The wind directionality factor is calculated as per Table 6-4 of ASCE 7-02 or Table 26.6-1 of ASCE 7-10 / 16. **Note:** Not applicable for ASCE 7-95.
Use Ke	(ASCE 7-16 only) Select this option to specify a ground elevation factor. If not selected, the ground elevation factor is calculated and displayed. The ground elevation factor is calculated as per Table 26.9-1 of ASCE 7-16.

Structure type : Chimney, Tank and similar Structures

Height(H)	Height of the structure as defined by the term “h” in Figure 6-19 of ASCE 7-02, Figure 29.5-1 of ASCE 7-10, or Figure 29.4-1 of ASCE 7-16.
Least Horizontal Dimension (W)	Smaller of the plan dimensions. In case the cross section of the structure in plan is circular, the diameter needs to be specified.
Horizontal Cross-Section Type	This is the cross section of the structure in plan as defined in Figure 6-19 of ASCE 7-02, Figure 29.5-1 of ASCE 7-10, or Figure 29.4-1 of ASCE 7-16. The available options include square with wind being normal to face or acting along the diagonal, hexagonal, octagonal and round. For ASCE 7-16, additional options are octagonal (non-axisymmetric), octagonal (axisymmetric), round (non-axisymmetric), and round (axisymmetric).
Depth of protruding elements such as ribs and spoilers (D’)	For round type cross sections, depth of protruding elements need to be defined which is a measure of the surface roughness as indicated in Figure 6-19 of ASCE 7-02, Figure 29.5-1 of ASCE 7-10, or Figure 29.4-1 of ASCE 7-16.

Structure type: Solid Signs

Height (H)	Height of the structure which is used for calculating the height to width ratio as defined by the term "v" in Figure 6-20 of ASCE 7-02 or the term "h" in Figure 29.4-1 of ASCE 7-10 or Figure 29.3-1 of ASCE 7-16.
Horizontal Dimension of Sign (M)	Horizontal dimension of the solid sign as defined by the term "B" in Figure 29.4-1 of ASCE 7-10 or Figure 29.3-1 of ASCE 7-16.
Vertical Dimension of Sign (N)	Vertical dimension of the solid sign as defined by the term "s" in Figure 29.4-1 of ASCE 7-10 or Figure 29.3-1 of ASCE 7-16. **Note:** If the sign is at the ground level, the height (H) and vertical dimension (N) should both be specified the same value.

Structure type: Open Signs / Lattice Frame Work

Ratio of Solid Area to Gross Area	Ratio of solid area to gross area as indicated by the term "$\in$" in Figure 6-21 of ASCE 7-02, Figure 29.5-2 of ASCE 7-10, or Figure 29.4-2 of ASCE 7-16.
Orientation of the members exposed to wind	The type of member surfaces which are exposed to wind. Select flat-sided members or rounded members in Figure 6-21 of ASCE 7-02, Figure 29.5-2 of ASCE 7-10, or Figure 29.4-2 of ASCE 7-16.
Diameter of typical round member	Diameter for round members as defined by the term "D" in Figure 6-21 of ASCE 7-02, Figure 29.5-2 of ASCE 7-10, or Figure 29.4-2 of ASCE 7-16.

Structure type : Trussed Tower

Horizontal Cross Section	The type of cross section of the tower in plan as defined in Figure 6-22 of ASCE 7-02, Figure 29.5-3 of ASCE 7-10, or Figure 29.4-3 of ASCE 7-16. The available options include square and triangle.

Building Design Pressure tab

Building Wall to generate Wind Load on:	Select the side of the structure, with respect to wind direction, for which you wish to generate a wind load. The pressure will be calculated as per Table 6-1 of ASCE 7-95 , Equation 6-23 of ASCE 7-02, Figure 27.4-1 of ASCE 7-2010, or Figure 27.3-1 of ASCE 7-16, based on the code selection made on the **Common** tab. The relevant equation will also be displayed below. • **Windward -** Used to generate the design wind pressure for the windward side. • **Leeward -** Used to generate the design wind pressure for the side wall. • **Side Wall -** Used to generate the design wind pressure for the side wall. **Note:** The pressure profile for each of the building walls has to be individually determined under a unique load type number. Thus, generating the profile for the three sides of the building constitutes three separate steps and thus, three separate types. Each type can then be applied with one load case or separate load cases and then applied in the relevant direction with the appropriate direction factor. Examples illustrating wind load generation can be found in the examples manual.
Use G	Select this option to specify a gust effect factor value.

If not selected, the Gust effect factor is calculated and displayed. The gust effect factor is calculated as per Table 6-1 of ASCE 7-95 or as per section 6.5.8 of ASCE 7-02.

For rigid structures (natural frequency ≥ 1Hz), the gust effect factor is calculated as per equation 26.9-6 for ASCE 7-10 or equation 26.11-9 for ASCE 7-16 . For flexible structures (natural frequency < 1Hz), the gust effect factor is calculated section 26.9-10 for ASCE 7-10 or section 26.11-10 for ASCE 7-16.

Use C_p Select this option to specify a wall pressure coefficient value.

If not selected, the wall pressure coefficient is calculated and displayed. The wall pressure coefficient is calculated as per as per Fig 6-3 of ASCE 7-95 or as per Figures 6-11 through 6-17 of ASCE 7-02. For ASCE 7-10, the wall pressure coefficient is calculated as per Figure 27.4-1, 27.4-2 and 27.4-3. For ASCE 7-16, the wall pressure coefficient is calculated as per Figure 27.3-1.

Use GC_{pi} Select this option to specify an internal pressure coefficient value.

If not selected, the internal pressure coefficient is calculated and displayed. The internal pressure coefficient is calculated as per Table 6-4 of ASCE 7-95 or as per Figure 6-5 of ASCE 7-02. For ASCE 7-10, the internal pressure coefficient is calculated as per Figure 27.4-1, 27.4-2 and 27.4-3. For ASCE 7-16, the internal pressure coefficient is calculated as per Figure 26.13-1.

Use C_f Select this option to specify a force coefficient value used for structures other than buildings. If not selected, the force coefficient is calculated and displayed as follows:

- ASCE 7-02: If not selected, the force coefficient is calculated as per Figures 6-19, 6-20, 6-21, or 6-22, depending on the non-building structure type selected.
- ASCE 7-10: If not selected, the force coefficient is calculated as per Figures 29.4-1, 29.5-1, 29.5-2 or 29.4-3, depending on the non-building structure type selected.
- ASCE 7-16: If not selected, the force coefficient is calculate as per sections C29.3.1., Figure 29.4-1, Figure 29.4-2, or Figure 29.4-3, depending on the non-building structure type selected.

The force coefficient is used for the calculation of the design pressure.

Height vs. Intensity table Displays the generated wind profile based on the current input in the dialog.

OK Accepts the current Height vs. Intensity table values displayed on the Building Design Pressure tab and applies them to the **Add New: Wind Definitions** dialog.

Apply Applies changes made in one of the dialog tabs to other tabs for use (e.g., the code selection was changed).

Cancel Closes the dialog without adding an ASCE wind definition.

Help Opens the STAAD.Pro Help window.

Generate Wind Definition and Wind Load Case for Chinese GB 50009 dialog

Used to enter code parameters for generating wind intensity values based on the GB 50009 2012 code

Opens when **Generate** is clicked in the **Add New Wind Definitions** dialog with the **GB 50009-2012** type selected.

Wind Definition tab

Calculate Wind Height Factor (mu_z)

The following parameters are input used calculate the height variation factor for the wind pressure, μ_z:

Specify Ground Line

Check this option to specify the **Mapped Ordinate in Model** value. This is the elevation of the bottom of the current calculation part of the current building. If unchecked, the program assumes a ground level of Y = 0.

> **Note:** STAAD.Pro supports negative values for the Y coordinate used for wind load generation for the GB 50009-2012 code only.

Focused Building Height (H)

This is the total height (H) of the current building. Click the **Geometry Figure** button to open a diagram with further explanation of the building height vs. ground level values.

Height (z) & Wind Intensity Curve

Select the method to sub-divide the height above ground into discreet points of the wind intensity curve:

- **Segment Count to Divide Height (H) Equally -** This is the segment count to divide equally the total height (H) of the current building. This is used to calculate the individual height (z) where the wind pressure needs to be calculated.
- **Equal Segment Length Along Height (H) -** This is the segment length, and the length is equal. The length is along the total height (H) of the current building. This is used to calculate the individual height (z) where the wind pressure needs to be calculated.
- **Provide Special Height (z) -** This is the special height (z) list. This is the individual height (z) where the wind pressure needs to be calculated. The delimiter for the individual height (z) can be comma (,) or space, such as `3,6,9`.

Roughness Type

This is the roughness type. The value can be A, B, C or D.

Modification Factor

This is the modification factor. This is to modify the height variation factor for the wind pressure.

Calculate Wind Shape Factor (mu_s)

The following parameters are input used to calculate the wind shape factor, μ_s:

Shape Item ID

The list of the shape item ID and the shape item name, these shape items are from Chinese load code GB 50009.

- 30 : Closed Polygon Building
- 37 : Circular Section Structure (Chimney)

Secondary Shape Type	The secondary shape types of the shape item 30 (Closed Polygon Building) are shown as the following: • Rectangle • L Shape • C Shape

Set Shape Factor ...	This is used to set the shape factor of the structure. STAAD.Pro will set the default values of the shape factor of the current secondary shape type of the current shape item from the config database on the **Set Shape Factor** dialog. You can modify the shape factor.
	Positive value is for the windward face.
	Negative value is for the leeward face.
	Every face name is shown in the first row, every direction of wind from is shown in the first column, on the **Set Shape Factor** dialog.
	Tip: Refer to the diagrams in the dialog for the which sides of the building each structure face label refers to.
	For circular structures, the shape factor is calculated based on several parameters:
	• Bulge Height on Face (delta) -
	• Section Diameter - select if there is any change in diameter along the height and if that change is linear or nonlinear:
	  • **No Change** (i.e., straight) - type the **Section Diameter** of the entire structure
	  • **Linear Change** (i.e., tapered) - type the **Section Diameter** (at the base) and the **Top Section Diameter**.
	  • **Nonlienar Change** (i.e., stepped) - type the height and diameter of each section along the structure in the table

Interference Factor from Other Building	This is the mutual interference factor from other building.

Calculate Reference Wind Pressure (w0)

The following parameters are used to calculate the reference wind pressure, $w0$:

Reference Wind Pressure (w0)	This is the reference wind pressure (w0).
Modification Factor	This is the modification factor. This is to modify the reference wind pressure (w0).

Calculate Along-wind Vibration Factor (beta_z)

The following parameters are input used to calculate the wind-induced vibration factor, β_z:

Consider Along-wind Vibration Factor	Consider the wind-induced vibration factor, β_z, along-wind or not.

Damping Ratio	This is the damping ratio of the current building. It should be greater than 0.
Basic Natural Vibration Period (T1)	This is the basic natural vibration period (T1) of the current building.
Structure Type	Select either: • **High-rise Building -** The structure type of the current building is high-rise building. The high-rise building is the modern building which is very tall and has many levels or floors. The width of the windward face of the high-rise building is larger than that of the high-tower structure. • **High-tower Structure -** The structure type of the current structure is high-tower structure. The width of the windward face of the high-tower structure is far less than its height, and is also less than that of the high-rise building.
Provide Width of Windward Face ...	This is used to provide the width of the windward face of the current structure. **Wind From**: This is the direction of the wind from. **Width**: This is the width of the windward face of the current structure. This is just for the high-rise building. **Tip:** It is recommended to use the top width of the windward face is equal to the bottom width for the high-rise building. **Bottom**: This is the bottom width of the windward face of the current structure. This is just for the high-tower structure. **Top**: This is the top width of the windward face of the current structure. This is just for the high-tower structure.

Set Influence Factor for Wind Direction: Click this to open a dialog where independent influence factors can be specified for each wind direction: Left (+X), Right (-X), Front (-Z), and Rear (+Z). These are all taken as unity (1.0) by default.

Wind Load Case tab

Generate Wind Load Case: The wind load case associated with the wind definition will be generated when this parameter is checked, otherwise, the wind load case will be not generated.

Define Range of Wind Load ...: This is used to define the range of the wind load action for every face of the structure. Every face is shown in the first column on the dialog.

X Min	The min value of X axis for the current face of the structure.
X Max	The max value of X axis for the current face of the structure.
Y Min	The min value of Y axis for the current face of the structure.

Y Max	The max value of Y axis for the current face of the structure.
Z Min	The min value of Z axis for the current face of the structure.
Z Max	The max value of Z axis for the current face of the structure.
Open	The structure is open or not.

IS-875 (Part 3): Wind Load dialog

Used to enter code parameters for generating wind intensity values based on the IS-875 (Part 3): Wind Load code

Opens when **Generate** is clicked in the **Add New Wind Definitions** dialog with the **IS-875 (Part 3): Wind Load** type selected.

Notes: The following limitations pertain to generation of IS 875 (Part 3) : 2015 wind loads:

- The wind profile for the loading is calculated based on Y ordinate set to 0 rather than lowest point of the building. Thus, the topographical factor (k3) may not be relevant and should be applied with caution.
- Only Y-up models may be used (that is, the `SET Z UP` command may not be used).
- The resulting wind load intensity vs. height values generated for IS 875 (Part 3) : 2015 are in metric, regardless of the current input units.
- The dynamic effect of wind load is not considered.
- Cl. 6.3.2.4 and Annex B for changes in terrain categories (Table 3 Fetch and Developed Height Relationships) are not considered.
- For rectangular buildings, the frictional drag per Cl. 7.4.1 is not considered.
- For free standing walls and hoarding type structures, the check for oblique wind loads per Cl. 7.4.2.3 is not considered.
- For lattice tower structures, the corner wind effect on square lattice towers with flat-sided members per Cl. 7.4.3.5(b) is not considered.

Common tab

Year of Publication	Select the edition of the IS-875 code from the drop-down list. • 2015
Structure Type	Select the type of structure from the drop-down list: • Rectangular Clad Building • Unclad Building • Free Wall and Hoardings • Lattice Tower

Maximum Height	By default, this dimension is taken as the maximum Y coordinate of the structure. You may also type a **Height** value.	
Ground Level Elevation	(Read-only) Always assumed as zero.	
Height Interval for Intensity	The vertical interval (along the global Y axis) for calculating the wind intensity.	
Basic Wind Speed (Vb)	**Cities**	Select the name of the location from the drop-down list to use the mapped wind speed per Annex A of IS 875 (Part 3) : 2015.
	Use Custom	Check this option to type the wind speed directly in m/s.
Wind Parameters	Based on the selected or typed values, the Design Wind Speed is automatically calculated using the formula ($Vb \times k1 \times k2 \times k3 \times k4$) per clause 6.3 of IS 875 (Part 3) : 2015 at given height interval. A Height vs. Velocity graph is plotted for the value of height and design wind speed (Vz).	
	Class of Structure	Select class of structure from drop-down option and corresponding **Risk Coefficient Factor (k1)** value will be automatically selected as per Table 1 of IS 875 (Part 3) : 2015. Alternatively, select **Custom** from the drop-down list to directly type the k1 value for use.
	Terrain Category	Select terrain category from drop-down option and corresponding height factor (k2) will be automatically calculated as per Table 2 of IS 875 (Part 3) : 2015 and corresponding Aerodynamic Roughness Height (z0i) value will be automatically selected as per clause 6.3.2.1 of IS 875 (Part 3) : 2015. The Aerodynamic Roughness Height is used for calculating hourly mean wind speed factor (k2,i) and determined mean hourly wind speed at different height as per clause 6.4 of IS 875 (Part 3) : 2015. Alternatively, select **Custom** from the drop-down list to directly type the k2,i and z0i values for use.
	Importance of Structure	Select the importance category of the structure from drop-down option and corresponding Importance Factor (k4) value will be selected as per Clause 6.3.4 of IS 875 (Part -3) : 2015.
	Topography Factor (k3)	Type the topographic factor to use. The value should be between 1 to 1.36 as per clause 6.3.3.1 of IS 875 (Part3) : 2015.

<structure type> tab

Note: The title and parameters on this tab vary based on the **Structure Type** selection made on the **Common** tab.

Rectangular Clad Buildings

Wind Direction	Select one of the global directions for the wind: +X, -X, +Z, or -Z.

Building Dimensions	By default, the dimensions are calculated based on the minimum and maximum global coordinates of the structure along the X, Z, and Y global axes, respectively. You may also type the **Length Along X (Lx)**, **Length Along Z (Lz)**, and **Height (H)** dimension values.
Use Coefficient Factor	Select the option for evaluating the coefficient factor: • **None -** no coefficient factor is multiplied with wind intensity value. • **Pressure Coefficient -** select this option to specify parameters to calculate the pressure coefficients on building face per Cl. 7.3.2 and 7.3.3. • **Force Coefficient -** select this option to directly specify the **Force Coefficient Factor (Cf)** on the building per Cl. 7.4.2.
Pressure Coefficient on Face	Use these options when the **Use Coefficient Factor** option selected is **Pressure Coefficient**:

Wind on Face	Select the face of the structure (as labeled in the diagram in the dialog) to which this wind definition is applicable.
External Pressure Coefficient (Cpe)	Select to use either the **Code Calculated** or **Custom** (manually typed) value of Cpe. If the maximum range of l/w from Tabe 5 of IS 875 (Part 3): 2015 is exceeded, then the upper values of Cpe for $3/2 < l/w < 4$ are still used. You may also enter custom Cpe values.
Internal Pressure Coefficient (Cpi)	Check this option to include the Internal Pressure Coefficient (Cpi).
Building Permeability	Select the range of openings to overall building exterior from the drop-down list. This is used to select the Cpi and Cpnet values per Clause 7.3.2.1 of IS-875. Alternatively, select **Custom** from the drop-down list to type a value to use for Cpi
Use (-) Cpi	Check this option to use negative Internal Pressure Coefficient (Cpi) value to calculate Net Pressure Coefficient (Cpnet)

Force Coefficient on Building	Type the Force Coefficient (Cf) value as per clause 7.4.2 of IS-875 when the **Use Coefficient Factor** option selected is **Force Coefficient**.

Unclad Frame Building

Frame Type	Select if the structure contains a **Single** frame or **Multiple** frames spaced along the wind direction. For either frame type, you must specify the **Solidity Ratio** (Φ) at each height interval of the structure in the frame information table. For multiple frames, you must also specify the **Effective Solidity Ratio** (Φ_e) at each height interval. Providing the **Solidity Ratio** (Φ) for a single frame at the given height interval, the force coefficient (Cf) will be selected according to the user provided solidity ratio values from Table 31 of IS 875 (Part 3) : 2015 by interpolation. Providing the **Effective Solidity Ratio** (Φ_e) for multiple frames at the given height interval, the shielding factor (H) will selected according to the user provided effective solidity ratio values from Table 32 of IS 875 (Part 3) : 2015 by interpolation.
Member Profile Cross Section	Select if the cross section profile of the frame(s) is **Flat Sided** or **Rounded.** For rounded members, you must also specify the **Diameter** of the members used at each height interval in the frame information table.

Frame Spacing Ratio For **Multiple** frames, type the frame spacing ratio as indicated in Table 32 (Clause 7.4.3.4) of IS-875.

Force Coefficient The intermediate values along with the calculated values are displayed in the table.

If the **Custom** option is selected, then you must specify the Force Coefficient (**Cf**) values at each height interval. For multiple frames in the Custom option, you must also specify the **Shielding Factor** at each height interval in the table.

Free Wall and Hoardings

Walls or Hoarding Parameters

Horizontal Dimension (b)	Type the horizontal dimension of the wall or hoarding component.
Vertical Dimension (h)	Type the vertical dimension of the wall or hoarding component.
Structure Height (H)	This is calculated as the difference between the maximum and minimum Y coordinates in the model. You may also type a value here.

Height Above Ground Select either the **Automatic** (calculated) or **Custom** option. For the automatic option, the height above ground (h') value used is taken as the structure height, H, minus the vertical dimension, h. The custom option lets you type a different value.

Force Coefficient The Force coefficients factor (Cf) will be calculated automatically based on the width to height ratio (horizontal dimension, b, divided by vertical dimension, h) and whether the free-standing wall or hoarding are above ground or on ground as given in Table 26 of IS 875 Part (3) : 2015. No interpolation of Table 26 is assumed. So if a width to heigh ratio, b/h, is between to tabulated values, then the next greater value of Cf is used.

If the **Custom** option is selected, then you must specify the Force Coefficient (**Cf**) value.

Lattice Tower

Tower Information

Structure Cross Section	Select if the tower structure cross section is **Square** or **Equilateral Triangle**.
Member Profile Cross Section	Select if the cross section profile of the tower is **Flat Sided** or **Rounded**. For rounded members, you must also specify the **Diameter** of the members used at each height interval in the solidity ratio table.

Solidity Ratio For either tower type, you must specify the **Solidity Ratio** of the front face (Φ) at each height interval of the structure in the solidity ratio table.

Force Coefficient The Force coefficients factor (Cf) will be calculated at each height interval automatically based solidity ratio and the tower type as per the following table (with linear interpolation between tabulated values). The force coefficient table also displays the intermediate calculated values.

Tower Type	Member Cross Section	Code Reference
Square	Flat Sided	Table 33 / Clause 7.4.3.5(a)

Tower Type	Member Cross Section	Code Reference
	Rounded	Table 34 / Clause 7.4.3.5(d)
Equilateral Triangle	Flat Sided	Table 33 / Clause 7.4.3.5(a)
	Rounded	Table 35 / Clause 7.4.3.5(e)

If the **Custom** option is selected, then you must specify the Force Coefficient (**Cf**) value.

Design Wind Pressure tab

This tab displays the resulting height vs. design wind pressure (pd) chart and graph per Cl. 7.2 of IS 875 (Part 3). The program includes a check for the minimum design wind pressure of $0.7 \times pz$. The intensity values generated are the net pressure coefficient *or* the force coefficient times the design wind pressure (pd).

Wind Directionality Factor (Kd)	Defaults to 1.0.
Area Averaging Factor (Ka)	Defaults to 1.0.
Combination Factor (Kc)	Defaults to 1.0.

Add New Snow Definition dialog

Used to define parameters used for generating snow loading on a structure per the ASCE 7-02 code.

Opens when the **Snow** tool is selected in the **Define Load Systems** group on the **Loading** ribbon tab.

The feature is currently implemented for structures with flat or sloping roofs. Snow load generation for members of open lattice structures like electrical transmission towers is currently not part of this facility. Hence, the feature is based on panel areas, not the exposed width of individual members.

As a result, the members for which the snow load is to be generated must be clustered together into Floor Groups. For details on creation of groups, refer to TR.16.1 Listing of Entities by Specifying Groups (on page 2235) .

Type No:	Specify an integer value (1, 2, 3, etc.) which denotes a number by which the snow load type will be identified. Multiple snow load types can be created in the same model.
Ground Snow Load	The pressure or, weight per unit area, to be used for the calculation of the design snow load, in current units. Use a negative value to indicate loading acting towards the roof (upwards) as per section 7.2 of the SEI/ASCE 7-02 code.
Exposure Factor	Specify the exposure factor as per Table 7-2 of the SEI/ASCE-7-02 code. It is dependent upon the type of exposure of the roof (fully exposed/partially exposed/sheltered) and the terrain category, as defined in section 6.5.6 of the code.
Thermal Factor	Specify the thermal factor as per Table 7-3 of the SEI/ASCE-7-02 code. It is dependent upon the thermal condition.

Importance Factor	Specify the snow importance factor as per Table 7-4 of the SEI/ASCE-7-02 code. This value depends on the category the structure belongs to, as per section 1.5 and Table 1-1 of the code.

Add New Seismic Definitions dialog

Used to define the parameters for performing a dynamic analysis using the static equivalent approach as outlined in the various seismic codes supported by STAAD.Pro.

Opens when the **Seismic** > ***<code name>*** tool is selected in the **Define Load Systems** group on the **Loading** ribbon tab.

Weights are added to a seismic definition through the other tabs of the **Add New: Seismic Definition** dialog. Seismic load items using this definition are applied using the **Add New : Load Items** dialog.

Seismic Parameters tab

Type

Select the code you wish to use for defining seismic parameters.

- TR.31.2.22 UBC 1994 or 1985 Load Definition (on page 2429)
- TR.31.2.23 UBC 1997 Load Definition (on page 2432)

- TR.31.2.6 Chinese Static Seismic per GB50011-2010 (on page 2375)
- TR.31.2.7 Colombian NSR-98 Seismic Load (on page 2382)
- TR.31.2.8 Colombian NSR-10 Seismic Load (on page 2384)

Include Accidental Load	Select this option to calculate the accidental torsion component described in the appropriate code.
Include IS 1893 Part 4	(IS 1893 - 2002/2005 only) Set this option to specify loads per IS 1893 (Part 4) 2005 for industrial or stack-like structures. When set, the a value for ST is required (1 or 5). When set and ST of 5 is used, CV and DV are also required. **Notes:** If this check box is clear, then IS 1893 (Part 1) 2002 is used. To use IS 1893 (Part 4) 2015, select that code separately.
Generate	(IS 1893 - 2002/2005 only) Opens the **IS:1893 Seismic Parameters** dialog box, which is used to populate the parameter fields with appropriate values for the IS 1893 - 2002 code.
Parameters table	A table of the code-relevant seismic parameters is listed. Refer to TR.31.2 Definitions for Static Force Procedures for Seismic Analysis (on page 2349) for technical details on each code parameter. **Note:** Required parameters are marked with an "*".

Wall Area tab

Used to add shear wall areas for the first story above ground necessary to compute static seismic loads for IS1893 2016 only. Specify seismic resisting walls for each global direction (X and Z) only. The width is the thickness of the wall and length is the length along the global direction (i.e., plan dimensions of the walls).

Note: Specifying wall data for any seismic code *other* than IS1893 2016 has no effect.

Refer to Wall Area Definitions (on page 2352) for details.

Self Weight tab

Used to add the selfweight of the structure.

SelfWeight Factor	The factor to be used to multiply the selfweight.

Joint Weights tab

Used to add the concentrated weights acting at one or more joints.

Joint Weight	Specify the magnitude of the joint weight.

Member Weights tab

Used to add distributed and concentrated weights acting on member spans.

Loading Type	Select either a **Concentrated** or **Uniform** load type.
Weight	Specify the intensity of the distributed weight or magnitude of the concentrated weight.

Starting / Ending Distance	Specify the location along the member where the weight is applied, in current units.

Element Weights tab

Used to add pressure loads on slabs if the structural model consists of plate elements representing entities like floor slabs.

Pressure	Specify the magnitude of the uniform pressure, in the current units. Since it is a weight, it is a quantity without a sign.

Reference Load tab

Used to add reference loads to the seismic definition.

Available Load Cases	A list of all previously defined reference loads included in the STAAD.Pro input file. Reference loads are created using the Add New Reference Load Definitions dialog (on page 2839).
Referenced Load	A list of included reference load cases for to be used in the seismic definition are included here. You may specify a different **Factor** value by which the reference load case is multiplied when used for the seismic load.
Along	Select a global direction along which the reference load case acts as a weight.

Floor Weights tab

Used to add floor loads when no slab is present or defined in the structural model.

For additional information on the Floor Load command, refer to TR.32.4.3 Floor Load Specification (on page 2483) . The parameters for Floor Weight are analogous to those for the Floor Load command.

Tip: If the floor has a shape consisting of a mixture of convex and concave edges, then break up the floor load command into several parts, each for a certain region of the floor. This will force the program to localize the search for panels and the solution will be better. See illustrative example at the end of this section

Range	Select this option to specify a Floor load or One-way load by specifying a range.
Group	Select this option to specify a Floor load or One-way load to act on a previously defined Floor group. Groups are created using the Create Group dialog (on page 2950).
Pressure	Specify the magnitude of the uniform pressure, in the current units. The pressure value is provided as a quantity without sign because it is contributing to the overall weight - a numerically positive term.
Define Y/X/Z Range	Specify **Minimum** and **Maximum** values to define a range in the global directions when the Range option is selected.
One Way Distribution	Set this option to use a one-way load distribution. Refer to TR.32.4.2 One-way Load Specification (on page 2476) for additional information on using a one-way load.

Towards	(One-way Distribution only) Select an existing member onto which the loading is directed and defines the span direction for the one way loading. Otherwise, the load will be distributed to the longer member.
Member Group	Select a previously defined floor group from the list.
Inclined	(Group option only) This option is required to be set when a group of members that form a panel are inclined to the global XY, YZ, or ZX planes.

IS:1893 Seismic Parameters dialog box

Used to populate the parameter fields with appropriate values for the IS 1893 - 2002 code.

Opens when **Generate** is clicked in the Add New Seismic Definitions dialog (on page 2895) with the **IS 1893 - 2002** code selected.

Refer to TR.31.2.10 IS:1893 (Part 1) 2002 & Part 4 (2005) Codes - Lateral Seismic Load (on page 2387) for additional information on all parameters.

Zone Factor Choice	In the first drop-down list, select either City or Zone. The second drop-down list is then populated with a list of major Indian cities or seismic zones. The corresponding zone factor, Z, is displayed for the current selection.
Response Reduction	Select the type of lateral load resisting system, as defined by the IS 1893 code, used in the structure for the direction of loading.
Importance Factor	Select the importance classification, as defined by the IS 1893 code.
Rock/Soil Type	Select the soil classification for the structure site.
Structure Type	Select the material used for the structure.
Damping Ratio	Type a damping ratio, in percent.
Foundation Depth	Set this option to display a field in which to type the depth of foundation below ground level, in the current units of length.
Period in X (sec)	Set this option to display a field in which the period of structure (in sec) in X direction.
Period in Z (sec)	Set this option to display a field in which the period of structure (in sec) in Z direction.
Generate	Closes the dialog box and populates the values in the Seismic Parameters dialog box.
Cancel	Closes the dialog box without generating the values for the Seismic Parameters dialog box.

Add New Direct Analysis Definition dialog

Used to define parameters used in the direct analysis method described in AISC 360 Appendix 7.

Opens then the **Direct Analysis** tool is selected in the **Define Load Systems** group on the **Loading** ribbon tab.

Note: This feature is used in conjunction with the **Perform Direct Analysis** command.

Refer to TR.31.7 Definition of Direct Analysis Members (on page 2454) for additional details.

Each tab in the dialog contains a different parameter used for direct analysis. The parameters are:

FLEX Identification of members whose flexural stiffness is considered to contribute to the lateral stability of the structure, along with the initial value of τb that should be used. Members listed with `FLEX` will have their EI factored by 0.80 times τ_b while performing the global solution. The final member forces and code check will be with 100% of the flexural stiffness.

AXIAL Identification of members whose axial stiffness is considered to contribute to the lateral stability of the structure. These members will have their EA factored by 0.80 while performing the global solution. The final member forces and code check will be with 100% of the axial stiffness.

Add New Vehicle Definitions dialog

Used to define different types of moving loads. Several load cases can be generated by applying these types of loads.

Opens when the **Vehcile** tool is selected in the **Define Load Systems** group on the **Loading** ribbon tab.

In order to generate a set of static loads, due to the movement of the vehicle or load on the structure, there are two steps involved. The first step is to define the vehicle. The second step involves the Load Generation dialog (on page 2866).

Define Load tab

Used to define a moving load system in the input file.

Vehicle Type Ref	This is the reference number.
Width	Specify a wheel spacing, if applicable. The **Width** is the spacing between loads perpendicular to the direction of movement. If omitted, one directional loading is assumed.
Load, Dist table	Enter the value of the concentrated loads and the distance between them. The first load is used as the Reference load for vehicle placement in the **(Moving) Load Generation Type** dialog.

AASTHO Spec tab

Used to specify a standard AASHTO load in the input file.

Vehicle Type Ref	This is the reference number.
AASHTO Specification	Choose from the following standard AASHTO loading: HS20, HS15, H20 and H15.
Factor	Specify a multiplying factor, if applicable. The default factor is 1.0.
Variable Spacing	(For use with HS loads only) Specify a value for a variable wheel spacing between the second and third axles, per Fig. 3.7.7A of AASHTO Standard Specification or Cl. 3.6.1.2.2 of the AASHTO LRFD. Valid range from 14 feet to 30 feet (inclusive), with the default being 14 feet if not specified.

File Input tab

Used to specify a moving load defined in an external file.

Vehicle Type Ref	This is the reference number.
File Name	Name of the external file containing moving load data. File name should be limited to 16 characters, reside in the same directory as the current input and have no file extension. For more information on creating an external moving load file, see TR.31.1 Definition of Moving Load System (on page 2346).
Load Name	Name assigned to the moving load system in the external file.
Factor	Specify a multiplying factor, if applicable.

Add New : Pushover dialog

Used to define structural parameters for a pushover analysis.

Opens when the **Pushover** tool is selected in the **Define Load Systems** group on the **Loading** ribbon tab.

Common Dialog Controls

Add	Adds the parameters set on the current tab to the input file.
Close	Closes the dialog.
Help	Opens the STAAD.Pro help window.

Define Input tab

Used to define general definition and member specific parameters for a pushover analysis.

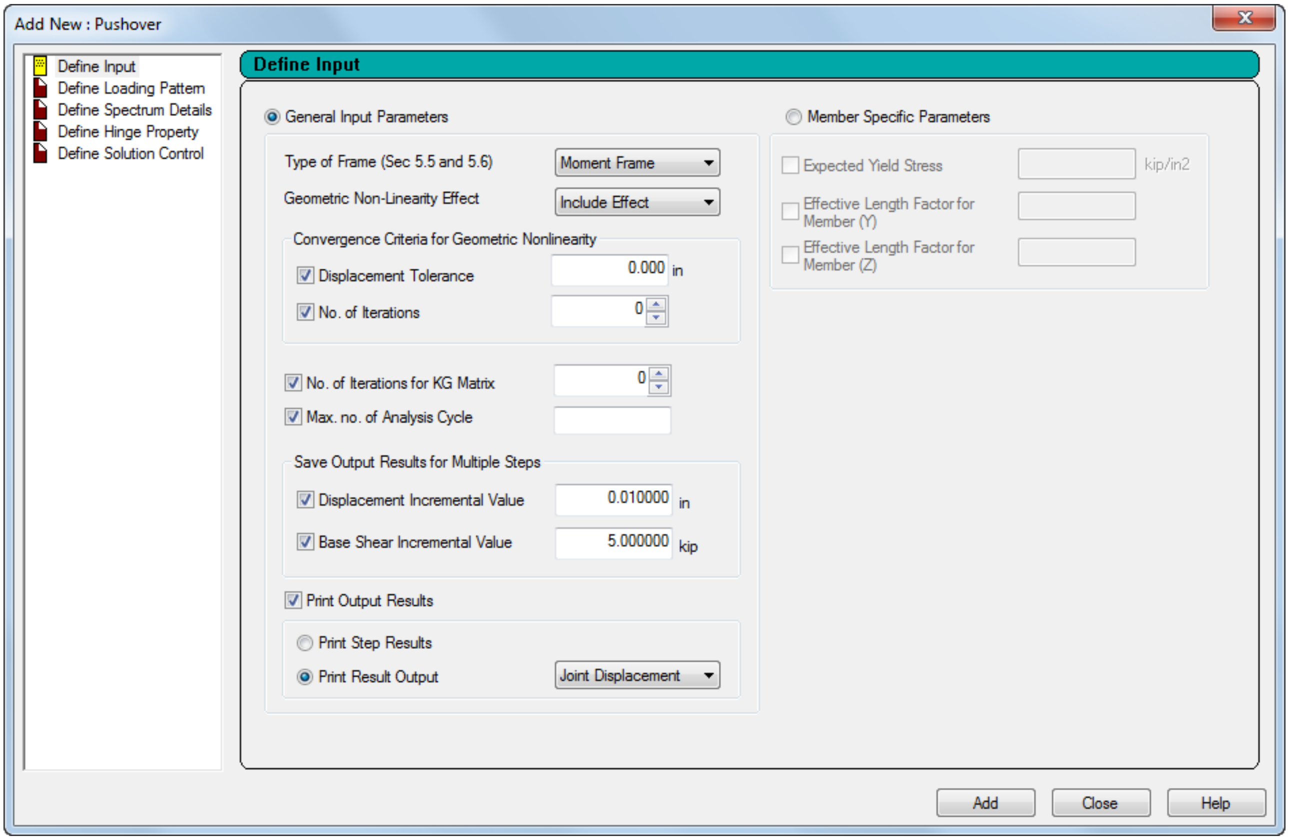

Figure 345: Add New : Pushover dialog Define Input tab

General Input Parameters

Select this control to add general parameters for the entire structure.

Type of Frame
Select either a fully restrained **Moment Frame** (FR) or a (Concentric) **Braced Frame** (CBF) to defined the type of steel frame.

Geometric Non-Linearity Effect
Select either **Ignore Effect**, if nonlinear effects are not to be considered, or **Include Effect**, if nonlinear effects are to be considered.

Displacement Tolerance
(For when Geometric Non-Linearity Effect is considered only) Set this option to specify a displacement tolerance for convergence, in current input units.

No. of Iterations
(For when Geometric Non-Linearity Effect is considered only) Set this option to specify a target number of iterations for geometric nonlinearity convergence.

No. of Iterations for KG Matrix
Set this option to specify the number of iterations to be performed for geometric stiffness, KG, matrix. The value is a integer, with a maximum value of 50.

Max. no. of Analysis Cycles
Set this option to specify a maximum number of cycles to be considered during the strain hardening stage for the load increment stage.

Displacement Incremental Value
Set this option to include intermediate displacement increments, in current units of length, at which the program will record analysis results for post-processing.

Base Shear Incremental Value	Set this option to include intermediate base shear increments, in current units of force, at which the program will record analysis results for post-processing.
Print Output Results	Set this option to print analysis results for the final state for a nonlinear static analysis. • Select the **Print Step Results** option to include the analysis results of the final load step in the output. • Select the **Print Results Output** option and then a results type to limit the output.

Member Specific Parameters

Select this control to add parameters for members which will be assigned later.

Expected Yield Stress	Expected yield strength of the material based on Section 5.3.2.3 and Tables 5-1 and 5-2 of FEMA 356.
Effective Length Factor for Member (Y/Z)	The effective length factor, k, defined for any member in either the local Y or local Z direction.

Define Loading Pattern tab

Used to define general definition and member specific parameters for a pushover analysis.

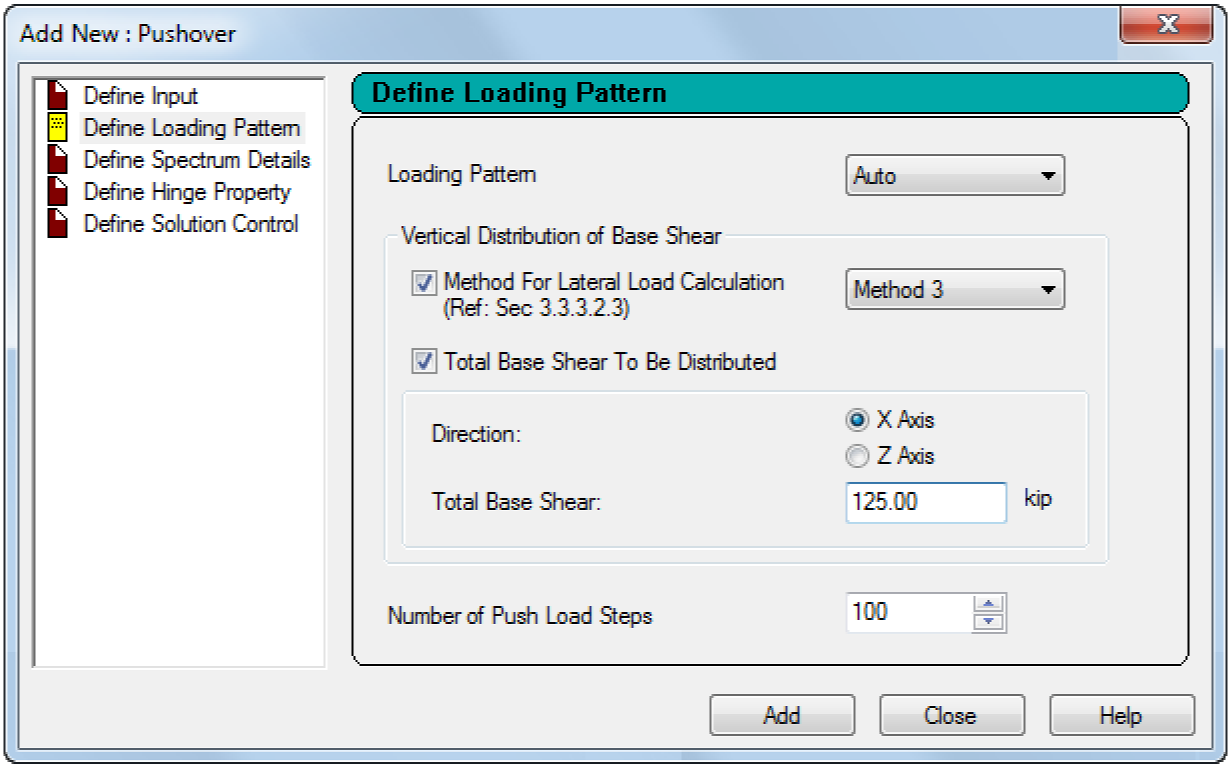

Figure 346: Add New : Pushover dialog Define Loading Pattern tab

Loading Pattern	Select either **Auto** or **User Defined** method for specifying loading patterns.
Method for Lateral Load Calculation	(Auto loading pattern only) Set this option to specify the G.17.4.1.8 Lateral Load Distribution (on page 2177) for defining the load pattern.
Total Base Shear To Be Distributed	(Auto loading pattern only) Set this option to define base shear that will be distributed vertically along the height of the structure at each floor level. If no value is specified, the program distributes 10 percent of gravity loading as lateral load.
Direction	(Total base shear distributed only) Select the global direction in which the pushover load acts.
Total Base Shear	(Total base shear distributed only) Base shear value in current units of force used for loading.
Number of Push Load Steps	The number of load steps. The lateral load at each floor divided by the number of load steps gives the push load increment at that floor level.

Define Spectrum Details tab

Used to define the response spectrum according to FEMA 356.

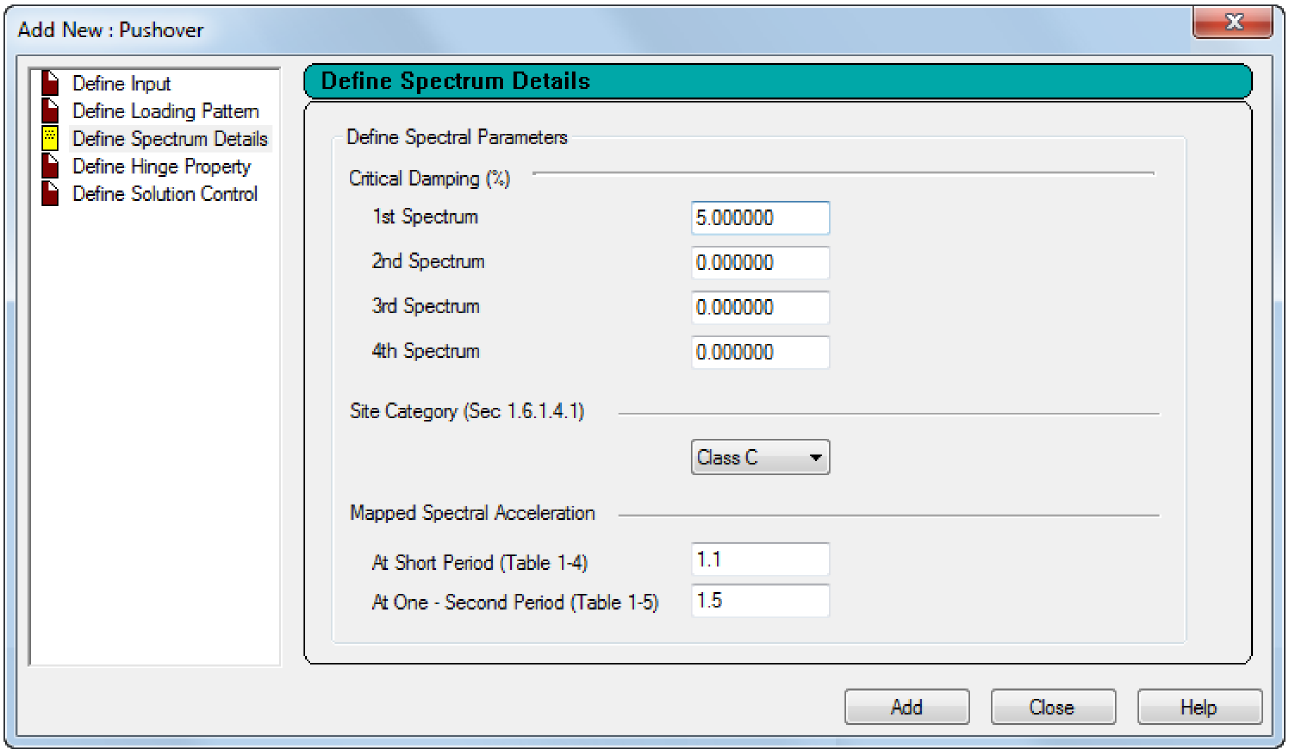

Figure 347: Add New : Pushover dialog Define Spectrum Details tab

Critical Damping (%) 1st | 2nd | 3rd | 4th Spectrum	Specify critical damping ratios to be used for the first (required, 0.05 is the default) through the fourth spectra.
Site Category	Specify the site category which describes the soil conditions.
At Short Period	Specify the mapped spectral acceleration at short period, S_s.
At One-Second Period	Specify the mapped spectral acceleration at one-second period, S_1.

Define Hinge Property tab

Used to define the hinge type used in the pushover analysis and create custom hinge definitions.

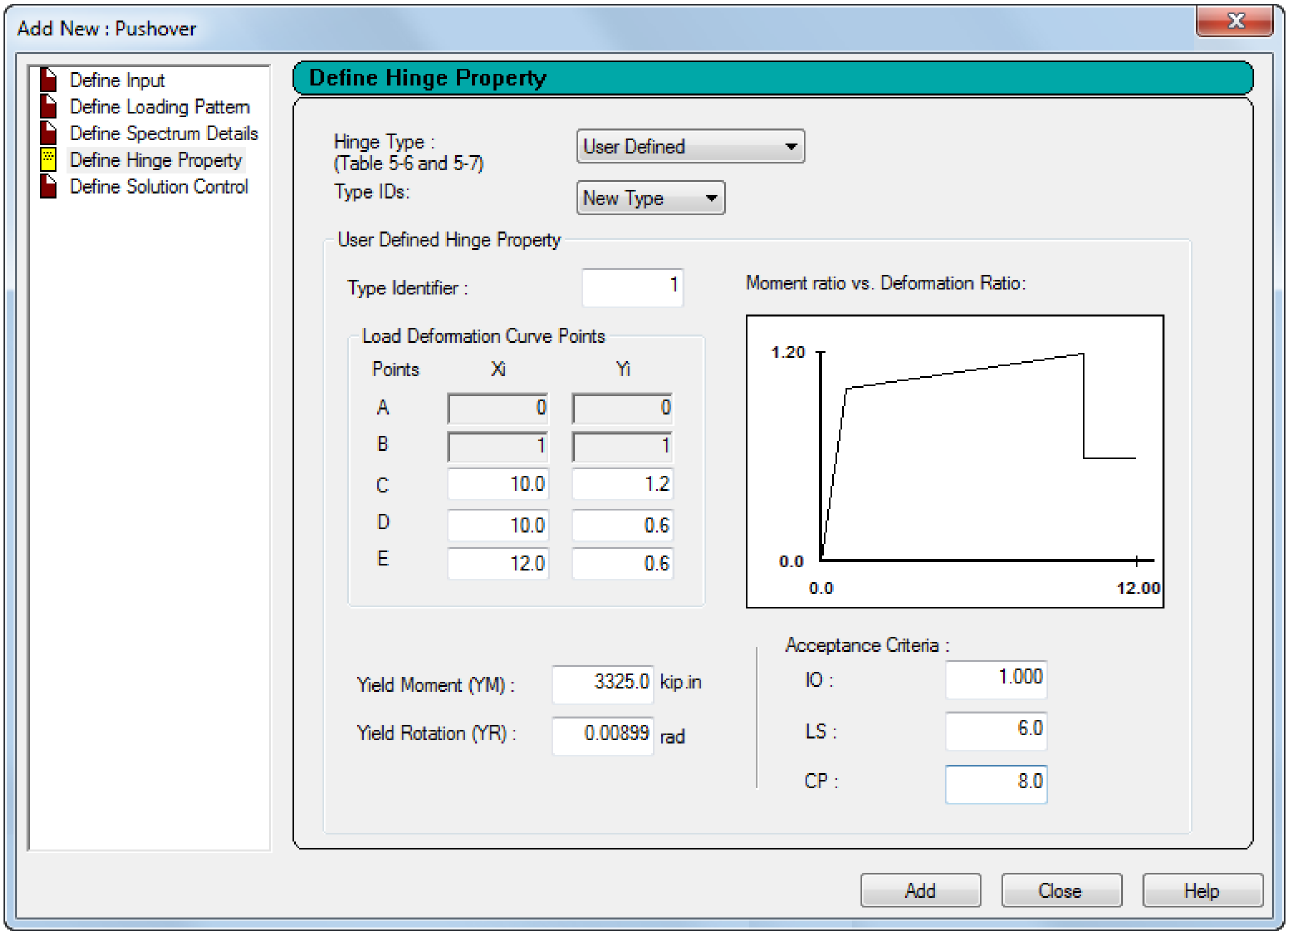

Figure 348: Add New : Pushover dialog Define Hinge Property tab

Hinge Type

Select either

- **FEMA** — instructs the program to use the built-in hinge definitions.
- **Ignore** — instructs the program to ignore hinge formation in some members.
- **User Defined** — used to define a custom hinge by **Load Deformation Curve Points**, **Yield Moment**, **Yield Rotation,** and **Acceptance Criteria**.

Type IDs

(User defined type only) Select an existing hinge type ID number of select **New Type** to define a new hinge type..

Type Identifier

(User defined type only) Specify an unique ID number for the hinge type (hinge property number).

Load Deformation Cure Points

Points on the load deformation curve at points A, B, C, D and E as specified in FEMA. The Xi and Yi coordinates of the load deformation curve represent the Deformation Ratio and Moment Ratio, respectively. The coordinates of A and B are preset at 0,0 and 1,1, respectively, to normalize the ratio curve.

Yield Moment (YM)

Yield moment in current force units.

Yield Rotation (YR)	Yield rotation in radians.
IO	Acceptance criteria limit (deformation ratio) for Immediate Occupancy level.
LS	Acceptance criteria limit (deformation ratio) for Life Safety level.
CP	Acceptance criteria limit for (deformation ratio) Collapse Prevention level.

Define Solution Control tab

Used to define the limit of the pushover analysis by either limiting base shear or displacement at a control joint.

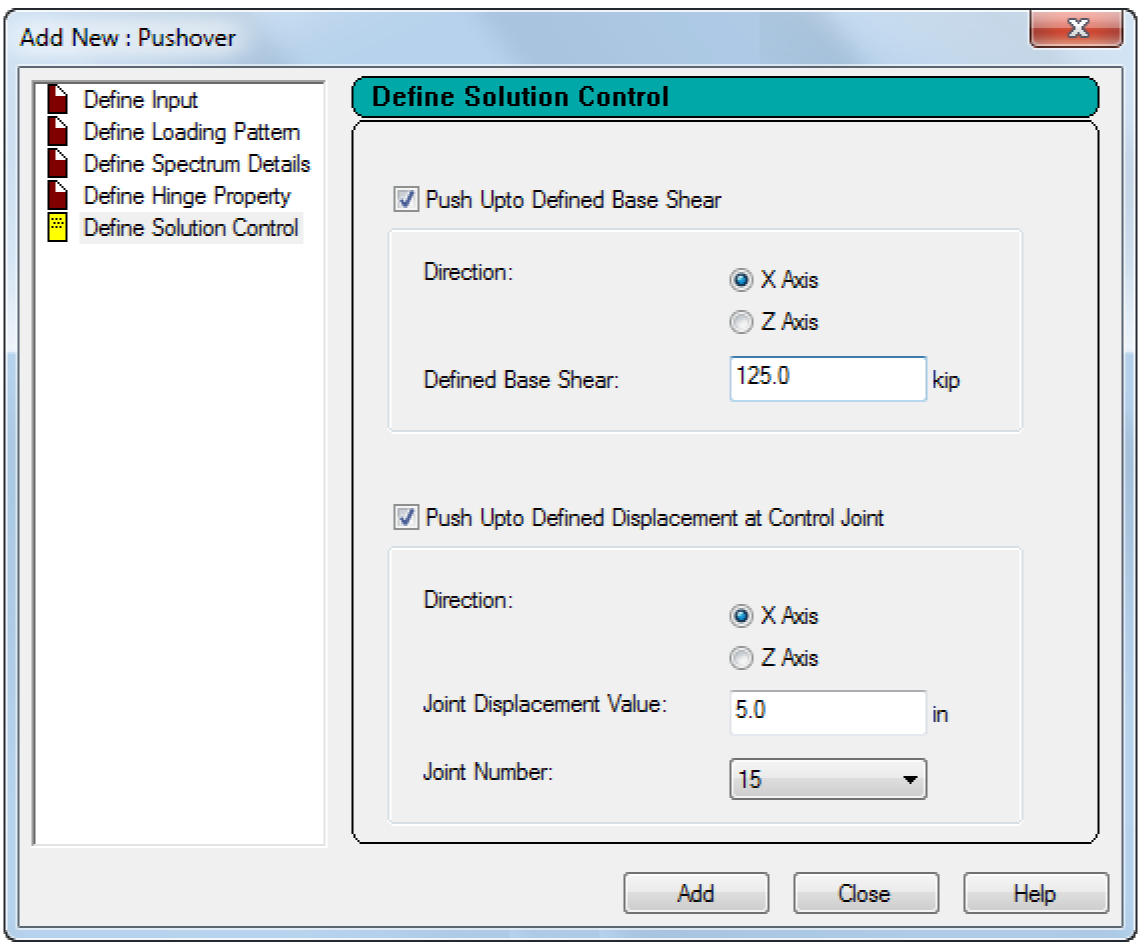

Figure 349: Add New : Pushover dialog Define Solution Control tab

Push Up to Defined Base Shear	Set this option to limit the analysis by force. The pushover analysis will continue until the cumulative base shear is less than or equal to the base shear specified by this command or the structure has additional strength.
Direction	Select the global direction of base shear for this solution control.
Defined Base Shear	Specify a target base shear value, in current units of force.
Push Up to Defined Displacement at Control Joint	Set this option to limit the analysis by displacement. The pushover analysis will continue until the displacement at the specified joint at the specified direction exceeds specified displacement.
Direction	Select the global direction of displacement for this solution control.
Joint Displacement Value	Specify a target displacement value, in current units of length.
Joint Number	Select the control joint from the list of nodes.

Add New Time History Definitions dialog

Used to define the Forcing Function of a time varying load.

Opens when the **Time History** > **Forcing Fucntions** tool is selected in the **Dynamic Specifications** group on the **Loading** ribbon tab.

Note: Refer to TR.31.4 Definition of Time History Load (on page 2441) for additional information.

Note: After defining a Time History Load, use the **Create New Load Items** dialog **Time History** tab to apply the load to the structure.

Integration Time Step	Solution time step used in the step-by-step integration of the uncoupled equations.
Consider Missing Mass Mode	Check this option to include the missing mass procedure in the time history analysis.
Type	This refers to the number of the type of functions.
Loading Type	Select the **Acceleration**, **Force**, or **Moment** option to define the type of function being input.
Save	Select this option to create an external file (input file name with a `.tmh` extension) containing the history of the displacements of every node of the structure at every time step.

The following function type options are available:

Select the *Define Time vs. Acceleration, Harmonic Function* or *From External File* option and provide function data.

Define Time vs. <Loading Type>

Used to specify a time history forcing function, where the loading type is that selected above (either Moment, Force, or Acceleration).

Specify the values Time and corresponding *Force* or *Acceleration*.

Note: The time history forcing function is plotted on the graph at the bottom of the dialog as data pairs are entered.

From External File

File Name	If the **From External File** option is selected, the **File Name** edit box becomes active. Type the name of the external file containing time history data. File name should be no more than 8 characters, reside in the same directory as the current input and have no file extension. The data must be provided as one time-force or time-acceleration pair per line. **Note:** For more information on creating an external time history file, see TR.31.4 Definition of Time History Load (on page 2441).

Harmonic Function

To specify a time history harmonic function, check the *Harmonic Function* button.

Curve Shape	Specify if the harmonic function is a **SINE** or **COSINE** curve.
Frequency or RPM	Choose *Frequency* and enter a circular frequency in cycles per second or *RPM* and enter revolutions per minute.
Amplitude	Max. Amplitude of the forcing function in current units.
Phase	Phase Angle in degrees.
Cycles	No. of cycles of loading.
Step or SubDiv	Choose the Step option to time step of loading or SubDiv to subdivide a ¼ cycle into this many integer time steps.

Spectrum

Select this Function Option to provide Spectrum parameters for your time history loading.

Tmax	The maximum time (in seconds) in the generated time history. Must be greater than **T3**.
DeltaT	Difference (delta) value in subsequent time steps in the generated time history.
Damp	Damping ratio (5% is entered as 0.05) associated with the input spectrum.
T1 / T2 / T3	Ending time of the acceleration rise, stead acceleration, and acceleration decay, respectively (in seconds).

> **Note:** The value of **T1** must be greater than zero. Further, **T3** > **T2** > **T1** and **Tmax** must be greater than **T3**.

Random Seed Enter a positive integer (1 to 2,147,483,647) to be used as a unique random number generation "seed." A unique time history will be produced for each seed value. Change this value when you want to produce a "different (from the time history generated with the prior seed value)" but statistically equivalent time history.

No of digitized Freq. The input shock spectrum will be re-digitized at this number of equally spaced frequencies by interpolation. The default is taken as the greater of 35 or the number of points in the input spectrum.

No. of Iteration The number of iterations which will be used to perfect the computed time history.

Define (Time History) Parameters dialog

Used to define time step, damping, and arrival times for time history loads.

Opens when the **Time History** > **Parameters** tool is selected in the **Dynamic Specifications** group on the **Loading** ribbon tab.

Time Step Specify a solution time step to be used in the step-by-step integration of the uncoupled equations. The default value of *Time Step* is determined as explained in TR.31.4 Definition of Time History Load (on page 2441) .

Damping The following options are available for specifying damping:

- **Damping** – This is to be used for specifying a single modal damping ratio which will be applied to all modes. The default value is 0.05.
- **CDAMP -** If a damping ratio has already been specified under `CONSTANTS` based on the type of material in the structure, that value may be used directly in the time history analysis. Check this option for that purpose.
- **MDAMP -** In we wish to utilize individual damping ratios for individual modes, that is achieved through the means of the MDAMP option. The first step to doing this is the specification of those individual damping ratios, as explained under TR.26.4 Modal Damping Information (on page 2312) , and is done graphically by using the **Modal Damping** tool on the **Loading** ribbon tab. If this first step has been completed, the instruction to utilize `MDAMP` is done by selecting this option shown above.

Arrival Time
Specify values of possible arrival times of the various dynamic load types. The arrival time is the time at which a load type begins to act at a joint (forcing function) or at the base of the structure (ground motion). The same load may have different arrival times for different joints and hence all these values must be specified here. The arrival times and time-force pairs for the load types are used to create the load vector needed for each time step of the analysis.

Add
Adds the specified load details to the currently selected load case in the Load dialog and closes the dialog.

Close
Closes the dialog without adding any load data.

Help
Opens the STAAD.Pro Help window.

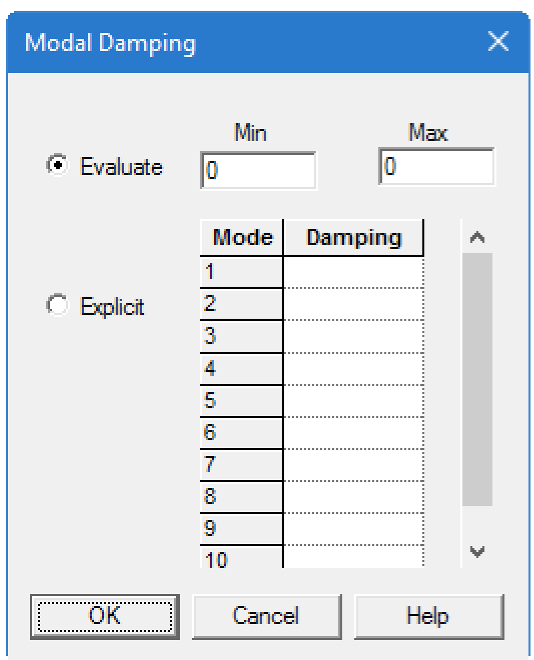
- *G.17.3.5 Response Time History* (on page 2165)
- *M. To define time history parameters* (on page 880)

Modal Damping dialog

Used to define unique damping ratios for the individual modes used in a dynamic analysis. It is used in response spectrum and time history analysis.

Opens when the **Modal Damping** tool is selected in the **Dynamic Specifications** group on the **Loading** ribbon tab.



Note: STAAD.Pro is also capable of calculating each mode's damping based on the frequency of the mode, the mass-proportional damping coefficient (α), and the stiffness-proportional damping coefficient (β). This input must be provided using the STAAD.Pro Editor. Refer to Calculate Damping (on page 2160) for additional details.

Evaluate This option is to instruct STAAD.Pro to calculate the damping ratio for each mode based on the frequency of the mode and the **Min**imum and **Max**imum values entered in the respective fields.

The formula used to evaluate the damping ratio is explained in Evaluate Damping (on page 2162).

Explicit Provide values of damping ratio for the corresponding mode number.

Refer to Explicit Damping (on page 2160) for additional details.

Related Links

Analysis and Design tab

Table 327: Analysis Data group

Tool name		Description
 **Analysis Commands**		Opens the **Analysis/Print Commands** dialog for analysis commands, which is used to define the analysis commands to be included in the Input Command File.
 **Pre Analysis Commands**		Opens the **Analysis/Print Commands** dialog for pre-analysis print commands, which is used to define the pre-analysis print commands to be included in the Input Command File.
 **Post Analysis Commands**		Opens the **Analysis/Print Commands** dialog for post-analysis print commands, which is used define the post-analysis print commands to be included in the Input Command File.
 **Miscellaneous**	**Input Width**	Opens the **Input Width** dialog, which is used to set the maximum allowable number of characters per line in the input command file for processing. Choose 72 or 79 columns and then click **OK**. Refer to TR.4 Input/Output Width Specification (on page 2205) for additional information.

Tool name		Description
Commands >	**Output Width**	Opens the **Output Width** dialog, which is used to set the maximum allowable number of characters per line in the output file. Choose 72 or 118 columns and then click **OK**. **Note:** If you choose 118 Columns, your printer must have the capability of supporting that wide of an output. Refer to TR.4 Input/Output Width Specification (on page 2205) for additional information.
	Floor Diaphragm Options	Used for analysis of a seismic requirements for IS 1893 (Indian) or ASCE 7 (US) codes. Refer to TR.28.2.1 Soft Story Checking (on page 2331) for additional information.
	Set NL	Opens the **Set NL** dialog, which is used to specify the maximum number of primary load cases for processing. It is required if multiple cycles of analysis is performed. Type the **Maximum Number of Primary Loads** to provide in the input file and then click **OK.** Refer to TR.5 Set Command Specification (on page 2206) for additional information.
	Set Echo	Opens the **Set Echo** dialog, which is used to activate or deactivate the echoing of input commands to the output (`.ANL`) file. By default, Echo is On (i.e., input commands are echoed to the output file). This option is used if you want to process any structure in which a node may be associated with more than 16 other joints. Refer to TR.5 Set Command Specification (on page 2206) for additional information.
	Set Z Up	By default, STAAD.Pro assumes that the global X and Z axes are horizontal and the Y axis is vertical. This command is used to orient the global Z axis as the vertical axis and sets X and Y to be the horizontal axes. Refer to TR.5 Set Command Specification (on page 2206) for additional information.
	Set Displacement	Opens the **Maximum allowable displacement tolerance** dialog, which is used to specify limiting values for nodal displacements for `PDELTA` and `NONLINEAR` analyses. **Tip:** Make sure it is in the current length unit (see the bottom right hand corner of the STAAD.Pro window for the current input units). Refer to TR.5 Set Command Specification (on page 2206) for additional information.

Tool name		Description
	Set Floor Load Tolerance	Opens the **Tolerance used in Floor load calculation for length** dialog, which is used to specify the tolerance for out of plane nodes in a floor load. The value is given as a length, in current units.
	Set Floor Angle Tolerance	Opens the **Tolerance used in Floor load calculation for angle** dialog, which is used to specify the he tolerance for out of plane nodes in a floor load. The value is given in degrees.
	Set SDAMP	Opens the **Damping ratio to be used for all springs** dialog, which allows damping property of springs to be considered in computing the composite modal damping for each mode in a dynamic solution. Refer to TR.5 Set Command Specification (on page 2206) for additional information.
	Set Warp	Opens the **Warping restraint ratio to compute torsional rigidity** dialog, which allows end warping restraint to be considered for I-shaped members. Refer to TR.5 Set Command Specification (on page 2206) for additional information. Assign a value which in the range 0 to 1. 0 indicates no restraint. 1 indicates full restraint. A fraction indicates a partial restraint.
	Set Shear	This command is used for omitting the additional pure shear distortion stiffness terms in forming beam member stiffnesses. With this command you can exactly match simple textbook beam theory results. A message dialog opens to confirm you wish to omit the additional shear distortion terms. Refer to TR.5 Set Command Specification (on page 2206) for additional information.
	Set ITERLIM	Opens the Maximum number of tension/compression iterations dialog, which is used to override default limits for the maximum number of iterations of analysis performed for cases involving tension-only and compression-only components. Refer to TR.5 Set Command Specification (on page 2206) for additional information.
	Set NoWarning	This command will toggle off all warning messages in the output file. A message dialog opens to confirm you wish to toggle off all warning messages. Refer to TR.5 Set Command Specification (on page 2206) for additional information.

<table>
<tr><th colspan="2">Tool name</th><th>Description</th></tr>
<tr><td></td><td>Set Eigen Method</td><td>Opens the Set Eigen Method dialog, which is used to specify the method used for eigen vectors or to use load-dependent Ritz vectors instead.

Refer to TR.5 Set Command Specification (on page 2206) for additional information.

Refer to G.17.3.1 Solution of the Eigenproblem (on page 2155) for details on load-dependent Ritz vectors.</td></tr>
<tr><td></td><td>Cut Off Mode Shape</td><td>Opens the Cut Off Mode Shape dialog, which is used to instruct the program to extract a higher or lower number of modes. By default, STAAD.Pro calculates only a specific number of modes during modal calculation, response spectrum analysis, and time history analysis. This defaults to the first six modes.

<table><tr><th>Option</th><th>Description</th></tr><tr><td>Allow Automatic Shifting</td><td>When the Arnoldi/Lanczos method is selected in the Set Eigen Method dialog, this option can be set to reduce memory demand. This allows for efficient solution of large models with a large number of degrees of freedom.</td></tr><tr><td>Modes Per Shift</td><td>If the Allow Automatic Shifting option is set, then you must specify a targeted number of eigen modes to be searched in each shift.</td></tr><tr><td>Initial Shift Frequency</td><td>When the Arnoldi/Lanczos method is selected in the Set Eigen Method dialog, you may specify an initial frequency shift value.</td></tr></table>
Provide the maximum number of mode shapes we want the program to extract, and click OK.

Refer to TR.30.1 Cut-Off Frequency, Mode Shapes, or Time (on page 2344) for additional information.</td></tr>
<tr><td></td><td>Cut Off Frequency</td><td>Opens the Cut Off Frequency dialog, which is used to over-ride the built in cut off limit. During modal calculation, response spectrum analysis, and time history analysis, STAAD.Pro will extract only those modes whose frequency is below a built-in cut-off level.

Refer to TR.30.1 Cut-Off Frequency, Mode Shapes, or Time (on page 2344) for additional information.</td></tr>
<tr><td></td><td>Cut Off Time</td><td>Opens the Cut Off Time dialog, which is used to compute the results for a longer period of time than that at which the loads stop acting, specify the value using the CUT OFF TIME command. During time history analysis, by default, STAAD.Pro calculates displacements, forces, reactions and stresses for only up to a time which is equal to the duration of the longest acting forcing function or ground motion.

Refer to TR.30.1 Cut-Off Frequency, Mode Shapes, or Time (on page 2344) for additional information.</td></tr>
</table>

Tool name		Description
	Clear Above Commands	Opens the **Delete Miscellaneous Commands** dialog, which is to the delete previously specified Miscellaneous commands such as Input Width, Set CO, etc. Check the boxes associated with the commands you want to delete and then click **Delete.**
Load List		Opens the **Load List** dialog, which is used to specify a list of existing load cases and load combination cases to be used for subsequent processes, like design, print, plot etc.

Table 328: Analysis group

Tool name	Description	Shortcut
Run Analysis	Performs the STAAD analysis as directed by input commands. The **STAAD Analysis and Design** window opens to display the progress of the design engine. When completed, you can select a next process and then click **Done.**	**<Ctrl+F5>**

Table 329: Cloud Analysis Services group

Tool name		Description
Run Cloud Analysis		Opens the **Run Cloud Analysis** dialog, which is used to select a solution, name your scenario, and submit for analysis via Bentley's Scenario Services. **Note:** Requires you to be logged into your valid CONNECT account.
Download Results	**Download & Load Results**	Select to download and open the results in the typical postprocessing workflow.
	Download Results To	Select to save the output from a cloud analysis to your local computer.

Table 330: Design Commands group

Tool name	Description
Steel Design	Opens the **Steel Design - Whole Structure** dialog, which is used to select a steel design code, select parameters to use for design, and assign parameters to the model.

Tool name	Description
Concrete Design	Opens the **Concrete Design - Whole Structure** dialog, which is used to select a concrete design code, select parameters to use for design, and assign parameters to the model.
Aluminium Design	Opens the **Aluminum Design - Whole Structure** dialog, which is used to select a aluminum design code, select parameters to use for design, and assign parameters to the model.
Timber Design	Opens the **Timber Design - Whole Structure** dialog, which is used to select a timber design code, select parameters to use for design, and assign parameters to the model.

Analysis - Whole Structure dialog

Used to view, add, and assign analysis commands to the STAAD input file.

Opens when the **Analysis** page is selected.

Command Tree The dialog box shows a tree view (called Command Tree) of the commands in the Input Command File. The Command Tree is a pictorial view of the Input Command File with the commands displayed as "Nodes" of the tree in the same sequence in which they appear in the Input Command File. Click on a command Node to expand the branch of the command and the command parameters appear as the "leaves" under that command node. The following paragraph describes the conventions followed in the Command Tree.

- Green Check ( ) marks: Commands which can be re-specified or modified.
- Gray Check ( ) marks: Commands which may not be changed.
- Question ( ) marks: Commands which have been added but not assigned to any structural element (joint/member/element).

Define Commands... Opens the Analysis/Print Commands (on page 2916), which is used to define the analysis commands to be included in the Input Command File.

Close Closes the dialog.

Help Opens the STAAD.Pro help window.

Analysis/Print Commands

Used to define the analysis commands to be included in the Input Command File. Commands are indicated by their respective tab.

Opens when the **Analysis Commands** tool is selected from the **Analysis Data** group on the **Analysis and Design** ribbon tab.

After current Select this option to add the analysis statement being defined in the Command Tree after the currently selected (highlighted) command.

Add Assigns the selected print command to the input command file.

Assign	Used to assign the command to the current selection set.
Cancel	Closes the dialog.
Help	Opens the STAAD.Pro help window.

Perform Analysis tab

Used to direct STAAD.Pro to perform a linear elastic analysis.

Refer to TR.37.1 Linear Elastic Analysis (on page 2620) for additional information.

The dialog contains several print options, of which one may be selected.

No Print	No analysis results will be printed to the output file.
Load Data	Prints all the load data.
Statics Check	Provides a summation of the applied loads and support reactions as well as a summation of moments of the loads and reactions taken around the origin.
Statics Load	Prints everything that **Statics Check** does, plus a summation of all internal and external forces at each joint. This option potentially generates a large volume of output. **Note:** Since `PRINT STATIC LOAD` generates voluminous output, the printing of summation of internal and external forces at each joint is done for structures which have less than 1,000 joints. If the structure has 1,000 joints or more, this printing will be skipped.
Mode Shapes	Prints mode shape values at the joints for all calculated mode shapes.
Both	This option is equivalent to the **Load Data** plus **Statics Check** options.
All	This option is equivalent to the **Load Data** plus **Statics Check**.

Related Links

- *A. To specify a linear elastic analysis* (on page 952)

P Delta Analysis tab

Used to direct STAAD.Pro to perform a second order analysis.

Refer to TR.37.2 P-Delta Analysis Options (on page 2621) for additional information.

Number of Iterations	Specify the number of iterations to be performed. If specified, the program will perform the specified number of iterations whether or not the solution converges.
Use Geometric Stiffness (Kg)	P-Delta analysis including stress stiffening effect of the KG matrix. With this option the global stiffness is adjusted with every iteration. A regular STAAD.Pro P-Delta Analysis performs a first order linear analysis and obtains a set of joint forces from member/plates based on the large P-Delta effect. These forces are added to the original load vector. A second analysis is then performed on this updated load vector (5 to 10 iterations will usually be sufficient). In the new P-Delta KG Analysis, that is, with the Kg option selected, the effect of the axial stress after the first analysis is used to modify the stiffness of the member/plates. A second analysis is

then performed using the original load vector. Large & small P-Delta effects are always included (1 or 2 iterations will usually be sufficient).

Small Delta Select this option to include both P-small and large Delta effects (recommended), sometimes referred to as P-δ & P-Δ. Leave this box uncheck to only include the "PlargeDelta" effects (P-Δ only).

Without the **Small Delta** option (i.e., a default STAAD.Pro P-Delta analysis), STAAD.Pro performs a first order linear analysis and obtains a set of joint forces, from members/plates based on the large P-Delta effect, which are then added to the original load vector. A second analysis is then performed on this updated load vector.

With the **Small Delta** option selected, both the large & small P-Delta effects are included in calculating the end forces, (5 to 10 iterations will usually be sufficient).

Print Option Standard STAAD.Pro analysis print options:

No Print No analysis results will be printed to the output file.

Load Data Prints all the load data.

Statics Check Provides a summation of the applied loads and support reactions as well as a summation of moments of the loads and reactions taken around the origin.

Statics Load Prints everything that **Statics Check** does, plus a summation of all internal and external forces at each joint. This option potentially generates a large volume of output.

Note: Since `PRINT STATIC LOAD` generates voluminous output, the printing of summation of internal and external forces at each joint is done for structures which have less than 1,000 joints. If the structure has 1,000 joints or more, this printing will be skipped.

Mode Shapes Prints mode shape values at the joints for all calculated mode shapes.

Both This option is equivalent to the **Load Data** plus **Statics Check** options.

All This option is equivalent to the **Load Data** plus **Statics Check**.

Related Links

- *G.17.2.1 P-Delta Analysis* (on page 2141)
- *A. To specify a P-Delta analysis* (on page 952)

Perform Cable Analysis tab

Used to assign the commands required to perform a non-linear cable analysis on the model. This requires the presence of non-linear cables in the structure.

Note:

Refer to TR.37.3 Nonlinear Cable Analysis (on page 2624) for additional information.

Refer to G.8.2 Cable Members (on page 2122) for an explanation of non-linear cable input options.

Advanced Cable Analysis group

The options in this group are used to specify the advanced cable analysis feature and options specific to that analysis type.

Advanced Cable Analysis
Set this option to specify an advanced cable analysis. Refer to G.17.2.8 Advanced Nonlinear Cable Analysis (on page 2150) for details on the Advanced Cable analysis.

> **Note:** Use of the Advanced Cable analysis feature requires the Advanced Analysis License. This option is the default if you have the license.

Use Modified Newton-Raphson
Set this option to use the modified Newton-Raphson method, which can reduce computation effort in compared to the full Newton-Raphson method (at the expense of more iterations).

Use Geometric Matrix (Kg)
Set this option to specify the use of geometric stiffness.

Cable Analysis Parameters group

Steps
Specify the number of load steps. The applied loads will be applied gradually in this many steps. Each step will be iterated to convergence. Should be in the range 5 to 145, with 145 as the recommended number.

Eq-Iterations
Maximum number of iterations permitted in each load step. Should be in the range of 10 to 500, with 300 as the recommended number.

Eq-tolerance
The convergence tolerance for the above iterations.

Sag Minimum
Cables (not trusses) may sag when tension is low. This is accounted for by reducing the E value. Sag minimum may be between 1.0 (no sag E reduction) and 0.0 (full sag E reduction). As soon as **Sag Minimum** becomes less than 0.95 the possibility exists that a converged solution will not be achieved without increasing the steps to 145 or the pretension loads. The **Eq-Iterations** may need to be 300 or more. The **Eq-tolerance** may need to be greater or smaller.

Stability Stiffness
Specify a stiffness matrix value that is added to the global matrix at each translational direction for joints connected to cables and nonlinear trusses for the first number of **Load Steps**. The amount added linearly decreases with each of the Load Steps. If a Stability Stiffness value is specified, it should be within the range of 0.0 to 1000.0. This parameter alters the stiffness of the structure.

Load Steps
The number of load steps over which the **Stability Stiffness** is gradually applied. Default is one step.

KSMALL
A stiffness matrix value that is added to the global matrix at each translational direction for joints connected to cables and nonlinear trusses for every load step. The range for KSMALL is between 0.0 and 1.0, with a default of 0.0. This parameter alters the stiffness of the structure.

Print Option

Standard STAAD.Pro analysis print options:

No Print
No analysis results will be printed to the output file.

Load Data
Prints all the load data.

Statics Check	Provides a summation of the applied loads and support reactions as well as a summation of moments of the loads and reactions taken around the origin.
Statics Load	Prints everything that **Statics Check** does, plus a summation of all internal and external forces at each joint. This option potentially generates a large volume of output. **Note:** Since `PRINT STATIC LOAD` generates voluminous output, the printing of summation of internal and external forces at each joint is done for structures which have less than 1,000 joints. If the structure has 1,000 joints or more, this printing will be skipped.
Mode Shapes	Prints mode shape values at the joints for all calculated mode shapes.
Both	This option is equivalent to the **Load Data** plus **Statics Check** options.
All	This option is equivalent to the **Load Data** plus **Statics Check**.

Related Links

- *A. To specify a nonlinear cable analysis* (on page 955)
- *A. To specify a nonlinear cable analysis* (on page 955)

Change tab

Used to add the Change command to the input command file.

Related Links

- *G.19 Multiple Analyses* (on page 2194)
- *A. To add a change command* (on page 958)

Perform Direct Analysis tab

Used to instruct STAAD.Pro to perform a direct analysis per AISC 360 Appendix 7.This method accounts for the second order effects resulting from deformation in the structure due to applied loading, imperfections and reduced bending stiffness of members due to the presence of axial load.

This is a non-linear iterative analysis as the stiffness of the members is dependent upon the forces generated by the load. The analysis will iterate, in each step changing the member characteristics until the maximum change in any τ_b is less than the **Tau** tolerance. If the maximum change in any τ_b is less than 100x the **Tau** tolerance *and* the maximum change in any displacement degree of freedom is less than the **Displacement** tolerance; then the solution has converged for this case.

This analysis method is to be used in conjunction with Direct Analysis definition command. The Define Direct command should be added prior to instructing the program to perform this type of analysis.

Additionally, a direct analysis typically requires the definition of Notional Load (on page 2864).

Note: Refer to TR.37.5 Direct Analysis (on page 2630) and AD.2007-03.2.2 Direct Analysis (on page 263) for additional information.

Option	Select if the design methodology is Load Resistance and Factor (LRFD) or Allowable Stress (ASD).

Tolerances	**Tau**	The limit to the change in the τ_b value in each iteration. If this value is exceeded by any member, then an additional iteration will be required unless the maximum number of iterations has been achieved
	Displacement	The limit to the change in the maximum displacement in each iteration. If this has been exceeded, then an additional iteration will be required unless the maximum number of iterations has been achieved.

No. of Iterations	Specify the maximum number of iterations.
PDelta Iterations	Select the number of iterations to be used for a PDelta with Small Delta analysis. Typically this should be from 5 to 25. The default number of 15 is recommended.
Reduced EI	Check this option to use the reduced EI (Tau-b × 0.8 ×EI) for member section moment & section displacement. Clear the check box to use the full EI value.
Perform Tau-b Iteration	Check this box to instruct the program to iterate Tau-b.
Print Option	Standard STAAD.Pro analysis print options:

No Print	No analysis results will be printed to the output file.
Load Data	Prints all the load data.
Statics Check	Provides a summation of the applied loads and support reactions as well as a summation of moments of the loads and reactions taken around the origin.
Statics Load	Prints everything that **Statics Check** does, plus a summation of all internal and external forces at each joint. This option potentially generates a large volume of output.

Note: Since `PRINT STATIC LOAD` generates voluminous output, the printing of summation of internal and external forces at each joint is done for structures which have less than 1,000 joints. If the structure has 1,000 joints or more, this printing will be skipped.

Mode Shapes	Prints mode shape values at the joints for all calculated mode shapes.
Both	This option is equivalent to the **Load Data** plus **Statics Check** options.
All	This option is equivalent to the **Load Data** plus **Statics Check**.

- *A. To specify a direct analysis* (on page 953)

Generate Floor Spectrum tab

Used to specify the calculation of floor and/or joint response spectrum when subjected to a time history loading. This information can be used in conjunction with equipment that will be supported by these floors and is often required by the equipment manufacturers.

Note: This feature requires STAAD.Pro V8i (release 20.07.04) or higher and an Advanced Analysis Package license.

The Floor Response Spectrum command must immediately follow an analysis command. That analysis can only contain a single time history load case. The Create Group dialog (on page 2950) used to define a floor must be defined prior to adding this command. Results from this analysis will be displayed in the **Floor Spectrum** table in the Postprocessing workflow.

Note: Refer to TR.37.10 Floor Spectrum Command (on page 2657) for additional information.

Floor Groups table	Each row constitutes one floor which can have one or more floor groups assigned. • **GX / GY / GZ -** Select the global direction options for which acceleration vs frequency spectrums will be generated for this floor. • **Title -** Provide an optional title for this floor. • **Node Groups -** Click the Selected Nodes to open a drop-down list of all previously defined node groups. The resulting response spectra will be based on the collective responses of all the nodes in the selected groups.
Lowest Frequency	Lowest frequency to be in the calculated spectrum. This value should be at least 0.01 Hz.
Highest Frequency	Highest frequency to be in the calculated spectrum.
Frequency Interval	The change in frequency values used for each interval calculation. The spectrum will be calculated at this interval from the **Lowest Frequency** to **Highest Frequency** specified.
Damping Ratios table	Up to ten damping values may be entered. One spectrum will be generated for each damping value for each global direction requested for each floor defined. The spectrum will be based on these modal damping ratios. Damping is specified as a fraction of one (that is, 3% damping should be entered as 0.03). The default is 0.05.
Relative Acceleration?	Select this option if there is ground motion defined and you want the spectrums to be based on the relative acceleration of the floor to the ground acceleration. Otherwise, absolute values are considered.
Print Time History Acceleration used?	Select this option to print the time history acceleration being used in each spectrum calculation.
Print Calculated Spectrum?	Select this option to print the calculated spectrum.

- *A. To generate a floor spectrum* (on page 959)

Nonlinear Analysis tab

Used to direct STAAD.Pro to perform a nonlinear analysis which can account for nonlinear effects of moderate displacement and small strain. This solution holds for where the element distortion is small and small rotations are assumed.

Note: This requires a STAAD.Pro Advanced license.

Refer to TR.37.8 Geometric Nonlinear Analysis (on page 2654) for additional information.

The first analysis step must be stable, otherwise use ARC control to prevent instability. The procedure does not use follower loads. Loads are evaluated at the joints before the first step; then those loads translate with the joint but do not rotate with the joint. Equilibrium is computed in the displaced position.

Nonlinear entities such as tension/compression members, multilinear springs, gaps, etc. are not supported when using a nonlinear analysis. Temperature loads are *not* supported for geometric nonlinear analysis. Additionally, nonlinear analysis does not account for post-buckling stiffness of members.

Note: The older `NONLINEAR nn ANALYSIS` command will adopt the new procedure unless a `SET` command is used. If a `SET` command is entered this will invoke the old procedure for backward compatibility.

The values for the Displacement Limit are used to limit analysis cycle to a specified displacement value and degree of freedom for a monitored node. When two or more **Load Steps** are specified, the calculated displacement or rotation is compared to the **Target Value** along or about the **DOF** for the specified **Node** each step. If the calculated displacement or rotation meets or exceeds the target value, then the analysis is stopped.

ARC
Specify a displacement control, which is the value of the absolute displacement limit for the first analysis step. If the maximum displacement is greater than this limit, ARC will calculate a new step size for the first step and a new value for **Load Step**. Value should be in current length units.

Note: ARC = 0 indicates no displacement control.

Iterations
Max. Number of iterations to achieve equilibrium in the deformed position to the tolerance specified.

Tolerance
For convergence, two successive iteration results must have all displacements the same within this tolerance. Value entered is in current units.

Load Steps
Specify the number of load steps to be used. Load is applied in stages if entered. One means that all of the load is applied in the first step.

Rebuild Steps
Frequency of rebuilds of the tangent K matrix per load step & iteration.

0 = once per load step
1 = every load step & iteration

Use KG
Select this option to add the geometric stiffness, KG, to the stiffness matrix, K.

Node
Enter a node number or click **[...]**. to enter the selected node to monitor during the geometric nonlinear analysis.

DOF
Select the degree of freedom to monitor during the analysis for specified **Node**.

Target Value
Specify a target displacement value along or about the selected **DOF** for the monitored **Node**.

Print Option
Standard STAAD.Pro analysis print options:

No Print
No analysis results will be printed to the output file.

Load Data
Prints all the load data.

Statics Check
Provides a summation of the applied loads and support reactions as well as a summation of moments of the loads and reactions taken around the origin.

Statics Load	Prints everything that **Statics Check** does, plus a summation of all internal and external forces at each joint. This option potentially generates a large volume of output. **Note:** Since `PRINT STATIC LOAD` generates voluminous output, the printing of summation of internal and external forces at each joint is done for structures which have less than 1,000 joints. If the structure has 1,000 joints or more, this printing will be skipped.
Mode Shapes	Prints mode shape values at the joints for all calculated mode shapes.
Both	This option is equivalent to the **Load Data** plus **Statics Check** options.
All	This option is equivalent to the **Load Data** plus **Statics Check**.

Perform Imperfection Analysis tab

Used to instruct STAAD.Pro to perform an imperfection analysis, which will reflect the secondary effects only if the camber and/or drift is specified in a using the Define Imperfection command. For combination of load cases, with imperfection, use the Repeat Load specification rather than the Load Combination.

Refer to sections TR.26.6 Member Imperfection Information (on page 2313) and TR.37.9 Imperfection Analysis (on page 2657) for additional details.

There are no other parameters associated with this command.

Print Option Standard STAAD.Pro analysis print options:

No Print	No analysis results will be printed to the output file.
Load Data	Prints all the load data.
Statics Check	Provides a summation of the applied loads and support reactions as well as a summation of moments of the loads and reactions taken around the origin.
Statics Load	Prints everything that **Statics Check** does, plus a summation of all internal and external forces at each joint. This option potentially generates a large volume of output. **Note:** Since `PRINT STATIC LOAD` generates voluminous output, the printing of summation of internal and external forces at each joint is done for structures which have less than 1,000 joints. If the structure has 1,000 joints or more, this printing will be skipped.
Mode Shapes	Prints mode shape values at the joints for all calculated mode shapes.
Both	This option is equivalent to the **Load Data** plus **Statics Check** options.
All	This option is equivalent to the **Load Data** plus **Statics Check**.

Perform Buckling Analysis tab

Used to instruct STAAD.Pro to perform a buckling analysis.

Refer to TR.37.4 Buckling Analysis (on page 2628) for additional information.

Iterative method: When this option is selected, the program will perform a P-Delta analysis including Kg Stiffening (geometric stiffness of members & plates) due to large & small P-Delta effects. If a non-singular stiffness matrix can be created, then buckling has not occurred. Then the load is increased from the last increment repeatedly until buckling does occur. Then the load is decreased halfway back to the prior increment. This bounds the buckling factor between the last 2 increments. Then STAAD.Pro proceeds to halve the interval until either the change between increments is 0.1% of each other, or the specified number of increments has been exceeded. The resulting factor is reported in the output file. The buckling deformed shape is simply the deformed shape from a static analysis with the near buckling load applied. This could appear more like a crushing, small displacement shape rather than a buckling mode shape. At least 15 iterations are recommended. Buckling will be applied to all primary cases.

- **Number of Iterations**: Maximum number of iterations. Fifteen is recommended.

  Note: This parameter is only used for the iterative method. It is ignored for the eigen method.

Eigen method: This buckling method may only be used if an Advanced Analysis license is available. When using the Advanced Solver, the corresponding “buckling modes” are included in the output file.

Print Option: Standard STAAD.Pro analysis print options:

- **No Print**: No analysis results will be printed to the output file.
- **Load Data**: Prints all the load data.
- **Statics Check**: Provides a summation of the applied loads and support reactions as well as a summation of moments of the loads and reactions taken around the origin.
- **Statics Load**: Prints everything that **Statics Check** does, plus a summation of all internal and external forces at each joint. This option potentially generates a large volume of output.

  Note: Since `PRINT STATIC LOAD` generates voluminous output, the printing of summation of internal and external forces at each joint is done for structures which have less than 1,000 joints. If the structure has 1,000 joints or more, this printing will be skipped.

- **Mode Shapes**: Prints mode shape values at the joints for all calculated mode shapes.
- **Both**: This option is equivalent to the **Load Data** plus **Statics Check** options.
- **All**: This option is equivalent to the **Load Data** plus **Statics Check**.

Analysis/Print Commands dialog (Pre Print)

Used to define the pre-analysis print commands to be included in the Input Command File. Commands are indicated by their respective tab.

Opens when:

- The **Pre Analysis Commands** tool is selected from the **Analysis Data** group on the **Analysis and Design** ribbon tab, or
- **Define Commands** is clicked on the **Pre Analysis Print** dialog

Problem Statistics tab

This command was previously used to include structure information such as total number of joints, members, supports, disk space requirements, the estimated band-width of the stiffness matrix, etc.

Note: This command has been deprecated and will be ignored by the engine during analysis.

Joint Coordinates tab

Used to add the joint coordinate values.

Member Information tab

Used to add member length, member incidences, beta angles, and member specifications such as truss member, and the member release conditions at start and end of the member (i.e., 1 = released, 0 = not released).

Material Properties tab

Used to add material properties for the members, including E (modulus of elasticity), G (shear modulus), weight density and coefficient of thermal expansion (alpha) for frame members.

Note: This command is available for members only.

Support Information tab

Used to add information regarding restraints, releases and spring constant values of the supports and the joint numbers where they are located.

All tab

Used to print joint coordinates, member information, member properties, material properties, and support information, in that order.

Element Information tab

Used to add element incidences, element thickness, and Poisson ratios for plate elements.

Solid Information tab

Used to add element incidences and Poisson ratios for solid elements.

Member Properties tab

Used to add member properties including cross sectional area, moments of inertia, and section moduli in both axes.

After current	Select this option to add the pre analysis print statement being defined in the Command Tree after the currently selected (highlighted) command.

Add	Assigns the selected print command to the input command file.
Assign	Used to assign the command to the current selection set.
Cancel	Closes the dialog.
Help	Opens the STAAD.Pro help window.

Related Links

- *A. To specify pre-analysis commands* (on page 960)

Analysis/Print Commands dialog (Post Print)

Used to define the post-analysis print commands to be included in the Input Command File. Commands are indicated by their respective tab.

Opens when:

Load List tab

Used to select the Load Cases to be included in the output.

Load Cases list	All load cases and combinations in the input file are listed here.
Selection tools	
Load List	Contains all the selected load cases which will be included in the output.

Section tab

Used to specify up to five sections along the length of frame members where forces and moment results are desired.

Joint Displacement tab

Used to print joint displacements in a tabulated form. The displacements for all six degrees of freedom will be printed for all specified joints for all specified load cases.

Member Forces tab

Used to print member forces (i.e. axial force (AXIAL), shear force in local Y and Z axes (SHEAR-Y and SHEAR-Z), torsional moment (TORSION), moments about local Y and Z axes (MOM-Y and MOM-Z) in a tabulated form for all specified members for all specified load cases.

Global Selection this option to display the member forces in terms of the Global axis. Otherwise, member forces are presented in local member axis.

Support Reactions tab

Used to print support reactions in a tabulated form for all specified supports for all specified load cases.

Story Drift tab

Used to obtain a print-out of the average lateral displacement of all joints at each vertical level of the structure.

Cg tab

Prints the coordinates of the center of gravity of the structure.

Surface Forces tab

Physical Member Forces tab

Used to print produce member forces for all the analytical members in the physical member (PMEMBER) group

Buckling Shapes tab

Used to print the buckling shape for a Buckling Analysis.

Dia CR tab

Used to print the center of rigidity and center of mass for each rigid floor diaphragm in the model, which are used to determine the natural torsion moment for seismic loads which use that option.

Cable Sag

Used to include the sagging deflected shape of cable members for an Advanced Cable Analysis.

The output of a successful advanced cable analysis will report the cable sag in local XYZ coordinates. Post-analysis print will calculate the actual, nonlinear cable displacements along the length of cable.

Mode Shapes tab

Used to print mode shape values at every joint for all calculated modes.

Element Stress Solid tab

Used to print stresses at the center of solid elements for all specified solids for all specified load cases.

Print Element Stresses	Select this option to print center stresses.
Print Element Joint Stresses	Select this option to print stresses at the corner nodes.

Section Displacement tab

Used to calculate and print section displacements at sections (intermediate points) of frame members.

Number of Sections	Number of intermediate sections at which results are to be reported.
Options	The *Maximum* option prints only the maximum local displacements from among all load cases. The *Save* option saves the section displacements to a file for future reference. The *No Print* option does not print the section displacements to the .ANL file and should be used in conjunction with the *Save* option.
Assign	Select if the command is to be assigned to all members in the current view or to a selection of members. **Note:** Selection must be made prior to selecting the menu command item.

Force tab

Used to print force/moment envelopes for frame members for the specified *Number of Sections*. It prints the maximum and minimum values for every section for each specified load case.

Number of Sections	Specify the number of equally-spaced sections to be considered.

Max Force tab

Used to print force/moment envelopes for frame members for the specified *Number of Sections*. It prints the maximum and minimum values of all sections from among the specified load cases.

Number of Sections	Specify the number of equally-spaced sections to be considered.

Analysis Results tab

Used to print Joint Displacements, Support Reactions, and Member Forces for all specified joints/members for all specified load cases. A message dialog will open to confirm you wish to add the Analysis Results command.

Member Section Forces tab

Member Stresses tab

Used to print member stresses at the start and end joints and at all specified intermediate sections of selected members. These stresses include axial, (axial force over area), bending-y (moment-y over section modulus in local y-axis), bending-z (moment-z over section modulus in local z-axis), shear stress in both local y and z directions and combined (absolute combination of axial, bending-y and bending-z) stresses.

Element Forces/Stresses tab

Used to print stresses (FX, FY, FXY, QX, QY), moments per unit width (MX, MY, MXY) and principal stresses (SMAX, SMIN, TMAX) at the centroid of plate elements. The Von Mises stresses (VONT, VONB) as well as the angle (ANGLE) defining the orientation of the principal planes are also printed.

Selecting the Print Nodal Point Forces & Moments checkbox will also print stresses and moments at the corner nodes. The Print Force at Point option can be used to print element forces at any point within the element.

Note: For further information, please refer to G.5.1 Plate and Shell Elements (on page 2099) and TR.41 Section Specification (on page 2665) .

After current	Select this option to add the pre analysis print statement being defined in the Command Tree after the currently selected (highlighted) command.
Add	Assigns the selected print command to the input command file.
Assign	Used to assign the command to the current selection set.
Cancel	Closes the dialog.
Help	Opens the STAAD.Pro help window.

Floor Diaphragm Options dialog

Used to select a code by which the seismic code checks should be performed.

Opens when the **Miscellaneous Commands** > **Floor Diaphragm Options** tool is selected in the **Analysis Data** group on the **Analysis and Design** ribbon tab.

Design Code	Select one of the following codes: • **IS1893 2002** • **ASCE7 05/10/16** • **IS1893 2016**
Check Soft Story	Check this option to check for soft story (vertical irregularities) between two adjacent diaphragms.
Check Irregularities	(inactive for IS1893 2002) Check this option to check for plan as described in TR.28.2.2 Check Irregularities (on page 2333).

- For IS1893 2016, this will check for torsion irregularities, reentrant corner irregularities, mass irregularities, and irregular modes of oscillation (when zone 4 or 5 have been selected in the static seismic definition).
- For ASCE7 05/10/16, this will check for torsion irregularities, reentrant corners, and mass irregularities.

Base Level If the base level of the structure is not at the minimum global Y value of the entire model, then check this option and type the value in the current length units.

No of Diaphragms Displays the number of diaphragms in the model. This is field is for information only and cannot be edited from this dialog.

Load List dialog

Used to specify a list of existing load cases and load combination cases to be used for subsequent processes, like design, print, plot etc.

Opens when the **Load List** tool is selected from the **Analysis Data** group on the **Analysis and Design** ribbon tab.

Load Cases list All existing load cases including combination load cases are listed in the left hand side list box. These load cases can be selected and transferred to the right hand side **Load list**.

List Operators

Click this button…	to…
>	Add the selected primary load case to the Load list
>>	Add all primary load cases to the Load list.
<<	Remove all entries in the Selected Load Combinations list, load combination is placed in the Load Cases list.
<	Remove the selected entry from the Selected Load Combinations list.

Load list This list box contains the list of selected load cases to be included in the load group.

Related Links

STAAD Analysis and Design dialog

This dialog box displays the status of the analysis process.

If an error occurs during the analysis, the above dialog box displays the error message.

> For example, if you are running a demonstration version, or the hardware lock is not found, you may encounter an error message like the following:
>
> ```
> DEMO VERSION: Analysis Limited to 6 members.
> ```

The following options allow you to control what happens when you click **Done**.

- **View Output File** – opens the STAAD Output Viewer with the analysis results presented in a textual format.
- **Go to Post Processing Mode** – opens the STAAD.Pro Postprocessor workflow where you can graphically view results.
- **Stay in Modeling Mode** – closes the dialog while staying in the Analytical Modeling workflow.

Steel Design - Whole Structure dialog

Used to select a steel design code, select parameters to use for design, and assign parameters to the model.

Opens when the **Design** > **Steel Design** tool is selected from the **Design** group on the **Analysis and Design** ribbon tab.

Note: For additional information on steel design codes available in STAAD.Pro, refer to D. Available Steel Design Codes (on page 969). The D. Design Codes (on page 1086) section contains detailed descriptions of the design parameters used for each code.

Current Code	Select the code to use for design from the drop-down list.
Command Tree	Displays a summary of all input file commands. Each command is represented with that commands parameters as child elements. Click the [+] icon to expand the command to display parameters. • Green Check ( ) marks: Commands which can be re-specified or modified. • Gray Check ( ) marks: Commands which may not be changed. • Question ( ) marks: Commands which have been added but not assigned to any structural element (joint/member/element).

Highlight Assigned Geometry	Select this option to have model objects highlighted in the View Window as commands are selected in the **Command Tree**
Toggle Assign	Select this option to use the toggle mode. In this mode, when an attribute is selected and assigned using the "Use Cursor to assign" method, the following happens. • Click on the member or element once - the attribute gets assigned. • Click on the same member or element a second time - the attribute gets de-assigned. • Click on the same member or element again, - the attribute gets re-assigned. Thus each click will result in an assign if the attribute was un-assigned, and a de-assign if the attribute was assigned.
Select Parameters...	Opens the Parameters Selection dialog (on page 2934), which is used to select the parameters included in the STAAD.Pro input file for design
Define Parameters...	Opens the Design Parameters dialog (on page 2934) for the selected code, which is used define design parameters and add them to the input file
Commands...	Opens the Design Commands dialog (on page 2935), which is used to add design commands for the selected design code to the input file.
Assignment Method	Select the method for command/parameter assignment. • Assign to Selected <objects> - Available once objects are selected in the View window. Used to assign a Design option to selected joints, members or elements, first select the command from the **Command Tree**. Note that the label for this button changes depending on whether nodes, members or elements are selected. • Assign to View - Assigns the selected parameter all objects in the active View window. Only objects to which the parameter is relevant will receive the parameter (e.g., steel member design parameters are only assigned to beams). • Use Cursor To Assign - Use the mouse pointer to assign the parameter to model objects. Once selected, click the Assign button to activate this mode and click again to deactivate. The **Toggle Assign** option can also be used to aid in this mode. • Assign To Edit List - Used to assign with a typed list of object numbers, first select the material tag from the Materials dialog box. The selected material is highlighted. Select the Assign To Edit List radio button, then type the list of member or element numbers and click the Assign button. • Select Group/Deck - (Steel Design only) Active if either a group or deck has been defined in the input file and an appropriate parameter is selected. Opens the Select Group / Deck (on page 2936), which is used to select the group for assignment. Once an assignment method has been selected, the
Assign	Used to assign the selected parameter to the selected objects.
Close	Closes the dialog.
Help	Opens the STAAD.Pro help window.

Parameters Selection dialog

Used to select the parameters included in the **Design Parameters** dialog.

Opens when **Select Parameters** is clicked on a **<material> Design - Whole Structure** dialog.

Available Parameters — Lists all available parameters for the current design code.

Selected Parameters — Parameters added to this list will be made available for use for the current design code in the Define Parameters... dialog.

> **Note:** By default, all parameters are added to the list.

Click this button...	to...
>	Include the selected design parameter in the Selected Parameters list.
>>	Include all design parameters in the Selected Parameters list.
<<	Remove all design parameters from the Selected Parameters list.
<	Remove the selected design parameter from the Selected Parameters list.

OK — Updates the Parameters list in the Design Parameters dialog (on page 2934) and closes the Parameter Selection dialog.

Cancel — Closes the dialog without updating changing the selected parameters.

Help — Opens the STAAD.Pro help window.

Design Parameters dialog

Used to define design parameters for the current design code and add them to the input file.

Opens when **Define Parameters** is clicked on a **<material> Design - Whole Structure** dialog.

Parameter list — All parameters available for the current design code are displayed here.

> **Note:** For details on each design code parameters, refer to D. Design Codes (on page 1086).

After Current — Select this option to have the new design parameter inserted after the currently selected in the Design dialog explorer list.

Add	Adds the selected design parameter to the current code in the input file. The design parameter must then be assigned to model objects.
Assign	Active if appropriate model objects were selected prior to clicking **Define Parameter**. Adds the design parameter to the input file and assigns the design parameter to the selected objects.
Close	Closes the dialog.
Help	Opens the STAAD.Pro help window.

Select Group / Deck

Used to select the group for assignment of commands.

Opens when **Select Group/Deck** is clicked in a **<material> Design - Whole Structure** dialog.

List	Lists all previously defined groups and composite decks in the input file, organized by type.
OK	Assigns the parameter selected in the Design dialog list to the selected group or deck.
Cancel	Closes the dialog without making any assignments.

Concrete Design - Whole Structure dialog

Used to select a concrete design code, select parameters to use for design, and assign parameters to the model.

Opens when the **Design** > **Concrete Design** tool is selected from the **Design** group on the **Analysis and Design** ribbon tab.

Note: For additional information on concrete design codes available in STAAD.Pro, refer to D. Available Concrete Design Codes (on page 1067). The D. Design Codes (on page 1086) section contains detailed descriptions of the design parameters used for each code.

Current Code

Select the code to use for design from the drop-down list.

Command Tree

Displays a summary of all input file commands. Each command is represented with that commands parameters as child elements. Click the [+] icon to expand the command to display parameters.

- Green Check ( ) marks: Commands which can be re-specified or modified.
- Gray Check ( ) marks: Commands which may not be changed.
- Question ( ) marks: Commands which have been added but not assigned to any structural element (joint/member/element).

Highlight Assigned Geometry

Select this option to have model objects highlighted in the View Window as commands are selected in the **Command Tree**

Toggle Assign

Select this option to use the toggle mode. In this mode, when an attribute is selected and assigned using the "Use Cursor to assign" method, the following happens.

- Click on the member or element once - the attribute gets assigned.
- Click on the same member or element a second time - the attribute gets de-assigned.
- Click on the same member or element again, - the attribute gets re-assigned.

Thus each click will result in an assign if the attribute was un-assigned, and a de-assign if the attribute was assigned.

Select Parameters...

Opens the Parameters Selection dialog (on page 2934), which is used to select the parameters included in the STAAD.Pro input file for design

Define Parameters...	Opens the Design Parameters dialog (on page 2934) for the selected code, which is used define design parameters and add them to the input file
Commands...	Opens the Design Commands dialog (on page 2935), which is used to add design commands for the selected design code to the input file.
Assignment Method	Select the method for command/parameter assignment. • Assign to Selected <objects> - Available once objects are selected in the View window. Used to assign a Design option to selected joints, members or elements, first select the command from the **Command Tree**. Note that the label for this button changes depending on whether nodes, members or elements are selected. • Assign to View - Assigns the selected parameter all objects in the active View window. Only objects to which the parameter is relevant will receive the parameter (e.g., steel member design parameters are only assigned to beams). • Use Cursor To Assign - Use the mouse pointer to assign the parameter to model objects. Once selected, click the Assign button to activate this mode and click again to deactivate. The **Toggle Assign** option can also be used to aid in this mode. • Assign To Edit List - Used to assign with a typed list of object numbers, first select the material tag from the Materials dialog box. The selected material is highlighted. Select the Assign To Edit List radio button, then type the list of member or element numbers and click the Assign button. • Select Group/Deck - (Steel Design only) Active if either a group or deck has been defined in the input file and an appropriate parameter is selected. Opens the Select Group / Deck (on page 2936), which is used to select the group for assignment. Once an assignment method has been selected, the
Assign	Used to assign the selected parameter to the selected objects.
Close	Closes the dialog.
Help	Opens the STAAD.Pro help window.

Aluminum Design - Whole Structure dialog

Used to select an aluminum design code, select parameters to use for design, and assign parameters to the model.

Opens when the **Design** > **Aluminum Design** tool is selected from the **Design** group on the **Analysis and Design** ribbon tab.

Note: For additional information on aluminum design codes available in STAAD.Pro, refer to D. Available Aluminum Design Codes (on page 1081). The D. Design Codes (on page 1086) section contains detailed descriptions of the design parameters used for each code.

Current Code	Select the code to use for design from the drop-down list.

Command Tree

Displays a summary of all input file commands. Each command is represented with that commands parameters as child elements. Click the [+] icon to expand the command to display parameters.

- Green Check ( ) marks: Commands which can be re-specified or modified.
- Gray Check ( ) marks: Commands which may not be changed.
- Question ( ) marks: Commands which have been added but not assigned to any structural element (joint/member/element).

Highlight Assigned Geometry

Select this option to have model objects highlighted in the View Window as commands are selected in the **Command Tree**

Toggle Assign

Select this option to use the toggle mode. In this mode, when an attribute is selected and assigned using the "Use Cursor to assign" method, the following happens.

- Click on the member or element once - the attribute gets assigned.
- Click on the same member or element a second time - the attribute gets de-assigned.
- Click on the same member or element again, - the attribute gets re-assigned.

Thus each click will result in an assign if the attribute was un-assigned, and a de-assign if the attribute was assigned.

Select Parameters...

Opens the Parameters Selection dialog (on page 2934), which is used to select the parameters included in the STAAD.Pro input file for design

Define Parameters...

Opens the Design Parameters dialog (on page 2934) for the selected code, which is used define design parameters and add them to the input file

Commands...

Opens the Design Commands dialog (on page 2935), which is used to add design commands for the selected design code to the input file.

Assignment Method

Select the method for command/parameter assignment.

- Assign to Selected <objects> - Available once objects are selected in the View window. Used to assign a Design option to selected joints, members or elements, first select the command from the **Command Tree**. Note that the label for this button changes depending on whether nodes, members or elements are selected.
- Assign to View - Assigns the selected parameter all objects in the active View window. Only objects to which the parameter is relevant will receive the parameter (e.g., steel member design parameters are only assigned to beams).
- Use Cursor To Assign - Use the mouse pointer to assign the parameter to model objects. Once selected, click the Assign button to activate this mode and click again to deactivate. The **Toggle Assign** option can also be used to aid in this mode.
- Assign To Edit List - Used to assign with a typed list of object numbers, first select the material tag from the Materials dialog box. The selected material is highlighted. Select the Assign To Edit List radio button, then type the list of member or element numbers and click the Assign button.
- Select Group/Deck - (Steel Design only) Active if either a group or deck has been defined in the input file and an appropriate parameter is selected. Opens the Select Group / Deck (on page 2936), which is used to select the group for assignment.

Once an assignment method has been selected, the

Assign	Used to assign the selected parameter to the selected objects.
Close	Closes the dialog.
Help	Opens the STAAD.Pro help window.

Timber Design - Whole Structure dialog

Used to select a timber design code, select parameters to use for design, and assign parameters to the model.

Opens when the **Design** > **Timber Design** tool is selected from the **Design** group on the **Analysis and Design** ribbon tab.

Note: For additional information on timber design codes available in STAAD.Pro, refer to D. Available Timber Design Codes (on page 1084). The D. Design Codes (on page 1086) section contains detailed descriptions of the design parameters used for each code.

Current Code

Select the code to use for design from the drop-down list.

Command Tree

Displays a summary of all input file commands. Each command is represented with that commands parameters as child elements. Click the [+] icon to expand the command to display parameters.

- Green Check ( ) marks: Commands which can be re-specified or modified.
- Gray Check ( ) marks: Commands which may not be changed.
- Question ( ) marks: Commands which have been added but not assigned to any structural element (joint/member/element).

Highlight Assigned Geometry

Select this option to have model objects highlighted in the View Window as commands are selected in the **Command Tree**

Toggle Assign

Select this option to use the toggle mode. In this mode, when an attribute is selected and assigned using the "Use Cursor to assign" method, the following happens.

- Click on the member or element once - the attribute gets assigned.
- Click on the same member or element a second time - the attribute gets de-assigned.
- Click on the same member or element again, - the attribute gets re-assigned.

Thus each click will result in an assign if the attribute was un-assigned, and a de-assign if the attribute was assigned.

Select Parameters...

Opens the Parameters Selection dialog (on page 2934), which is used to select the parameters included in the STAAD.Pro input file for design

Define Parameters...

Opens the Design Parameters dialog (on page 2934) for the selected code, which is used define design parameters and add them to the input file

Commands...	Opens the Design Commands dialog (on page 2935), which is used to add design commands for the selected design code to the input file.
Assignment Method	Select the method for command/parameter assignment. • Assign to Selected <objects> - Available once objects are selected in the View window. Used to assign a Design option to selected joints, members or elements, first select the command from the **Command Tree**. Note that the label for this button changes depending on whether nodes, members or elements are selected. • Assign to View - Assigns the selected parameter all objects in the active View window. Only objects to which the parameter is relevant will receive the parameter (e.g., steel member design parameters are only assigned to beams). • Use Cursor To Assign - Use the mouse pointer to assign the parameter to model objects. Once selected, click the Assign button to activate this mode and click again to deactivate. The **Toggle Assign** option can also be used to aid in this mode. • Assign To Edit List - Used to assign with a typed list of object numbers, first select the material tag from the Materials dialog box. The selected material is highlighted. Select the Assign To Edit List radio button, then type the list of member or element numbers and click the Assign button. • Select Group/Deck - (Steel Design only) Active if either a group or deck has been defined in the input file and an appropriate parameter is selected. Opens the Select Group / Deck (on page 2936), which is used to select the group for assignment. Once an assignment method has been selected, the
Assign	Used to assign the selected parameter to the selected objects.
Close	Closes the dialog.
Help	Opens the STAAD.Pro help window.

Utilities tab

Table 331: Geometry Tools group

Tool Name		Description
 **Structure Tools >**	**Multiple Structures**	Opens the **List of Structures** dialog, which is used to determine if the current model consists of more than one unconnected structure. Select a Structure in the list to see each structure highlighted.

Tool Name		Description
	Beam Plate Connectivity	Used to check for plates that are improperly connected to beams. Beams must be connected to plates at their nodes in order to ensure proper coupling and load transfer. This tool will inform the user if any improper connections are present in the model.
	Merge Properties	Used to merge the properties of two or more similar objects. When a STAAD input file has a number of references of the same property, this tool can be used to consolidate all these properties into a single command. When a STAAD file has a number of references of the same property, there is now a tool to consolidate all these properties into a single command. Clicking the Yes button, all instances of a given section property will be collated into a single property reference. **Note:** Properties references with differing additional parameters will not be collated. Properties references with differing assigned material properties will not be collated.
	Cut Section	Opens the **Section** dialog, which is used to cut a section through the structure along a specified global plane at a desired location of the 3rd axis.
Node Tools >	**Duplicate Nodes**	Opens the **Remove Duplicate Nodes** dialog, which is used to set the tolerance distance between two nodes the program should consider as duplicate. Used for detecting the presence of two or more instances of the same node.
	Orphan Nodes	Highlights all nodes in the structure which are not connected to any member, element, or solid.
	Remove Orphan Nodes	Used to remove all detected orphan nodes.
	Node to Node Distance	Display the distance between nodes.
	Remove Node to Node Distance	Used to remove the display of all node to node dimensions from the current view.
Beam Tools >	**Duplicate Beams**	Opens the **Remove Duplicate Beams** dialog, which is used to set the tolerance distance between two beams the program should consider as duplicate. Used for detecting the presence of two or more instances of the same beam.

Tool Name		Description
	Zero Length	Opens the **Zero Length Tolerance** dialog, which is used to set the tolerance for zero length members. A member connected between duplicate nodes, which have the same (X,Y,Z) coordinates, will have a length of zero. This tool detects such members.
	Overlapping Collinear Members	When two members are collinear, and further, at least one of the nodes of one of those members happens to lie within the span of the other, but the two members are not connected at that node, those two members are considered as overlapping collinear members. This tool detects such members. The usefulness of this tool comes from the fact that it enables you to detect modeling errors which are not easily visible. Two lines overlapping on the drawing area become indistinguishable on large models, and this is one of the tools that can spot such errors.
	Beam Incidence	Used to reverse the incidence of selected beams so that the global coordinates of the end node are farther from the origin than that of the start node.
	Dimension Beams	Display the dimension of the members in the structure.
 **Plate Tools >**	**Duplicate Plates**	Opens the **Remove Duplicate Plates** dialog, which is used to set the tolerance distance between two plates the program should consider as duplicate. Used for detecting the presence of two or more instances of the same plate.
	Warped Plates	A warped plate is defined as a four-noded plate whose nodes do not lie on the same plane. This tool detects such plates.
	Plate Connectivity	Checks the model for plates that overlap or intersect each other at their boundaries and, if found, opens the Overlapping Collinear Plates dialog. Typically, these overlaps cause improper load transfers or instabilities in the model.
 **Solid Tools >**	**Negative Volume**	Used to verify that the solid elements in their model have the proper sequence (order) of node numbering to prevent warnings in the output file of solids containing negative volumes.
	Warped Solids	Used to check if a solid element is warped. Warped solids cannot be analyzed and will produce errors in the output file.

Tool Name	Description
Physical Member Restraints	Used to automatically generate top and bottom flange restraint conditions for the selected physical members. **Note:** The PBRACE command generated by this menu item is valid only for D2.B.12 Physical Member Design (on page 1372) per AS 4100-1998 (Australian) steel design. When selected, the program will search through all the nodes along the Physical Member and determine if any other beam is connected besides the beams in the current physical member definition. If another beam is present, a full restraint is placed on both the flanges. Otherwise, an unrestrained condition is imposed on both the flanges.
Groups	Opens the **Create Group** dialog, which is used to cluster a set of joints, beams, plates or solids into a single entity identified by a distinct name. **Note:** If no groups exist, you will be prompted to create a group using the **Define Group Name** dialog.

Table 332: Physical Model group

Tool name	Description
Drop Physical Model	For models that have a linked physical model, this will open a confirmation dialog asking if you want to remove that link. Removing this link will enable the model to be edited using all analytical modeling tools as well as remove the disabled sections of the input file in the STAAD.Pro Editor.

Table 333: Query group

Tool Name		Description
Query >	**Beams**	Used to view detailed information for one beam at a time in a dialog.
	Physical Members	Used to view detailed information for one physical member at a time in a dialog.
	Plates	Used to view detailed information for one plate at a time in a dialog.
	Solids	Used to view detailed information for one solid at a time in a dialog.

Tool Name		Description
	Nodes	Used to view detailed information for one node at a time in a dialog.

Table 334: Display group

Tool name	Description
 **Insert Text**	Opens the **Write Text to Insert** dialog, which is used to add custom text to the View window (and, subsequently to pictures you take of the window).

Table 335: Edit group

Tool Name	Description
 **Command File**	Opens the current input command file (file extension `.std`.) in the STAAD.Pro Editor. If any change has been made in the structure that has not been saved, you are prompted to save the structure first. **Note:** Refer to I. STAAD.Pro Editor (on page 2043) for additional assistance.

Table 336: View group

Tool Name	Description
 **Analysis Output**	Opens the results of a successful Analysis and Design run in the STAAD.Pro Editor window.
 **Analysis Log**	Opens the analysis and design results file (file extension `.anl`) in the STAAD.Pro Editor.

Tool Name	Description
Error Log	If analysis errors occurred, this tool is active. Click to open the error log in the STAAD.Pro Editor.

Table 337: Tools group

Tool Name		Description
Connection Tags >	**Load Connection Tag File**	
	Edit Connection Tag File	
	View Connection Tags	Opens the **Assign Connection Tags** dialog.
	Check Connection Tags	(Active only after a successful analysis has been performed) Opens the **Assign Connection Tags** dialog and **Check Connection Tags** dialog, the latter of which is used to check the load case results from the analysis against the defined connection capacities in the Connection Tags XML data file.
Calculator		Opens the **STAAD.Pro Calculator** window, which is capable of performing mathematical operations.
Unit Converter		Opens the **STAAD.Pro Converter** window, which is used to convert data from one unit system to another.
Take Picture		Used to take a snapshot image of current view. The picture is automatically added to a picture album. **Tip:** The picture is stored in a STAAD-native format and can be subsequently included in custom reports during Report Setup. The Copy Picture and Export View tools may be used to copy a model image or to save it to a common file format.

Tool Name	Description
Copy Picture	Used to copy the current picture to the clipboard for pasting in other Windows applications such as image editors, spreadsheet applications, or word processors,.
 **AVI File**	Opens the **Create AVI File** dialog, which is used to create a video file recording of for animated deflection, section displacement, mode shape, and plate stress contour diagrams.

Table 338: Developer group

Tool name	Description
 **Macro Editor**	Opens the **STAAD.Pro Script Editor** window, which is used to write macros.
 **Macros**	Opens the Macro dialog, which is used to create, manage, and run Visual Basic Script macros in STAAD.Pro.

Table 339: User Tools group

Tool Name		Description
 **Configure**		Opens the Customize User Defined Tools dialog (on page 2957), which is used for running a macro utilizing OpenSTAAD functions. For additional information, refer to the OpenSTAAD (on page 7000).
 **User Tools**	**Export Model to AutoPIPE**	Opens the **Export STAAD Model to AutoPipe** dialog. Refer to M. To export STAAD.Pro model data into AutoPIPE (on page 907) for information on using this macro.
	AIJ Route 2 Utility	Opens the **AIJ Route 2 Design Tool** which is custom tool for use with the Japanese design code.

Tool Name		Description
	List Object GUIDs	Generates a custom table with tabs containing the unique IDs for each node, member, and physical member in the model.
	CIS/2 Object Update Report Tool	Opens the **Report Option** dialog, which is used to select the CIS/2 object report type to generate.
	Export Model to SACS	Opens the **Export STAAD Model to SACS** dialog. Refer to I. To export to a SACS input file (on page 2081) for information on using this macro.
	Euro Code Load Combination Generator	Opens the **Eurocode Combination Generator** dialog. Refer to M. To generate load combinations per Eurocode (on page 890) for information on using this macro.
	Add Material	Opens the **Add Materials** dialog, which is used to add standard material definitions to your model. Refer to M. To add a predefined material (on page 795) for details on using this macro.
	Additional user tools	Any user tools you have added will also appear in this list.

Improper Connectivity dialog

Used to the model for plates that are improperly connected to beams. Beams must be connected to plates at their nodes in order to ensure proper coupling and load transfer. This tool will inform the user if any improper connections are present in the model.

If there are improper connections between beams and plates (not connected by their nodes), a dialog box displaying a list of the plates and the beams intersecting them (but not connected at the node) will be shown.

Opens when the **Structure Tools** > **Check Beam Plate Connectivity** tool is selected in the **Geometry Tools** group on the **Utilities** ribbon tab.

Overlapped Entities list	A list overlapping entities is displayed. Select one to highlight in the active view window by the selected option.

Highlight options	The first option (Highlight-Both) will highlight both of selected entities listed while the last two options will highlight either beam .
Close	Closes the dialog.

Example

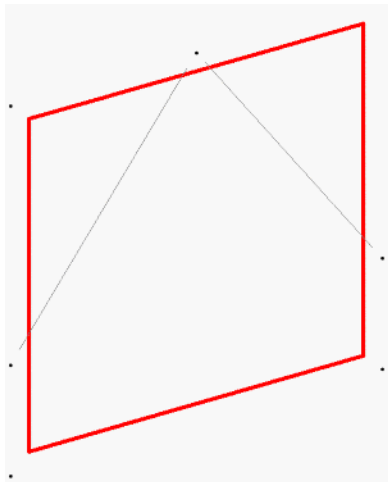

Figure 350: An example of improper beam to plate connectivity

List of Duplicate Nodes / Beams / Plates dialog

Used to detect the presence of two or more instances of the same beam or plate, depending on the ribbon tool selected.

Opens when either:

- **Node Tools** > **Duplicate Nodes** is selected from the Geometry Tools group on the **Utilities ribbon** tab,
- **Beam Tools** > **Duplicate Beams** is selected from the Geometry Tools group on the **Utilities ribbon** tab,
- **Plate Tools** > **Duplicate Plates** is selected from the Geometry Tools group on the **Utilities ribbon** tab.

If any duplicates of the selected object type are detected (that is, beams that share common end nodes or plates that share all common vertices), then a list of the duplicate beam or plate pairs is displayed.

Retain	When a pair is selected, click **Retain.** You are then prompted to select which member or plate number to retain.
Remove All Duplicates	Click to remove all duplicate items in the model. You are prompted to confirm you want to remove the second and additional items listed from the model. Click **OK.**
Show Node Coordinates	(Nodes only) Click to display a list of nodal coordinates for the duplicate nodes.

Related Links

- *M. To check for and remove duplicate entities* (on page 914)

Overlapping Plates dialog

Used to determine if two or more plates have intersecting boundaries not attached at nodes or otherwise overlap in the same plane.

An overlapping plate is defined as a plate whose nodes intersect other plates at points other than the defined nodes. This entails plates whose boundaries with adjacent plates are not attached at the nodes or plates within other plates (in the same plane). However, if two elements are such that the plane of one element is at an inclination to the plane of the other, and none of the nodes of one element lie on the plane of the other, those cannot be detected.

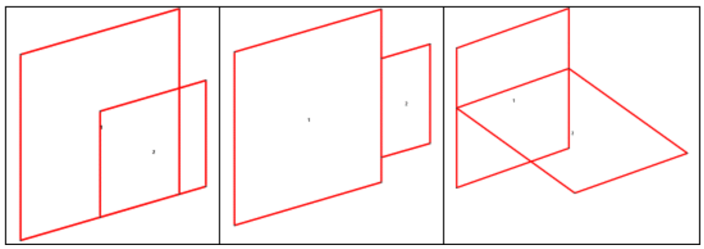

Figure 351: Examples of overlapping plates

Tip: Typically, a more refined meshing of the overlapping elements is required to eliminate the above problem.

Overlapped Entities list	A list overlapping plate pairs is displayed. Select one to highlight in the active view window by the selected option.
Highlight options	The first option (Highlight-Both) will highlight both of the plates listed while the last two options will highlight each individual plate separately.

Display/Remove Dimensions dialog

Used to display dimensions of beams in the view.

Opens when the **Beam Tools** > **Dimension Beams** tool is selected in the **Geomtry Tools** group on the **Utilities** ribbon tab.

Dimensions can be displayed or removed from the entire structure, selected beams, or a list of beam numbers.

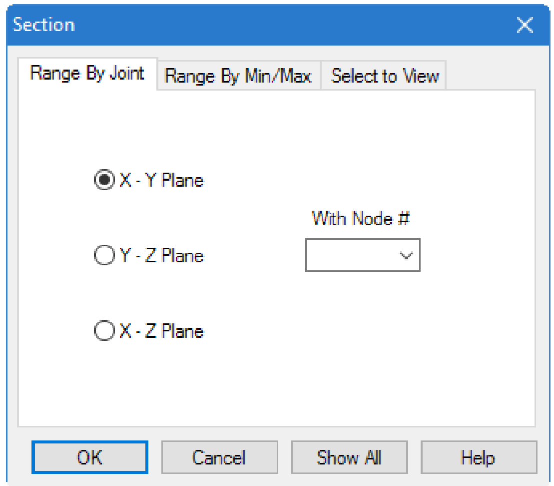
Related Links

- *M. To display beam lengths* (on page 918)

Section dialog

Used to cut a section through the structure along a specified global plane at a desired location of the third axis. Sectional views parallel to global XY, YZ, and XZ planes may be created.

Opens when the **Structure Tools > Cut Section** tool is selected from the **Geometry Tools** group on the **Utilities** ribbon tab.



Range By Joint tab

Select the plane of the section by selecting either the **X-Y Plane**, **Y-Z Plane**, or **X-Z Plane** option. In the **With Node #** drop down list, select the joint which lies on the sectional plane.

> For example, if the section is to be drawn parallel to XY plane at Z=5, then, select the **X-Y Plane** option and select a joint number with a Z coordinate of **5**.

Range By Min/Max tab

Select the plane of the section by selecting either the **X-Y Plane**, **Y-Z Plane**, or **X-Z Plane** option. The **Minimum** and **Maximum** fields represent the boundary distances along the axis perpendicular to the sectional plane. Every object lying between these two distances would be displayed.

> For example, if the section is to be drawn parallel to XY plane at Z=5, select the **X-Y Plane** option and select a **Minimum** value of 4 and a **Maximum** value of 6.

Select to View tab

Used to specify the portion of the structure to view by using selected objects.

Window/Rubber Band allows you to select the portion of the structure to view by specifying a rubber-band window around it.

View Highlighted Only displays only the selected (highlighted) objects on screen. You must select the members and elements to view before choosing this option.

Select To View allows you to view only Beams, Plates, and/or Solids, depending on the selection of the corresponding options.

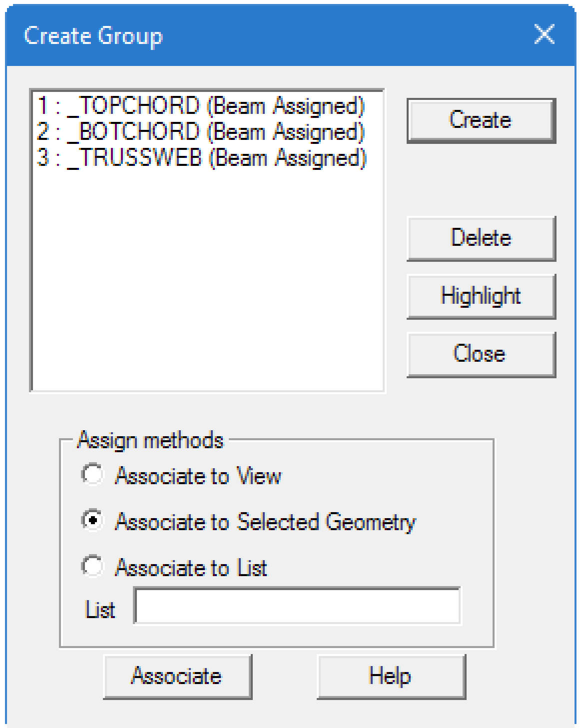
Create Group dialog

Used to cluster a set of joints, beams, plates or solids into a single entity identified by a distinct name.

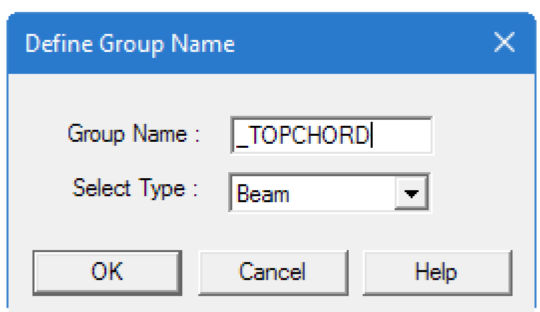
Opens when the **Groups** tool is selected in the **Geometry Tools** group on the **Utilities** ribbon tab.

The group name may be subsequently used instead of a joint, member, or element list to specify properties, supports, loads, etc. This prevents the need for you to repeat the same list of objects within your model. Additionally, group names can be used to highlight geometry using the **Group Selection** tool.

For example, the top chord members of an truss can be grouped into a name called "_TOPCHORD".



Create Opens the **Define Group Name** dialog, which is used to assign a group name and specify Node, Beam, Plate, Geometry, or Floor from the drop down list, as shown below.



Caution: Group names must begin with the underscore "_" character.

Delete This button allows us to delete any group that has already been created. The names of all available groups are displayed along with a reference number in a list box. Select the one we wish to remove and click on the Delete button. That group will be removed from the list.

Highlight	This button allows us to highlight the structural components which comprise a given group. From the list box where the available group names are displayed with a reference number, select the group we wish to highlight.
Close	Click group specification is complete.
Assign Methods	Options: • **Associate to View** – assigns all geometry shown in the current view to the group • **Associate to Selected Geometry** – assigns selected (highlighted) geometry to the group • **Associate to List** – assigns a typed list of joint, member or element numbers to the group
Associate	Click to add the joints, members, or elements to the group. **Note:** Only the objects in the current view, selection set, or list will be added to the selected Group name. Any objects previously in that group that are not in the association method will no longer be contained in that group.

Related Links

- *M. To create a group from a selection* (on page 689)

Check Connection Tags dialog

Used to check the load case results from the analysis against the defined connection capacities in the Connection Tags XML data file.

Opens when **Connection Tags** > **Check Connection Tags** is selected from the right-click pop-up menu when a member is selected.

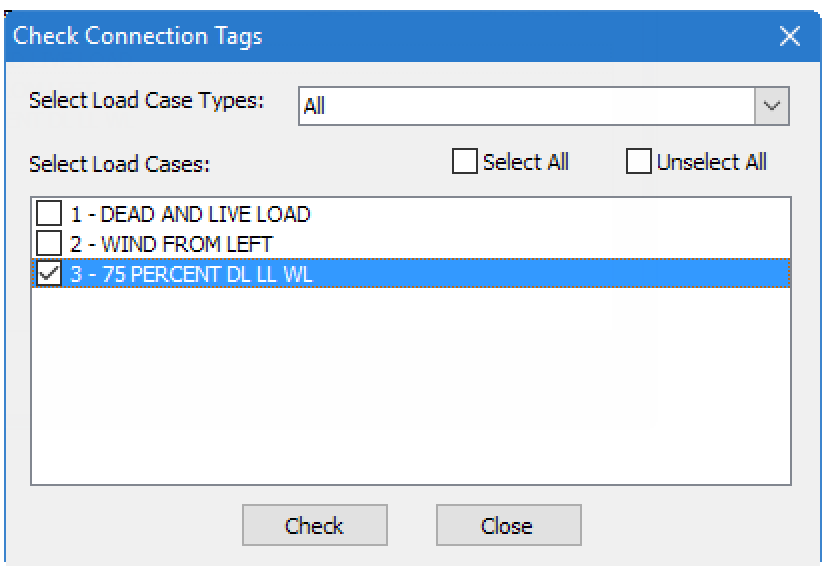


*Figure 352: The **Check Connection Tags** dialog*

Select Load Case Types	Select All load cases, only Primary Load Cases, or only Load Combinations to display in the list.

Select Load Cases	Select one or more load cases from the list by setting the individual check boxes. You can set the **Select All** check box to select all displayed load cases (those filtered by the **Select Load Case Types** selection). To clear all load cases selections, set the **Unselect All** check box.
Check	Checks analysis results at each member end with a connection tag assigned from the selected set of beam members against the connection capacities defined in the Connection Tag XML file. A table with the results of the check opens.
Close	Closes the dialog.

Related Links

- *D. Connection Tags Capacity Checks* (on page 1051)
- *D. To check connection tags* (on page 1050)

STAAD.Pro Calculator utility

STAAD.Pro includes an on-screen calculator which is displayed in a separate window.

Opens when the **Calculator** tool is selected from the **Tools** group on the **Utilities** ribbon tab.

The calculator functions similar to a handheld calculator.

Normal, Engineering, and Integer mode are available.

Create AVI File dialog

Used to create a video file recording of for animated deflection, section displacement, mode shape, and plate stress contour diagrams.

Opens when the **Create AVI File** tool is selected in the **Tools** group on the **Utilities** ribbon tab.

Total No. of Frames	Sets the number of frames used for the entire animation in the AVI file. This value divided by the Frame Rate /sec is the total length of the animation, in seconds.
Frame Rate /sec	The number of frames displayed per second of animation. In other words, this is the speed at which the animation is displayed.
Animation Type	Select the analysis results to be animated from the available options: • **Deflection** — animates the deflected shape of the currently selected load case or combination. • **Sectional Displacement** — animates the local displacement of members. • **Mode Shape** — animates the deflection of the selected mode. Only active if the Frequency tab (on page 2865) in the current STAAD input file. • **Stress Contour** — animates the selected **Plate Stress Type** or **Solid Stress Type.** Only active if Plates or Solid elements are included in the current STAADinput file.
OK	Opens a Save As dialog, which is used to specify a location and file name for the AVI file. Click OK and
Cancel	Closes the dialog without creating an AVI file.

Video Compression dialog

Used to select the video compression codec and set associated compression parameters for an AVI file. AVI files can be quite large, and compression is a technique by which the size of these files may be reduced.

Opens when **OK** is clicked in the Create AVI File dialog (on page 2953).

Compressor

Select one of the included means of video compression:

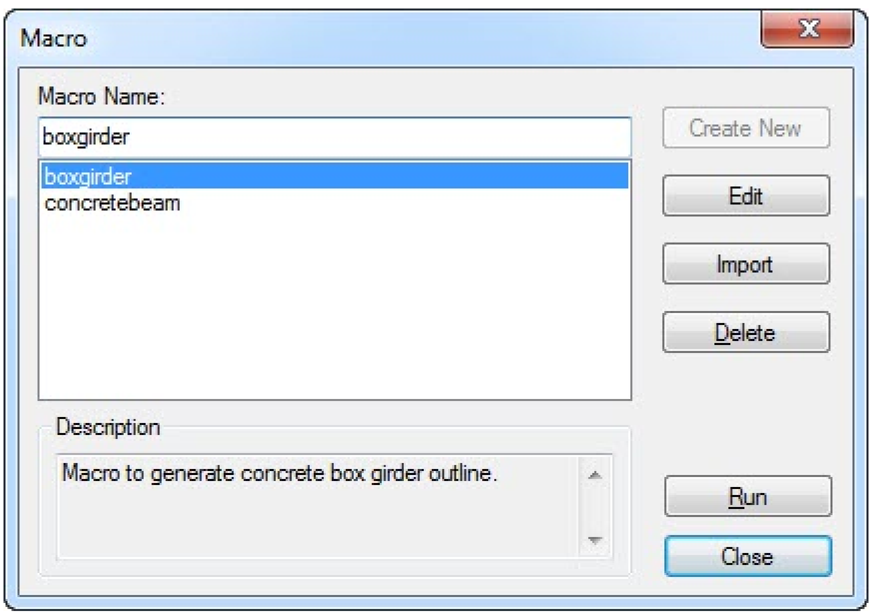
Compressor	Description	Settings
Full Frames (Uncompressed)	No video compression is used. This results in the largest file size but does not require any additional settings or video codecs installed.	none
Microsoft RLE	The Microsoft Run Length Encoding codec is supported in Windows Media Player 9 and higher as well Microsoft Windows XP SP2 and newer.	Compression Quality
Microsoft Video 1	Uses the Microsoft Video 1 Compressor.	Compression Quality
Intel IYUV codec	An uncompressed video codec. The compression quality is set to 75%.	none
Cinepak Codec by Radius	The Cinepak video codec is supported in Windows Media Player 9 and higher as well Microsoft Windows XP SP2 and newer.	Video can be compressed to color or black & white. Compression Quality
VMnc v2	The VMware lossless (uncompressed) codec.	none
TechSmith Screen Capture Codec	Uses the TechSmith Screen Capture Codec, which provides high compression rates with little video degradation for screen recordings.	Compression Control

Compression Quality	Use the slider control to set the compression percentage. The lower the number, the higher the compression amount but with reduced video quality. The default setting for each Compressor is recommended. A value of 100 means no compression is used.
OK	Accepts the settings and produces the AVI video. A message dialog displays the status of the video creation and the animation opens in the AVI Player window.
Cancel	Closes the dialog without creating the AVI video.
Configure	(For select codecs only) Opens a dialog with additional video compression settings, as described in the table above.
About	(For select codecs only) Opens a dialog displaying additional license and contact information about he codec supplier.

Macro dialog

Used to manage VB macros in STAAD.Pro.

Opens when the Run VB Macros tool is selected.



Macro name and list	The first box displays the name of the currently selected macro file, if one is selected. The list box displays a list of all linked macro files.
Description	Displays a brief description of the macro, if available.
Create New	Opens the Select New Macro File Name dialog, which is used to specify a file name, file type, and description for an empty VB macro file. The Macro editor window then opens, which used to record or edit macro commands. Active only when no macro is selected.
Edit	Opens the Macro editor window, which is used to record or edit macro commands.

Import Opens the Add an existing Macro dialog, which is used to select macro for linking to STAAD.Pro.

Delete Removes the macro from the linked macros list.

Note: The macro file is not deleted from the disk, only the link association in STAAD.Pro.

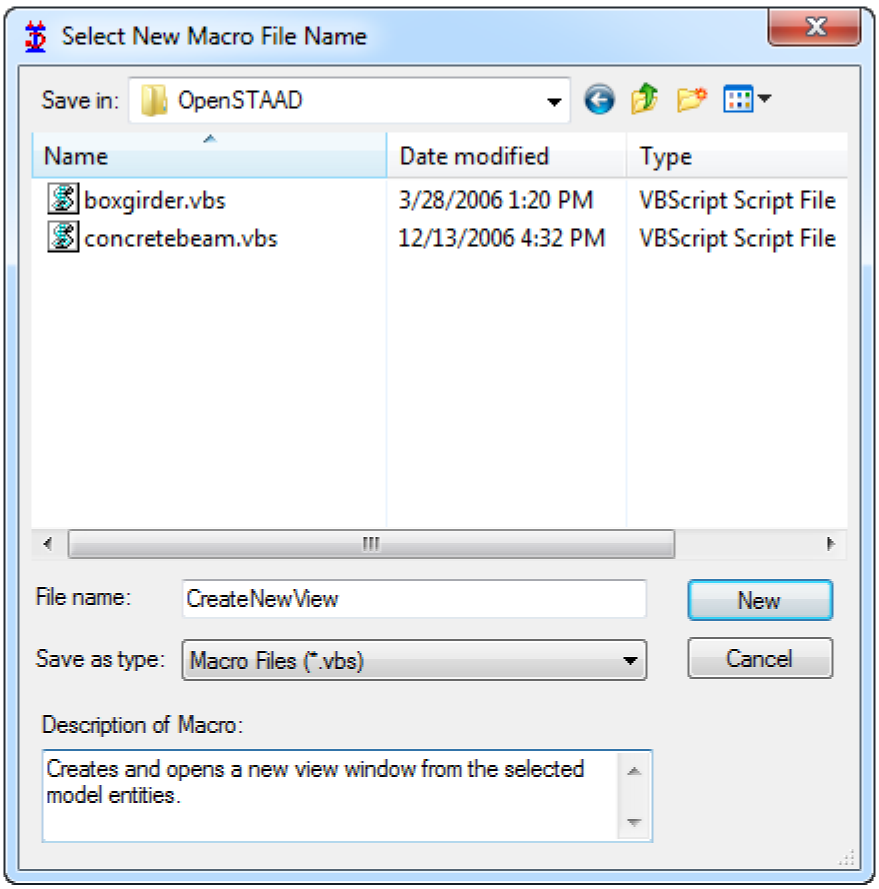
Run Runs the selected macro.

Close Closes the dialog.

Select New Macro File Name dialog

Used to create a new VB macro file for use in STAAD.Pro.

Opens when either **Edit > Create New VB Macro...** is selected or **Create New** is clicked in the Macro dialog (on page 2955).



Save in Select the drive and folder where the new macro file will be saved. Several common Windows folder navigation tools are provided.

File list A list of existing macro files is displayed here.

File name Specify the file name in this text box.

Save as type VB macros can be saved in one of two file types, depending on the level of file protection you want.

- A VBS macro file is a standard macro file, the contents (code) of which can be viewed by other users in any standard text editor.
- A VBZ macro file is a protected macro file, the contents of which cannot be viewed even in an external editor like *Notepad*. This is useful when you want to sell the macro or simply protect its contents from unintentional editing as part of a quality control program.

Description Used to add a brief description of the macros function. This is helpful in identifying similarly named macros

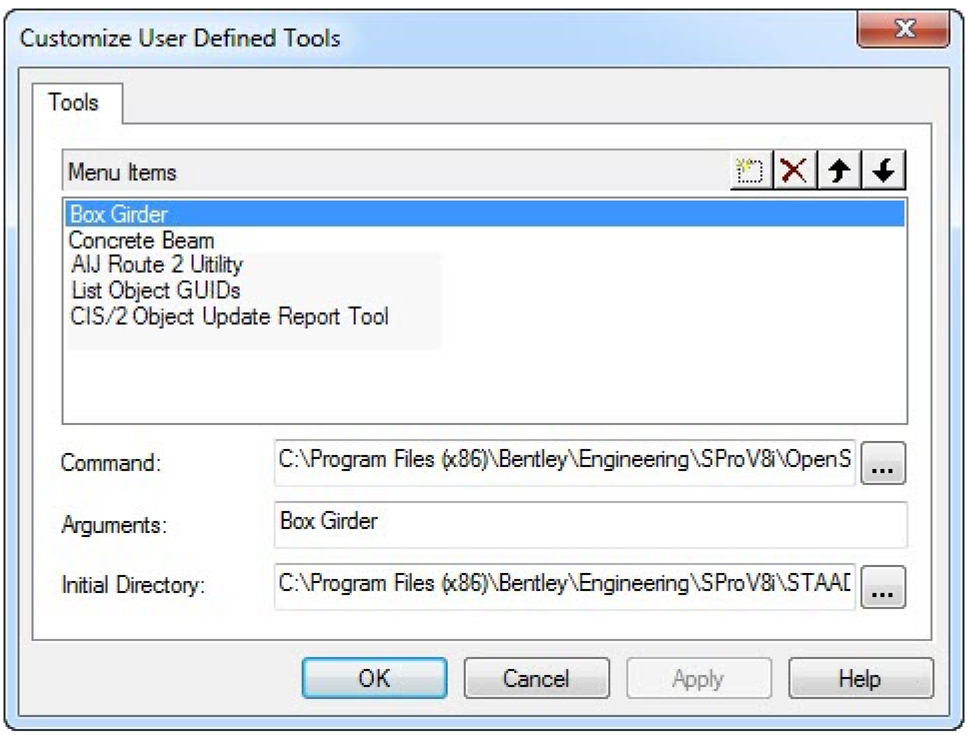
Create New Creates the file with the specified information and opens the file in the STAAD.Pro Macro Editor window.

Cancel Closes the dialog without creating a new macro file

Customize User Defined Tools dialog

Used to customize the tools which appear in the User Tools drop-down menu.

Opens when **Tools** > **Configure User Tools** is selected.



Toolbar

Tool	What it Does
New tool	Adds an empty entry to the Menu Items list. Type a name for a new menu item.

Tool	What it Does
Delete	Removes the current tool from the User Tools list
Move Up	Moves the selected tool up in the Menu Items list.
Move Down	Moves the selected tool down in the Menu Items list.

Command Type the path and filename of the linked macro for the menu item. Click [...] to open a file Select File dialog, which is used to locate and select files.

Arguments Specify any additional parameters associated with the macro, if required.

Initial Directory

OK Saves the changes and closes the dialog.

Cancel Closes the dialog without saving any changes since the Apply was clicked.

Apply Saves any changes made in the dialog.

Help Opens the STAAD.Pro Help contents.

Export STAAD Model to SACS

Used to export the current STAAD.Pro model to a SACS model, which can be opened in the SACS system Interactive Modeling program.

Opens when the **User Tools** > **STAAD to SACS Export** tool is selected in the **User Tools** group on the **Utilities** ribbon tab.

Staad Input File Displays the path and filename for the current STAAD input file.

SACS Model File The file path and file name for the SACS model file (file extension `.inp`) to which you want to export STAAD.Pro data.

[...] Opens a Windows **Save As...** dialog box, which is used to navigate your computer's storage and provide a file name.

Title Specify a model title for use in the SACS file.

About Displays version information about the macro behind this export facility.

OK Closes the dialog and generates the SACS file.

Cancel Closes the dialog without generating a SACS file.

Export STAAD Model to AutoPIPE

This feature is not yet documented.

Piping tab

Table 340: Models group

Tool Name		Description
 **Interop >**	**Import**	Opens a **Open** dialog with the **Files of Type** filter set to PipeLink files (file extension `.pipelink`.), which are piping data files created by the PipeLink utility to transfer data between Bentley AutoPIPE (V8i SELECTseries 2 and greater) and STAAD.Pro (V8i SELECTseries 2 and greater).
	Export	Opens the Export Revised Model dialog (on page 2961), which is used to specify the user name and optional comment associated with the updated data set being sent from STAAD.Pro.
	Reload	Reloads the current PipeLink database and initiates the **Support Connection Wizard**. Any changes made to the active model since the last save action will be discarded. Only the current active model is reloaded. **Note:** A reload is always performed when a model is re-imported.
	Remove	Used to remove all imported pipe data and transferred loads from the STAAD.Pro project. A warning message will appear to confirm you wish to proceed with removing the pipe model data. **Caution:** This action cannot be undone.
	Save	Saves the current state of the active pipe model. **Note:** Any changes to the currently active model are saved to the local database whenever the pipe mode is left, the model is deactivated due to another model becoming active, an export operation is initiated, or the **Save** tool is selected on the **Piping** ribbon tab.
 **Pipe Models**		Opens the **Pipe Model** dialog, which is used to select the active pipe model for the Piping workflow. Job and import information for the active model is also displayed here.

Table 341: Connection group

Tool name	Description
 **Support Connection Wizard**	Opens the Support Connection Wizard (on page 2964), which is used to establish logical data links between pipe stress model data imported from a PipeLink file and the current STAAD.Pro model.
 **Connect Support**	Used to specify a connection between a piping model support and the STAAD.Pro structural model. Once this item is selected, the mouse pointer changes to the support connection cursor (), which is used to draw a support association between piping model supports and structural model nodes.
 **Pipe Supports**	Opens the **Pipe Supports** table, which identifies supported pipe nodes and details each support.

Table 342: Loading group

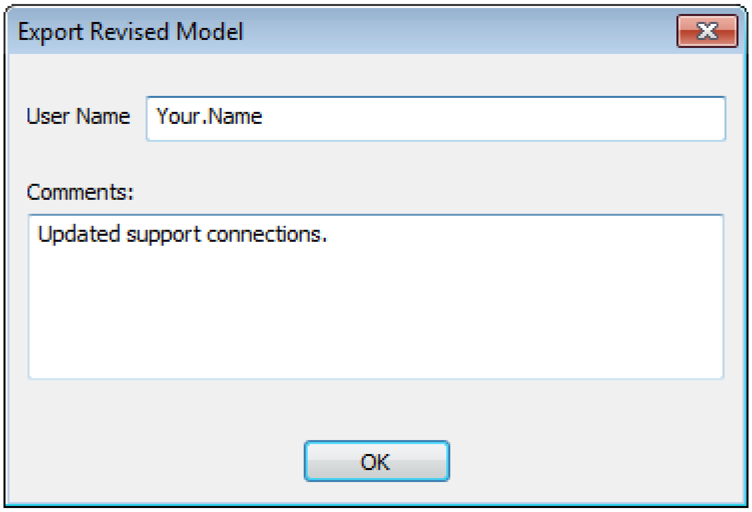
Tool name	Description
 **Transfer Loading**	Opens the **Transfer Pipe Reactions to Structure Model** dialog, which is used to specify STAAD.Pro load data for importing pipe support load data.

Export Revised Model dialog

A database may be created for importing into AutoPIPE. This database includes the pipe information, the structural model (including loads and analysis results), and the connection and load mapping information. This database is not constructed by the STAAD.Pro but rather the PipeLink application.

Note: The STAAD model should be analyzed (if loaded at all) prior to the export. Otherwise, a warning dialog will appear instructing you to do so.

Opens when **Piping** > **Export** is selected.



User Name Typically, enter the name of the engineer responsible for the structural analysis. The current Windows user name is specified here by default.

Comments (Optional) Enter any comments regarding actions performed for reference purposes.

OK Opens the PipeLink for STAAD.Pro V8i application, which is used to select the AutoPIPE data file for exchanging database information.

> **Note:** Refer to the PipeLink manual for assistance in using this utility application.

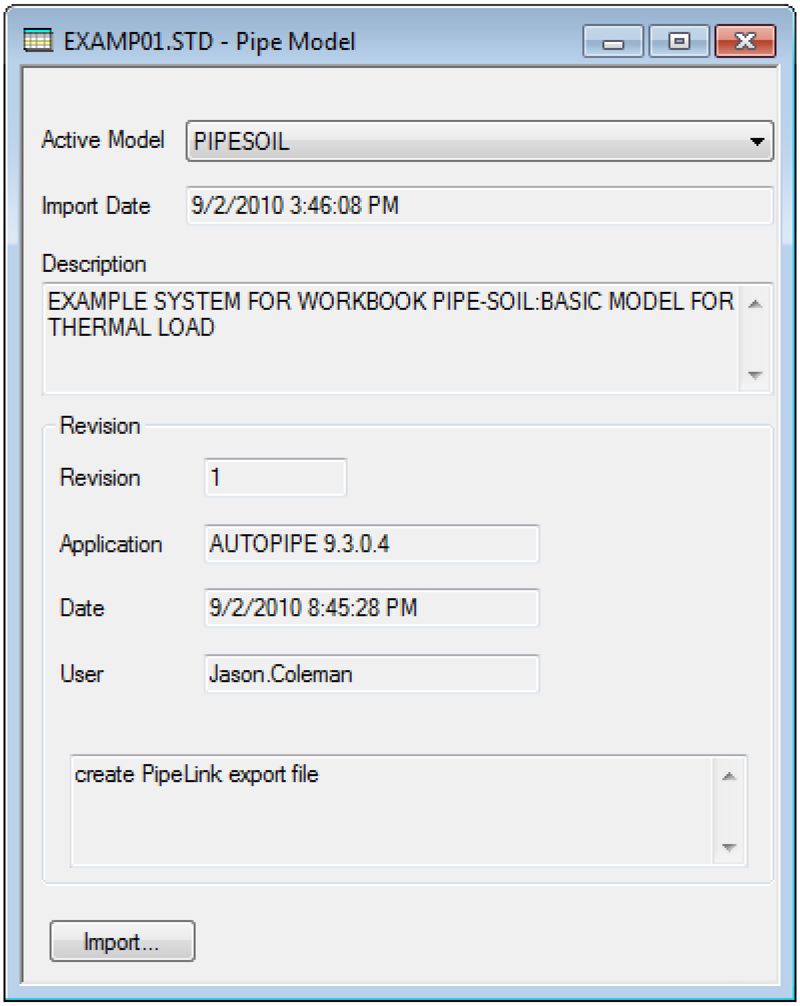
Related Links

- *M. To export model data for use in AutoPIPE* (on page 906)

Pipe Model dialog

Used to select the active pipe model for the Piping workflow. Job and import information for the active model is also displayed here.

Opens when the **Piping** page is selected in the **Piping** workflow.



Active Model

Used to select the current active model. Any actions taken in the Piping mode are done only on the active model.

Note: The view window displays all models, with the inactive models displayed in the color set in the Diagrams dialog Pipe tab (on page 2972). Supports and labels are not displayed for inactive models for clarity.

Import Data, Description, and Revision

The most recent revision is detailed and the date/time when the model was imported into the local database is also displayed. The revising application version number is shown along with the application name.

Import...

Opens a **Open** dialog with the **Files of Type** filter set to PipeLink files (file extension `.pipelink`.), which are piping data files created by the PipeLink utility to transfer data between Bentley AutoPIPE (V8i SELECTseries 2 and greater) and STAAD.Pro (V8i SELECTseries 2 and greater).

Related Links

- *M. To import a piping model* (on page 903)

Support Connection Wizard

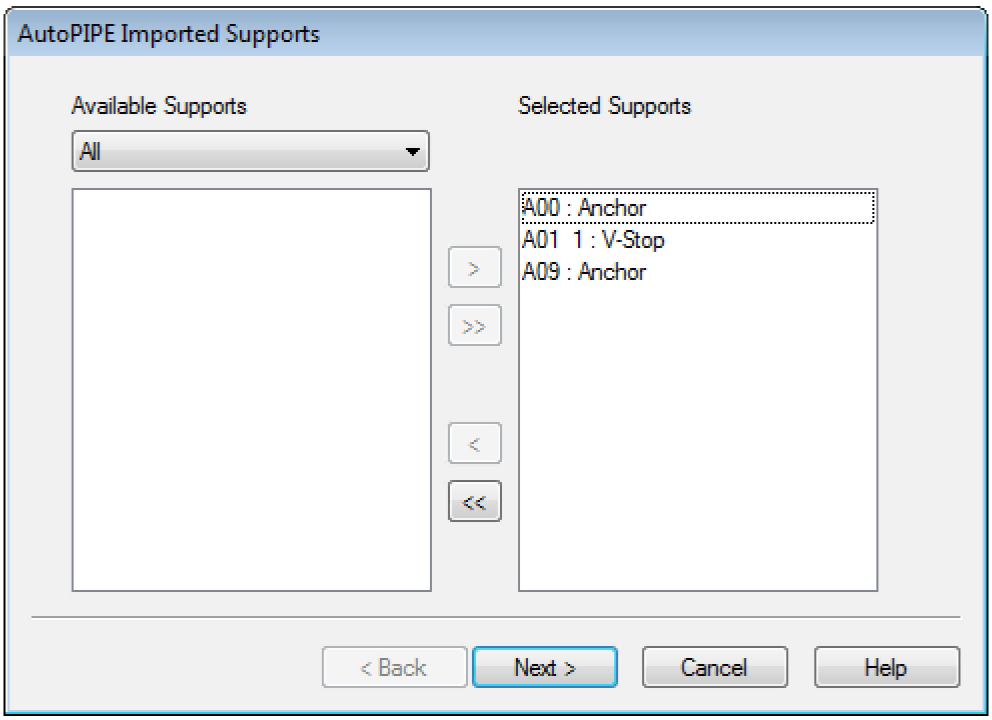
Used to establish logical data links between pipe stress model data imported from a PipeLink file and the current STAAD.Pro model.

Opens when:

- A PipeLink database is successfully imported or reloaded, or
- the **Support Connection Wizard** tool is selected in the **Connection** group on the **Piping** ribbon tab.

AutoPIPE Imported Supports page

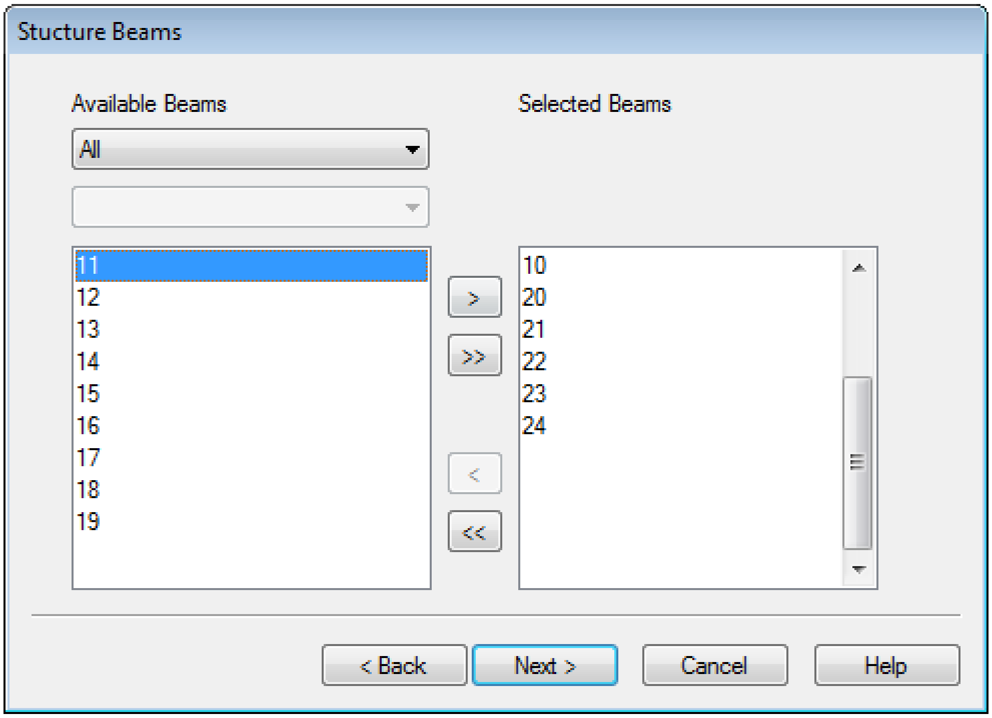
Used to select pipe supports which were defined in the AutoPIPE model.



Available Supports list	Lists all available supports which were exported from the AutoPIPE model. This list can be filtered using the drop-down list. The filtering options are All, Connected, Unconnected, V-Stop, or Anchor (relating to whether a connection to the STAAD.Pro model has been defined). When support type information is available the filter will be expanded to include these as well.
Selected Supports list	All supports added to this list will be imported from the PipeLink data file into the STAAD.Pro Piping mode.

Structure Beams page

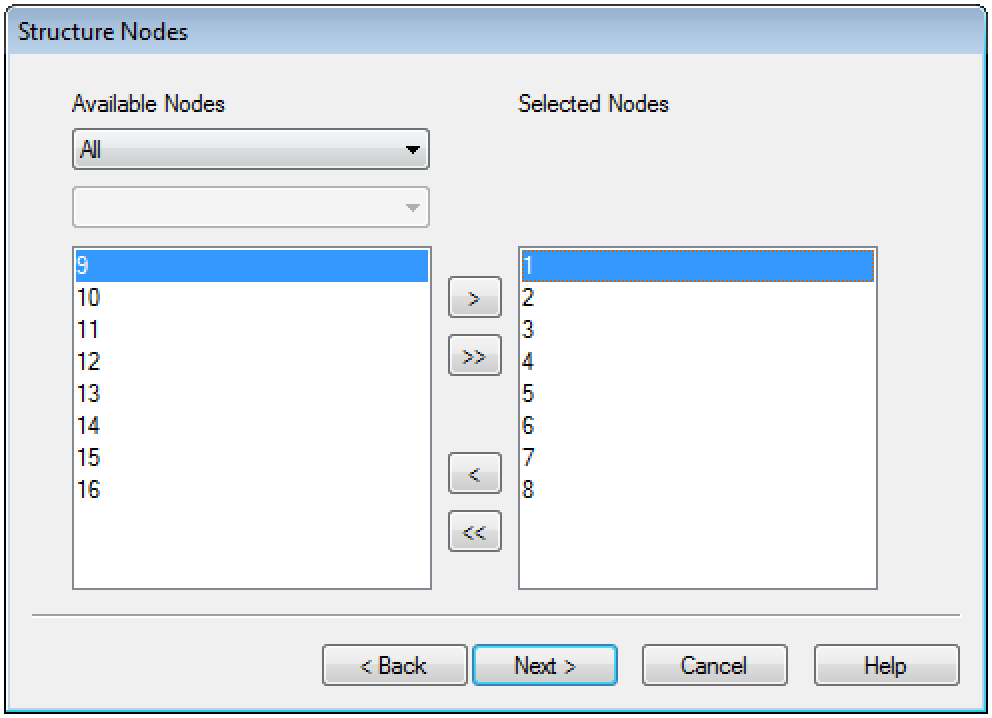
Used to select which structure elements will be used.



Available Beams list	The filtering options are implemented with two combo boxes, one for the category and one to identify the subset within that category. Available filtering options are All, Group, View, and Property.
Selected Beams list	All members added to this list will be used in the STAAD.Pro Piping mode.

Structure Nodes page

Used to select which structure nodes will be used.

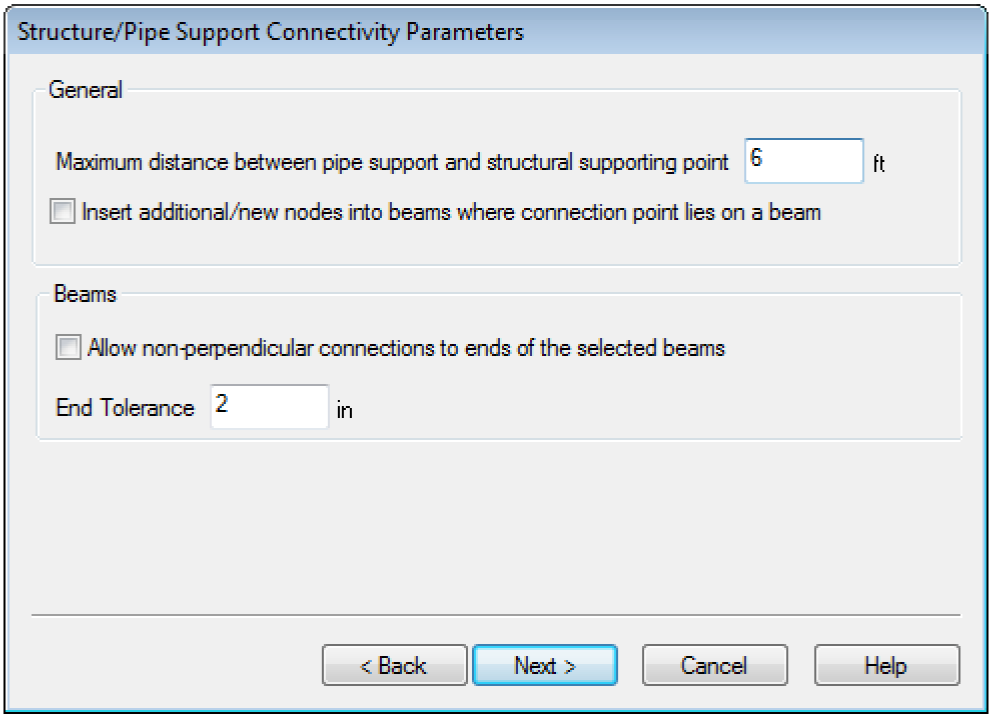


Available Nodes list The filtering options are implemented with two combo boxes, one for the category and one to identify the subset within that category. Available filtering options are All, Group and View.

Selected Nodes list

Structure/Pipe Support Connectivity Parameters page

Used to set parameters for the pipe wizard to establish connections. These parameters provide a means of controlling the results returned by the wizard in attempting to find suitable support points on the structure. The default values of distance-based parameters will depend on the base unit of STAAD.Pro.



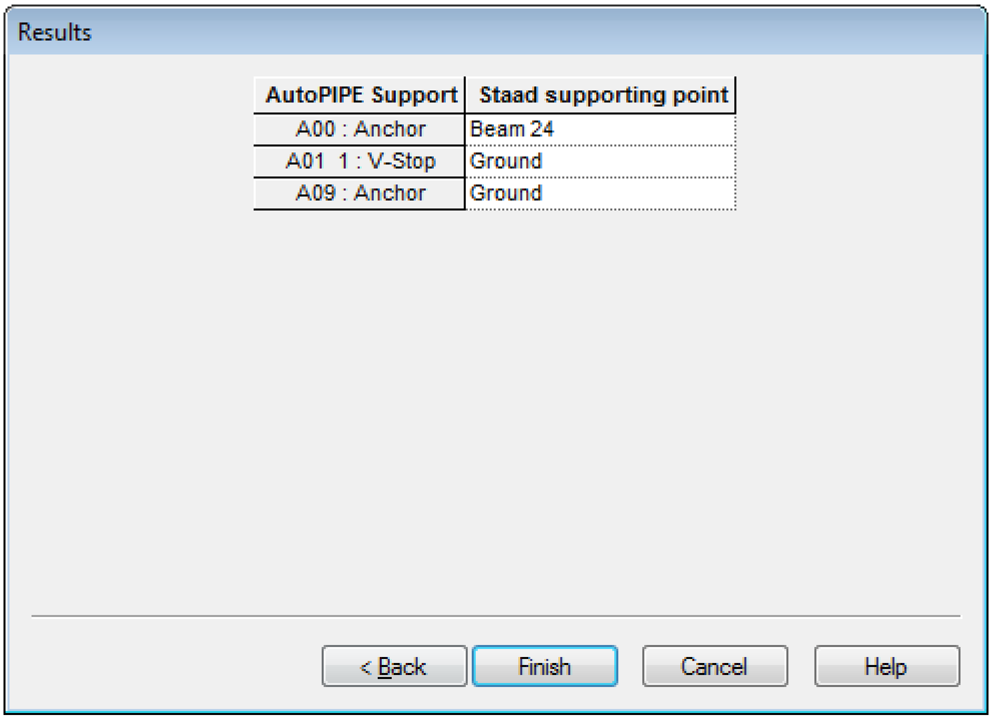
Maximum Distance between pipe support and structural supporting point	This is the sensitivity of the connection wizard when attempting to locate appropriate points on the structure to which to connect piping support nodes. The default value is 2m / 6 feet. Any potential connections beyond Max. Range will be discarded by the wizard.
Insert additional/new nodes into beams where connection points lies on a beam	This parameter effects the connection of the structures rather the point finding algorithm. If set true a new node will be created at each intermediate beam point and the connection made to that rather than to the beam itself. If the algorithm finds new node points within "End Tolerance" of each other then only one new node will be added. This option is not selected by default.
Allow Non-Perpendicular Connection at End Nodes	Select this option to include the beam end nodes in the node search. Otherwise, the end nodes of a given beam will only be considered for connections perpendicular to the beam, unless they have been explicitly added to the node subset. This is only relevant if the node subset does not explicitly include the nodes at the end of members in the beam subset.
End Tolerance	To allow for differences in precision and to avoid very short beam breaks this parameter will determine at what distance from the node the perpendicular will be considered to be at the node itself. The default value is 5 cm / 2 inches.

Results page

Used to review the results of the pipe data import. If changes are necessary, you may go back to previous steps in the wizard to make changes. The connection finding routine runs in two parts. First looking at beams (length of perpendicular from beam) and then looking at nodes (straight line length). The five closest found connectable points are saved to be presented on the results page.

The results will be presented in a table with columns for pipe node id and for the structural item it is to be connected to. This second column will provide a drop list allowing you to choose either **No connection** or one of up to 5 closest items. The items will be listed with the closest at the top. The initial state will be the closest item or **Ground**, if no good matches were found.

Note: Pipe-structure links are not part of the undo system. Nodes created at the end of the wizard will be removed by an undo but the links are not changed.



< Back Return to the previous import wizard page.

Next > Advance to the next page in the import wizard.

Finish (Results Page only) Accepts the import settings and closes the wizard. The pipe data is displayed in the active view window.

Cancel Closes the wizard without importing any pipe data.

Help Opens the STAAD.Pro help window.

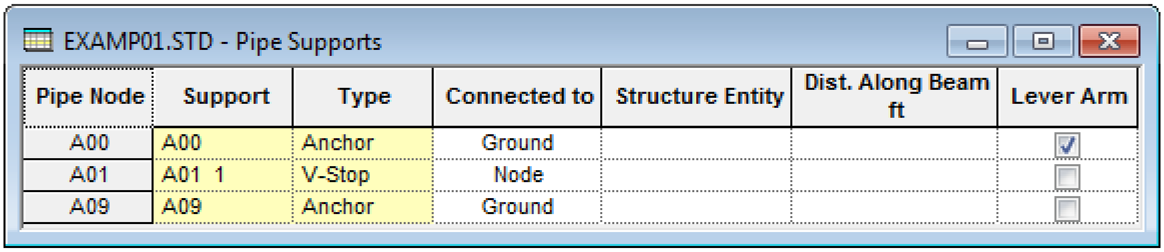
- *M. To use the Support Connection Wizard* (on page 904)

Pipe Supports table

Identifies supported pipe nodes and details each support.

Note: The rows are initially sorted by Pipe Node. Clicking in the headers for Support or Type will sort on that field. As the Pipe Node button is used to select the entire contents it is not possible to return to Pipe Node sorting without using the pop up menu.

Opens when the **Supports** page is selected in the **Piping** workflow.



Tip: Multiple Pipe Nodes (rows) can be selected by holding down the <CTRL> key while making selections.

Pipe Node / Support / Type
Each imported **Pipe Node** is listed in the table, along with the associated **Support** ID and support **Type**. These fields are imported from the pipe stress model and may not be edited.

Connected to
The type of model entity to which the **Pipe Node** is connected. If set to **Ground** (default when the wizard can not establish a connection), then the Pipe Node is assumed as not supported by the structure. You may manually connect the Pipe Node here by selecting either **Beam** or **Node**.

Note: This will be updated automatically if the Connect Supports tool is used.

Structure Entity
The Beam or Node number (as specified in the **Connected to** column) to which this **Pipe Node** is connected.

Dist. Along Beam
(Connected to Beam only) The distance from the start node of the beam where the pipe node is connected, in the current length units.

Lever Arm
Select this option to indicate that the Pipe Node connection is a **Lever Arm** and thus capable of transferring the pipe loads not only as force but also as a moment. If this option is not selected, the loads transferred to STAAD.Pro will not consider the connection rigid for moment transfer (default). This is analogous to setting the connection as “fixed” versus “pinned” in STAAD.Pro for the generated forces applied to the structural model.

For example, this option would be selected for the case of an intermediate pipe anchor where the connection is rigidly attached at both pipe and structure ends or the for case when the connection at the structure end has a moment resisting design.

Right-click Pop-up Menu

Contains tools used for controlling connections and sorting the Pipe Supports table.

Menu Item	Description	Save Effect As...
Set All as Lever	Sets the option for all Pipe Nodes as Lever Arms in the active model.	
Set All as Not Lever	Removes the Lever Arm option for all Pipe Nodes in the active model.	
Set Selection as Lever	Sets the option for the selected Pipe Node(s) as Lever Arms.	

Menu Item	Description	Save Effect As...
Set Selection as Not Lever	Removes the Lever Arm option for the selected Pipe Node(s).	
Disconnect All	Removes the connection for all Pipe Nodes in the active model	
Disconnect Selection	Removes the connection for the currently select Pipe Node(s).	
Sort by Pipe Node	Sorts the table by the Pipe Node name (default)	
Sort by Pipe Support	Sorts the table by the name in the Support column.	Double-clicking the Support column heading
Sort by Support Type	Sorts the table by the name in the Type column.	Double-clicking the Type column heading

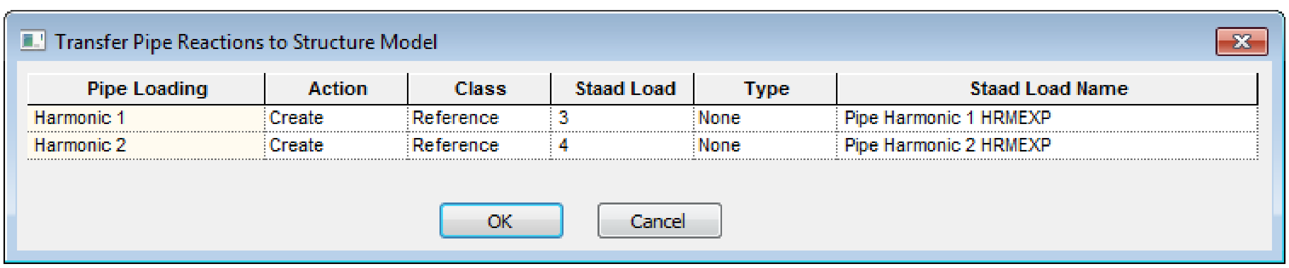
Transfer Pipe Reactions to Structure Model dialog

Used to specify STAAD.Pro load data for importing pipe support load data.

Opens when **Piping** > **Transfer Loadings** is selected.



Load data table

The table contains the following columns:

- Pipe Loading - Each pipe support is included as a separate row, with the nature of the load and load number described here.
- Action - Set to Create (for generating a new load) or No Action (which does not result in a new load).

  If the loads are being updated, additional options to Update or Remove existing loads are provided.
- Class - Specify if the load is a Primary load case or Reference load case type.

> **Tip:** You can quickly set all new loads (Action = Create) to either Primary or Reference class by right-clicking anywhere along the column heading and selecting the appropriate option from the pop-up menu.

- STAAD Load - The load case number which will be assigned to the load.
- Type - You can classify the load type, which is used for automatic load combination generation.
- STAAD Load Name - A description load name is generated here. You may enter a different title if needed.

OK Closes the dialog and proceeds with the load data transfer. A message dialog opens to provide you with a summary of the transfer process.

> **Note:** Warnings are displayed in orange and errors are displayed in red.

Cancel Closes the dialog without transferring any load data.

Related Links

- *M. To transfer load data for structural analysis* (on page 906)

Merging Support Connection dialog

Used to determine which of the conflicting connection definitions to use. All data contained within the table is read-only except for the **Keep Local** options for each pipe node.

Opens when clashes are detected during the import or re-import process.

	Import Rev.	Import Connection	Local Rev.	Local Connection	Keep local
A00 1	1	Ground	1*	Node 110 : No force lever	☑
A01 1	1	Ground	1*	Beam 35 0.4572 : No force lever	☑
A02 1	1	Ground	1*	Node 164 : No force lever	☑
A03 1	1	Ground	1*	Node 163 : No force lever	☑
A04 1	1	Ground	1*	Beam 33 0.4572 : No force lever	☑
A05 1	1	Ground	1*	Node 162 : No force lever	☑
A06 1	1	Ground	1*	Node 161 : No force lever	☑
A07 1	1	Ground	1*	Node 160 : No force lever	☑
A08 N1	1	Ground	1*	Beam 20 1.06375 : No force lever	☑
A08 F1	1	Ground	1*	Beam 20 0.758952 : No force lever	☑
B00 1	1	Ground	1*	Beam 32 0.4572 : No force lever	☑
B01 1	1	Ground	1*	Beam 36 0.4572 : No force lever	☑
B02 1	1	Ground	1*	Node 155 : No force lever	☑
B03 1	1	Ground	1*	Node 154 : No force lever	☑
B04 1	1	Ground	1*	Beam 34 0.4572 : No force lever	☑
B05 1	1	Ground	1*	Node 157 : No force lever	☑
B06 1	1	Ground	1*	Node 158 : No force lever	☑
B07 1	1	Ground	1*	Node 159 : No force lever	☑

Pipe Supports data table Select the **Keep Local** option for any pipe node support which you do not wish to be overwritten during the import process.

Cancel Closes the dialog and cancels the import process.

OK	Accepts the clash decisions made in the **Keep Local** choices selected and proceeds with the data import.

Related Links

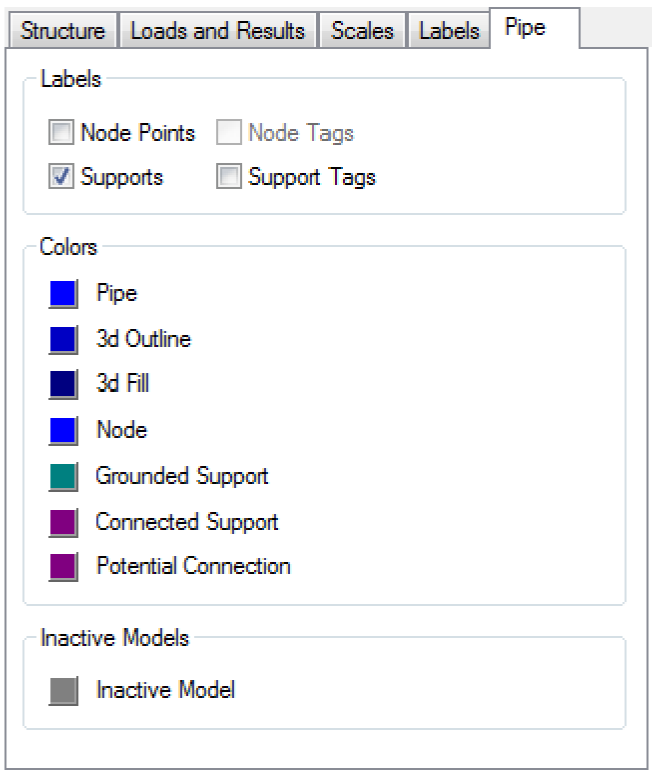
Diagrams dialog Pipe tab

An additional set of view controls is available to you in the Piping mode. This tab is only active when STAAD.Pro is in the Piping mode.

Note: The Structure tab, Loads and Results tab, Scales tab, and Labels tab from the Modeling mode are available in the Piping mode.

Opens when **View** > **Structural Diagrams** is selected (Piping mode only).



Tip: 3D Rendering of Piping models can be viewed using the 3D Rendering features of STAAD.Pro by either toggling on the Full Sections view in the Diagrams dialog or by using the 3D Rendering view.

Labels	Toggles the display of pipe support and node labels.
Colors	Used to select colors for pipe model elements.
Inactive Models	Controls the color for inactive models. No support or node data is displayed for inactive models.

Bridge Deck tab

Table 343: Deck group

Tool name		Description
 **Create Deck**		Used to create a deck definition from the selected structure geometry. **Note:** When a deck is defined from beam elements, the program will generate a surface of fictitious, triangular plate elements which are used in determining the load distribution. These elements have no inherent stiffness and are not transferred to STAAD.Pro for analysis of the structure. These plate elements may be reviewed by toggling on their display in the Deck tab (on page 2988).
Create Deck >	**Rename**	Opens the **Rename Deck** dialog. 	Delete	Used to delete the selected deck definition. **Note:** Structure geometry objects (i.e., plates or beams) used in the deck definition are not deleted.
 **Select Deck**		Opens the Select Plates in Deck dialog (on page 2975), which is used to select the members and plates associated with a previously created deck definition.
 **Define Roadway**		Opens the Roadways dialog (on page 2974), which is used to create and manage roadway definitions.

Table 344: Loading group

Tool name		Description
 **Loading >**	**Influence Surface Generator**	Initiates the STAAD Analysis and Design engine to generate influence surfaces for the structure. **Note:** When selected, the **STAAD Analysis and Design** dialog opens to display the progress of the analysis used in influence surface generation. This dialog automatically closes upon completion.
	Influence Diagram	Opens the Influence tab (on page 2987), which is used to control the display of influence diagrams on the defined bridge deck.
	Run Load Generator	Opens the Load Generator Parameters dialog (on page 2981), which is used to select design codes, specify code relevant data, and select points of interest for placing loads.
	View Results file	Opens the results file (file extension `.bva`) in a text editor for your review and for use in post-processing.
	Browse Load Generator Results	
	Create Loading in Staad Model	Used to create a primary load cases in the current STAAD input file for each action requested in the Load Generator Parameters dialog (on page 2981). These load cases can then be used in the same way any other static load case would be used for analysis and design.

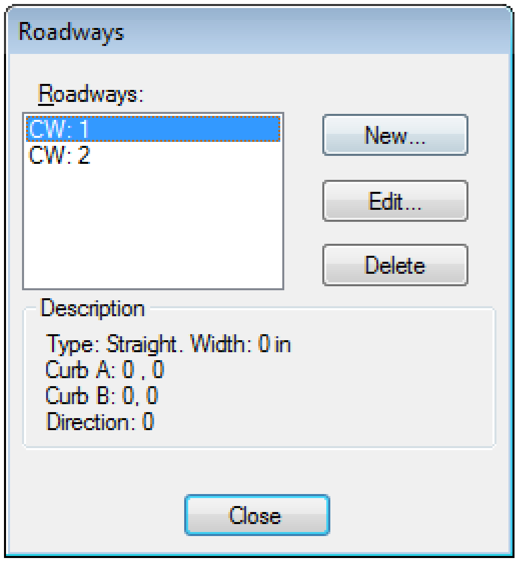
Table 345: Vehicle group

Tool name	Description
 **Database**	Opens the Vehicle Database dialog (on page 2989), which is used to display code specified vehicle load data and to create user-defined loads.

Roadways dialog

Used to create and manage roadway definitions. This should be the clear roadway width between curbs or other barriers. The program will determine the number of traffic and design lanes available in this width.

Opens when **Deck > Define Roadways** is selected.



Roadways list A list of each roadway definition for the selected deck is contained here. Selecting a Roadway definition in the list will display the characteristic parameters in the Description block below.

New... Opens the Roadways dialog (on page 2974), which is used to parametrically define straight, curved, or custom roadways.

Edit... Opens the Roadways dialog (on page 2974), which is used to edit the selected roadway definition.

Delete Deletes the selected Roadway definition.

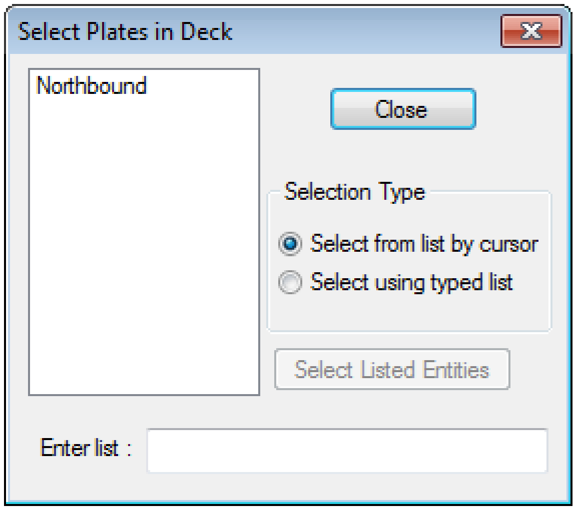
> **Caution:** No confirmation is required to delete a Roadway definition. This action cannot be undone.

Close Closes the Roadways dialog.

Select Plates in Deck dialog

Used to select the members and plates associated with a previously created deck definition.

Opens when **Deck** > **Select Deck** is selected.

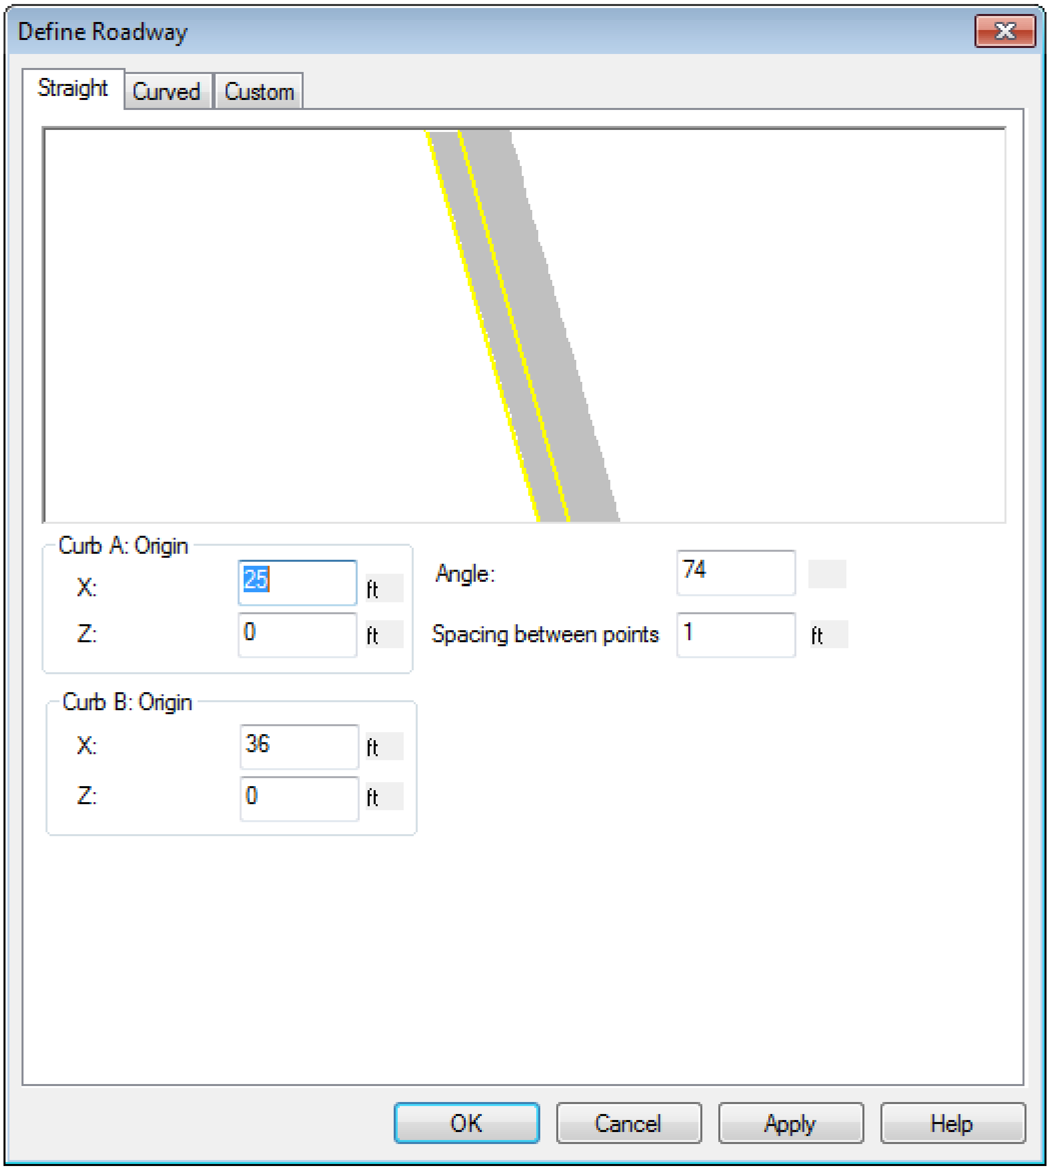


decks list	Lists all deck definitions in the current STAAD project.
Close	Closes the dialog.
Selection Type	Used to either **Select from list by cursor**, which allows you to select the deck by name from the decks list, or to **Select using type list**, which allows you to type a list of deck names in the **Enter list**.
Select Listed Entities	Used with the **Select using type list** option to select the entities specified in the **Enter list**.
Enter list	Specify the names of decks here.

Define Roadway dialog

Used to define roadways for vehicle loading on a selected deck. Either Straight, Curved, or Custom roadways may be defined.

Opens when the **New** or **Edit** buttons are clicked in the Define Roadway dialog (on page 2976).



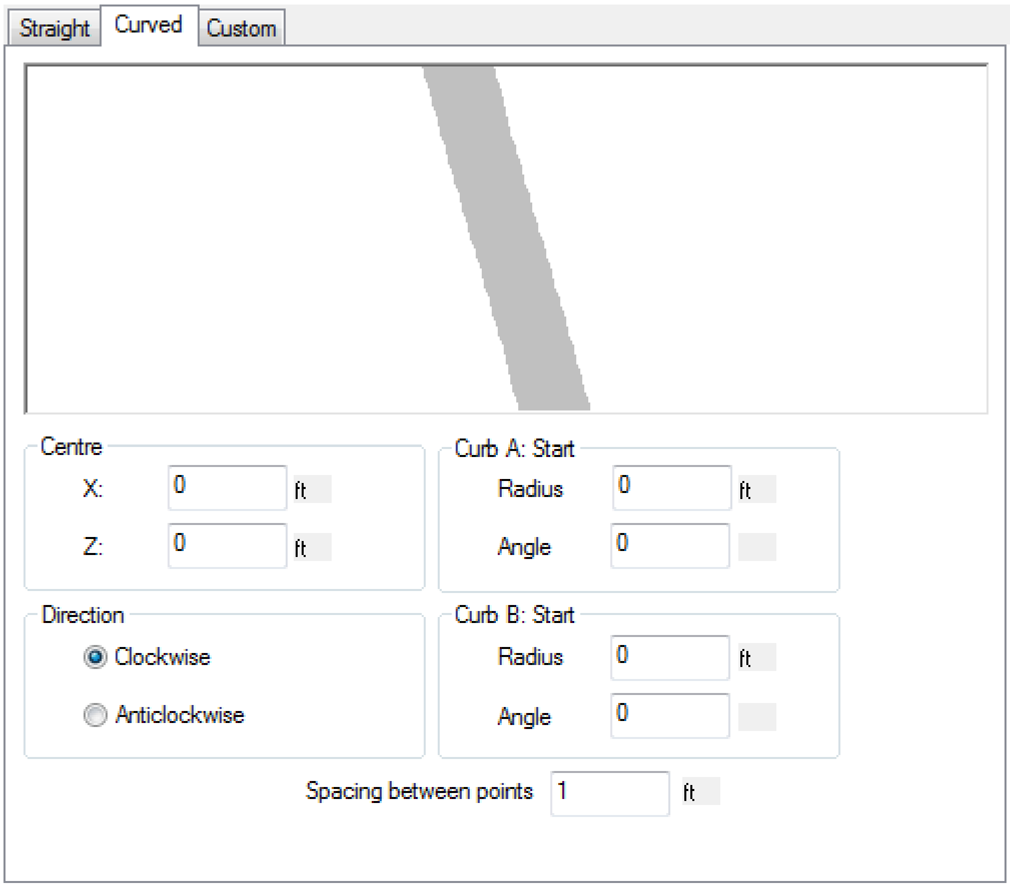
Straight tab

Used to parametrically define a straight roadway.

Curb A / B Origin	Curb A is the closes to the origin, with Curb B being the other side of the roadway. Dimensions are all taken from the origin (i.e., the distance to Curb B is not taken from Curb A).
Angle	The angle of the roadway taken clockwise from the positive X axis.
Spacing between points	Spacing ... in current length units.

Curved tab

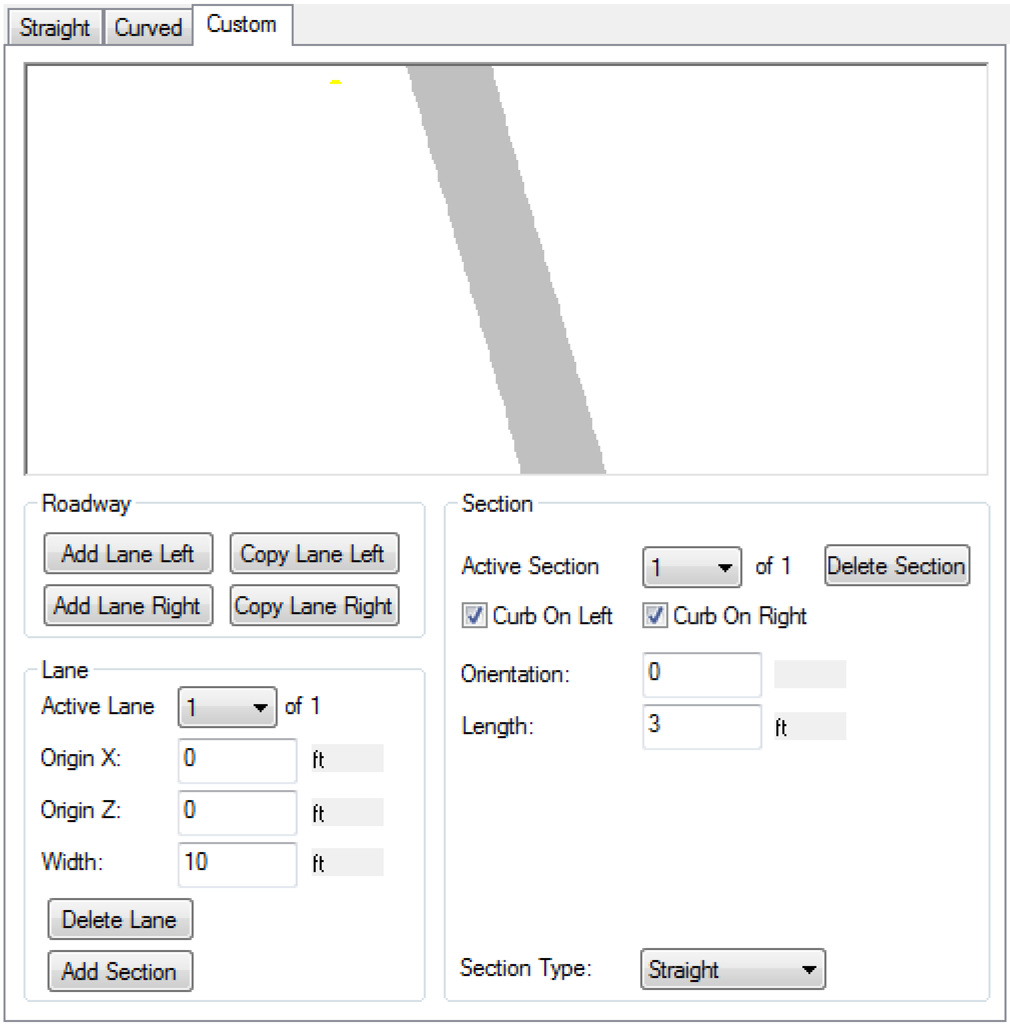
Used to parametrically define a curved roadway.



Center	Define the center of a circular arc.
Direction	Select if the arc sweep is defined as Clockwise or Anticlockwise (Counter-clockwise) from ...
Radius	
Angle	
Spacing between points	Spacing ... in current length units.

Custom tab

Used to define a generic roadway section.



Add Lane Left

Copy Lane Left

Add Lane Right

Copy Lane Right

Active Lane Select the lane you wish to create or edit from the drop down list. The total number of lanes present is also displayed.

Origin X / Z

Width

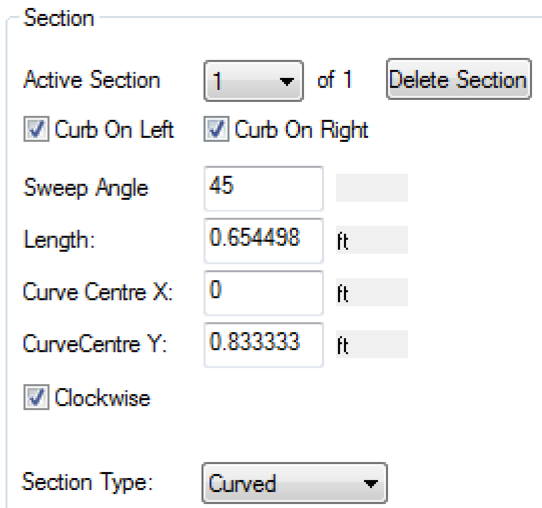
Delete Lane

Add Section

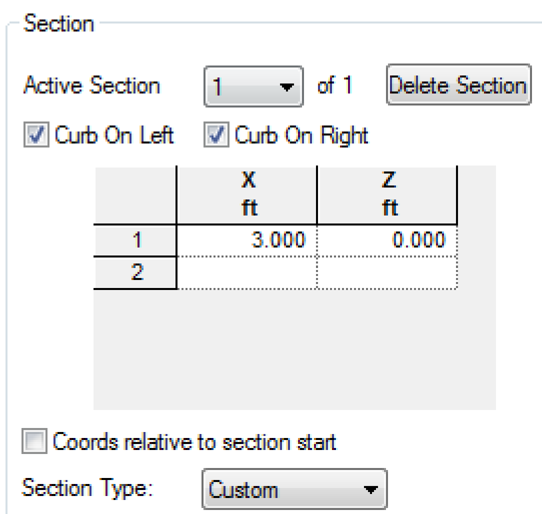
Section Type Select if the roadway segment is **Straight**, **Curved**, or **Custom**. The section panel updates to allow entering parameters for this selection.

- Straight section

    Active Section
    Delete Section
    Curb on Left / Right
    Select either or both of these options to ...
    Orientation
    Length
- Curved section



- Custom section



OK Closes the dialog and creates a new roadway or updates changes made to an existing roadway.

Cancel Closes the dialog without saving any changes or creating a roadway definition.

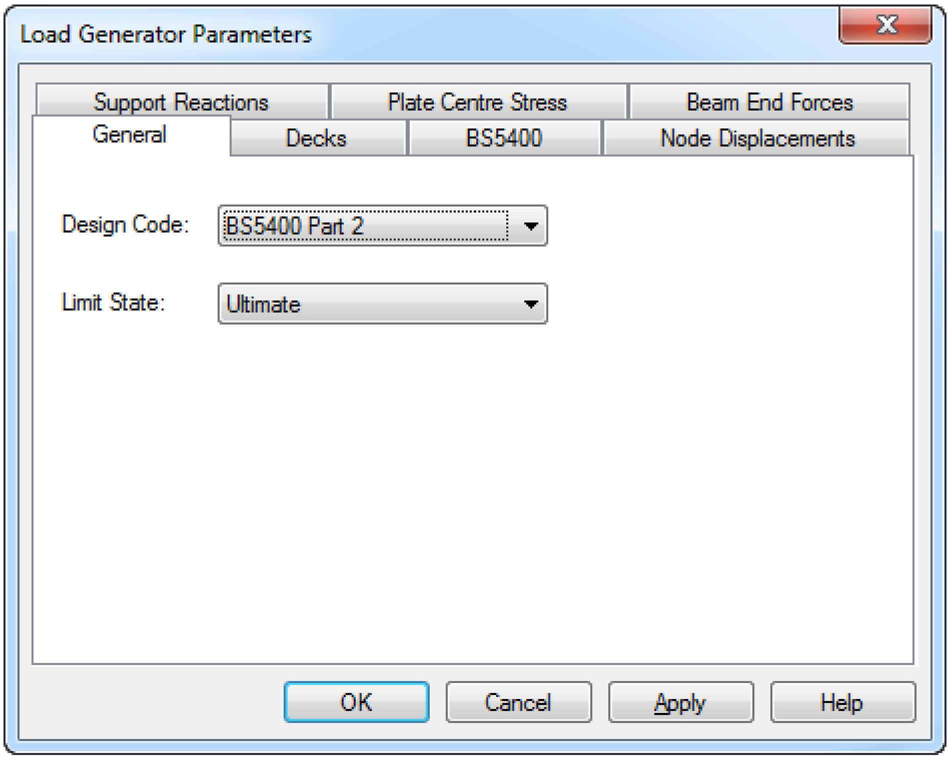
Apply Updates the current roadway definition with any changes made in the dialog.

Help Opens the STAAD.Pro help window.

Load Generator Parameters dialog

Used to select design codes, specify code relevant data, and select points of interest for placing loads.

Opens when **Loading** > **Run Load Generator** is selected.



General tab

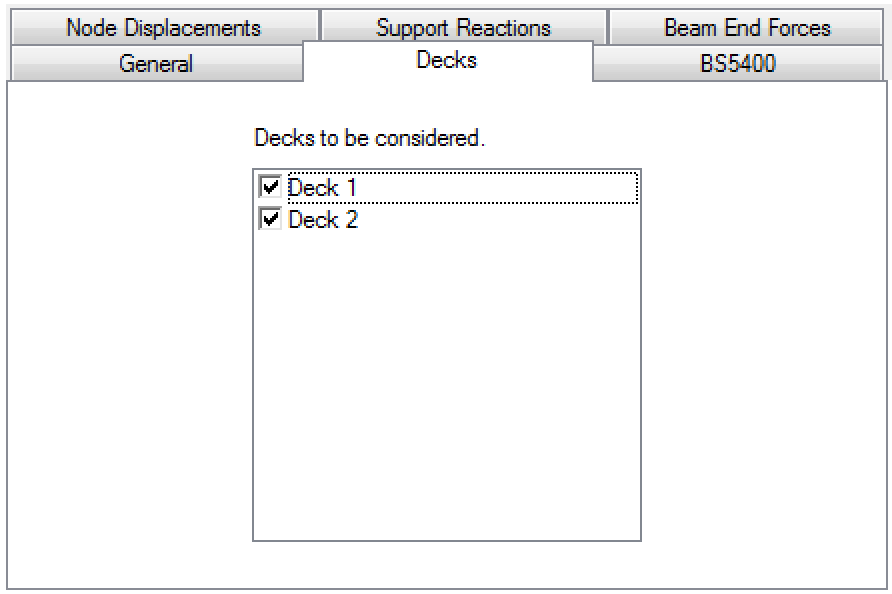
Design Code Select the specification from which the loadings are to be taken.

> **Note:** The ***<code>*** tab updates accordingly with this choice.

Limit State Specify if the vehicle loads are to be used with the Ultimate or Serviceability limit state.

Decks tab

Used to select the previously defined decks to be considered for loading. A check is placed in the box associated each deck name to be considered.



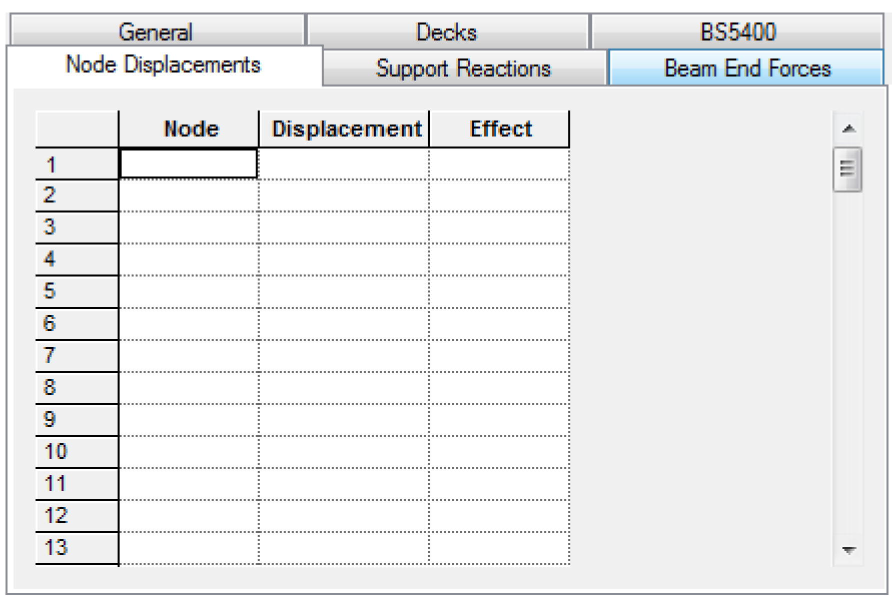
<code> tab

Used to input code-specific parameters. This tab dynamically updates based on the Design code selection made on the General tab.

Note: The following pages provide details on these code-specific parameters.

Node Displacements / Support Reactions / Beam End Forces/ Plate Center Stress tabs

Used to specify a structural object, action, and effect as a point of interest for influence surfaces which determine the placement of the design loads on the structure to achieve maximum (or minimum) action.



Node / Beam / Plate Specify the number of the structural object to act as a point of interest. The point of interest is the location on the structure the resulting action at which will be used to determine the placement of the loads.

Displacement / Support Reaction / Stress Force The action of interest. This is usually the direction of the displacement, force, moment, or stress.

In the case of beam end forces, you must select the member end as well as the direction of force or moment.

In the case of plate stresses, additional options for the maximum combined effect (von Mises or Principle stresses) are also available.

Effect Select either the maximum (+ve) or minimum (-ve) effect at the point of interest due to the selected action.

OK Accepts the specified parameters and closes the dialog.

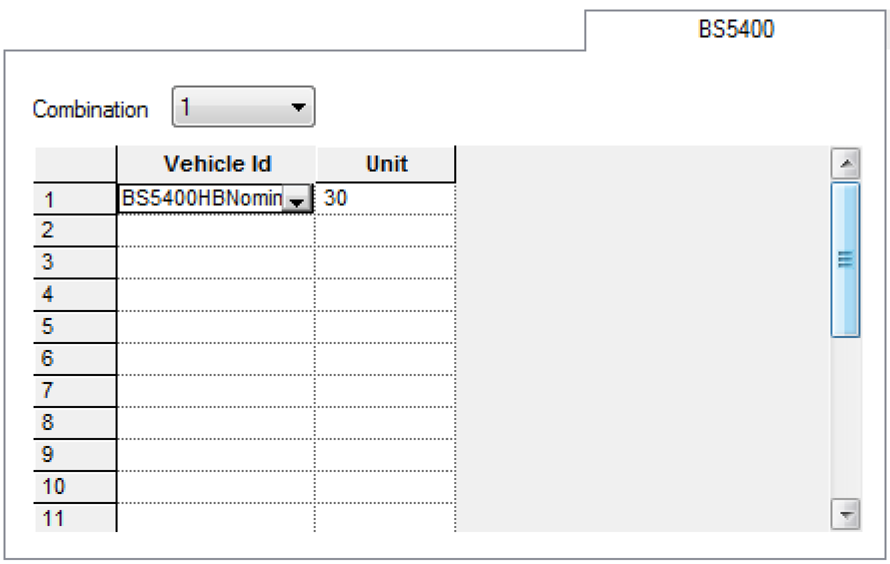
Cancel Closes the dialog without adding load generation parameters.

Apply Applies the parameters from the current tab.

Help Opens the STAAD.Pro help window.

BS 5400 Specific Parameters

Used to input parameters for loading per Cl.6.3.1 of British Standard 5400 “Steel, concrete and composite bridges, Part 2. Specification for loads”.



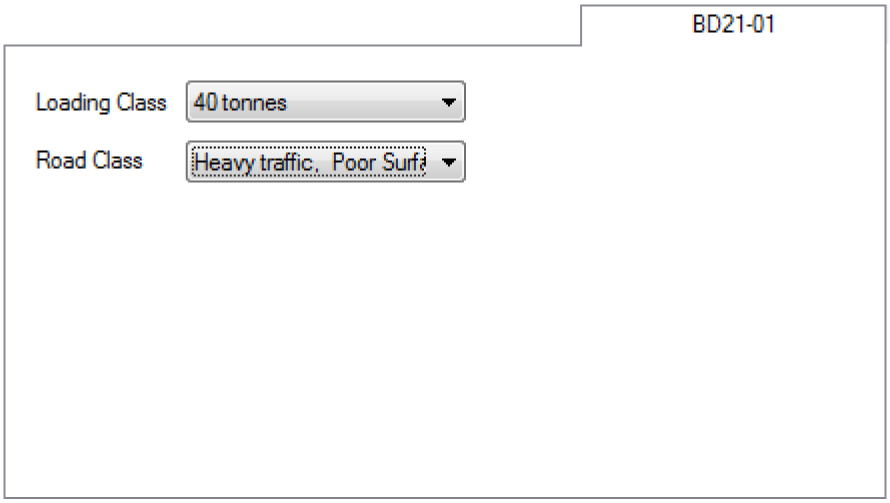
Combination Select the load combination number to be considered which include highway bridge live loading (BS 5400:Part 2 table 1). Refer to Cl.6.2.7 and 6.3.4 for the load factors used in the program for the load combinations.

Vehicle table Select the design vehicle to use. The default is the HB vehicle per Cl.6.3.1. User defined vehicles may also be selected.

Specify the number of units of 10 kN load per axle to be used for type HB to be used per Cl.6.3.

BD21/01 Specific Parameters

Used to input parameters for loading per BD21/01 “The Assessment of Highway Bridges and Structures”.

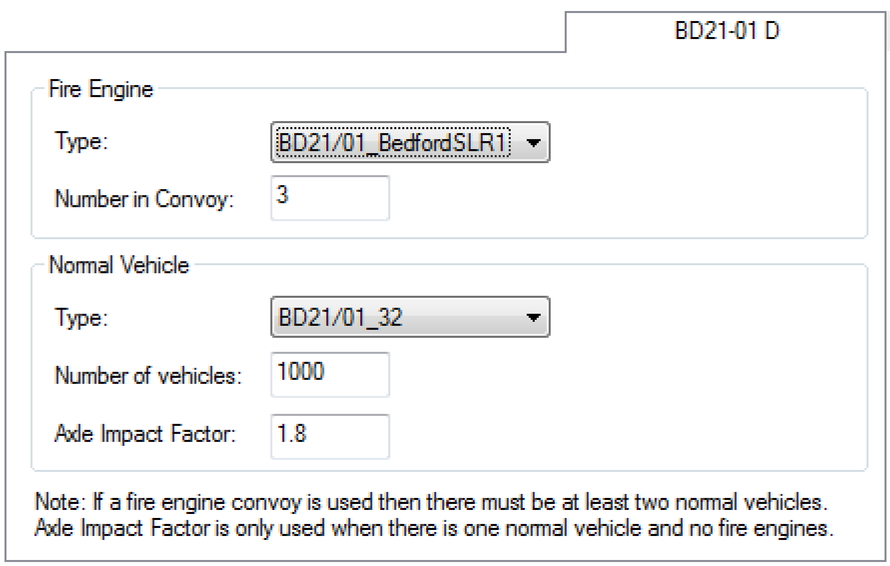


Loading Class Select the Assessment Loading vehicle from this list per Cl.5.12 through 5.17 of BD21/01

Road Class Select the bridge situation in terms of road surface characteristics and traffic level per Cl.5.22 of BD21/01.

BD21/01 Annex D Specific Parameters

Used to input parameters for loading per Annex D: Loading From Vehicles of BD21/01 Annex D. This code is used for traffic on cross girders and transversely spanning slabs.



Fire Engine
Select the make of fire engine from Table E1 of BD21/01 Annex E as the **Type**. Specify the **Number in Convey** to indicate the number of fire engines (all same type) with which to simultaneously load the bridge.

Nominal Vehicle
Select the nominal vehicle Type from Tables D1 and D2 of BD21/01 Annex D.

Vehicle nomenclature:

```
BD21/01_WT[_#][dir]
```

Where:

WT Either the vehicle gross weight value (Table D1 vehciles) or the vehicle reference (Table D2 vehicles).

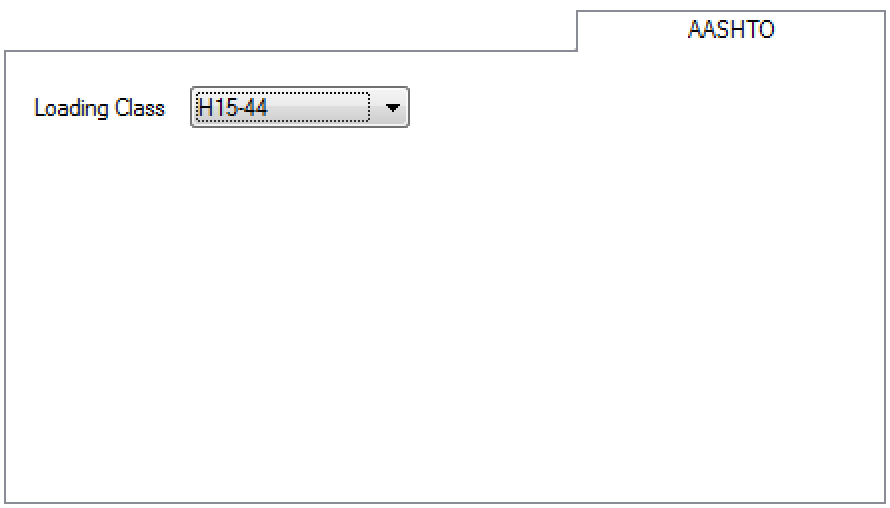
Separate id number for vehicles which are listed more than once in the table.

div a or b signifies a vehicle in which the W2 and W3 loads have exchanged position.

Specify the **Number of vehicles** to indicate the number of nominal vehicles (all same type) with which to simultaneously load the bridge. Specify an Axle Impact Factor for use with a single vehicle per Cl.D.3(a).

AASHTO Specific Parameters

Used to input parameters for loading per “Standard Specification for Highway Bridges”, AASTHTO ASD / LFD.

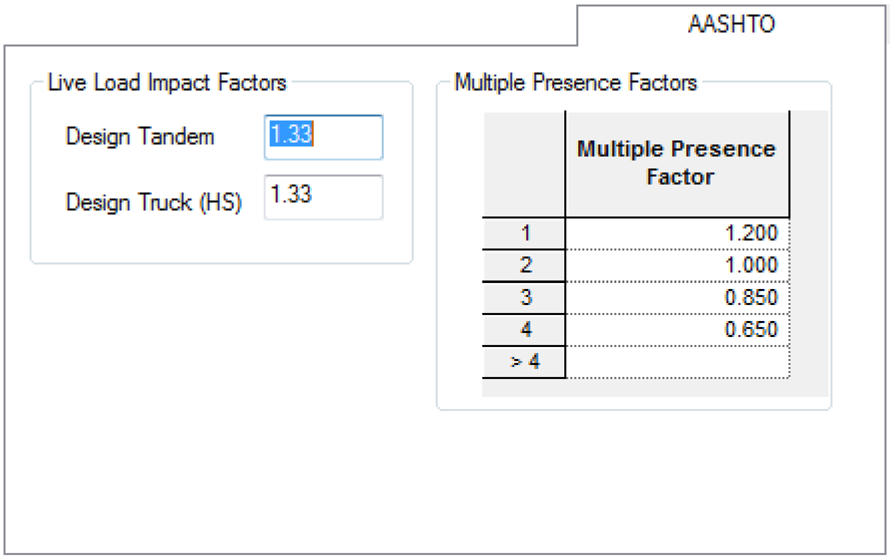


Loading Class
Select the nominal vehicle load to use per Cl.3.7. All vehicles in the Vehicle Database dialog are listed here, with the following being provided in the AASHTO ASD/LFD code:

- H15-44
- H20-44
- HS15-44
- HS20-44

AASHTO LRFD Specific Parameters

Used to input parameters for loading per the AASTHTO LRFD Bridge Design Specifications.



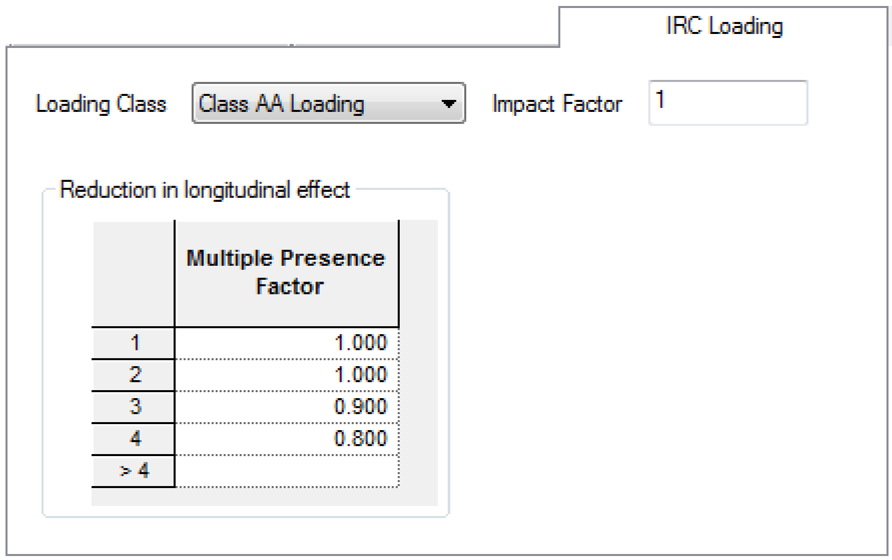
Live Load Impact Factors — Multiplier accounting for imperfection in road surface resulting in additional dynamic loading. These factors vary depending upon the bridge component being designed. The default value of 1.33 is specified for bridge components (other than deck joints) for limit states other than fatigue or fracture (AASHTO LRFD table 3.6.2.1-1). Separate values may be specified for the **Design Tandem** vehicle and the **Design Truck (HS)**.

Multiple Presence Factors — Multipliers for design vehicles based on the number of design lanes in the transverse section of a roadway. The multiple presence factors, m, account for the statistical improbability of three or more adjacent lanes being loaded simultaneously with the design vehicle. The default values are taken from AASHTO LRFD table 3.6.1.1.2-1.

IRC Specific Parameters

Used to input parameters for loading per IRC Chapter 6.

The IRC rules have been implemented such that the program will select the appropriate live loads, number of design lanes, and generate all the possible load combinations as stated for a specified roadway width.



Loading Class	Select the vehicles to be used for this load generation.
Impact Factor	Specify a value to account for dynamic effects resulting for road surface imperfections.
Reduction in longitudinal effect	Contains a table of Multiple Presence Factor for the number of lanes for a specified roadway.

- *AD.2007-07.3.5 Transverse IRC Loading in STAAD.Beava* (on page 210)

Diagrams dialog

The diagrams dialog contains additional tabs in the Bridge Deck mode used to control the display of decks and influence diagrams.

Opens when **View > Structural Diagrams** is selected.

Influence tab

Used to control the display of influence diagrams on the defined bridge deck as displayed on the **Deck | Deck Definition** page.

Opens when:

- **View** > **Structure Diagrams** is selected, or
- **Loading > Influence Diagrams** is selected.

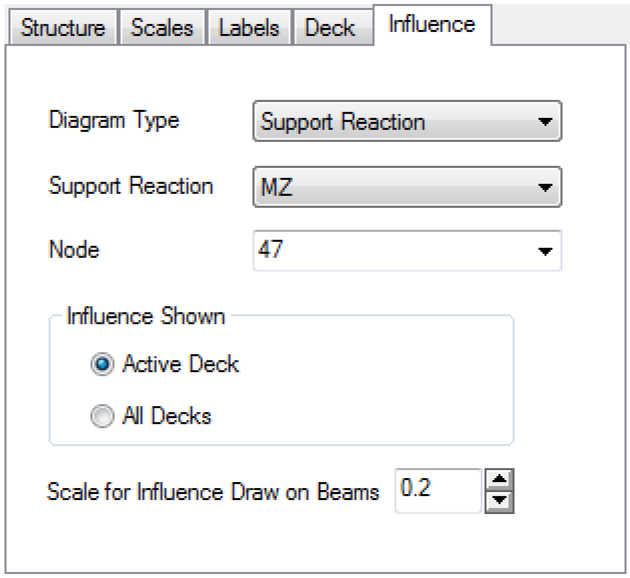

Diagram Type Select the type of action you wish to display in a contour plot the deck. The <action type> and <structural object> fields update with the selected type.

<action type> Select the action and direction for the action.

<structural object> Select the node, beam, or plate for which the action will be displayed.

Influence Show Select if the influence is drawn for **All Decks** defined in the Bridge Deck mode or only the **Active Deck**.

Tip: The Active Deck is the selected deck in the View toolbar.

Scale for Influence Draw on Beams Adjusts the scale for influence curves drawn onto beam objects.

Deck tab

Used to control the display of bridge decks and loads on the **Deck | Deck Definition** page.

Opens when:

- **View** > **Structure Diagrams** is selected, or
- **Loading > Influence Diagrams** is selected.

Roadways This option will display the defined roadways and the design lanes, as determined by the program. Different colors are available for the Active (currently selected) and Inactive elements.

Results These options are used to display the Loads and Vehicles on the structure. Different colors are available for the Active (currently selected) and Inactive loads.

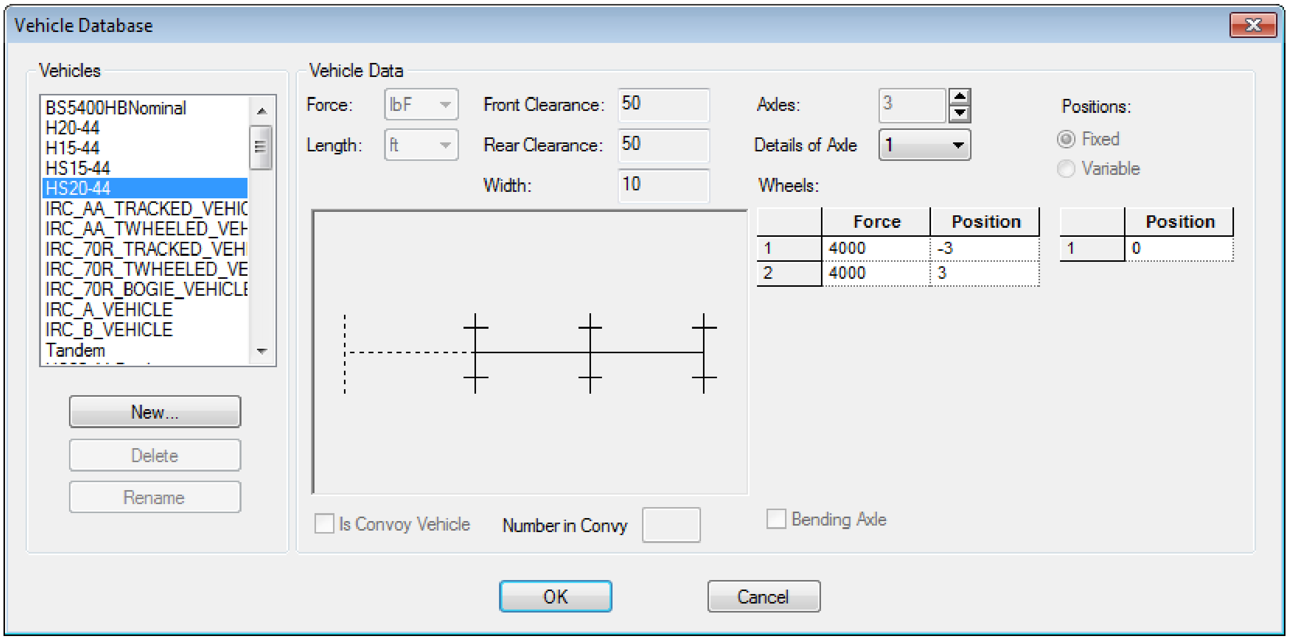
Triangulation Used to display the triangular, pseudo-plate elements created when a deck is defined from beam members only.

Vehicle Database dialog

Used to display code specified vehicle load data and to create user-defined loads.

Note: Vehicles included in Bridge Deck may not be edited or deleted.

Opens when **Vehicle > Database** is selected.



Vehicles list — All vehicle definitions in Bridge Deck are listed here. User-defined vehicles are added at the bottom of this list. Select a user-defined vehicle to make any changes.

New ... — Opens the **Add New Vehicle** dialog, which is used to specify a name for the vehicle load to be added.

Delete — (User-defined loads only) Deletes the currently selected vehicle definition.

Caution: There is no confirmation of this action and this action cannot be undone.

Rename — (User-defined loads only) Opens a Rename Vehicle dialog, which is used to specify a new name for the selected vehicle definition.

Vehicle Data — The dialog contains a set of simple parameters which can be used to define virtually any vehicle load.

- Force / Length - Select the units for use when specifying **Force** (lbF or kN) and **Length** (m, mm, or ft) values.
- Front / Rear Clearance - Specify the clear distance between the first and last axle, respectively, to another vehicle or load within the same design lane.
- Width - Specify the total width (half on either side of the vehicle center line) for placement within a design lane.

- A plan diagram displays the configuration of the vehicle load. Axle 1 is the right-most solid line, with subsequent axles to the left. Variable and multiple Fixed axle Positions are shown in dashed lines.
- Is Convoy Vehicle - Select this option to signify to the program that this vehicle is to applied repeatedly along the design lane, using the Front and Rear Clearances specified.
- Number in Convoy - Specify the number of vehicles present in the convoy.
- Axles - Use the combo box to select the number of axles (fixed or variable) on the vehicle.
- Details of Axle - Select the axle (up to the number of Axles specified) for which the current load and position data is entered.
- Wheels - Use the table to enter the Force (wheel weight) and Position (distance from vehicle center line), in the selected units, for the currently selected axle.
- Bending Axle - Select this option ...
- Positions - Select if the current axle is a **Fixed** distance (or a number of different fixed distances) from the previous axle or if the distance is **Variable**. For **Fixed** positions, the table below allows for one or more set distances between the current and previous axle. For **Variable** positions, a **Min**imum and **Max**imum distance must be specified, along with an **Increment** value for generating a finite number of positions.

OK	Accepts changes made to the currently selected vehicle (user-defined only) and closes the dialog.
Cancel	Closes the dialog without saving any changes.

Results tab

Table 346: View Results group

Tool name	Description
Load	Select the active load case, load combination, or load envelope from the pop-up dialog.
 **View Loading Diagram**	Click to toggle the display of the current load case on the structure.
 **Deflection**	Displays the deflected shape on the structure using nodal displacements.

Tool name	Description
 **Displacement**	Displays the nodal and beam sectional displacements. **Tip:** This will show a more accurate representation of the deflected shape compared to the **Deflection** tool, but may take longer to render for large structures.
 **Utilization Ratio**	Displays the design code based utilization ratio, for code checks and member selection operations, in annotated form on the structure diagram. **Note:** The colors representing the pass or fail status of a member can be controlled using the **Color Manager** dialog and the **Diagrams** dialog Design Results tab.
 **FX**	Displays the axial force diagram on the structure.
 **FY**	Displays the shear force Y diagram on the structure.
 **FX**	Displays the shear force Z diagram on the structure.
 **MX**	Displays the torsion diagram on the structure.
 **MY**	Displays the bending moment Y diagram on the structure.

Tool name		Description
 **MZ**		Displays the bending moment Z diagram on the structure.
 **Beam Stress**		Displays the beam stress diagrams on the structure.
 **Plate Stress**		Displays plate stress contours on the structure.
 **Solid Stress**		Displays solid stress contours on the structure.
 **Layouts >**	**Displacement**	Displays the nodal and beam sectional displacements, along with the P. Node Displacements table (on page 2002) and P. Beam Relative Displacement Detail table (on page 2003). This has the same effect as selecting the **Displacements** page in the Postprocessing workflow.
	Reaction	Displays the support reactions, along with the P. Support Reactions table (on page 2003) and P. Statics Check Results table (on page 2004). This has the same effect as selecting the **Reactions** page in the Postprocessing workflow.
	Instability	Displays unstable joints if any were detected in the analysis along with the P. Unstable Joints table (on page 2004). **Note:** This tool is only active if instabilities are detected during the analysis.
	Base Pressure	Displays the soil pressure at support node locations for slabs consisting of plate elements generated using either the elastic mat or plate mat commands along with the P. Base Pressure table (on page 2004). **Note:** This tool is only active if `ELASTIC MAT` or `PLATE MAT` commands are present in the input file.

Tool name		Description
	Beam Forces	Displays the force diagram on the structure for the selected load case along with the P. Beam End Forces table (on page 2005) and **Beam Force Detail** table. This has the same effect as selecting the **Beam Results** page in the Postprocessing workflow.
	Beam Stress	Displays the member stress diagram on the structure (same as the **Beam Stress** tool), along with the **3D Beam Stress Contour** view and P. Beam Combined Axial and Bending Stress table (on page 2007).
	Utilization	Displays the design code based utilization ratio, for code checks and member selection operations, in annotated form on the structure diagram (same as the **Utilization** tool) along with the P. Design Results table (on page 2008).
	Graphs	Displays the current loading on the structure in the main view along with a set of three Beam Graph windows which display force or bending diagrams for the currently selected member.
	Plate Stress	Displays the graphical plate stress contour diagram superimposed on the elements along with the P. Plate Corner Stress table (on page 2009) and P. Plate Center Stress table (on page 2009). This item will also open the Diagrams dialog to the Plate Stress Contour tab.
	Results Along Line	Opens the **Results Along Line** dialog along with the line graph and **Result along selected line** table.
	Solid Stress	Displays the graphical Solid Stress Contour diagram superimposed on the elements along with the P. Solid Corner Stress table (on page 2010) and the P. Solid Center Stress table (on page 2011). This has the same effect as selecting the **Solid Results** page in the Postprocessing workflow. This item will also open the Diagrams dialog to the Solid Stress Contour tab.
	Node Displacement	Displays the deflected shape for the selected load case and load step, along with the **Node Displacements Curve** graph and **Node Displacement** table.
	Beam Forces	Opens the Load Level vs Section Forces diagram and **Beam Force Detail** table.

Table 347: Dynamics group

Tool name	Description
Mode	Select the mode number from the drop-down list.

<table>
<tr><th colspan="2">Tool name</th><th>Description</th></tr>
<tr><td colspan="2">Mode Shape</td><td>Displays the mode shape diagrams for individual modes.</td></tr>
<tr><td colspan="2">Relative Response</td><td></td></tr>
<tr><td colspan="2">
Time Steps</td><td>Opens a drop-down control which allows you to move through time history steps using a slider control or by typing the time directly.</td></tr>
<tr><td rowspan="7">Layouts ></td><td>Dynamic - Mode Shape</td><td>Displays the mode shape diagram on the structure, along with a table of mode shapes. This has the same effect as selecting the Dynamics page in the Postprocessing workflow.</td></tr>
<tr><td>Dynamic - Displacement</td><td>Displays the time-displacement graphs for a selected node or node group in the structure.</td></tr>
<tr><td>Dynamic - Velocity</td><td>Displays the time-velocity graphs for a selected node or node group in the structure.</td></tr>
<tr><td>Dynamic - Acceleration</td><td>Displays the time-acceleration graphs for a selected node or node group in the structure.</td></tr>
<tr><td>Dynamic - Floor Spectrum</td><td>Displays the Response Spectrum graph and Response Spectrum table.</td></tr>
<tr><td>Pushover - Loads</td><td>Opens the (Pushover) Load Values table (on page 2012), which displays the nodal load values and total base shear for the selected load step, along with the Capacity Curve table.
The magnitude and direction of the loads in the current load step are displayed in the view window.</td></tr>
<tr><td>Pushover - Graphs</td><td>Opens the Capacity Curve graph (on page 2013), which displays displacement vs. force for the pushover analysis.
The Capacity Curve table contains the roof or control joint displacement and base shear values recorded for each load step.</td></tr>
</table>

Tool name		Description
	Pushover - Node Results	Displays nodal displacements and rotations in the (Pushover) Node Displacements table (on page 2014) and the support reactions in the (Pushover) Support Reactions table (on page 2015) for the selected load step. The deflected shape is overlaid on the structure in the view window.
	Pushover - Beam Results	Opens the (Pushover) Beam Hinge Results table (on page 2016) which displays the status of the beam and hinge conditions along each beam's length. The (Pushover) Beam Force Details table (on page 2017) displays the cross-sectional forces and moments at sections along each beam's length are displayed for the selected load step. The status of beams and hinges are displayed in the view window.
	Steady State - Displacement	Displays the frequency-displacement graphs in the global directions for a steady state analysis.
	Steady State - Velocity	Displays the frequency-velocity graphs in the global directions for a steady state analysis.
	Steady State - Acceleration	Displays the frequency-acceleration graphs in the global directions for a steady state analysis.
	Buckling	Opens the **Buckling Factors** table, which displays the calculated buckling factors from a buckling analysis, along with the **Buckling Modes** table.

Table 348: Animation group

Tool name	Description
 **Animation**	Opens the **Diagrams** dialog **Animation** tab, which is used to control what effect is being animated on the Animation page in the **Postprocessing** workflow.

Table 349: Configuration group

Tool name	Description
 **Select Load Case**	Opens the **Results Setup** dialog, which is used to select the load cases, mode shapes, and structural elements (beams, nodes, elements, etc.), which are included in the Postprocessing operations

Tool name	Description
 **Structure**	Opens the **Diagrams** dialog, which is used to customize the view of the structure by setting different view-related parameters.
 **Scale**	Opens the **Diagrams** dialog to the **Scales** tab, which is used to specify the scales to which the different diagrams for viewing input and results should be plotted. **Tip:** Select the **Enable Automatic Scaling** option on the **Results View Options** tab of the **Results Setup** dialog to automatically scale displays in the View window.
 **Annotate**	Opens the **Annotation** dialog, which is used to annotate the display of results annotations in the View window with numerical values.

Table 350: Properties group

Tool name	Description
 **Update Properties**	Updates the section properties assigned to members in the input file to those which are the result of a design member selection or group member command. If member selection is carried out for steel, timber or aluminum sections in the model, or if a `GROUP MEMBER` command is specified (see TR.50 Group Specification (on page 2680)), the properties of the structure at the end of these processes will no longer be the same as what we assigned initially or started out with. A warning dialog opens to confirm you wish to proceed before making any changes. **Note:** By performing this operation, the input file gets modified. Consequently, the analysis results are no longer compatible with the modified structure. Therefore, the **Analytical Modeling** workflow is automatically selected so the structure can be re-analyzed. Before doing so, it is advisable to go back and replace the `SELECT` and `GROUP`ing commands with `CHECK CODE` commands.

Table 351: Reports group

Tool name		Description
 **Reports >**	**Node Displacement**	When a node selection is made, this tool opens Node Displacement dialog, which is used to generate

Tool name		Description
	Support Reaction	Display tabular results for support reaction.
	Beam Property	Opens the **Beam Property** dialog, which is used to generate a sorted table of the selected beams for inclusion in the report.
	Beam End Forces	Display tabular results for beam end forces.
	Section Displacement	Display tabular results for beam section displacements.
	Section Forces	Display tabular results for beam stresses.
	Beam Stresses	Display tabular results for beam stresses.
	Column Transfer Force	Opens the **Transfer Forces for Selected Members** dialog, which is used to report transfer forces across beam connections on either side of columns for a selected set of members.
	Plate Stresses	Display tabular results for plate element stresses.
	Principal Stresses	Display tabular results for plate element stresses.
	Floor Vibration Report	Opens the **Floor Vibration Output** dialog, which is used to review the floor vibration analysis per AISC Design Guide No. 11 for a specific floor system and load combination. To utilize this feature, the floor system must be defined as a composite deck in the modeling mode.

Annotation dialog

Used to annotate the display of results annotations in the View window with numerical values.

For example, when a bending moment diagram is displayed in the Main Window area, we may use this option to display the values of the maximum bending moment and/or the end-moment values of selected members.

Opens when the **Annotate** tool is selected in the **Configuration** group on the **Results** ribbon tab.

Ranges tab

Used to select the members and nodes for which we want to display the values.

None	Does not annotate any Member, Element, or Node.
All	Annotates all Members, Elements, and Nodes in the current view.

View Annotates all Members, Elements and Nodes in a previously saved view. Select the desired view from list of available views using the drop down list.

Group Annotates all Members, Elements and Nodes in a previously saved group of structural elements. Select the *Group* option and then select the desired group from the view from list of available groups using the drop down list.

Property Select this radio button to select the members by assigned Property Reference Number and description.

Ranges Specify Node, Member and/or Element numbers. You may specify individual values separated by comma, by a list, or specify a range such as 5-10.

Beam Results tab

Used to select the values, which will be displayed on the diagram.

Bending This group of check boxes determines the Bending Moment values which will be displayed on the Bending Moment Diagram. *Ends* option will display the end-moments of the members. *Maximum* option will display the maximum moment value. *Mid point* option will display the Bending Moment value at the mid point of the member.

Shear This group of check boxes determines the Shear Force values, which will be displayed on the Member Force diagram. *Ends* option will display the values at the two end nodes of the member. *Maximum* option will display the maximum force value. *Mid point* option will display the force value at the mid point of the member.

Axial Switch this on to annotate the axial tension or compression values at the start and end of selected members.

Max Resultant Displays the maximum resultant section displacement value for each member.

Combined Bending and Axial Stress This group of check boxes determines the stress values, which will be displayed on the Stress diagram. *Ends* option will display the values at the two end nodes of the member. *Maximum* option will display the maximum value. *Mid point* option will display the value at the mid point of the member

Node tab

Nodal point displacements can be annotated using these options. More than one may be used simultaneously.

Global X / Y / Z Display the point displacements of a node in any of the global directions.

Resultant Displays the SRSS resultant displacement. That is, the displacement as calculated by:

$$\sqrt{(\text{Global-X}^2 + \text{Global-Y}^2 + \text{Global-Z}^2)}$$

Reactions tab

Used to select the Annotation type for the Support Reactions diagram.

Direct/Bending Check one or more check boxes from Global X/Global rX, Global Y/Global rY, Global Z/Global rZ to select the degrees of freedom to Annotate.

Show Lines Check this box to display line or arc with arrowhead to show the direction of the Reactions.

Scale	Use these spin boxes to specify the Scale factors for the Reaction force and Reaction moment in the diagram.

Annotate	Applies the selected annotation(s) to the View window.
Remove All	Removes all annotations from the View window.
Close	Closes the dialog box.

Related Links

- *P. To graphically display reactions at each support* (on page 1981)

Beam Property dialog

Used to generate a sorted table of the selected beams for inclusion in the report.

Opens when the **Report** > **Beam Property** tool is selected in the **Reports** group on the **Results** ribbon tab.

Sorting tab

Sort By Properties	Select the criteria by which the selected beams will be sorted in the generated table.
Absolute Values	Select this option to sort by absolute value of the selected property.
Set Sorting Order	Select the order by which the selected property is to sorted.

Report tab

Title	Enter a title for the generated table.
Save Report	Select this option to save the properties of the generated table

OK	Closes the dialog and generates a beam table for inclusion in a report.
Cancel	Closes the dialog without generating a beam report.
Help	Opens the STAAD.Pro help window.

Results Setup dialog

Used to select the load cases, mode shapes, and structural elements (beams, nodes, elements, etc.), which are included in the Postprocessing operations.

Opens when:

- the Postprocessing workflow is first selected, or
- when the **Select Load Case** tool is selected in the **Configuration** group on the **Results** ribbon tab.

Loads tab

Used to select the Load Cases to be included for Post Processing.

The **Available** list on the left displays all available load cases.

Click this button…	to…
>	Add the selected load case to the Selected list
>>	Add all load cases to the Selected list.
<<	Remove all entries in the Selected list, load combination is placed back in the Available list.
<	Remove the selected entry from the Selected list.

The **Selected** list displays load cases that have been selected.

Modes tab

For dynamic analyses including response spectrum and time history analysis and/or modal extraction commands, the *Modes* tab becomes activated. This tab lists all available mode shape numbers.

Range tab

Offers selection conditions based on the attributes of Members, Nodes, Groups, Properties, etc. These options determine whether the result tables are to be displayed for all Members/Nodes/Elements, or for the selected ones.

All Selects all structural elements.

View Selects the structural elements stored in a previously saved view. The drop down list displays all previously saved views for selection.

Group Selects the structural elements stored in a previously saved group. The drop down list displays all previously saved groups for selection.

Property Selects the structural elements having a specified property tag. The drop down list displays all existing property tags.

Ranges These edit boxes allow you to select *Nodes* and *Beams* by specifying a range. Specify Node, Member and/or Element numbers. You may specify individual values separated by comma, by a list, or specify a range such as 5-10.

Detail Tables The **Increments** option specifies the number of segments into which a member would be broken up for printing section forces, displacements, etc. These are used in some output tables, such as:

P. Beam Relative Displacement Detail table (on page 2003)
P. Statics Check Results table (on page 2004)

Results View Options tab

STAAD.Pro provides you with two choices in the size to which results such as displacements and moment diagrams are plotted :

a. Instruct STAAD.Pro to plot the result diagrams using a scale that will best fit the diagram within the window bounds. The drawback of this approach is that the variation in result values from one load case to the next will be hard to perceive if all load cases are plotted to the same maximum size dictated by the bounds of the drawing window.

b. Instruct STAAD.Pro to use the same basic scale for all load cases. The drawback of this approach is that while some load cases will have their results fit within the window bounds, some others may be too hard to perceive due to their small values, and others may go out of the bounds of the screen. The user is then required to modify the scale of each plot individually to better see each plot.

Choosing between these two settings is done using this facility.

Enable Automatic Scaling Use this to switch on the type of scaling described in (a). If we wish to use (b) instead, leave this box unchecked.

Displacement/Deflection/ Mode Shape/Beam Results These are the check boxes for the individual result types for which we want Auto-Scaling enabled. Any box left unchecked will be subject to the rules of method (b).

Node Displacement dialog

Used to create a Joint Displacement report for the selected node(s).

Opens when the **Report** > **Joint Displacement** tool is selected in the **Reports** group on the **Results** ribbon tab.

Sorting tab

Sort By Properties Select the criteria by which the selected beams will be sorted in the generated table.

Absolute Values Select this option to sort by absolute value of the selected property.

Set Sorting Order Select the order by which the selected property is to sorted.

Loading tab

Used to select the load cases to be considered in the sorted report.

Available List List of available load cases in the model which will not be included in the generated table.

List Operators

Click this button…	to…
>	Add the selected load case to the Selected list
>>	Add all load cases to the Selected list.
<<	Remove all entries in the Selected list, load combination is placed in the Discarded Load Combinations list.
<	Remove the selected entry from the Selected list.

Selected list List of loads for which the nodal displacement results will be included in the generated report.

Report tab

Title	Enter a title for the generated table.
Save Report	Select this option to save the properties of the generated table

Related Links

Transfer Forces for Selected Members dialog

Used to report transfer forces across beam connections on either side of columns for a selected set of members.

STAAD.Pro calculates the "Transfer force" (i.e., "pass through force"), which can be used for connection design. This feature is based on a paper on the subject by Dr. William. A. Thornton.

Transfer force is simply the maximum net horizontal force that gets transferred from the one side of the column to the other through the connection. So STAAD.Pro checks the forces in the members framing into each side of the column and finds out the resultant horizontal force for either side. Typically the resultant forces on the two sides would not be equal as some amount of force will be taken up by the column in shear. The greater of the two resultants is reported by STAAD.Pro as the transfer force. The option to determine transfer force automatically, will save engineers considerable time and effort as in most cases, they have to report the transfer forces in the design drawings. The same concept can be applied to floor bracing in horizontal plane.

Opens when the **Report** > **Column Transfer Forces** tool is selected in the **Reports** group on the **Results** ribbon tab.

Loads	Displays the load cases that has been considered to calculate the transfer force. By default, all load cases are considered but one can exclude a few of them by simply clicking on the load case within the Loads box.
Left / Right Beams	List all the members on the respective sides of the column along with their incidences. The boxes Left TF and Right TF shows the resultant horizontal force from either side. Max TF reports the transfer force.
Insert to Table	Generates the Transfer Force Report table which contains all the transfer force information and can be included in reports.
Close	Closes the dialog.

Related Links

- *P. To generate transfer forces report* (on page 1996)

Floor Vibration Output dialog

Used to review the floor vibration analysis per AISC Design Guide No. 11 for a specific floor system and load combination. To utilize this feature, the floor system must be defined as a composite deck in the modeling mode.

Opens when the **Report** > **Floor Vibration Report** tool is selected from the **Reports** group on the **Results** ribbon tab.

The adequacy of a floor system from the standpoint of its vibration serviceability due to human activity, specifically walking excitation, can be assessed using STAAD.Pro. The procedures of Chapters 3 and 4 of the AISC Steel Design Guide Series No. 11 - *Floor Vibrations due to Human Activity* are used by the program.

The vibration calculation is done for:

a. beam or the joist mode
b. girder mode

The two modes are then combined to obtain the system frequency and other results of the combined mode using the Dunkerley relationship described in chapter 3 of the AISC Design Guide. Results for the 2 basic modes and the combined mode are provided in a tabular form.

The output for the combined mode consists of:

a. the peak acceleration for walking excitation
b. allowable acceleration (known in the code as the acceleration limit)

The design criterion as stated in the code in the third paragraph in Chapter 4 is that a floor system is satisfactory if the peak acceleration does not exceed the acceleration limit.

Select Select a previously defined Composite Deck.

> **Note:** Composite Decks are defined use the **Composite Deck Layout** tool.

Load Case Select the load case for analysis.

Check Performs the floor vibration checks per AISC Design Guide 11.

Print Opens a Print dialog, which is used to create a hard copy of the currently displayed floor vibration report.

Steel AutoDrafter tab

Table 352: Edit group

Tool name	Description
 **Grids**	Opens the **Grid Manager** dialog, which is used to select which plan grids and elevation marks are displayed on the structure as well as in generated drawings.

Tool name	Description
 **Drawing Groups**	Opens the Drawing Groups tab in the **Drawing Lists & Groups** panel.
 **Drawing Style Manager**	Opens the **Drawing Style Manager** dialog, which is used to create drawing styles for use in Steel AutoDrafter.

Table 353: View group

Tool name	Description
 **Node Number**	Controls the display of node numbers in the view area.
 **Member Number**	Controls the display of member numbers in the view area.
 **Member Property**	Controls the display of member material names in the view area.
 **Grids**	Controls the display of grids in the view area.

Table 354: Drawings group

Tool name	Description
 **View Drawings List**	Opens the **Drawing List & Groups** panel in the view area. This panel is used to generate drawings individual, all drawings in the list, and to manage groups.

Table 355: Material Take Off group

Tool name	Description
 **Drawing**	Opens the material take-off for the entire structure in a drawing.
 **Text**	Opens the material take-off for the entire structure in an HTML text table.

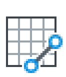
Related Links

- *P. To open the Steel AutoDrafter workflow* (on page 2019)

Grid Manager dialog

Used to select which plan grids and elevation marks are displayed on the structure as well as in generated drawings.

Opens when the **Grids** tool is selected from the **Edit** group on the **Steel AutoDrafter** ribbon tab.



The program will generate a grid line for nodal X and Z coordinate in the model. An elevation mark will be generated for each nodal Y coordinate.

Check the option for each grid or elevation mark to display it n the view area and in generated drawings.

Change grid or elevation mark labels by typing in the associated field for each.

Dialog controls

Import	Used to import grids from an existing `adfx` file.
OK	Updates the grid display and closes the dialog.
Cancel	Closes the dialog without saving any changes.

Related Links

- *P. To edit grid labels* (on page 2028)

Drawing Style Manager dialog

Used to create drawing styles for Steel AutoDrafter. This facilitates production of drawings as per selected style. You can also create standard styles with the required variations.

Opens when the **Drawing Style Manager** tool is selected from the **Edit** group on the **Steel AutoDrafter** ribbon tab.

All aspects of the drawing; Layer Descriptions, Layer colors, Connection / Member Descriptions, Dimension styles, Text Styles and sizes, and gird styles can be changed to create new text styles.

The Drawing Style can be imported, exported, and restored from the default file.

Drawing Style can be imported from another `adfx` file using the import grid option provided. The `adfx` file will be available along with the relevant STAAD.Pro file in the same folder.

Layers tab

This table lists all the layers that are used in the drawings generated by Steel AD. The layer descriptions and the colors can be changed.

Member Labels tab

Member / Connection type table lists all the various symbols that are used in the drawings. These symbols can be changed as desired.

In case you do not wish to have any symbols in the drawing, keep the symbols column blank.

The Section Referencing box, determines how the various sections will be labeled in the drawing, by using a reference number or the entire description of the section.

Appearance tab

This tab lists all the appearance related data. Fonts, Text Heights, Dimensions Styles and Grid Styles can be set in this tab.

Chinese Steel Design tab

Table 356: Settings group

Tool name	Description
 **Secondary Member**	Opens the **Assign Secondary Member** dialog, which is used to identify a member as a secondary member. The members they frame into will not be considered as restrained when determining automatic effective length calculations.
 **Brace Angle**	Opens the **Brace Angle** dialog, which is used to set the angle between the brace and the beam in both directions.
 **Material**	Opens the **Material Parameter** dialog, which is used to add or modify a custom steel material for use in the Chinese Steel Design workflow.
General Section	Opens the **General Section** dialog, which is used to specify built-up section profiles for general shapes used in analysis.

Table 357: Design group

Tool name	Description
 **Design**	Opens the **Chinese Steel Design** dialog, which is used to select the design options and checks to be performed as well as to initiate the design process.

Table 358: Solution group

Tool name	Description
 **Configuration**	Opens the **Configure Solultion** dialog, which is used to select parameters to include within a solution set. This allows you to run different solution scenarios within the same model.
Solution Selection	Select the current solution set name from the drop-down list to use in the design process.

Table 359: Select group

Tool name	Description
 **Failed**	Selects all members that have failed one or more design checks.
 **Passed**	Selects all members that passed all the design checks.
 **Minimal**	Selects all members that have a maximum utilization of less than 30% of the design requirements.

Tool name	Description
Not Designed	Selects all members that have not been included in a design.
Inverse	All beams in the selection set are deselected and any previously unselected beams are added to the selection set.
Parallel	Select beams that are parallel to the selected global axis. • **To XY** • **To YZ** • **To XZ**
Group	Opens the **Select Groups** dialog, which is used to select objects in a named group.
Property Name	Used to select nodes and members based on specifications associated with them. A number of specification types are included in the sub-menu list.
Missing Parameter	Select members which do not have parameter set assigned.

Table 360: Labels group

Tool name	Description
Parameter	Toggles the display of assigned parameter name for members.

Tool name	Description
 **Ratio**	Toggles the display of governing code check ratio for members.

Table 361: Results group

Tool name	Description
 **Apply Optimize Results**	Click to apply any update section sizes selected in the Results detail dialog. You will be prompted to re-analyze the structure.
 **Table Settings**	Opens the **Define Results Column** dialog, which is used to select the table columns included in the results.

Table 362: Output group

Tool name	Description
 **Member Report**	Opens the detailed design results for a single member. Use the tools to select which items are included in the report as well as to export it to different outputs.
 **Export Report**	Opens the **Export Report** dialog, which is used to select portions of the results to include in a report.

Assign Secondary Member dialog

Used to identify a member as a secondary member. The members they frame into will not be considered as restrained when determining automatic effective length calculations.

Opens when the **Secondary Member** tool is selected on the **Chinese Steel Design** ribbon tab in the **Settings** group.

Related Links
- *D. To assign secondary members* (on page 981)

Brace Angle dialog

Used to set the angle between the brace and the beam in both directions.

Opens when the **Brace Angle** tool is selected on the **Chinese Steel Design** ribbon tab in the **Settings** group.

When the angle is exceeded, the brace will not work. You can also set the member extend angle, when the angle is exceeded, the extended member will not work.

Brace and member major axis angle (1)	Type a maximum value for considering a brace between the member's major axis and the brace. The default value is 60°.
Brace and member minor axis angle (2)	Type a maximum value for considering a brace between the member's minor axis and the brace. The default value is 60°.
Member extend angle (3)	Type the maximum angle between two adjacent members to be considered as coplanar. The default value is 15°.

Related Links
- *D. To specify brace angle threshold values* (on page 982)

Material Parameter dialog

Used to add or modify a custom steel material for use in the Chinese Steel Design workflow.

Opens when the **Material** tool is selected on the **Chinese Steel Design** ribbon tab in the **Settings** group.

Tip: A set of predefined steel materials from GB50017-2017 Table 4.4.1 are included in the **Materials - Whole Structure** dialog and can be used for the model.

Note: Custom materials added in the Chinese Steel Design workflow are saved to the current model only.

Click **Add** to add a new user-defined material which can then be edited by selecting it in the table below and then clicking **Modify**. Only user-defined materials can be edited or deleted.

Material Name	Type a unique ID used to identify the material in parameters and reports.

Max Thickness	Type the maximum thickness for which this material can be used (in mm). If a section element exceeds this thickness when the material is used, a warning will be generated in the design results.
Yield Strength	fy
Tensile Strength	f
Shear Strength	fv
Section Bearing Strength	fce
Ultimate Tensile Strength	The rupture tensile strength, fu.

Related Links

- *D. To add a custom material definition* (on page 982)

General Section dialog

Used to specify built-up section profiles for general shapes used in analysis.

Opens when the **General Section** tool is selected on the **Chinese Steel Design** ribbon tab in the **Settings** group.

Type

Select the general section type from the drop-down list:

Type name	Cross Section
I Section	
Type name	Cross Section
Box	CrossedH	CrossedP1	
Type name	Cross Section
CrossedP2	Lattice 1	Lattice 2	
Type name	Cross Section
EnhancedH	
Outstanding Width of Flange (BF)

Thickness of Flange (TF)

Height of Web (BW)

Thickness of Web (TW)

Distance from neutral axis in Z direction to the bottom (y0)

Distance from neutral axis in Y direction to the left (y0)

Chinese Steel Design dialog

Used to specify the code check items to be performed and then perform a code check.

Opens when the **Design** tool is selected on the **Chinese Steel Design** ribbon tab in the **Design** group.

Click **OK** to perform the selected code checks. The **Results** window opens to display the results of the code check operation.

Structure tab

Setup Default Design Parameters	Used to specify the design settings for members which do not have a specific design parameter set assigned.
Seismic Option	Option to include the seismic provisions and to identify the precautionary intensity to use:

G6
G7
G8
G9

> **Note:** In order to include seismic design, the mode should include one or more seismic load cases and the “Seismic Measure Grade” should be specified in the member parameter sets.

Design Range

Select whether the design process should be performed on the entire model or only the currently selected members.

Optimize Option

The standard design process will check the structure using the data of the member profiles assigned to the model. However, it is possible to determine if a different profile would be better suited using an optimisation design. This action is applied to the members included in a parameter set that has the option **Optimise Design** set in the General Parameter page.

The optimization of any given member is determined by checking the applied forces on the given member against all the profiles in the section table from which the member was specified and selecting the profile that provides a maximum utilization that is as large as possible, but less than 1.0.

Note to view the profiles that are assigned to the members after an optimized design

When performing the optimization, there are three options that can be used to manage the optimization process.

Group Optimize

With this option a single profile is selected that provides a maximum utilization, but less than 1.0, when used on all the members in the parameter set that has the **Optimise Design** specified. This resulting in all members in the parameter set having the same Optimized Profile.

Fast Optimize

With this option specified, each member will be designed by sequentially stepping through the table of profiles from which the profile has been specified ordered by either

- None, i.e. defined by the table sequence, or
- the profile area AX, or
- the profile major moment of inertia IZ,

until a suitable profile has been identified. If not set, then every section profile in the table is checked.

Iterations

If a number of iterations is specified (i.e., a number >0), then after performing an optimization, the new profiles are assigned to each optimized member and a new analysis is performed. In doing so this may result in a new/different distribution of forces and stresses. The design is then re-performed. These steps are repeated for the number of iterations specified.

Design Checks tab

Select the code check you want the program to perform. There are buttons on the left to quickly select those that pertain to strength, stability, displacement, and detailing. There are also selection tools for all, none, or inverting the selection set.

Note: You can hold **<Ctrl>** to select multiple items.

Related Links

- *D. To perform steel design per the Chinese code* (on page 983)

Configure Solution dialog

Used to select parameters to include within a solution set. This allows you to run different solution scenarios within the same model.

Opens when the **Configuration** tool is selected on the **Chinese Steel Design** ribbon tab in the **Solution** group.

Select Solution	Select the solution set name from the drop-down list for management. **Note:** The type of analysis associated with the solution is indicated at the bottom-left corner of the dialog.
Parameter List	All parameter sets in the current solution set can be added for use in the solution set here. Use the **Used** (included) and **Unused** (excluded) lists and controls to configure the solution set.
Add	Click to add a new solution set.
Delete	Click to remove the current solution set from the model.
Rename	Click to rename the current solution set.

Related Links

- *RR 22.08.00-4.4 Multiple Parameters in Chinese Steel Design* (on page 100)

Assign Design Parameter dialog

Used to modify and assign design parameters per the Chinese steel design code.

Opens when the **Chinese Steel Design** workflow is selected.

A list of the current parameter sets associated with the current STAAD model. is displayed in the top portion of the dialog.

Add	Opens the **Add new: Chinese Steel Design Parameters** dialog, which is used to add a parameter definition to the model for use in Chinese steel design.

Edit	Used to edit the currently selected parameter set in the **Edit: Chinese Steel Design Parameters** dialog.
Edit Parameters (Text)	Opens the parameter sets in a plain text editor (e.g., Notepad) for editing. **Note:** No data validation of any kind is performed in the plain text editor. Therefore, the accuracy and validity of these changes is dependent upon the user to verify.
Delete	Delete the selected parameter set from the model.
Load Template	Used to open a set of parameters in a plain text (file extensions `.gsp` or `.txt`) for use in the current STAAD model.
Save As Template	Save the current parameter sets as a template file which can be loaded for use in other STAAD input file for Chinese steel design.
Assignment Method	The options under the **Assignment Method** are used to assign parameter sets to steel members. The assignment method can be one of **Assign To Selected Beams, Assign To View, Use Cursor To Assign** or **Assign To Edit List**. • Assign To Selected Beams **-** To assign a specification to selected members, first select the parameter set from the table. Then select the members to which this parameter set is to be assigned. This is done by going to the **Select** menu, then choosing the appropriate cursor option. Select the desired members using the cursor. When all desired nodes, members or elements are selected, click the **Assign To Selected Beams** radio button, then click the **Assign** button. • Assign To View **-** To assign a parameter set to all members in a view, first select the parameter from the table. Select the **Assign To View** radio button, then click the **Assign** button. All members in the structure are assigned this parameter set. • Use Cursor To Assign **-** To assign a parameter set to members using the cursor, first select the parameter set from the table. Select the **Use Cursor To Assign** radio button, then click the **Assign** button. The button will appear active and the label will change to **Assigning**. Use the appropriate cursor (from the Select menu) to assign the selected parameter set to the individual members. Click on the **Assign** button again to finish. • Assign To Edit List **-** To assign a specification using a typed list of node, member or element numbers, first select the parameter set from the table. Select the **Assign To Edit List** radio button, then type the list of member numbers and click the **Assign** button.

Chinese Steel Design Parameters dialog

Used to add a parameter definition to the model for use in Chinese steel design.

Opens when the **Add** or **Edit** button is clicked on the **Chinese Steel Design Parameters - Whole Structure** dialog.

General Parameters tab

Parameter Name	Type a unique label used to identify the parameter set.
Steel No	Select the steel grade used (independent of any steel grade assigned as part of a material definition):

- Q235 (default)
- Q345
- Q355
- Q390
- Q420
- Q460

Refer to Steel Grade (on page 990) for additional details.

Member Type

Select the member type for design:

- Automatic (default) - the actual type of the member is determined by the program based on the **Principle** selection.
- Bending - a beam for which bending (MZ, MY) are considered but axial force (FX) is ignored for design.
- Truss - only axial force (FY) is considered for design.
- Column - both moment and axial force are considered for design.
- Defined - for this type of member, the provisions for code checks are all user-defined.

Refer to Member Type (on page 989) for additional details.

Principle

Select the option which the program should use to determine the member type for Automatic:

- **Geometry -** uses the geometric conditions of the member for selection as follows:

geometric condition	member type
member in a horizontal plane	bending
member with a truss specification	truss
any other condition	column

- **Stress Feature -** uses the stress conditions of the member for selection as follows:

stress condition	member type
no axial force	bending
no bending moment	truss
any other condition	column

Refer to Member Type (on page 989) for additional details.

Check as Cantilever Member

Specify any cantilever member checks:

- None (default)
- Both - both major and minor axes
- Major Axis
- Minor Axis

Truss Secondary Moment

Section Slenderness Grade	Select the slenderness grade to check the width-to-thickness ratio of beam and column members per Table 3.5.1: • S1 • S2 • S3 (default • S4 • S5
Use Axis forced member Post-Buckling	
Displacements Load List	Click **[...]** to open the **Select Load Case for Displacements** dialog, which is used to select the load cases and combinations which the program should use for displacement checks.
Fatigue Check Request	
Force Loads List	Click **[...]** to open the **Select Load Case for Design** dialog, which is used to select the load cases and combinations which the program should use for design checks.
Optimize Design	
Failure Ratio Above	
Safety Ratio Below	

Seismic Design tab

Seismic Adjusting Factor	Check this option to specify the seismic adjusting factor values for **Stability** and **Strength** checks from the following: • Auto (default) • 0.75 • 0.8 • 1.0
Seismic Measure Grade	Select the levels as per Clauses 8.3.1, 8.3.2, and 8.4.1 and from Table 8.3.2. Select from the following: • None (default) • Level 1 • Level 2 • Level 3 • Level 4
Reduction Factor of Bearing Capacity	

Allowable Slenderness tab

Allowable Compression Slenderness

Select the allowable value of slenderness ratio for members in compression:

- Auto (default) - the value is determined as per Table 7.4.6
- 150
- 200

Allowable Tension Slenderness

Select the allowable value of slenderness ratio for members in tension:

- Auto (default) - the value is determined as per Table 7.4.7
- 200
- 250
- 300
- 350
- 400

Seismic Brace, GB50011-2010 8.4.1

Seismic Multi-storey Plant, GB50011-2010 H.2.8

Seismic Column, GB50011-2010 8.3.1

Seismic Single-storey Plant, GB50011-2010 9.2.13

Plastic Development Factor tab

The plastic development coefficient is a coefficient related to the shape of the section. The coefficient can be according to article 6.1.2 8.1.1 of the specification. If you enter the design parameters γ_z, γ_y, γ_{sharp}, the program will use those values. If you select to use automatic calculation, the program will use values for γ_z, γ_y, γ_{sharp} as specified in Plastic Development Coefficients γx, γy, γsharp (on page 992).

Major Axis (Z Axis)

The γ_z value.

- Auto (default)
- 1.05
- 1.20

Minor Axis (Y Axis)

The γ_y value.

- Auto (default)
- 1.05
- 1.20

Sharp (Tee/Double Angle/Channel)

The γ_{sharp} value.

- Auto (default)
- 1.05
- 1.20

Equivalent Moment Factor tab

The equivalent moment coefficient is used to "correct" the bending moment when checking the stability of the solid web bending member with bending moment acting on the symmetry axis plane, so it is divided into in-plane equivalent moment coefficient and out of plane equivalent moment coefficient. These coefficients can be calculated automatically by program or manually input.

Equivalent Moment Factor in-Plane

- Auto (default)
- 1.00
- 0.85
- 0.65

Equivalent Moment Factor out-Plane

- Auto (default)
- 1.00
- 0.85
- 0.65

Lateral Load Along Local y

- Auto (default)
- 1.00
- 0.85
- 0.65

Lateral Load Along Local z

- Auto (default)
- 1.00
- 0.85
- 0.65

Deflection Parameters tab

Refer to Deformation Parameters (on page 991) for additional details.

Span/Deflection (DFF) Select the span-to-deflection ratio limit:

- 150
- 200
- 250
- 300
- 350
- 400 (default)
- 500
- 600
- 750
- 1,000

Start Joint (DJ1) Select the starting joint used to define the member for deflection checking:

- Auto - forms a continuous beam

- Member start joint - selects the current member start joint

End Joint (DJ2)	Select the ending joint used to define the member for deflection checking: • Auto - forms a continuous beam • Member end joint - selects the current member end joint
Check Horizontal Section Displacement	

Stability Factors tab

The stability coefficient is divided into overall stability coefficient of flexural member (beam) and stability coefficient of axial compression member (truss). The program can automatically calculate the coefficients according to the section type and force characteristics of the designed member as described in Stability Coefficient (on page 992).

Overall Stability Factor of Beam	**Major Axis (Z Axis)**	• Auto
	Minor Axis (Y Axis)	• Auto
	Stress Feature (GB50017-2017 Appendix Table C.1)	• Type1 • Type2 • Type3 • Type4 • Type5 • Type6 • Type7 • Type8 • Type9 • Type10
Stability Factor of Axial Compression	**Major Axis (Z Axis)**	• Auto
	Minor Axis (Y Axis)	• Auto
Axial Compression Section Type	**Major Axis (Z Axis)**	• Auto • Class a • Class b • Class c • Class d
	Minor Axis (Y Axis)	• Auto • Class a • Class b

- Class c
- Class d

Effective Length tab

The unsupported effective length and effective length coefficient are the calculation parameters needed to check the stability of members. The direction of the strong axis and the weak axis of the principal inertial axis should be considered respectively. For complex structures, it can difficult to select the effective length and effective length coefficient of members. Therefore, the program can automatically compute these values. When these coefficients are automatically calculated by the program, they are calculated as described in Unsupported Effective Length and Effective Length Coefficient (on page 993). The values may also be user-specified.

Unbraced Length: The unbraced length (in meters) of the members, in both the **Major Axis (Z Axis)** and **Minor Axis (Y Axis)**.

Effective Length: Select the member bracing condition in the **Brace Type** drop-down. Then, specify the effective length coefficients, μ_z (**Major Axis (Z Axis)**) and μ_y (**Minor Axis (Y Axis)**).

> **Note:** If the current solution set is set to use a P-Delta analysis type, then the effective length options are disabled. An effective length of 1.0 is used for all design parameter sets for this solution set type.

Gyration Radius Calculation of Single Angle: Select the option to use for the radius of gyration for single angles:

- Parallel Leg Calculation (Y-Z Axis) - the geometric axes
- Strong Weak Axis Calculation (U-V Axis) - the primary axes

Refer to Rigid Fixed Stepped Column at the Lower End of Frame of Single Story Workshop (on page 996) for details.

Detailing Checks tab

The structural requirement parameters specified here refer to the limits of flange width thickness ratio and web height thickness ratio, as well as the section type of axial compression members. Generally, this parameter is automatically calculated by the program. However, in order to make it easier for users to design the program more flexibly, you can also set the parameters required here. Refer to Construction Requirements (on page 1002) for details.

Flange Slenderness Limit (b/t)

- Auto

Web Slenderness Limit (h0/tw)

- Auto

Include check for web of H profiles in a Truss as per GB50017-2017, Table 8.5.2: Check this option to use the values for Table 8.5.2 instead.

Section Factor tab

The net section coefficient refers to the ratio of net section to gross section area and section modulus (temporarily replaced by net section modulus coefficients An, Wnz, and Wny). The default value is 1.0. Refer to Section Coefficient (on page 1003) for details.

Net Section Factor	**Net Area Factor (An/A)**	Type a value to use for the net section area to gross area ratio.
	Net Resistance Moment Factor (Wny/Wy)	Type a value to use for the net moment resistance to gross section moment resistance ratio about the y direction.
	Net Resistance Moment Factor (Wnz/Wz)	Type a value to use for the net moment resistance to gross section moment resistance ratio about the z direction.
Effective Section Factor of Axis Force (nA)	Type a value to use for the net section area to gross area ratio.	

Reduce Factor	**Reduce Strength of Angle Section (Ref. 7.6.1)**	Check this option to use a re
	Strength Reduction	• Auto • 0.70 • 0.85 • 0.90
	Stability Reduction	• Auto • 0.70 • 0.85 • 0.90
	Unequal Angle Connection	• Short leg • Long leg (default)

Optional Checks tab

Optional checks based on the selected member type. Any of the checks can be un-selected to prevent that check from being performed.

For bending members:

- Beam Bending Strength
- Beam Deflection
- Flange Slenderness
- Overall Stability
- Equivalent Stress
- Web Slenderness
- Shear Strength

For truss members:

- Compression Flange
- Compression Shear
- Compression Stability

- Compression Web Slenderness
- Compression Slenderness
- Truss Strength
- Tension Slenderness

For column members:

- Column Strength
- Compression Flange Slenderness
- Compression Slenderness
- Compression Web Slenderness
- Shear Strength
- Stability in-plane
- Stability out-plane
- Tension Slenderness

For defined members:

Strength	Select the strength check: • Beam Bending Strength • Truss Strength • Column Strength
Stability	• Overall Stability • Compression Stability • Stability in-plane
Flange Slenderness	• Flange Slenderness • Compression Flange Slenderness
Web Slenderness	• Web Slenderness • Compression Web Slenderness
Other	• Shear Strength • Compression Shear • Equivalent Stress • Stability out-plane • Beam Deflection • Compression Slenderness • Tension Slenderness

Connection Design tab

Table 363: Assign Connections group

Tool name		Description
 **Joint Cursor**		Used to select joints for connection design.
Select Joints >	*`<joint types>`*	Tools for selecting joints in the model by member type and orientation.
	Select Special Joints	Opens the **Special selection of joints** dialog, which is used to select joint types by category as well as by filtering for member depth and end release.
Select Connections >	**Select all connections**	This will select all the connection in the model
	Select identical connections	This will select all the identical connection in the view **Tip:** This effectively allows you to “group” connections together to edit as one.
	Select connections of the same type	This will select the connection of same type. **Note:** To use this feature, you must select at least one connection before selecting this tool.
	Select connections with same template	This will select the connection of same template. **Note:** To use this feature, you must select at least one connection before selecting this tool.
	Select connections of the same family	This will select the connection of same family name, as used in RAM Connection. **Note:** To use this feature, you must select at least one connection before selecting this tool.
	Select connections with same tag names	This will select the connection of same tag name, as used in RAM Connection. **Note:** To use this feature, you must select at least one connection before selecting this tool.

Tool name		Description
	Select connections with same template and sections	This will select the connection of same template and where the section of the members which participate in the connection are also same. **Note:** To use this feature, you must select at least one connection before selecting this tool.
	Select connection nodes and members	This will select all the nodes and members which participate in the connection. **Note:** To use this feature, you must select at least one connection before selecting this tool.
 **Assign Basic Connection**		Opens the **Basic Connections** dialog, which is used to assign basic connection templates to selected joints.
 **Assign Smart Connection**		Opens the **Smart Connections** dialog, which is used to assign smart connection templates to selected joints.
 **Assign Gusset Connection**		Opens the **Gusset Connections** dialog, which is used to assign gusset connection templates to selected joints.

Table 364: Frames group

Tool name	Description
 **Identify Beam and Grider**	Opens the **Beam-Girder Identification** dialog, which is used to switch the beam and girder assignments for connections. **Note:** If no Beam-Girder (BG) connections have been assigned, a warning dialog opens to notify you no matching connections could be found .

Tool name	Description
 **Create Seismic Frame**	Opens the **Seismic Frames** dialog, which is used to specify the type of seismic frame used for the selected members creating a seismic frame definition.

Table 365: Reports group

Tool name	Description
 **Connection Report**	Opens the **RAM Report Export** dialog, which is used to manage connections and other report details to include in an report.

Table 366: Configure group

Tool name	Description
 **Connection Database**	Opens the connection database dialog, which is used to manage and create connection templates.

Special Selection of Joints dialog

Used to select joint types by category as well as by filtering for member depth and end release.

Opens when the **Select Joints** > **Select Special Joints** tool is selected in the **Assign Connections** group on the **Connection Design** ribbon tab.

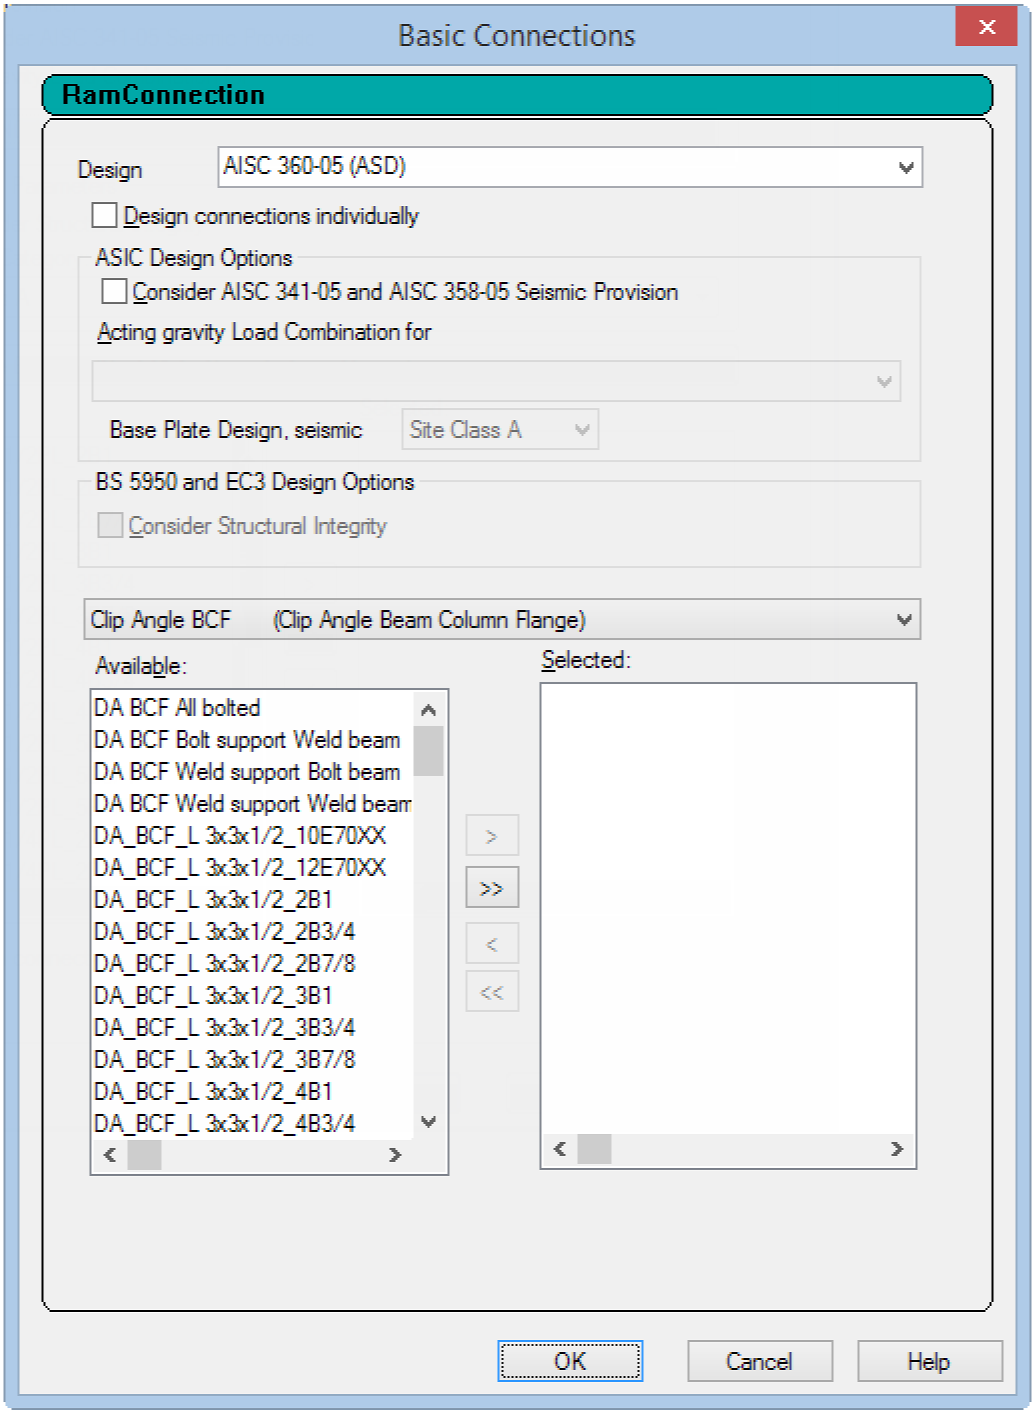
Select from	Choose an option by which to limit the selecting range if you had previously selected members prior to this dialog opening.
Family	Select one connection family type. These are the same options as found on the **Select Joints** tool n the **Assign Connections** group on the **Connection Design** ribbon tab.
Limit selection by beam depth	Check this option and provide minimum and maximum beam depth values (in the units displayed) in order to further limit the matching connections for selection.
Verify Releases	Check this option and then check one or both of the end release types (pinned or fixed).

Basic Connections dialog

Used to assign Basic connection templates to selected joints. A “Basic” connection template contains all the information about the connection (such as the plate sizes and bolt locations etc) which is applied to a joint and then checked for code compliance.

A set of joints that is to use Basic connections can contain multiple connections (i.e., each with a different plate size and bolt diameter). If the first connection does not achieve compliance, then the next is checked until either a suitable connection is defined or all the selected connections have been checked. Therefore, when assigning basic connections, you will typically select multiple connections to be checked.

Opens when **Connection Design** > **Assign Basic Connections** is selected.



Note: The definition of each connection template and the order in which they occur, are defined in a database which can be displayed and/or modified from the **Connection Design** menu. See the RAM Connection manual for more information on editing the connection database.

Design	Select the design code to be used. The field is populated with the default code selected in the RAM Settings dialog.

Seismic Provisions

(AISC codes only)

Select the Consider AISC 341-05 Seismic Provisions option to instruction the program to design the connections per this specification.

A gravity load combination must be selected when this option is used.

Consider Structural Integrity

(BS5950 only) Select this option to include the requirements for structural integrity in the design (Cl 2.4.5.2 BS5950 1:2000). A tie force not less than 75 kN is considered for these verifications. The appendices A to D (BS5950 1:2000) give the required information on the behavior and methodology to resist tying forces in the design.

Seismic Category

(Base Plate only) Specify the site class which best describes the soil conditions supporting the foundation and base plate.

Connection types

Select the class of connection to be used from this list. The connection types available depend on the code selected.

Available list

A list of all available connection templates for the selected connection type are listed here.

List Operators

Click this button…	to…
>	Add the selected connection template to the Selected list.
>>	Add all connection templates to the Selected list.
<<	Remove all entries in the Selected list.
<	Remove the selected entry from the Selected list.

Selected list

The connection templates selected for design will be added to the list.

Design Connections Individually

Select this option to instruct the program to optimize connections at each joint separately, rather than grouping for the worst case among common connections.

Button	Description
OK	Accepts the design criteria and performs a design for the selected joints using the selected connection templates.
Cancel	Closes the dialog without designing any connections.
Help	Opens the STAAD.Pro help window.

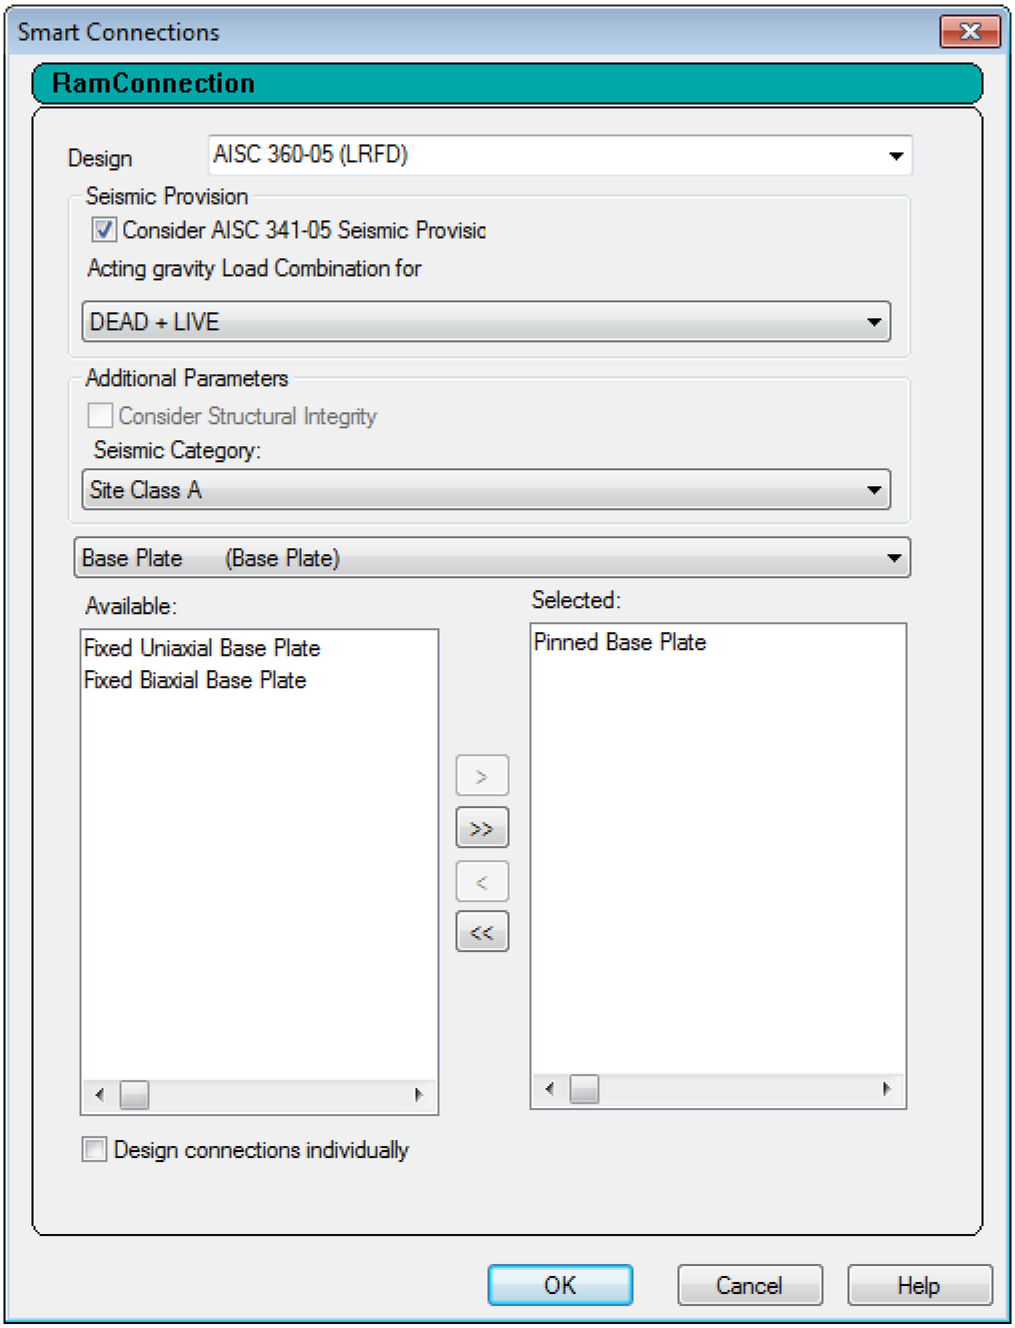
Related Links

- *D. Design Connections Individually* (on page 1037)
- *D. To select a basic connection template* (on page 1033)

Smart Connections

Used to assign smart connection templates to selected joints. A “smart” connection template contains parametric rules defined in a macro which allows characteristics of the connection to be modified (within limits) in order to achieve code compliance. A joint selection set that is to use a Smart connection can only specify a single smart connection definition.

Opens when **Connection Design** > **Assign Smart Connections** is selected.



Note: The definition of each connection template and the order in which they occur, are defined in a database which can be displayed and/or modified from the **Connection Design** menu. See the RAM Connection manual for more information on editing the connection database.

Design
Select the design code to be used. The field is populated with the default code selected in the RAM Settings dialog.

Seismic Provisions
(AISC codes only)

Select the Consider AISC 341-05 Seismic Provisions option to instruction the program to design the connections per this specification.

A gravity load combination must be selected when this option is used.

Consider Structural Integrity
(BS5950 only) Select this option to include the requirements for structural integrity in the design (Cl 2.4.5.2 BS5950 1:2000). A tie force not less than 75 kN is considered for these verifications. The appendices A to D (BS5950 1:2000) give the required information on the behavior and methodology to resist tying forces in the design.

Seismic Category
(Base Plate only) Specify the site class which best describes the soil conditions supporting the foundation and base plate.

Connection types
Select the class of connection to be used from this list. The connection types available depend on the code selected.

Available list
A list of all available connection templates for the selected connection type are listed here.

List Operators

Click this button…	to…
>	Add the selected connection template to the Selected list.
>>	Add all connection templates to the Selected list.
<<	Remove all entries in the Selected list.
<	Remove the selected entry from the Selected list.

Selected list
The connection templates selected for design will be added to the list.

Design Connections Individually
Select this option to instruct the program to optimize connections at each joint separately, rather than grouping for the worst case among common connections.

Button	Description
OK	Accepts the design criteria and performs a design for the selected joints using the selected connection templates.
Cancel	Closes the dialog without designing any connections.
Help	Opens the STAAD.Pro help window.

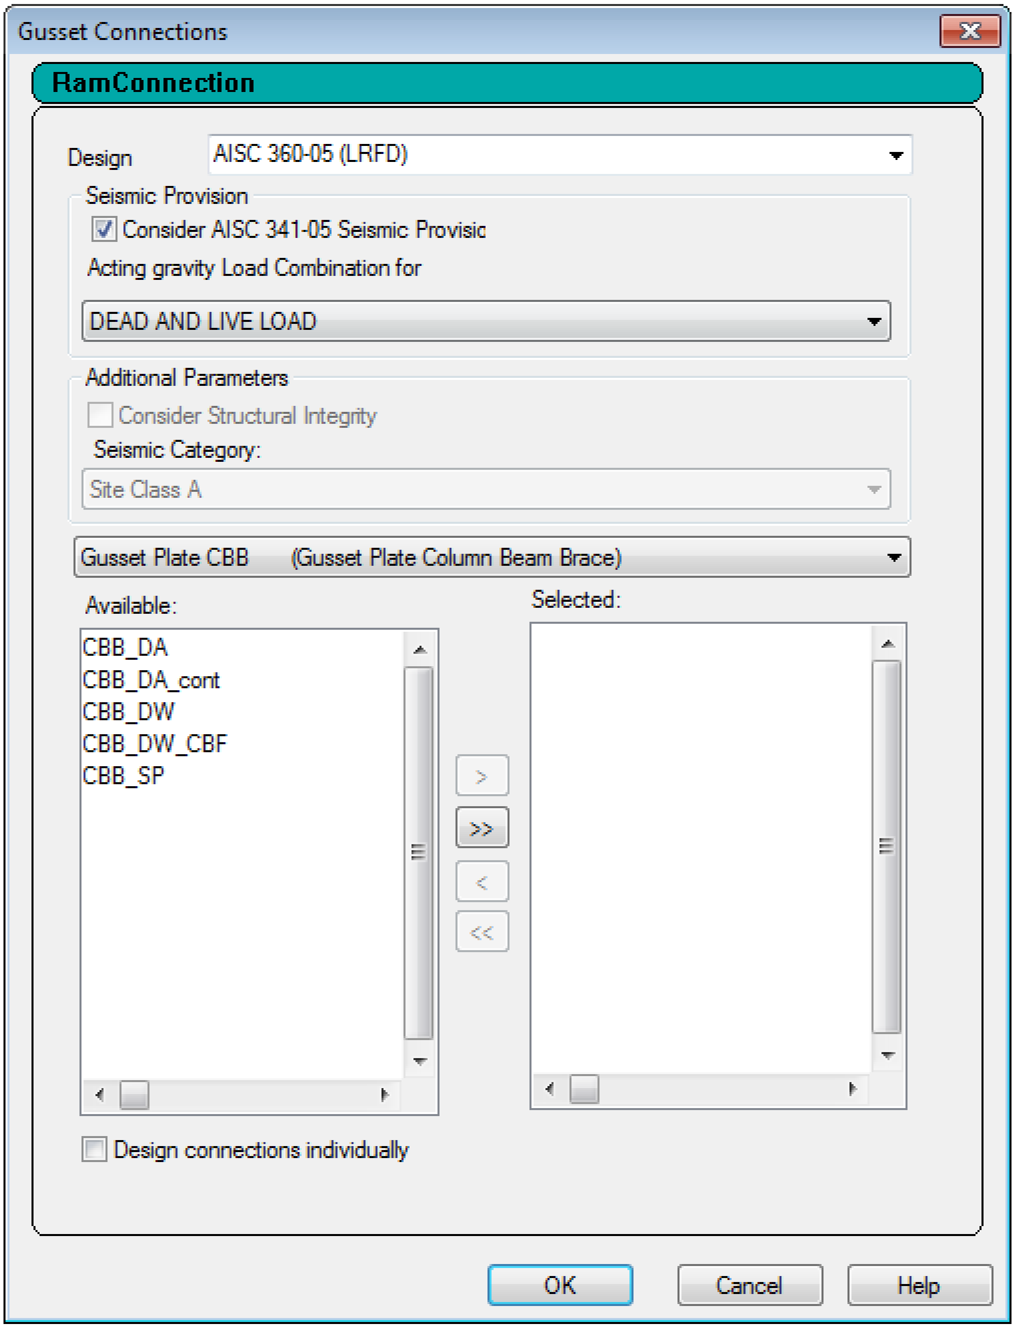
Gusset Connections dialog

Used to assign gusset connection templates to selected joints. A Gusset connection template contains parametric rules similar to those in a Smart connection template but that are limited to connections using gusset plates.

Opens when **Connection Design** > **Assign Gusset Connections** is selected.



Note: The definition of each connection template and the order in which they occur, are defined in a database which can be displayed and/or modified from the **Connection Design** menu. See the RAM Connection manual for more information on editing the connection database.

Design	Select the design code to be used. The field is populated with the default code selected in the RAM Settings dialog.
Seismic Provisions	(AISC codes only)

Select the Consider AISC 341-05 Seismic Provisions option to instruction the program to design the connections per this specification.

A gravity load combination must be selected when this option is used.

Consider Structural Integrity
(BS5950 only) Select this option to include the requirements for structural integrity in the design (Cl 2.4.5.2 BS5950 1:2000). A tie force not less than 75 kN is considered for these verifications. The appendices A to D (BS5950 1:2000) give the required information on the behavior and methodology to resist tying forces in the design.

Seismic Category
(Base Plate only) Specify the site class which best describes the soil conditions supporting the foundation and base plate.

Connection types
Select the class of connection to be used from this list. The connection types available depend on the code selected.

Available list
A list of all available connection templates for the selected connection type are listed here.

Beam-Girder Identification dialog

Used to switch beam and girder assignments in a Beam-Girder connection. STAAD.Pro will automatically assign the Beam and Girder designations. This dialog allows you to switch the assignment between the two members in the connection.

Opens when **Connections** > **Identify Beam and Girder** is selected.

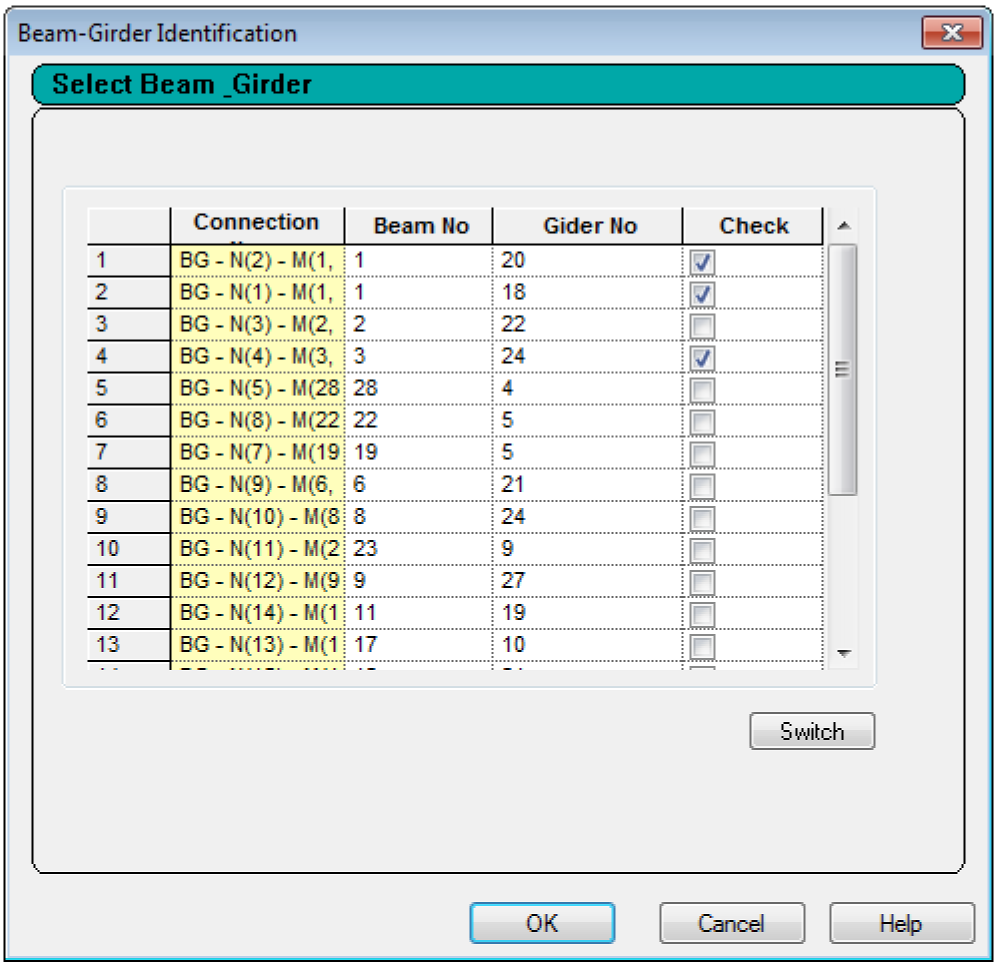

Table of BG Connections	All Beam-Girder (BG) connections in the model are listed here along with the members in the connection which are have been automatically assigned as Beam or Girder. Select the **Check** option for each connection for which you wish to switch member assignments.
Switch	Click this button to swap the **Beam No** and **Girder No** member assignments of members selected in the **Check** column.
OK	Accepts the settings changes and closes the dialog.
Cancel	Closes the dialog without saving changes.

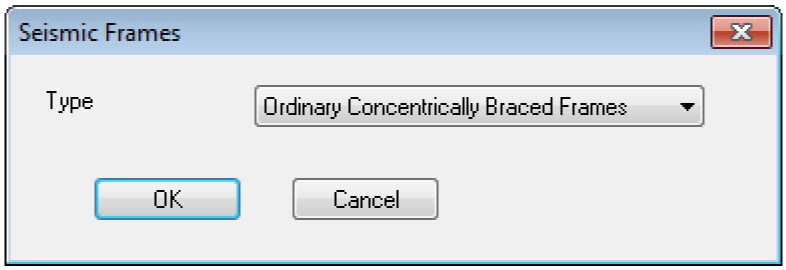
Help Opens the Help window.

Seismic Frames

Used to specify the type of seismic frame used for the selected members creating a seismic frame definition.

Note: This dialog is accessed from the D. Seismic Frames page (on page 1044).

Opens when **Connection** > **Create Seismic Frame** is selected.



Type Select the predefined method of lateral seismic force resisting system the frame represents.

- None
- Ordinary Moment Frames (OMF)
- Intermediate Moment Frames (IMF)
- Special Moment Frames (SMF)
- Ordinary Concentrically Braced Frames (OCBF)
- Special Concentrically Braced Frames (SCBF)

OK Accept the seismic frame assignment and closes the dialog.

Cancel Closes the dialog without making a seismic frame assignment.

RAM Report Export dialog

Used to manage connections and other report details to include in an report.

Note: The report is saved to a Microsoft Office Word document in the same folder as the STAAD.Pro input file, as `inputfile_Report.doc`, where *inputfile* is the STAAD.Pro Input filename.

Connection list Contains a list of all the designed connections. Use the **Up** and **Down** buttons to reorder the connections in the report. Select the connections you want to include in the report.

Data Report Check this option to include the input values in the report.

Result Report Set this option to include the code check output for the connections in the report.

formula Check this option to include the formulas used for code checks in the report.

Individual / Merged Report Select to generate either individual reports for each connection or a single report with all connections merged into a single file.

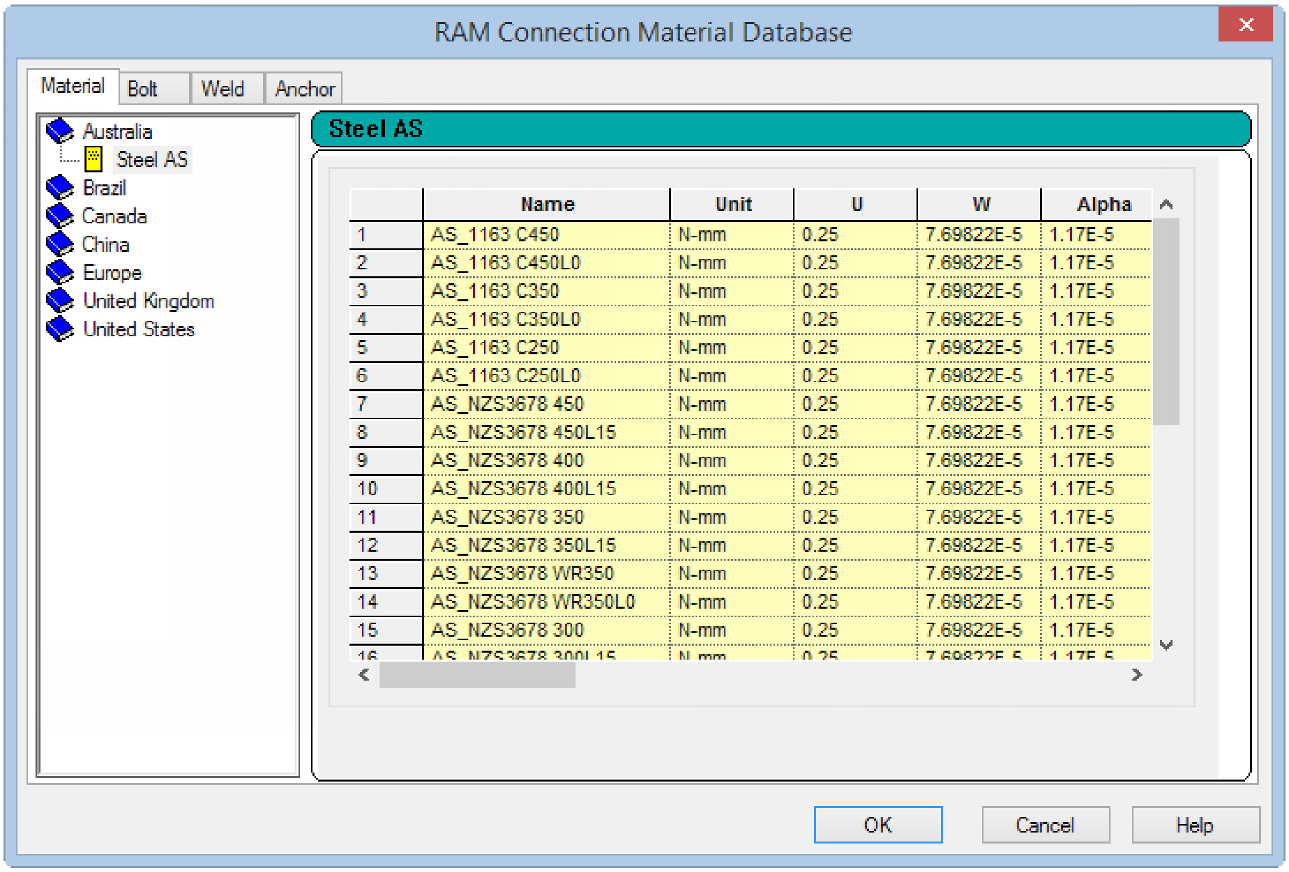
Related Links

- *D. To Export Connection Designs to a Report* (on page 1037)

RAM Connection Material Database dialog

Used to review additional material data required by Connection Design for the design of steel connections. Material strengths are displayed here to allow for the assignment of material grades.

Opens when **Connection Design** > **Show RAM Database** is selected.



Additional material data is required by RAM Connection beyond that which is kept in STAAD.Pro's databases. This information can be viewed and edited from the RAM Material dialog. In the case of the same material being defined in both STAAD and RAM Connection, the local STAAD value is used.

The STAAD materials are read from the STAAD.Pro `.ini` file. Some generic materials do not have any strength materials defined and these should be entered here.

Materials listed in the country tabs (i.e., United States or United Kingdom) are read from RAM Connection. These values are displayed in yellow fields and may not be edited in this dialog.

Materials table The following explains the columns used in the RAM Materials table:

Material Property	Description
Fy	Yield stress
Ry	Yield strength ratio
Rt	Ratio of the expected tensile strength to the specified minimum tensile strength, Fu
Fu	Specified minimum tensile strength
FCu	Ultimate strength of concrete

OK Accepts the material changes entered in the table and closes the dialog.

Cancel Closes the dialog without saving changes.

Help Opens the Help window.

Bolts tab

Database tables lists bolt geometry and material properties. The following tables are included:

- AISC - American Institute of Steel Construction bolts, in imperial units.
  - Db: Bolt Diameter
  - Fv: Nominal shear stress
  - Ft: Nominal tensile stress
  - Tm : Minimum Bolt pretension
  - Mu: Minimum Slip Coefficient
- BS - British Standard bolts, in metric.
  - Db: Bolt Diameter
  - Pt: Tensile Strength
  - Ps: Shear Strength
  - P0: Minimum Shank Tension
  - Mu: Slip Factor

Weld tab

Database table lists weld material properties. The following tables are included:

- AISC - American Institute of Steel Construction welds, in imperial units.
  - Fexx: Weld electrode Strength

Advanced Slab Design tab

Contains tools used for selecting elements of a defined slab as well as for transmitting data to RAM Concept for slab design.

Table 367: Highlight group

Tool name	Description
 **Highlight Plates**	Selects all plate elements associated with the selected slab definition in the Slabs table.
 **Highlight Beams**	Selects all beam members associated with the selected slab definition in the Slabs table.
 **Highlight Columns**	Selects all column members associated with the selected slab definition in the Slabs table.
 **Highlight Geometry**	Selects all structural elements associated with the selected slab definition in the Slabs table.

Table 368: RAM Concept group

Tool name	Description
 **Export to RAM Concept**	Creates the required data files for RAM Concept to analyze and design the selected slab definition in the Slabs table. **Note:** This command does not open the external slab design program nor does it execute the analysis and design functions in that program.
 **Open in RAM Concept**	Creates the required data files for RAM Concept to analyze and design the selected slab definition in the Slabs table. RAM Concept is launched. **Note:** If RAM Concept is not installed on your computer or if the version installed is not compatible with Advanced Slab Design link, a warning dialog opens to inform you that the data could not be sent to RAM Concept.

Node Tools tab

Note: The Clipboard group contains **Cut**, **Copy**, **Paste**, and **Delete** tools found on the **Geometry** ribbon tab.

Table 369: Model group

Tool name	Description
 **Move Joint**	Opens the **Move Entities** dialog, which is used to specify the translational offset for moving a selection of nodes.
 **Renumber Nodes**	Opens the **Renumber** dialog, which is used to renumber selected nodes starting with a specified number. The numbering sequence can be in an ascending or descending order and the order can be sorted by some criteria if needed.
 **Assign Supports**	Opens the **Supports - Whole Structure** dialog, which is used to define supports and assign them to nodes.

Table 370: View group

Tool name	Description
 **New View**	Opens the **New View** dialog, which is used to create a new view window for displaying the selected structural elements. You are prompted to indicate whether the selected view would be opened in a new (child) window or whether it would replace the current (parent) view. Any number of “child” view windows in this way. **Note:** This option becomes active only after you select one or more structural elements on screen.

Tool name	Description
 **3D Rendering**	Used to render the model using true lighting, reflection and shading in a separate window. It enables walk-through, dynamic zoom and panning capabilities in the 3D rendered view. Once the 3D Rendering option is chosen, a separate window opens displaying the rendered view. The structure can be dynamically rotated about all three axes by simply holding the left mouse button down and dragging the structure in the intended direction. Right-clicking the mouse button will display a myriad of viewing options. Depending on the material used (steel, concrete, etc.), an appropriate texture will be applied to the structure. A property or material must be assigned to the entities of the model before this feature can be used. This is for visual and presentation purposes only.

Node dialog

Displays information for the selected node.

Opens when a node is double clicked with the Nodes Cursor.

Node	Displays the node number and coordinates for the currently selected node.
Nodes	Opens the Nodes table (on page 714).
Supports	Opens the Node Supports (on page 715).
Loads	Opens the **Load Values** table.
Reactions	Opens the P. Support Reactions table (on page 2003).
Displacements	Opens the P. Node Displacements table (on page 2002). If no results have been setup, the Results Setup dialog (on page 2999) will be opened first to specify the results you wish to view.
Close	Closes the dialog.

- *GS. Object Properties Inspection* (on page 53)

Beam Tools tab

Note: The Clipboard group contains **Cut**, **Copy**, **Paste**, and **Delete** tools found on the **Geometry** ribbon tab.

Table 371: Model group

Tool name	Description
 **Move Beams**	Opens the **Move Selected Beams** dialog, which is used to specify the translational offset for moving a selection of beams.
 **Insert Node**	Opens the **Insert Node into Beam #** dialog, which is used to insert one or more nodes at specified distances along selected members.
 **Form Member**	Used to manually form a physical structural member from a selection of one or more connected analytical beam segments.
 **Stretch Beam**	Opens the **Stretch Member(s)** dialog, which is used to increase the length of a member in various ways.
 **Merge Beams**	Opens the **Merge Selected Beams** dialog, which is used to join two collinear beams and replace them with one beam.
 **Intersect Beams**	Splits members at detected intersection points and creates an addition node at this intersection point such that the members are now connected.
 **Renumber Beams**	Opens the **Renumber** dialog, which is used to renumber selected beams starting with a specified number. The numbering sequence can be in an ascending or descending order and the order can be sorted by some criteria if needed.

Tool name	Description
 **Define Section Profile**	Opens the **Define Section Profile** dialog, which is used to specify beam stress locations for general user-provided table sections for use in post-processing. **Note:** This tool is only active when a member using a general UPT section is selected in the Postprocessing workflow.
 **Properties**	Opens the **Beam** dialog which displays properties for the selected member. Additional tabs become available after analysis and design is performed.

Table 372: Connection Tags group

Tool name	Description
 **Assign**	Opens the **Assign Connection Tags** dialog and **New Connection tag** dialog, which are used to assign existing connection tags to member ends in the model and to create new connection tags, respectively.
 **Remove**	Opens the **Assign Connection Tags** dialog and initiates the remove connection tag tool for the connections on the selected member. A confirmation dialog opens to confirm the remove action.
 **View**	Opens the **Assign Connection Tags** dialog.
 **Check**	(Active only after a successful analysis has been performed) Opens the **Assign Connection Tags** dialog and **Check Connection Tags** dialog, the latter of which is used to check the load case results from the analysis against the defined connection capacities in the Connection Tags XML data file.

Table 373: View group

Tool name	Description
 **New View**	Opens the **New View** dialog, which is used to create a new view window for displaying the selected structural elements. You are prompted to indicate whether the selected view would be opened in a new (child) window or whether it would replace the current (parent) view. Any number of “child” view windows in this way. **Note:** This option becomes active only after you select one or more structural elements on screen.
 **3D Rendering**	Used to render the model using true lighting, reflection and shading in a separate window. It enables walk-through, dynamic zoom and panning capabilities in the 3D rendered view. Once the 3D Rendering option is chosen, a separate window opens displaying the rendered view. The structure can be dynamically rotated about all three axes by simply holding the left mouse button down and dragging the structure in the intended direction. Right-clicking the mouse button will display a myriad of viewing options. Depending on the material used (steel, concrete, etc.), an appropriate texture will be applied to the structure. A property or material must be assigned to the entities of the model before this feature can be used. This is for visual and presentation purposes only.

Plugins

Tool name	Description
Add Attribute	Opens the **Member Attribute** dialog which is used to select and apply a member attribute to selected members. Refer to TR.29 Definition of Member Attributes (on page 2340) for additional information on the member attributes assigned using this dialog.
List/Delete Attribute	Opens the **Member Attribute** dialog to display the currently used Member Attribute for a single selected member

Define Section Profile dialog

Used to specify beam stress locations for general user-provided table sections for use in post-processing.

Opens when either:

- the **Define Section Profile** tool is selected in the **Model** group on the **Beam** ribbon tab
- **Define Section Profile** is selected from the right-click pop-up menu

Note: This tool is only active when a member using a general UPT section is selected in the Postprocessing workflow.

Enter the local Y and Z coordinates of the section extreme fibers to specify stress points.

You can also "swap" the top and bottom sides () or left and right sides () in order to facilitate entering stress points by clicking the corresponding tools.

Tip: Additional profile name, material, and section properties are provided to assist in identifying the section.

Beam dialog

The member query box includes the ability to change many of the member attributes from the dialog box itself including the property definition, specifications (releases, truss, cable, etc.) and beta angle.

A list of the load items assigned to the member are displayed here. New load items can now be added to existing load cases, and, existing load items edited or deleted using the Member Query window.

Select Load Case	Choose the load case to you want to display or edit. This list will be empty if no primary load cases have been defined in the model.
Add new Load Item	Opens the Create New Load Items dialog, which is used to add new load items to the selected load case and assign them to the currently selected member. The list of load items displayed is limited to those which can be assigned to members.
Remove Selected Load Item.	Click to remove an existing load item selected in the list.
Edit Selected Load item	Click to make changes to the currently selected load item in the list. The load item dialog for the load type opens. Make the desired changes and then click **Change**.

Opens when a member is double-clicked with the Beams cursor.

Tip: While this dialog box is open, you may select any other member to Query by double-clicking it. This updates the dialog box contents automatically for the newly selected member. Also, the units can be changed dynamically while this dialog box is open. Changing the units using the *View* | *Options* or *Tools | set Current Display Units* menu affects the contents of this dialog box automatically.

To change the property, member specifications or the beta angle on the member, simply click on one of the buttons. If the member contains output result tabs (Displacement, Steel Design, etc.) in the query box, changing the member attributes will cause these tabs to disappear. This is due to the fact that the current output no longer reflects the new input.

Note: Changing the member attributes for one member will subsequently change the attributes of all other members belonging to the same attribute list. For example, if the current member's property is also assigned to other members, changing the property on the current member will change the property on all the members.

Geometry

Shows a diagram of the member property and lists the length, connecting nodes and their coordinates, and whether the member has a beta angle, any releases or other member specifications.One can assign/change the beta angle of the member by clicking on the **Change Beta** button.

Change Beta	Click to assign or change the beta angle for the selected member.
Change Releases at Start / End	Click to assign or change the start or end release attributes, member offsets, cable specification, truss specification, tension-only specification, compression-only specification, ignore stiffness, or inactive specifications.

Property

Shows a diagram of the member property and lists the length, cross sectional and material properties. One can assign/ change the property or member specifications of the member by clicking on the respective buttons.

Assign/Change Property	Click to assign or change the section property of the member. The choice of properties will only from the same family as the current cross-section. For example, if the current property is an America W12x45, only W, M, S, HP, and B shapes and sizes will be available.
Assign Material	Click to update the material definition with one selected from the drop-down list.

Shear Bending

This tab appears only after running the analysis. It also contains facilities for viewing values for shears and moments, selecting the load cases for which those results are presented, a slider bar for looking at the values at specific points along the member length, and a Print option for printing the items on display.

The slider bar in the member query box can be used to display the shear, bending and deflection values at any point along the beam. A corresponding edit box is also provided to manually type in the distance for which the aforementioned values will be calculated and displayed.

To obtain the values for the shear, bending or deflection at any point along the beam for a specific load case, grab the slider bar (the draggable arrow) and drag it to the desired location on the beam. The location of the slider bar is reported in the *Dist* edit box in the current display units. This edit box can also be manually changed which conversely, changes the location of the slider bar. The values for the results in question will automatically be updated every time the slider bar moves.

Deflection

This tab appears only after running the analysis. Shows deflection diagram in the global or local directions for the selected load case. Also lists tabulated deflection values. Points of inflection are displayed on the diagram. The points of inflection or contraflexure are the distances along the member where the sign of the force, deflection or moment changes (the point where these values are zero).

Refer to the next figure to see where the points of inflection are labeled. The distances are always reported from the start of the member (in the figure, the left-hand side of the member).

Composite Property

The dialog box displays various properties for the composite beam including effective width, whether shoring during construction has been considered or not, grade of concrete, unit weight of concrete, thickness of concrete above flutes, rib properties, stud properties etc. These data will enable the user to get a clear picture of the geometric properties for the composite beam.

Design Property

If the STAAD input file contains instructions for steel design - Member Selection (refer to TR.49.1 Member Selection Specification (on page 2678), and US or UK Example 1 in the Application Examples) which may result in a change of section property from the one originally assigned by the user - that new section name, and associated property values will be displayed under this tab. One can assign/change the material attributes for the beam by clicking on the Assign Material button.

Steel Design

This tab appears only after running the analysis if a steel design operation has been performed on the selected member. Shows a diagram of the member property and lists the length, design stresses, critical load, code being used, ratio, result, critical condition and slenderness value.

fSB	Actual Steel Stress before Concrete Hardens
FSB	Allowable Steel Stress before Concrete Hardens
fCB	Actual Concrete Stress before Hardening
FCB	Allowable Concrete Stress before Hardening
fSA	Actual Steel Stress after Concrete Hardens
FSA	Allowable Steel Stress after Concrete Hardens
fCA	Actual Concrete Stress after Hardening
FCA	Allowable Concrete Stress after Hardening
Critical load	The table displays information like critical load case, critical force values, and location of the critical section along the member length
Code	The design code followed for designing the composite beam
Result	Displays whether the beam has PASSED or FAILED the check
Ratio	Ratio of actual to allowable stresses
Critical	Reports the critical condition. In the previous dialog box CONC-STR-AH is displayed which indicates that Concrete Stress after hardening is the critical condition.
KLR	Reports the slenderness ratio (kL/r for compression or L/r for tension). The slender ratio value displayed is based on the critical axial force and is marked “T” for tension or “C” for compression.
STUDS	Display the number of shear connectors required and diameter of shear connectors.

Castellated Beam Design

Concrete Design

Related Links

- *GS. Object Properties Inspection* (on page 53)

Physical Member dialog

Used to display information about a selected physical member, similar to the member query dialog.

Opens when physical member is double-clicked with the Physical Member cursor.

Related Links

- *GS. Object Properties Inspection* (on page 53)

Assign Connection Tags dialog

Used to assign existing connection tags to member ends in the model.

Opens when **Connection Tags** > ***any* Connection Tags** is selected from the right-click pop-up menu when a member is selected.

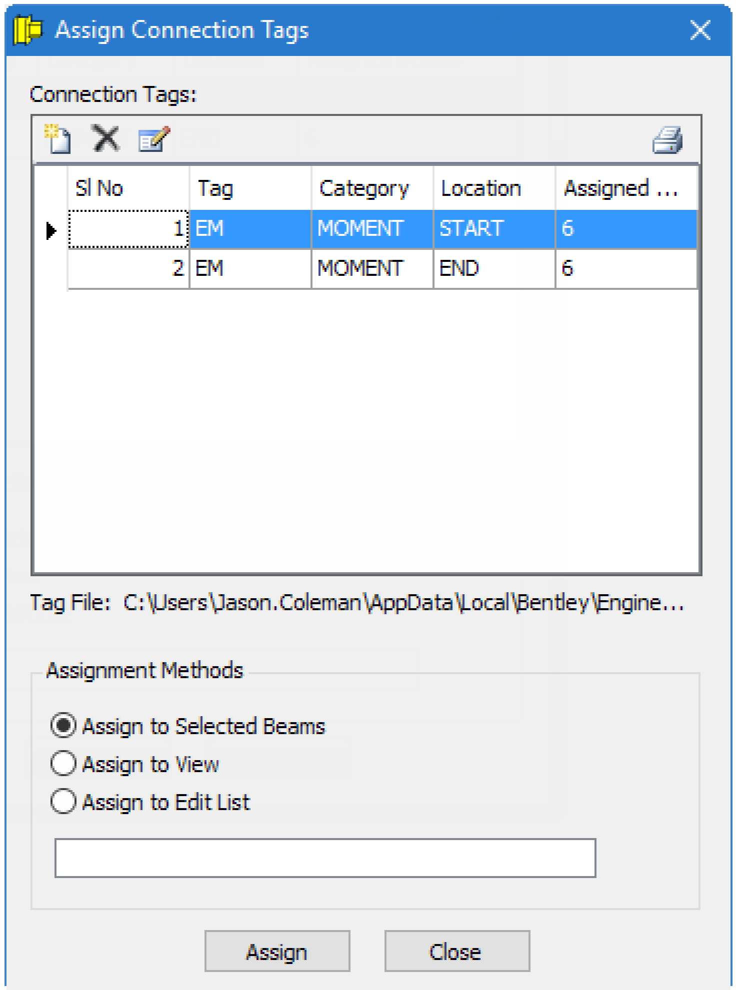

*Figure 353: The **Assign Connection Tags** dialog*

Table 374: Dialog toolbar controls

Toolbar icon	What It Does
New	Opens the New Connection Tag dialog, which is used to define new connection tags and optionally assign member end restraints associated with a connection tag.
Delete	Used to remove the selected connection tag entry from the table. A confirmation dialog opens to confirm you want to remove the entry.

Toolbar icon	What It Does
Check	(Disabled if no current analysis results are available for the current STAAD.Pro model) Opens the Check Connection Tags dialog, which is used to check the load case results from the analysis against the defined connection capacities in the Connection Tags XML data file.

table Each row in the table is a separate connection tag added to the model from the Connection Tags XML file.

Assignment Methods Select on of the following methods for assigning connection tags:

- **Assign to Selected Beams —** Uses the current members selected in the main view window
- **Assign to View —** Uses all members visible in the ain view window
- **Assign to Edit List —** Uses the member numbers listed in the associated text field

> **Tip:** You can type a dash between two numbers to indicate all member numbers, inclusive.

Assign Assigns the currently selected connection tags in the table using the selected Assignment Method. The members assigned area added to the Assigned Beams cell in the row.

Close Closes the dialog.

Related Links

- *D. To create a connection tag* (on page 1047)

New Connection Tag dialog

Used to define new connection tags and optionally assign member end restraints associated with a connection tag.

Opens when either:

- **Connection Tags** > **Remove Connection Tags** is selected from the right-click pop-up menu when a member is selected, or
- the **New** tool is selected in the Assign Connection Tags dialog

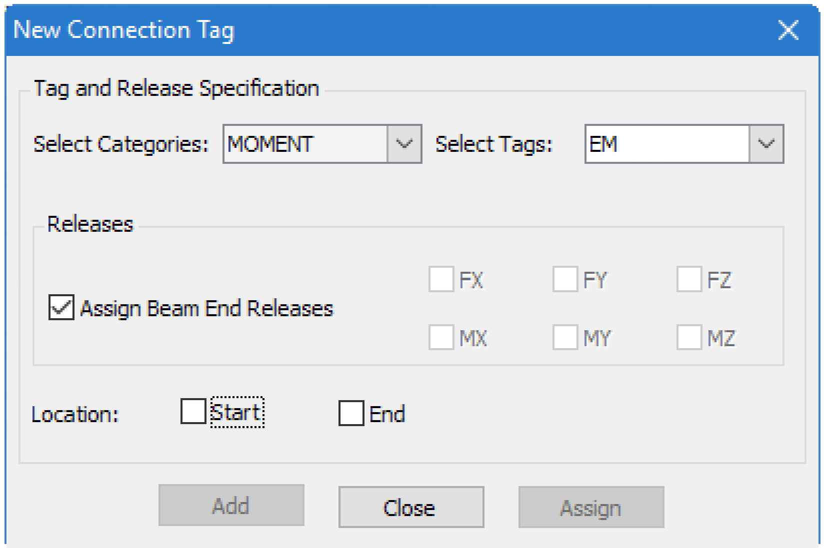

*Figure 354: The **New Connection Tag** dialog*

Select Categories Use the drop down list to select one of the connection tag categories defined in the Connection Tag XML file. Additional category descriptions are displayed.

Select Tags Use the drop down list to select one of the connection tags defined in the selected category. When selected, the member end releases defined for this connection tag are indicated in the inactive degree of freedom check boxes in the Releases group.

Assign Beam End Releases Set this check box option on to assign the indicated member end releases for the connection tag in the STAAD.Pro model when the connection tag is assigned.

> **Tip:** This is recommended so the releases match those assumed by the connection tag.

Location Select either the **Start** or **End** member end (or both) for adding this connection tag to the Assign Connection Tags dialog table or assigning to currently selected members.

> **Note:** At least one Location must be selected in order to add or assign the connection tag.

Start – The start node of the member.
End – The end node of the member.

Add Adds the selected connection tags at the selected location to the Assign Connection Tags dialog table.

Close Closes the dialog.

Assign Assigns the current connection tags to the current member selection in the STAAD.Pro model. These connection tags will also be added to the Assign Connection Tags dialog.

Related Links

- *D. To create a connection tag* (on page 1047)

Remove Connection Tags dialog

Used to select which member end from which the connection tag assignment will be removed.

Opens when **Connection Tags** > **Remove Connection Tags** is selected from the right-click pop-up menu when a member is selected.

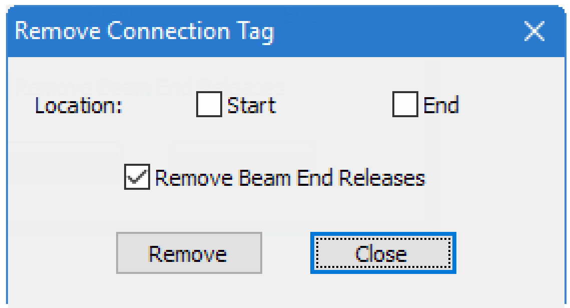

*Figure 355: The **Remove Connection Tag** dialog*

Location	Select one or both of the **Start** or **End** member ends for removing a connection tag assignment.
Remove Beam End Releases	Set this option to have the associated member end releases returned to default (fixed) in the STAAD.Pro input file.
Remove	Performs the assignment removal. A confirmation dialog opens
Close	Closes the dialog without removing any connection tag assignments.

Related Links

- *D. To remove connection tag assignments* (on page 1049)

Member Attribute dialog

Used to assign StructLink and member type attributes to selected members.

Note: These member attributes are separate attribute definitions from those which can be associated with adding new members (e.g., beta angle, section, etc.).

Opens when either:

- the **Add Attribute** tool from the **Plugins** group is selected on the **Beam Tools** ribbon tab, or
- **Add Member Attribute** is selected from the right-click pop-up menu

Attribute Name	Select the attribute you want to define for the member selection: • **STRUCTLINK -** the StructLink attribute • **MEMBTYPE -** member functionality used in RAM Connection design **Tip:** There are separate tools available on the **Beam Tools** ribbon tab and on the right-click pop-up menu for assigning Connection Tags, which are another member attribute type.

Attribute Values	For the selected **Attribute Name**, a list of predefined attribute values can be selected.

Related Links

- *D. To assign member type attributes* (on page 1031)

Plate Tools tab

This ribbon tab is available when one or more plate objects are selected.

Note: The Clipboard group contains **Cut**, **Copy**, **Paste**, and **Delete** tools found on the **Geometry** ribbon tab.

Table 375: Model group

Tool name	Description
 **Move Plate**	Opens the **Move Selected Plates** dialog, which is used to specify the translational offset for moving a selection of plates.
 **Renumber Plates**	Opens the **Renumber** dialog, which is used to renumber selected plates starting with a specified number. The numbering sequence can be in an ascending or descending order and the order can be sorted by some criteria if needed.
 **Generate Plate Mesh**	Used to generate a finite element mesh for an existing plate element. The polygon can be meshed into quadrilateral or triangular elements. You have control over parameters like number of divisions along each side of the polygon. Polygonal holes can also be defined within the surface during the meshing process for polygonal meshing.
 **Properties**	Opens the **Plate** dialog which displays properties for the selected element. Additional tabs become available after analysis and design is performed.

Table 376: View group

Tool name	Description
 **New View**	Opens the **New View** dialog, which is used to create a new view window for displaying the selected structural elements. You are prompted to indicate whether the selected view would be opened in a new (child) window or whether it would replace the current (parent) view. Any number of “child” view windows in this way. **Note:** This option becomes active only after you select one or more structural elements on screen.
 **3D Rendering**	Used to render the model using true lighting, reflection and shading in a separate window. It enables walk-through, dynamic zoom and panning capabilities in the 3D rendered view. Once the 3D Rendering option is chosen, a separate window opens displaying the rendered view. The structure can be dynamically rotated about all three axes by simply holding the left mouse button down and dragging the structure in the intended direction. Right-clicking the mouse button will display a myriad of viewing options. Depending on the material used (steel, concrete, etc.), an appropriate texture will be applied to the structure. A property or material must be assigned to the entities of the model before this feature can be used. This is for visual and presentation purposes only.

Plate dialog

Used to view a summary of the input and output data for a plate element, including geometry, properties, and output results.

If the structure has been successfully analyzed, there will be three tabs on the plate query box: Geometry, Property Constants and Stresses. If there are no analysis results, the last tab (Stresses) will not be shown.

Opens when a quad or triangular plate element is double-clicked with the Plates cursor.

Geometry tab

Displays the plate incidences, the plate corner coordinates and the lengths of each of the edges.

Plate Spec There are certain attributes which can be assigned to plates in order to simulate characteristics like the type of connections that are present at their corners. These are - Releases of individual degrees of freedom at its nodes, defining them as Plane Stress elements, ignoring their stiffness for the purpose of analysis, etc. If such attributes are assigned, those will be listed against the Plate Spec: field.

Property Constants tab

displays the thickness of each of the sides of the plate and the material properties. One may change/assign the properties of the plate by clicking on the Assign/Change Property button. One can also assign/change the material attributes by clicking on the Assign Material button.

Center Stresses tab

Displays the 8 center stresses along with the top and bottom Principal, Von Mises and Tresca stresses for a particular load case. The load case can be changed using the Load List dropdown box.

Corner Stresses tab

Used to display the stresses at the corner node points of the selected plate. The node numbers of the selected plate and the stresses at those nodes are displayed.

Load List	Select any one of the predefined load cases for displaying the corner stresses of the selected plate due to that particular type of loading.
Plate Corner Stresses	Different types of stresses at the corner nodal points of the selected plate under the specified load case are listed here.

Princ Stress and Disp tab

Used to display the nodal displacements at corner points of the selected plate.

Load List	Select any one of the predefined load cases for displaying the displacements at the corner node points and also the principal stresses of the selected plate due to that particular type of loading.
Plate Corner Displacement	After selecting a particular type of load case in the Load List, displacements in the X, Y and Z direction at the corner node points of the selected plate will be listed here.
Plate Principal Stresses	Top and bottom principal stresses of the selected plate under the specified load case are displayed here.

Related Links

- *GS. Object Properties Inspection* (on page 53)

Surface Query dialog

Used to view detailed information for one surface entity at a time.

Opens when a surface element is double-clicked with the Surface cursor.

While this dialog box is open, you can query any other surface element by double-clicking on it. The dialog updates automatically for the newly selected element. Similarly, the display units can be changed dynamically while this dialog box is open using the Change Graphical Display dialog.

Geometry tab

Shows a diagram of the surface element and a table listing all nodes on the perimeter of the element, as well as node to node distances along the perimeter.

Property tab

Lists surface element’s thickness and properties of the element’s material: Elasticity, Poisson’s ratio, Density, and thermal expansion coefficient (Alpha).

Surface Forces tab

(Available after a successful shearwall analysis and design) Reports internal forces (Fx, Fy, Fxy, Mx, My, Mz, Qx, and Qy) for five levels at which the shear wall design is carried out: 1/8h, 1/4h, 1/2h, 3/4h, and 7/8h. The forces may be viewed for all load cases / combinations included in the design.

Concrete Design (Shear wall) tab

(Available after a successful shearwall analysis and design) This page of the dialog box contains a full summary of the design, including shear wall geometry, concrete and steel strengths, min. reinforcing ratios, and reinforcing details for all of the five design levels. In addition, a diagram of the horizontal cross-section of the wall is shown for each level.

Solid Tools tab

This ribbon tab is available when one or more solid objects are selected.

Note: The Clipboard group contains **Cut**, **Copy**, **Paste**, and **Delete** tools found on the **Geometry** ribbon tab.

Table 377: Model group

Tool name	Description
 **Move Solid**	Opens the **Move Selected Solids** dialog, which is used to specify the translational offset for moving a selection of solids.
 **Renumber Solids**	Opens the **Renumber** dialog, which is used to renumber selected solids starting with a specified number. The numbering sequence can be in an ascending or descending order and the order can be sorted by some criteria if needed.

Table 378: View group

Tool name	Description
 **New View**	Opens the **New View** dialog, which is used to create a new view window for displaying the selected structural elements. You are prompted to indicate whether the selected view would be opened in a new (child) window or whether it would replace the current (parent) view. Any number of “child” view windows in this way. **Note:** This option becomes active only after you select one or more structural elements on screen.
 **3D Rendering**	Used to render the model using true lighting, reflection and shading in a separate window. It enables walk-through, dynamic zoom and panning capabilities in the 3D rendered view. Once the 3D Rendering option is chosen, a separate window opens displaying the rendered view. The structure can be dynamically rotated about all three axes by simply holding the left mouse button down and dragging the structure in the intended direction. Right-clicking the mouse button will display a myriad of viewing options. Depending on the material used (steel, concrete, etc.), an appropriate texture will be applied to the structure. A property or material must be assigned to the entities of the model before this feature can be used. This is for visual and presentation purposes only.

Solid dialog

Similar to the beam and plate query dialog box, this will enable the users to obtain information regarding only the geometry of the solid element. As in the case of beams or plates, the user can simply double click on the solid element to see the element node numbers and the global X, Y and Z coordinates of the boundary nodes without having to scan through the Nodes table.

Opens when a solid element is double-clicked with the Solids cursor.

The table in the query box (which is not editable) displays the solid node numbers and the corresponding global X, Y and Z coordinates for the nodes.

B
Verification Examples

The examples within this section are used to validate the accuracy of the STAAD.Pro analysis and design engine.

V. Notes on Comparisons

In each verification problem, a table is used to summarize the numerical outputs from STAAD.Pro with a reference or hand calculations. A difference column presents the percent deviation from the reference, when a significant difference exists.

Where a non-significant difference (typically taken to be less than 0.5%) is present, the difference is given is "negligible." Otherwise, the percent difference in results is listed. Where a difference of greater than 2% exists, a comment is provided regarding the difference.

This level of significance is intended to reflect that small differences in rounding or calculation methods do not present a realistic difference in the calculated result.

V.01 Beams

V. Axially Loaded Column

To find support reactions due to an axial load applied at two locations on a column with both ends pinned.

Reference

Hand calculation using the following reference:

Timoshenko, S., *Strength of Materials*, Part I, D. Van Nostrand Co., Inc., 3rd Edition, 1956. Page 26, Problem 10.

Problem

Find the support reactions at the end joints 1 and 4.

$E = 30\times(10)^6$ psi

$F_1 = 1,000$ lbs

$F_2 = 500$ lbs

$L = 3$ in.

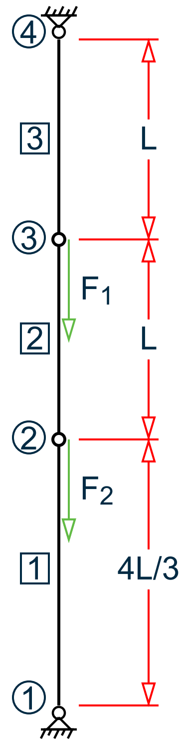

Figure 356: Pinned-pinned column with axial loads

Comparison

Table 379: Comparison of results

Result	Theory	STAAD.Pro	Difference
Reaction at Node 1 (lb)	600	600	none
Reaction at Node 4 (lb)	900	900	none

STAAD Input

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\01 Beams\Axially Loaded Column.STD`is typically installed with the program.

V. Beam on Elastic Foundation

To find deflection and stress at the center due to a uniform, static load on a simply supported beam on elastic foundation.

Reference

Hand calculation using the following reference:

Peterson, F.E., *Elastic Analysis for Structural Engineering (EASE2), Example Problem Manual*, Engineering Analysis Corporation, Berkeley, CA, 1981.

Problem

Find the vertical deflection and bending stress at the center of the beam.

beam width, $b = 1.0$ *in.*
beam depth, $h = 7.114$ *in.*

$$E = 30 \times (10)^6 \text{ psi}$$

L = 240 in.

w_u = 43.3 lb/in.

V. Bent Beam Thermal Loading

To find member forces and moments due to a temperature load on a Zee shaped plane bent.

Reference

Seeley, F.B., and Smith, J.O., *Advanced Mechanics of Materials*, 2nd Edition, John Wiley and Sons, 1955, Pages 494-497.

Problem

Calculate reactions and maximum moments in the structure due to a temperature increase of 430 ºF. Do not consider shear deformation.

$E = 26{,}400$ ksi

$\alpha = 7.26744 \times 10^{-6}$ in/in/ºF

OD = 12 in

ID = 10.255 in

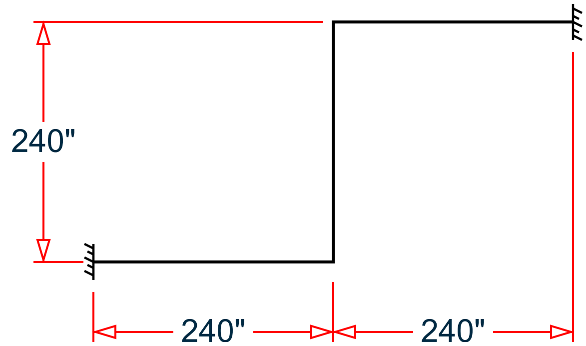

Figure 358: Frame subject to temperature change

Comparison

Table 381: Comparison of results

Result Type	Theory	STAAD.Pro	Difference	Comments
Horizontal reaction (lbs)	8,980	8,949.43	negligible	
Vertical reaction (lbs)	7,756	7,729.42	negligible	
Moment at supports (in·lb)	783,750	781,127.75	negligible	
Moment at node 2 (in·lb)	1,077,656	1,073,932.12	negligible

V. Bent Cantilever Deflection

Find deflection due to load at the free end of a cantilever plane bent.

Reference

Kinney, J. S., *Indeterminate Structural Analysis*, Addison - Wesley Publishing Co., 1957, Page 13, Problem 4 - 38.

Problem

Find the vertical, horizontal and rotational deflection components of point A.

E = 30,000 ksi

I = 200 in^4

A = 10 in^2

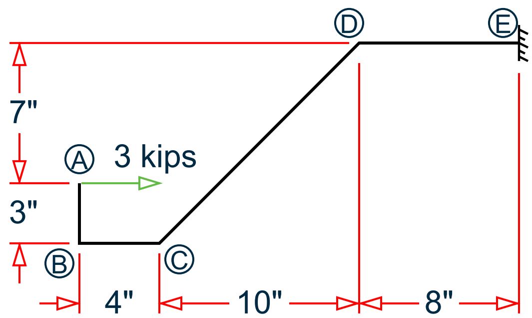

Figure 359: Bent plate frame

Comparison

Table 382: Comparison of results

Result Type	Theory	STAAD.Pro	Difference
Deflection right, δ_x (in)	0.53	0.53056	none
Deflection down, δ_y (in)	1.16	-1.17109	<1%
Rotation, θ (rad)	0.0049	0.00488	none

V. Curved Beam

To find the out-of-plane deflection and stress in a Circular cantilever member with a concentrated load at the free end.

Reference

Hand calculation using the following reference:

Timoshenko, S., *Strength of Materials*, Part I, D. Van Nostrand, 3rd Edition., 1955.

Problem

Calculate the displacement at the free end and the bending stress at the fixed end due to a concentrated load producing out–of–plane bending.

$E = 30\times(10)^6$ psi

$P = 50$ lb

$r = 100$ in.

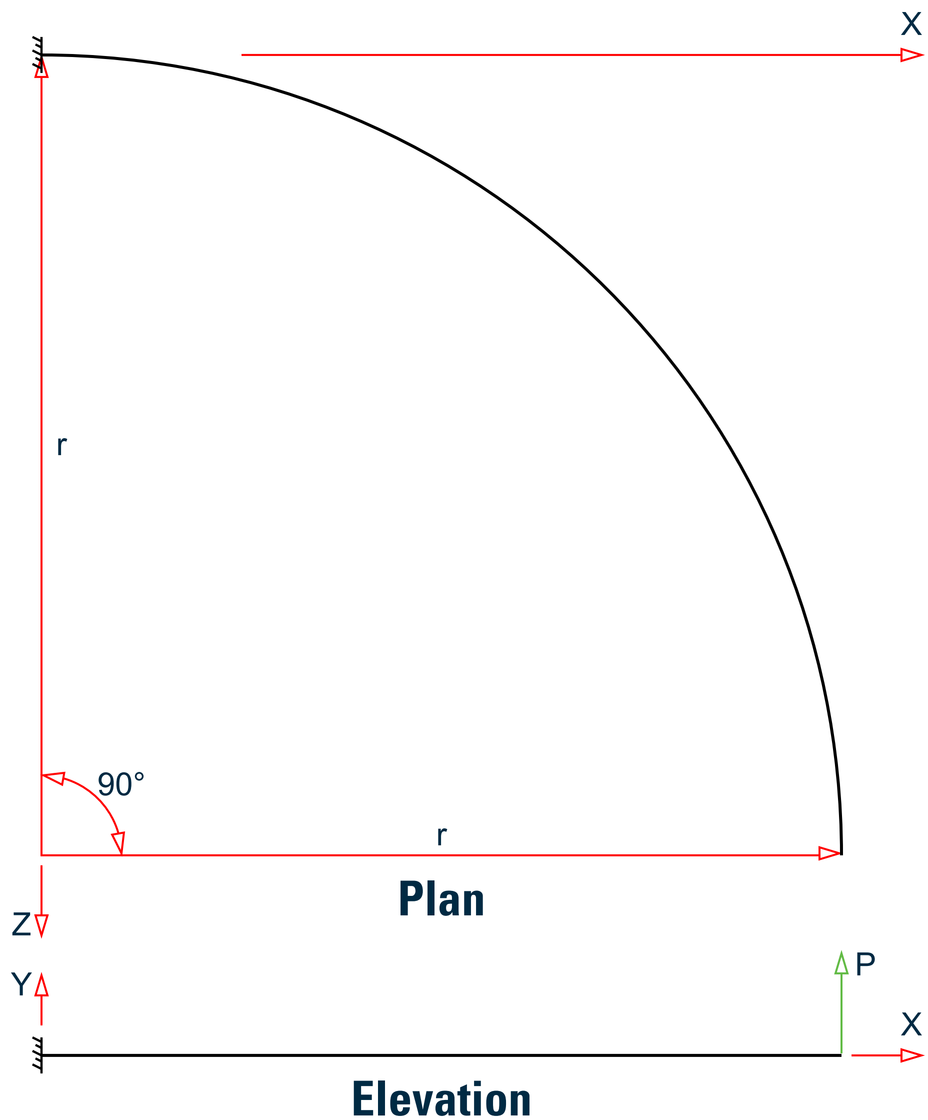

Figure 360: Curved beam

Comparison

Table 383: Comparison of results

Result	Theory	STAAD.Pro	Difference	Comments
Maximum deflection at free end (in.)	2.648	2.64658	negligible	

Result	Theory	STAAD.Pro	Difference	Comments
Principle stress (psi)	6,366.0	6,638.1	4.3%	The result from a classical theory of a beam curved in plan is compared with the result from a piecewise linear set of beams, which closely resembles the behavior of a curved beam, but not exactly. Hence the difference in results. The difference may be further reduced to a certain level by discretizing the curved beam in more smaller subdivisions.

STAAD Input

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\01 Beams\Curved Beam.STD`is typically installed with the program.

V. Deflection and Reactions in a Beam

To find the deflection and support reactions due to a trapezoidally varying load applied on part of the span of a pinned-fixed beam.

Reference

Hand calculation using the following reference:

Roark's Formulas for Stress and Strain, Warren C. Young, 6th edition, McGraw-Hill, Table 3, Case (2c), p.103

Problem

The beam in the following geometric, load, and section properties: $a = 3\ m$, $b = 4.5\ m$, $w_a = 4\ KN/m$, $w_l = 7\ KN/m$, $I_Z = 5{,}000\ cm^4$, $E = 200\ KN/mm^2$.

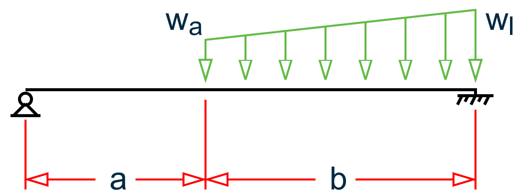

Figure 361: Beam with partial, trapezoidal load

Theoretical Solution

$$R_A = \frac{W_a}{8l^3}(l-a)^3\left(3l+a\right) + \frac{W_l - W_a}{40l^3}(l-a)^3\left(4l+a\right)$$

$$O_A = \frac{-W_a}{48EIl}(l-a)^3\left(l+3a\right) - \frac{W_l - W_a}{240EIl}(l-a)^3\left(2l+3a\right)$$

$$R_B = \frac{W_a - W_l}{2}\left(l-a\right) - R_A$$

$$M_B = R_A l - \frac{W_a}{2}(l-a)^2 - \frac{W_l - W_a}{6}(l-a)^2$$

where

l = a + b

Comparison

Table 384: Comparison of results

Result Type	Theory	STAAD.Pro	Difference
Rotation at A, O_A (radians)	0.0020	0.0020	none
Vertical reaction at A, R_A (kN)	3.2886	3.2886	none
Vertical reaction at B, R_B (kN)	21.461	21.461	none
Moment at B, M_B (kN·m)	25.9605	25.9605	none

Note: In the STAAD model, two load cases are used. In case 1, the load is applied using the `MEMBER LOAD - TRAP` option. In case 2, the load is applied using a combination of `MEMBER LOAD - UNI` and `MEMBER LOAD - LIN` options. Both cases yield identical results.

STAAD Input

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\01 Beams\Deflection and Reactions in a Beam.STD` is typically installed with the program.

V. End Moments in a Non Uniform Beam

To find end moments due to a uniform load on a beam with nonuniform sections, fixed at both ends.

Reference

Hand calculation using the following reference:

McCormack, J.C., *Structural Analysis*, Intext Educational Publishers, 3rd Edition, 1975.

Problem

Find the moment at the supports. Assume for input a unit width for the beam. Depths are as shown.

$E = 30\times(10)^6$ psi

$w = 4$ k/ft

$d_1 = 10$ in., $d_2 = 20$ in.

$L_1 = 12$ ft, $L_2 = 8$ ft

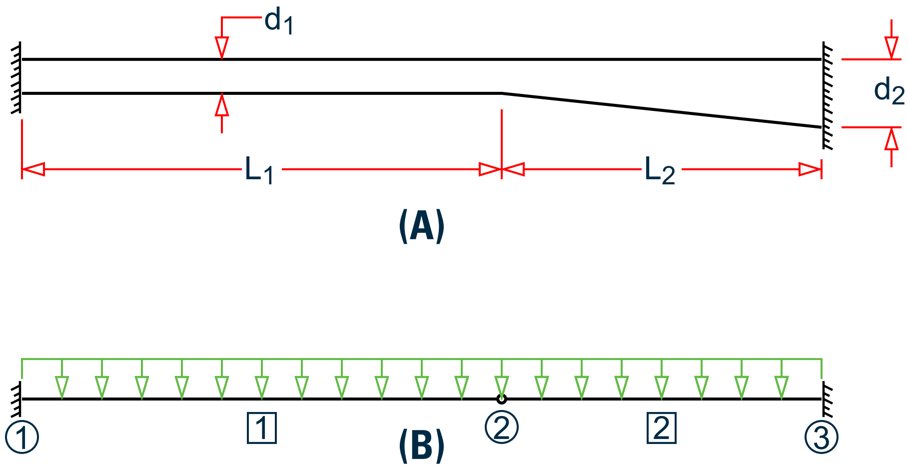

Figure 362: Beam A) problem sketch and B) mathematical model

V. Forces on a Propped Cantilever 1

To find the deflection and member forces due to an applied load on a propped cantilever beam with a compression only support.

Reference

Hand calculation using the following reference:

Manual of Steel Construction, Load and Resistance Factor Design, Second Edition, American Institute of Steel Construction, 1998, pp. 4-194, 4-197.

Problem

A propped cantilever beam with an propped-end support capable of resisting only a compressive force is analyzed for two concentrated loads at 0.6xL:

1. P = +0.5 lbs (up), and
2. P = -0.5 lbs (down)

$E = 10(10)^6$
width = 0.6 in
depth = 0.3 in
L = 4 ft

Note: A "dummy" member is used to represent a compression only support. The dimensions of this member are arbitrary; just that the member is specified as compression-only.

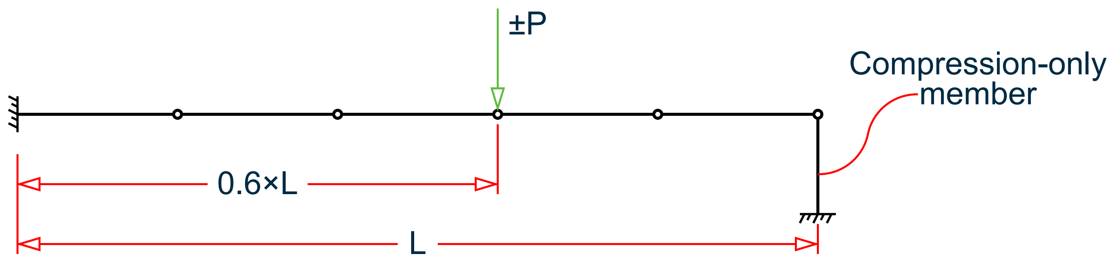

Figure 363: Propped cantilever member with a compression only support

Theoretical Solution

Load Case 1

General solution equations found on p.2-121 of the reference. In this case, the "propped" end carries no load as the support cannot carry tension. Thus, the member acts like a pure cantilever.

$$M(x < b) = -P(b - x) = -0.5lb(28.8 - x)$$

At the rigid support, $M = 14.4\ in \cdot lb$.

By inspection, fixed end shear is equal to load value = 0.50 lb.

$$\Delta\left(x < b\right) = \frac{Px^2}{6EI}\left(3x - b\right)$$

$$= \frac{0.5lb(28.8\text{in.})^2}{6\left(10,\ 000,\ 000psi\right)\left(0.00135\text{in.}^4\right)}\left[3\left(28.8\text{in.}\right) - 28.8\text{in.}\right] = 0.295\text{in.}$$

Load Case 2

General solution equations found on p.2-118 of the reference. In this case, the "propped" is capable of carrying load and thus the beam acts like a "propped" cantilever case.

$$R_1 = \frac{Pb^2\left(a + 2\ \ell\ \right)}{2\ell^3} = \frac{0.5lb(48\text{in.})^2}{2(48\text{in.})^3}\left[19.2\text{in} + 2\left(48\text{in}\right)\right] = 0.216lb.$$

$$\mathrm{R_2 = P - R_1 = 0.50lb - 0.216lb = 0.284lb.}$$

Moment at rigid support:

$$M(x < b) = R_1(\ \ell\ - x) - P(\ \ell\ - x - a)$$

$$= 0.216lb(48\text{in} - 0) - 0.5lb(48\text{in} - 0 - 19.2\text{in}) = -4.032\text{in}\cdot\text{lb}$$

Deflection at point of load:

$$\Delta\left(x < b\right) = \frac{-Pax^2}{12EI\ell^3}\left(3\ell^3\ - 3\ell^2\ x - 3a^2\ \ell\ + a^2x\right)$$

$$= \frac{-0.5\left(19.2\right)(28.8)^3}{12\left(10,\ 000,\ 000\right)\left(0.00135\right)(48)^3}\left[3(48)^3 - 3(48)^2(28.8) - 3(19.2)^2(48) + (19.2)^2(28.8)\right] = -0.040\text{ in.}$$

Comparison

V. Forces on a Propped Cantilever 2

To find deflections, stress and support reactions due to a uniform load on a beam with one end fixed and the other end supported by a roller.

Reference

Hand calculation using the following reference:

Roark, R.J., and Young, W.C., *Formulas for Stress and Strain*, 5th Edition, Page 109, Problem 23.

Problem

A horizontal beam of length = 100 in, area = 4 in^2, height = 2 in, and moment of inertia = 1.3333 in^4 is simply supported at one end and fixed at the other end (a "propped" cantilever). The beam is subjected to an arbitrary uniform loading. Determine the deflection, δ, at $x = 42.15$ *in.*, the slope, θ, at end A, the maximum bending stress, σ_{bend}, in the beam, and the support reactions.

$E = 30\times(10)^6$ psi

Density = 0.2821 lbs/in^3

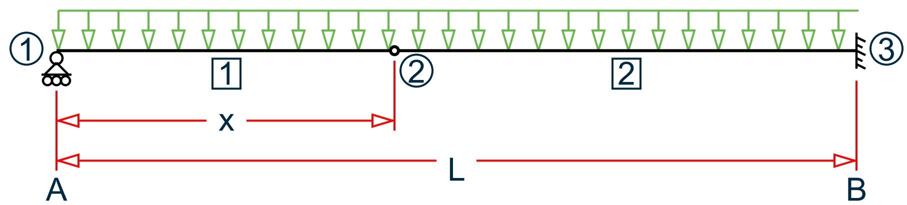

Figure 364: Propped cantilever beam model

Comparison

Table 387: Comparison of results

Result	Theory	STAAD.Pro	Difference
Reaction at Node 1 (lb)	42.31	42.31	none
Reaction at Node 3 (lb)	70.52	70.52	none
Moment at Node 3 (in·lb)	1,410.4	1410.4	none
Bending Stress, σ_{bend} at Node 2 (psi)	585.9	585.9	none
Rotation at Node 1 (rad.)	-.000588	-.00059	none

Result	Theory	STAAD.Pro	Difference
Deflection at Node 2 (in.)	-0.01528	-0.01528	none

V. Hanging Bar Axial Stress

Two vertical bars are supported by a rigid bar, which is pinned-supported on one end. Find stresses in vertical bars due to a load at the free end of the rigid bar.

Reference

Higdon, Ohlsen, Stiles, Weese and Riley, *Mechanics of Materials*, 3rd Edition, John Wiley & Sons, Page 135, Problem 3-37.

Problem

TBars A and B are connected by rigid links to a fixed support at the top and to a rigid bar at the bottom. Determine the axial stresses in bars A and B when the load P is 177.92888 kN applied as shown.

$P = 177.93$ kN

$A_A = 1{,}290.3\ mm^2$

$A_B = 1{,}612.9\ mm^2$

$E_A = 68.95$ GPa

$E_B = 206.84$ GPa

Assume the moment of inertia of member CD to be very large.

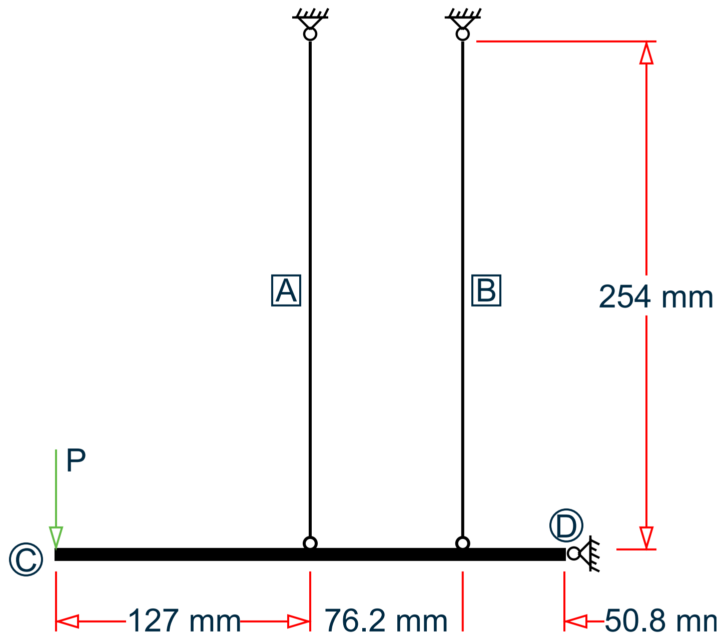

Figure 365: Rigid bar hanging from a pair of rods

Comparison

Table 388: Comparison of results

Result Type	Theory	STAAD.Pro	Difference
Stress in A (GPa)	0.17237	0.1723889	negligible
Stress in B (GPa)	0.20684	0.2068032	negligible

V. Stresses in a Cable due to Thermal Loading

A rigid bar is suspended by two copper wires and one steel wire. Find the stresses in the wires due to a rise in temperature.

Reference

Timoshenko, S., *Strength of Materials,* Part 1, D. Van Nostrand Co., 3rd edition, 1956, page 30, problem 9.

Problem

Assuming the horizontal member to be very rigid, determine the stresses in the copper and steel wires if the temperature rise is 10° F. Members 1 and 3 are copper and member 2 is steel.

$E_{steel} = 30\times(10)^6$ psi, $E_{copper} = 16\times(10)^6$ psi

$\alpha_{steel} = 70E\text{-}7$ in/in/°F, $\alpha_{copper} = 92E\text{-}7$ in/in/°F

$A_X = 0.1$ in^2

w = 400 lbf/in.

L = 20 in.

d= 5 in.

Tip: When modeling, assume a large moment of inertia for the horizontal rigid member and distribute of the concentrated load as uniform.

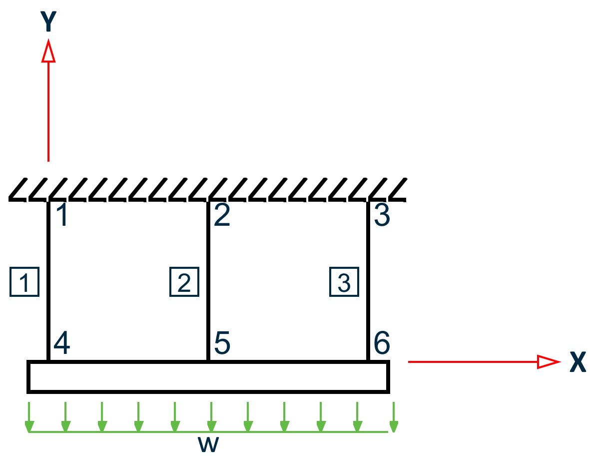

Figure 366: Model of a rigid wire suspended by wires

Comparison

Table 389: Comparison of results

Result Type	Theory	STAAD.Pro	Difference
σ_{Steel} (psi)	19,695	19,698.3	negligible
σ_{Copper} (psi)	10,152	10,150.8	negligible

STAAD Input

V. Stresses in a Circular Beam

Find deflections and stress at the center of a locomotive axle.

Reference

Timoshenko, S., *Strength of Materials*, Part- 1, D. Van Nostrand Co., 3rd edition, 1956.

p. 94, problems 1, 2.

Problem

Determine the maximum stress in a locomotive axle (as shown in the figure) as well as the deflection at the middle of the axle.

Diameter = 10 in.

P = 26,000 lbf

E = $30\times(10)^6$ psi

L1 = 13.5 in., L2 = 59 in.

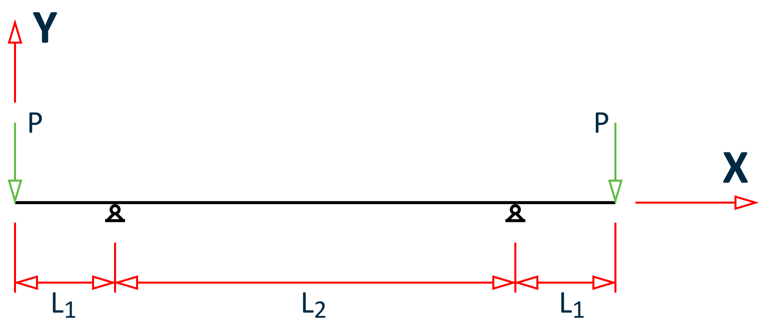

Figure 367: Locomotive axle model

Comparison

Table 390: Comparison of results

Result Type	Theory	STAAD.Pro	Difference
σ (psi), Node 3	3,575.*	3,575.3	negligible
δ (in.), Node 3	0.01040	0.01037	negligible

* The value is recalculated.

STAAD Input

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\01 Beams\Stresses in a Circular Beam.STD` is typically installed with the program.

V. Stresses in a Tapered Cantilever

To find the maximum deflection and principal stress due to a load on the free end of a cantilever beam with tapered section.

Reference

Hand calculation using the following reference:

Harris, C.O., *Introduction to Stress Analysis*, The Macmillan Co., 1959. Page 114, Problem 61.

Problem

Find the maximum deflection, δ, and the principal normal stress, σ, in the beam.

$E = 30\times(10)^6$ psi

Load at free end, P = 10 lb

Width at support, b = 3 in., Depth, d = 0.5 in.

Length, L = 20 in.

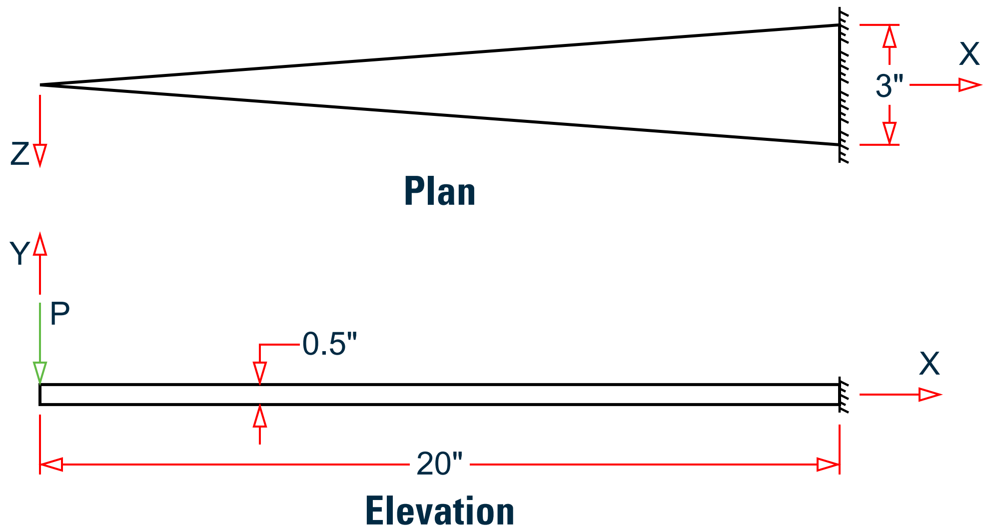

Figure 368: Beam with a tapering cross section

Note: The STAAD.Pro model is created using 10 beam segments, each with a tapered section. The tapered section is modeled using the tapered web and (effectively) no flanges, rotated 90°.

Comparison

Table 391: Comparison of results

Result	Theory	STAAD.Pro	Difference
Maximum deflection at free end (in.)	-0.04267	-0.04265	none
Principle stress (psi)	1,600	1,600	none

STAAD Input

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\ Verification Models\01 Beams\Stresses in a Tapered Cantilever.STD` is typically installed with the program.

V. Tee Shaped Cantilever

To find the stress due to an applied moment at the free end of a cantilever beam with inverted tee section.

Reference

Hand calculation using the following reference:

Crandall, S.H., and Dahl, N.C., *An Introduction to the Mechanics of Solids*, McGraw-Hill, Inc., 1959, Page 294, Problem 7.2..

Problem

Find the maximum bending stress in the beam of length L with due to moment, M, and the free end.

$E = 30\times(10)^6$ psi

$L = 10$ in.

$M = 1{,}000{,}000$ in.·lb.

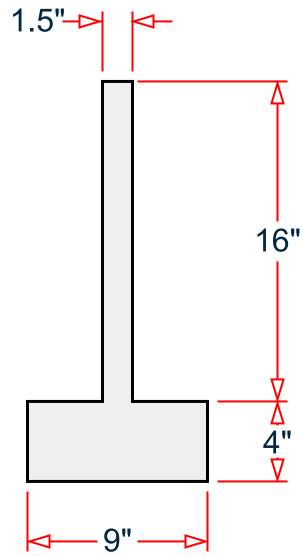

Figure 369: Cross section of cantilever beam

Comparison

Table 392: Comparison of results

Result	Theory	STAAD.Pro	Difference
Bending stress, σ (psi)	700	700	none

STAAD Input

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\01 Beams\Tee Shaped Cantilever.STD`is typically installed with the program.

V. Thermal Loading on a Beam

To find the support reactions due to a temperature loads applied on a fixed-fixed beam.

Reference

Hand calculation using the following reference:

Matrix Analysis of Framed Structures, 3rd edition, W.Weaver Jr. & J.M.Gere, Van Nostrand Reinhold, Table B2, Appendix B, p.500

Problem

The beam in the following geometric, load, and section properties: $L = 7.5\ m$, $\alpha = 11.7(10)^{-6} / °F, I_Z = 5{,}000\ cm^4$, $E = 200\ KN/mm^2$, $A = 50\ cm^2$.

Case 1: $T = 40°\ F$ (uniform across section)
Case 2: $T_1 = 0°\ F$ (below beam), $T_2 = 50°\ F$ (above beam)

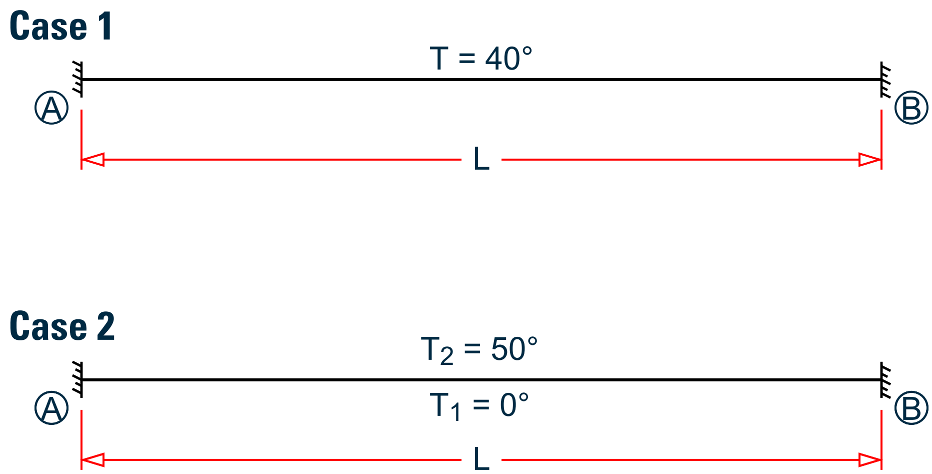

Figure 370: Fixed support beam with two different temperature load cases

Theoretical Solution

Horizontal reactions due to case 1 loads:

$$R_A = - R_B = EA\alpha\Delta T = [200(10)^6] \cdot [50(10)^{-4}] \cdot [11.7(10)^{-6}] \cdot (40) = 468 \text{ kN}$$

Moment reactions due to case 2 loads:

$$M_A = -M_B = \frac{\alpha EI\Delta T}{d} = \frac{\left[11.7(10)^{-6}\right] \cdot \left[200(10)^{-6}\right] \cdot \left[5,\ 000(10)^{-8}\right](50)}{0.3} = 19.5kN \cdot m$$

Comparison

Table 393: Comparison of results

Result Type	Theory	STAAD.Pro	Difference
Horizontal Reaction at Node A (kN)	468	468	none
Moment at Node A (kN·m)	19.5	19.5	none

Note: In the STAAD.Pro model, two load cases are used. In case 1, the uniform expansion is applied. In case 2, the temperature change between top and bottom flanges is applied.

STAAD Input

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\01 Beams\Thermal Loading on a Beam.STD` is typically installed with the program.

V. Torsion on a Stepped Cantilever

To find end rotation due to torques on a stepped cantilever shaft.

Reference

Hand calculation using the following reference:

Gere J. M., and Timoshenko, S. P., *Mechanics of Materials,* 2nd Edition, PWS Engineering, Page 171, Problem 3.3 - 1.

Problem

A stepped shaft is subjected to torques as shown in the figure. The material has shear modulus of elasticity G = 80 Gpa. Determine the angle of twist θ_x in degrees at the free end.

$T_1 = 3{,}000\ N{\cdot}mm$
$T_2 = 2{,}000 N{\cdot}mm$
$T_3 = 800 N{\cdot}mm$

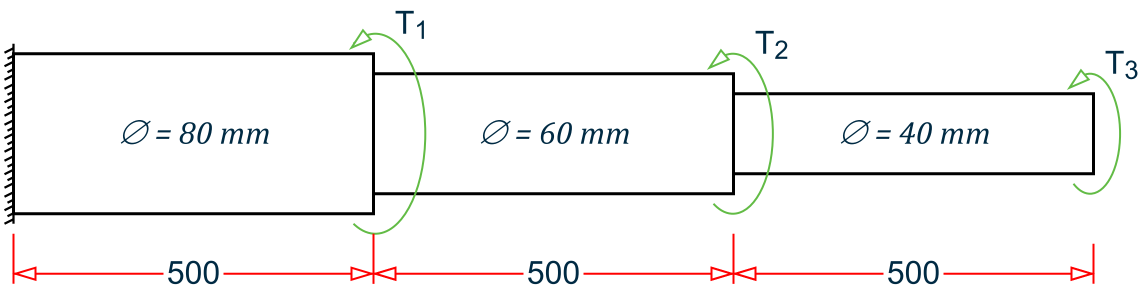

Figure 371: Cantilevered member subject to torsional loads

Theoretical Solution

Moment of Inertia:

$$I_{p1} = \frac{\pi(80mm/2)^4}{2} = 4.021(10)^6 mm^4$$

$$I_{p2} = \frac{\pi(60mm/2)^4}{2} = 1.272(10)^6 mm^4$$

$$I_{p2} = \frac{\pi(40mm/2)^4}{2} = 0.251(10)^6 mm^4$$

Angle of twist is given by:

$$\theta = \sum_i \frac{L_i T_i}{G I_p}$$

$$= \frac{5,\ 800\text{N-mm}(500mm)}{4.021(10)^6 mm^4 80GPa} + \frac{2,\ 800\text{N-mm}(500mm)}{1.272(10)^6 mm^4 80GPa} + \frac{,\ 800\text{N-mm}(500mm)}{0.251(10)^6 mm^4 80GPa}$$

$$= 0.0090 + 0.0138 + 0.0199 = 0.0427$$

which is equal to 2.446°.

Comparison

Table 394: Comparison of results

Result	Theory	STAAD.Pro	Difference
Angle of twist (rad.)	0.0427	0.0427	none

STAAD Input

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\01 Beams\Torsion on a Stepped Cantilever.STD`is typically installed with the program.

V. Twist in a Tapered Tube

To find the twist at the free end of a hollow tapered shaft of uniform thickness.

Reference

Hand calculation using the following reference:

Mechanics of Materials, F.P.Beer & E.R.Johnston, 1981, McGraw-Hill Review Problem 3.120, Page 149.

Problem

The beam in the following figure which has the following geometric, load, and section properties: $L = 2\ m$, outside diameter at fixed end = 80 mm, outside diameter at free end = 40 mm, uniform wall thickness of 10 mm, , $I_Z = 5{,}000\ cm^4$, $E = 200\ KN/mm^2$, $T = 2.0\ KNm$, and Poisson's ratio = 0.3.

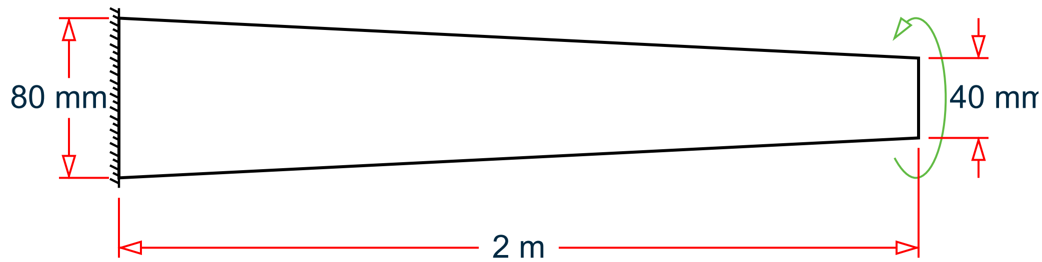

Figure 372: Cantilevered member with a tapered, hollow shaft cross section

Theoretical Solution

According to the reference, the twist at the free end is

$$\Phi_A = \left(\frac{TL}{4\pi G t}\right)\left(\frac{C_A + C_B}{C_A^2 C_B^2}\right)$$

where

C_A = centerline radius at free end = $40\ mm/2 - 10\ mm/2 = 15\ mm$

C_B = center line radius at fixed end = $80\ mm/2 - 10\ mm/2 = 35\ mm$

G = $\frac{E}{2(1+\nu)} = \frac{200kN/mm^2}{2(1+0.3)} = 76.9$

$$\Phi_A = \left(\frac{2,000kN \cdot m \times 2,000m}{4\pi \times 76.9kN/mm^2 \times 10mm}\right)\left[\frac{15mm + 35mm}{(15mm)^2(35mm)^2}\right] = 0.0751 \text{ rad.}$$

Comparison

V. Axial Force on a Cable

To find member force due to a member load in a plane articulate structure.

Reference

Kinney, J. S.,*Indeterminate Structural Analysis*, Addison - Wesley Publishing Co., 1957, p.275, Problem 6 - 19. (Original data is in US Customary Units)

Problem

Find the tensile stress in the cable. The cross - sectional area of the cable is 967.74 mm^2 with an E of 137.895 GPa. The timber beam 1-3 is 304.8 mm x 304.8 mm in section, with E = 11.03161 GPa. Each member of the steel cantilever truss has a cross - sectional area of 2,580.64 mm^2, and E of 206.8427 GPa.

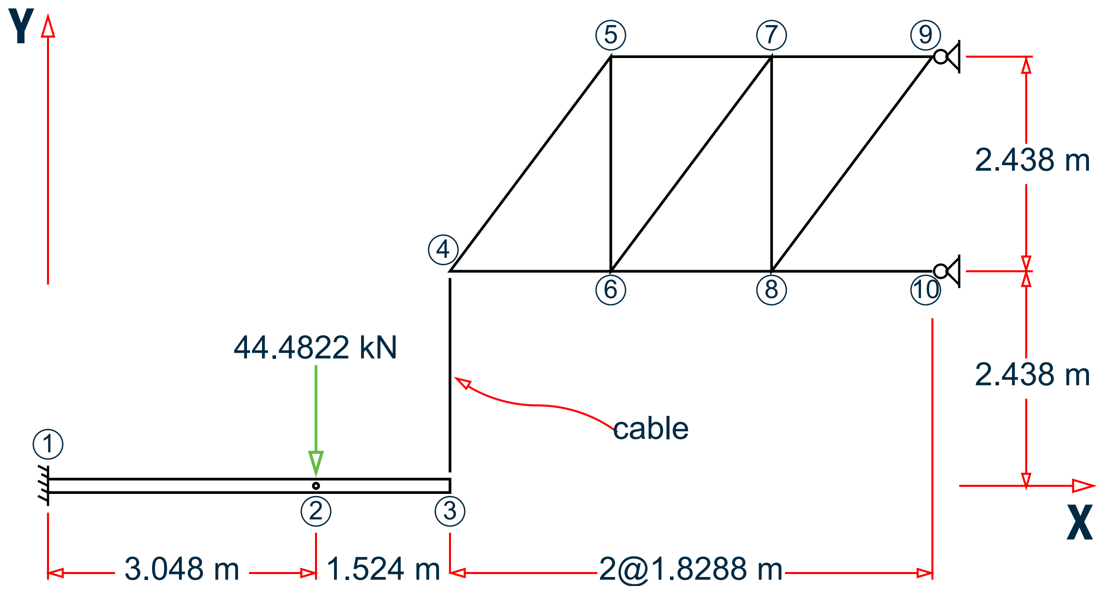

Figure 374: Plane articulate truss

Comparison

V. Axial Forces in a Plane Frame 2

To find member forces due to a thermal load in a plane truss.

Reference

Gere J. M., and Timoshenko, S. P., *Mechanics of Materials*, 2nd Edition, PWS Engineering, p.21, Problem 2.6 - 23.

Problem

A symmetric, three-bar truss ABCD undergoes a temperature increase of 20°C in the two outer bars and 70°C in the middle bar. Calculate the forces F_1 and F_2 in the bars.

$E = 200$ GPa

$\alpha = 14(10)^{-6}$ / °C

$A = 900$ mm^2

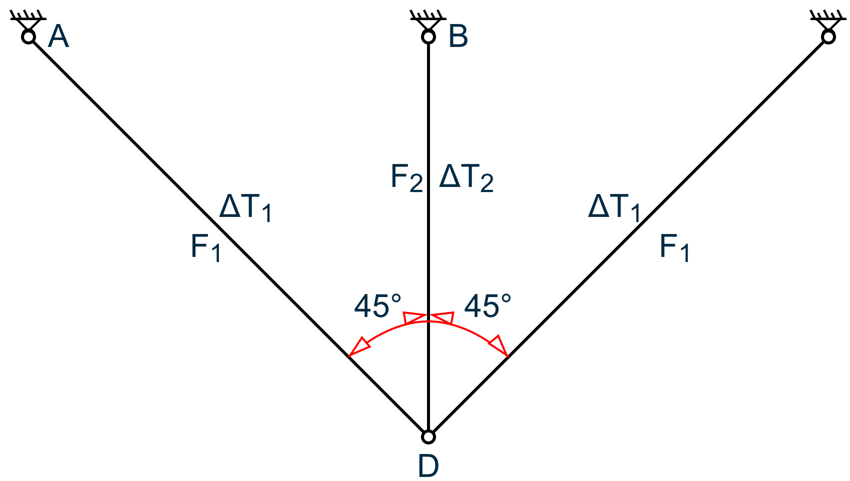

Figure 375: Plane truss subject to differential thermal loading

Comparison

V. Axial Forces on a 3D Space Model

To find support reactions and member forces due to a joint load in a space truss.

Reference

Beer F. P., and Johnston, E. R., *Vector Mechanics for Engineers - Statics*, 4th Edition, McGraw – Hill, Inc., p.216, Problem 6.20.

Problem

The space truss is supported by the six reactions shown. If a horizontal 2,700 N load is applied at A, determine the reactions and the force in each member.

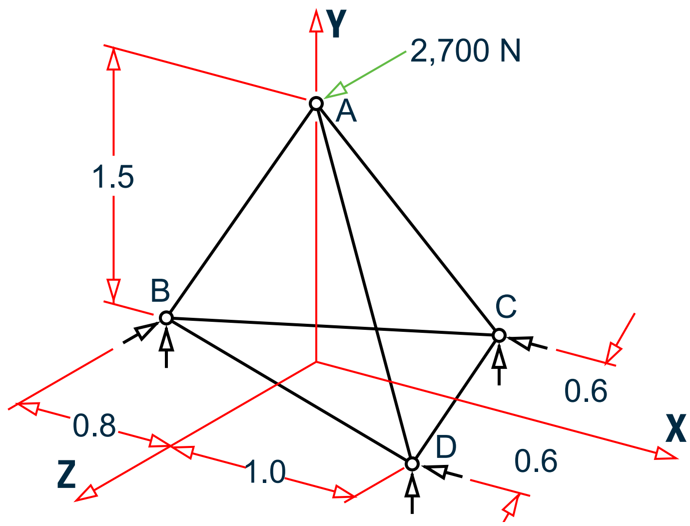

Figure 376: Space truss

V. Axial Stress on a Truss Model

To find member stress due to a joint load in a space truss using static analysis.

Reference

Beer, F.P., and Johnston, Jr., E.R., *Vector Mechanics for Engineers, Statics and Dynamics*, McGraw - Hill, Inc., New York, 1962, p.47, Problem 2.70.

Problem

A 50 lb load is supported by three bars which are pinned to a ceiling as shown. Determine the stress, σ, in each bar.

Area of each bar = 1 in^2, E = 30 (10)^6 psi

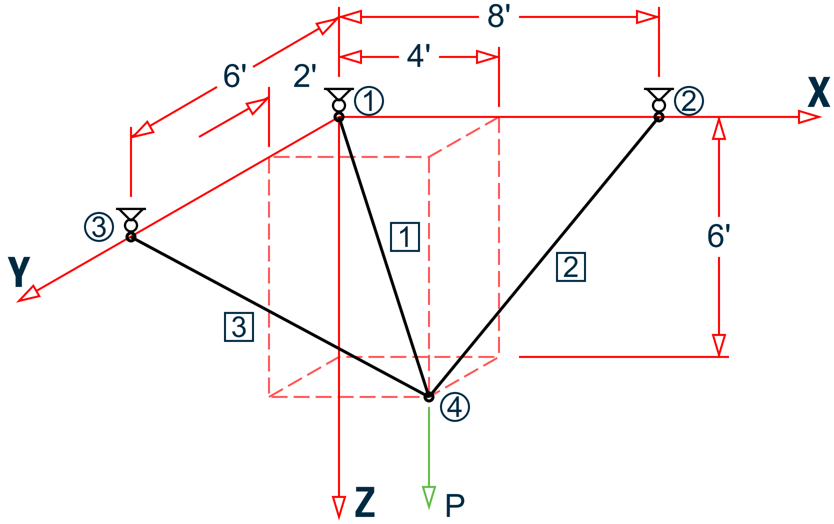

Figure 377: Space truss

P = 50 lbs

Comparison

V. Deflections in a 2D Truss Model

Find the joint deflection due to joint loads in a plane truss.

Reference

McCormac, J. C., *Structural Analysis*, Intext Educational Publishers, 3rd edition, 1975, page 271, example 18 - 2.

Problem

Determine the vertical deflection at point 5 of plane truss structure shown in the figure.

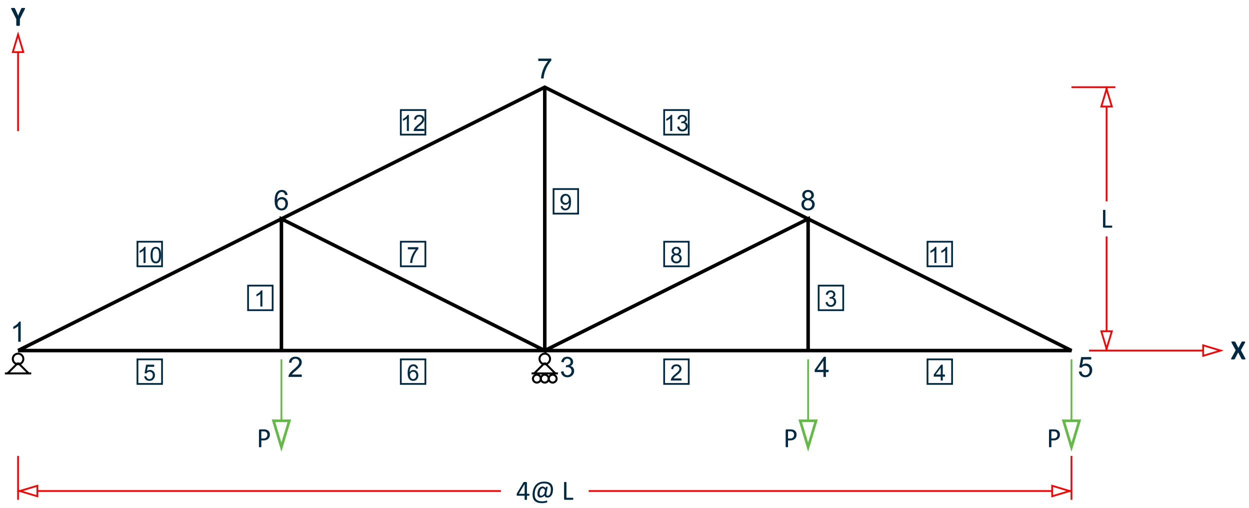

Figure 378: Plane truss model

P = 20 kip

L = 15 ft

Truss width = 4 spaces at 15 ft = 60 ft

Truss height = 15 ft

$A_{X\ 1\text{-}4} = 1\ in^2$, $A_{X\ 5\text{-}6} = 2\ in^2$, $A_{X\ 7\text{-}8} = 1.5\ in^2$,

$A_{X\ 9\text{-}11\ B} = 3\ in^{2\ P}$, $A_{X\ 12\text{-}13} = 4\ in^2$

E = 30E3 ksi

V. Reactions in a 2D Truss Model 1

To find support reactions due to joint loads in a plane truss.

Reference

McCormack, J.C. *Structural Analysis*, Intext Educational Publishers, 3rd Edition, 1975.

Problem

Find the vertical support reactions of the truss.

$$E = 30{,}000.0 \text{ ksi}$$

$$A = 100 \text{ in}^2$$

Loads as shown.

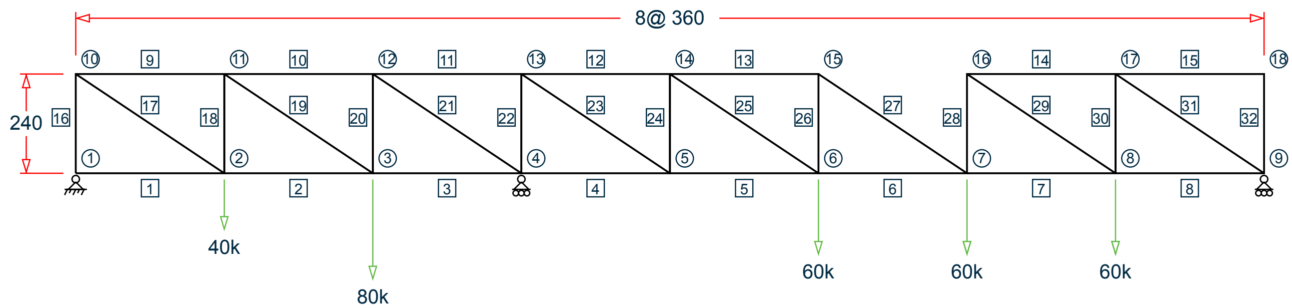

Figure 379: Plane truss

Comparison

Table 403: Comparison of results

Result Type	Theory	STAAD.Pro	Difference
R_1 (kips)	-76.7	-76.67	none

V. Reactions in a 2D Truss Model 3

Find the support reactions due to a joint load in a plane truss.

Reference

Timoshenko, S., *Strength of Materials*, Part 1, D. Van Nostrand Co., Inc., 3rd edition, 1956, p.346, problem 3.

Problem

Determine the horizontal reaction at support 4 of the system.

L = 50 in.

P = 10 kips

V. Roof Truss Axial Forces

To find the forces in the members of a truss structure due to fabrication defect in the length of one bar which is 0.75 cm too short.

Reference

C.K. Wang, *Intermediate Structural Analysis*, International Student Edition, 1983, McGraw Hill, Section 10.13, p. 387

.

Problem

Structure to be solved as a truss. To achieve this in the STAAD model, instead of declaring them truss members, define them as frame members, and release MZ at both ends of all members. In the above figure, the area of cross section of the members is as follows.

1 TO 4 = 20 cm^2

5, 6 = 24 cm^2

7, 8 = 30 cm^2

9, 10 = 15 cm^2

V. Stress in a 2D Truss Model

Find the joint deflection and member stress due to a joint load in a plane truss.

Reference

Timoshenko, S., *Strength of Materials*, Part 1, D. Van Nostrand Co., Inc., 3rd edition, 1956, page 10, problem 2.

Problem

Determine the vertical deflection at point A and the member stresses

$A_X = 0.5\ in^2$

$E = 30E6$ psi

$P = 5000$ lbf

$L = 180$ in.

angle = 30°

V. 2 Bay Frame Moments and Shear

To find the member forces in a 1x2 bay plane frame with members of rectangular section.

Reference

Manual of Steel Construction – Allowable Stress Design, AISC, 9th Edition, 1989.

Problem

The frame supports a uniformly distributed load and concentrated loads. Calculate the bending moment and shear force at the mid point of the beam of the first bay.

$$E = 30{,}000 \text{ ksi}$$

Columns are 12"×24", beams are 12"×30"

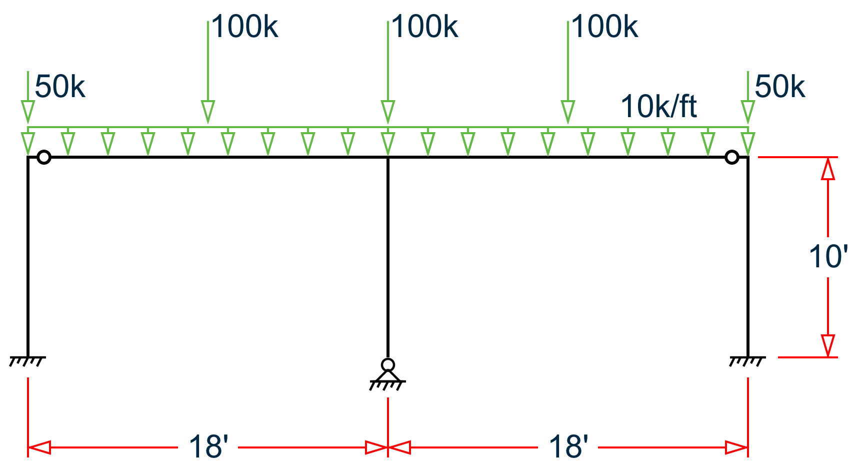

Figure 385: 2 bay frame

Comparison

Table 409: Comparison of results

Result Type		Theory	STAAD.Pro	Difference
Load Case 1	Moment , M (in·kips)	3,375	3,360.15	0.4%
	Shear, V (kips)	68.75	68.75	none
Load Case 2	Moment, M (in·kips)	2,430	2,425.12	negligible
	Shear, V (kips)	22.50	22.68	0.8%

V. 2D Portal Reactions 1

To find section properties, member forces and support reactions for a 1x1 bay plane frame with members of rectangular section.

Reference

Timoshenko, S., *Strength of Materials, Part I, Elementary Theory and Problems*, 2nd Edition, Van Nostrand Company, 1940, Pages 188-191,

Problem

The frame supports a concentrated load at middle of the horizontal member. Verify the internally calculated section properties, support reactions and bending moments at the ends of the horizontal member. Columns are square 2" x 2"; beams are rectangular with b = 2" and h = 4".

$P = 1{,}000$ lb

$h = 100$ in.

$l = 120$ in.

$E = 30\times(10)^6$ psi

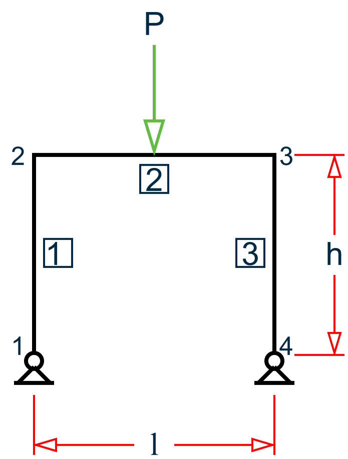

Figure 386: Symmetric portal frame

Calculations

From the reference:

$$M = \frac{Pl}{8}\frac{1}{1 + \frac{2}{3}\frac{h}{l}\frac{I_b}{I_c}} = \frac{1,\ 000(120)}{8}\frac{1}{1 + \frac{2}{3}\frac{100}{120}\frac{10.67}{1.333}} = 2,\ 754\text{in-lb}$$

Comparison

Table 410: Comparison of results

V. 2D Portal Reactions Sidesway 2

Find the maximum moment due to a concentrated load on the horizontal member in a 1x1 bay plane frame.

Reference

McCormac, J. C., *Structural Analysis*, Intext Educational Publishers, 3rd edition, 1975, page 385, problem 22 - 6.

Problem

Determine the maximum moment in the structure.

$P = 30$ kip

$L_1 = 20$ ft, $L_2 = 30$ ft

E and I same for all members

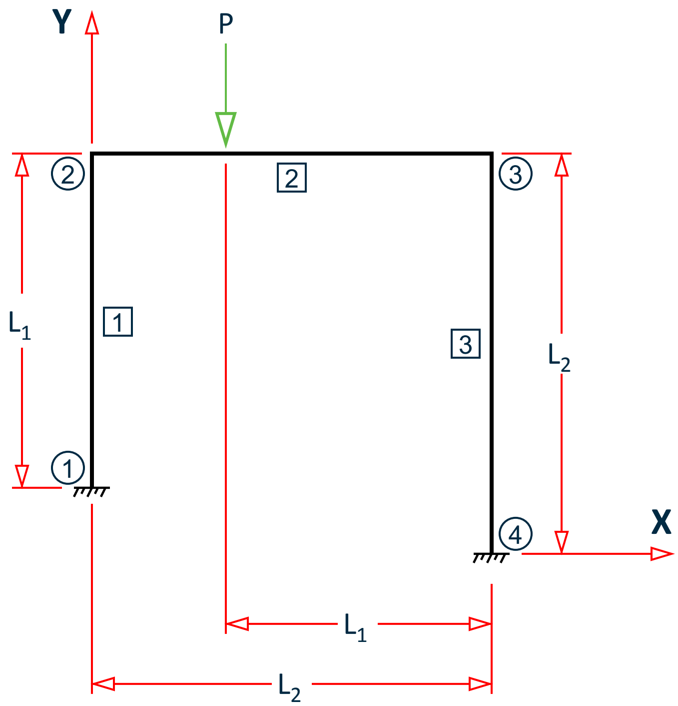

Figure 389: Unequal leg bay model

Comparison

Table 413: Comparison of results

Result Type	Theory	STAAD.Pro	Difference
M_{Max} (ft·kip)	69.40	69.44	negligible

STAAD Input

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\03 Frames\2D Portal Reactions Sidesway 2.STD` is typically installed with the program.

V. 3D Frame Max Forces

Find the maximum axial force and moment due to load and moment applied at a joint in a Space frame.

Reference

Weaver Jr., W., *Computer Programs for Structural Analysis*, page 146, problem 8.

Problem

Determine the maximum axial force and moment in the space structure.

F = 2 kip, P = 1 kip, M = 120 in·kip

L = 120 in.

E = 30E3 ksi,

AX = 11 in^2

IX = 83 in^4

IY = 56 in^4

IZ = 56 in^4

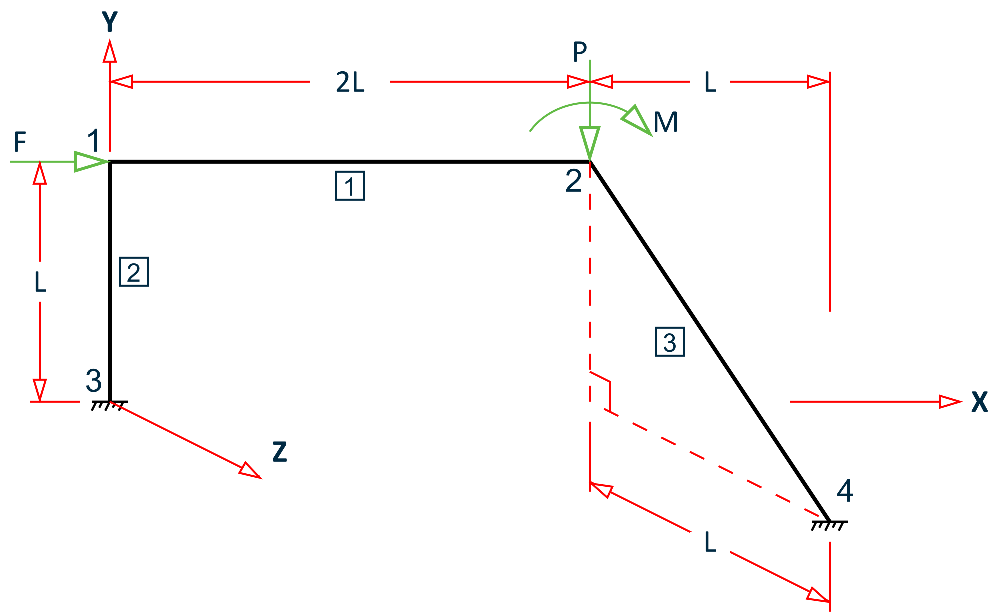

Figure 390: Space frame model

Comparison

Table 414: Comparison of results

Result Type	Theory	Advanced Analysis	Difference
F_{Max} (kips)	1.47	1.47	
$M_{Y,\ Max}$ (in·kip)	84.04	84.04	
$M_{Z,\ Max}$ (in·kip)	95.319	95.32	

STAAD Input

V. 3x2 Plane Frame Moments

To find the bending moments due to lateral joint loads in a 3x2 bay plane frame.

Reference

Noris and Wilbur, *Elementary Structural Analysis*, 2nd Edition, McGraw – Hill, Inc., Page 304.

Problem

Determine the bending moments in the members of frame.

E = 30,000 ksi

$I_{AE} = I_{EI} = 240\ in^4$

$I_{BF} = I_{FJ} = 480\ in^4$

$I_{CG} = I_{GK} = 600\ in^4$

$I_{DH} = I_{HL} = 360\ in^4$

$I_{EF} = I_{IJ} = 600\ in^4$

$I_{FG} = I_{JK} = 1{,}200\ in^4$

$I_{GH} = I_{KL} = 1{,}800\ in^4$

V. Support Reactions for a Simple Frame

Find support reactions due to a load at the free end of a cantilever bent plate with an intermediate support.

Reference

Timoshenko, S., *Strength of Materials*, Part 1, D. Van Nostrand Co., Inc., 3rd edition, 1956, page 346, problem 2.

Problem

Determine the reaction of the system as shown in the figure.

P = 1 kip

L = 10 in

V.04 Plate and Shell Elements

V. 2D Cantilever Beam End Deflection 1

To find the free end deflection due to a joint load on a Cantilever beam modeled using Plate/shell elements.

Reference

Hand calculation.

Problem

Using the finite element method calculate the deflection of the free end of the cantilever beam.

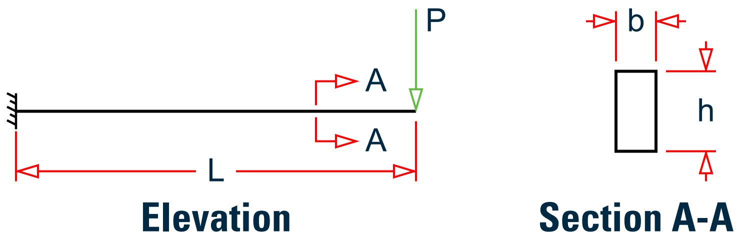

Figure 393: Cantilever beam and section

E = 4,278 ksi

h = 10 in

b = 5 in

P = 2 kips

L = 60 in

Theoretical Solution

Moment of Inertia:

$$I = (5 \text{ in})(10 \text{ in})^3/12 = 416.7 \text{ in}^4$$

Deflection at free end:

$$\delta = \frac{PL^3}{3EI} = \frac{2 \text{ kips}(60 \text{ in})^3}{3(4,278 \text{ ksi})(416.7 \text{ in}^4)} = 0.0808 \text{ in}$$

Comparison

Table 417: Comparison of results

Result Type	Theory	STAAD.Pro	Difference	Comments
Deflection at node B (in)	0.0808	0.08245	2.1%	The expression for deflection for beam is used to compare the results of a model with Plate Elements with FE formulation, hence the difference in results.

STAAD Input

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\04 Plates Shells\2D Cantilever Beam End Deflection 1.STD` is typically installed with the program.

V. 2D Cantilever Beam End Deflection 2

Find the deflection and moments for plate-bending finite element due to a pressure load.

Reference

Simple hand calculation by considering the entire structure as a cantilever beam.

Problem

A simple cantilever plate is divided into 12 4-noded finite elements. A uniform pressure load is applied and the maximum deflection at the tip of the cantilever and the maximum bending at the support are calculated.

Plate thickness = 25 mm

Uniform pressure= 5 N/mm^2

Plate length = 6 spaces at 50 mm = 300 mm

Plate width = 2 space at 50 mm = 100 mm

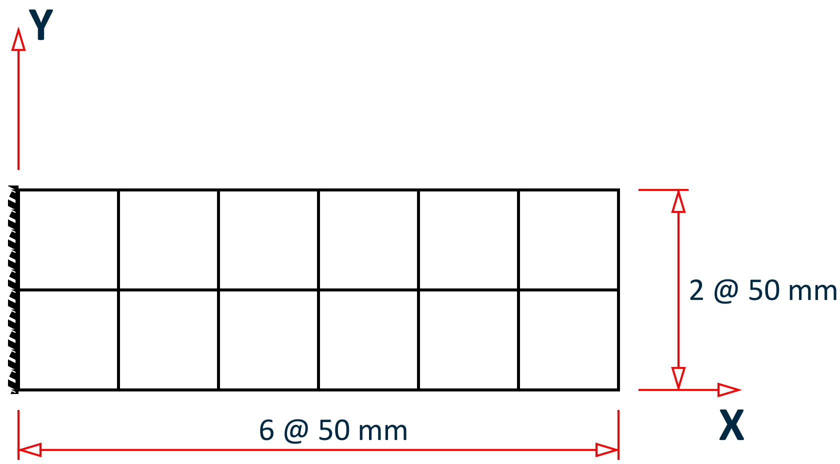

Figure 394: Finite element mesh of cantilevered plate.

Theoretical Solution

Maximum deflection is equal to $WL^3/8EI$, where:

$$\Delta_{max} = \frac{5(300)(100)(300)^3}{8(210 \cdot 10^3)\left(\frac{100 \cdot 25^3}{12}\right)} = \frac{4050(10)^9}{218.75(10)^9} = 18.51\text{mm}$$

Maximum Moment:

$$M_{max} = \frac{WL}{2} = \frac{5(300)(100)(300)}{2} = 22.5(10)^6 \text{N} \cdot \text{mm}$$

Comparison

Table 418: Comparison of results

Result Type	Hand Calculation	STAAD.Pro	Difference
δ_{max} (mm)	18.51	18.159	1.9%
M_{max} (kN·m)	22.50	22.50	none

Note: The maximum moment is taken as the sum of the moments at nodes 1, 8, and 15 (i.e., $5.47 + 11.56 + 5.47 = 22.5\ kN \cdot m$).

STAAD Input

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\04 Plates Shells\2D Cantilever Beam End Deflection 2.STD` is typically installed with the program.

V. 2D Circular Plate In-Plane Stresses

A thick cylindrical plate supported along 2 radial edges. Find the radial displacement, radial stress, tangential stress and longitudinal stress at inner surface due to a unit pressure applied at the inner surface.

Reference

MacNeal, R.H. and Harder, R.C., *A Proposed Standard Set of Problems to Test Finite Element Accuracy, Finite Element in Analysis and Design 1*, 1985.

Problem

Loading is unit pressure at inner radius

$E = 1 \times (10)^6$ psi

Poisson's ratio = 0.3

Inner radius = 3.0 in

Outer radius = 9.0 in

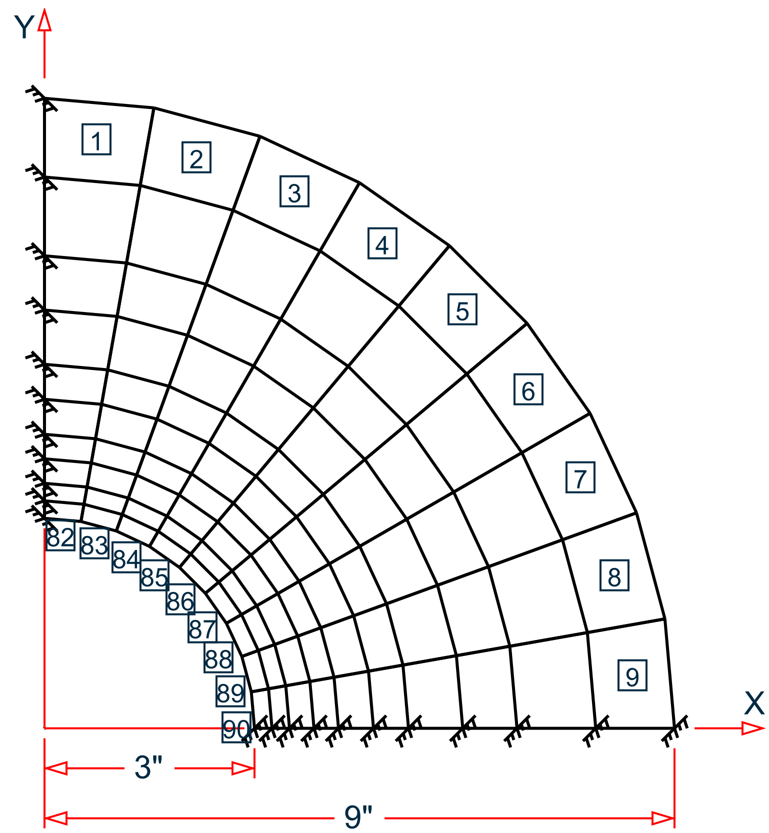

Figure 395: Semi-circular plate finite element model

Comparison

Table 419: Comparison of results

Result Type	Theory	STAAD.Pro	Difference
Radial deflection (10^{-3} in)	4.582	4.650[a]	1.5%
Radial stress (psi)	-1.00	-0.95[b]	5.0%
Tangential stress (psi)	1.25	1.26[b]	0.8%
Longitudinal stress (psi)	0.075	0.080	7.0%

a. Radial displacements are measured along FY at node 102 and FX at node 101.
b. On element 82, at node 102, SX is tangential stress, SY is radial stress.

STAAD Input

Tip: You can copy and paste this content directly into a `.std` file to run in STAAD.Pro.

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\04 Plates Shells\2D Circular Plate In-Plane Stresses.STD` is typically installed with the program.

V. 2D Circular Surface Displacements and Stresses

A circular plate is fixed along its perimeter. Using plate/shell elements, find the deflection at the center, maximum bending stress due to a uniformly distributed load, and a concentrated load at the center.

Reference

Timoshenko, S., *Strength of Materials*, Part II, 3rd Edition, Van Nostrand Co., 1956, pp.96-97, 103.

Problem

The circular plate shown below is subject to two load cases. Load 1 is a uniform pressure, w, and load 2 is a concentrated force, P, at the center. Determine:

- deflection at the center for both load cases
- bending stress at the support for both load cases
- moment at the center for load case 1

E = 30,000.0 ksi

Poisson's ratio = 0.3

r = 40 in.

t = 1 in.

w = 6 psi.

P = 7,539.82 lbs

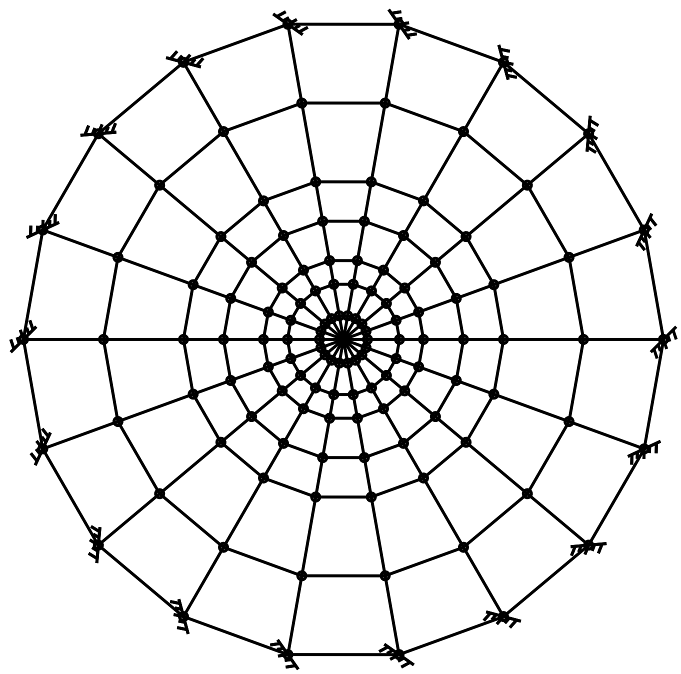

Figure 396: Finite element model of a circular plate

Comparison

Table 420: Comparison of results

Result Type		Theory	STAAD.Pro	Difference	Comments
Load Case 1	σ_{bend} (psi)	7,200	6,887[a]	4.3%	The theoretical results from classical Plate theory was compared with the results from Finite Element model - hence the difference in results.
	δ_{max} (in) (Y translation at Node 127)	-0.0874	-0.08618	1.4%	
	Moment at center (in·lb/in)	780	806.1[b]	3.4%	
Load Case 2	σ_{bend} (psi)	3,600	3,700[c]	2.8%	
	δ_{max} (in) (Y translation at Node 127)	-0.0874	-0.08646	1.0%	

a. In element 9 at node 10, My = 1,147.91 in·lb/in. This yields σ_{bend} = 1,147.91(6) = 6,887 psi.
b. In element 109 at node 127, Mx = 811.88 in·lb/in and My = 800.33 in·lb/in, the average of which is 806.1 in·lb/in.
c. In element 9 at node 10, My = 616.69 in·lb/in. This yields σ_{bend} = 616.19(6) = 3,700 psi.

STAAD Input

Tip: You can copy and paste this content directly into a `.std` file to run in STAAD.Pro.

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\ Verification Models\04 Plates Shells\2D Circular Surface Displacements and Stresses.STD` is typically installed with the program.

V. 2D Circular Surface Edge Stress

The objective of this example is to find the displacement at center, and bending stress at the center and at the perimeter of a circular plate fixed at its periphery.

Reference

Young, W. C., *Roark's Formulas for Stress and Strain*, McGraw-Hill Inc., 6th Edition, 1989, Page 429.

Problem

Find the normal stress on the edge of the circular hole for the plate shown, when an in-plane load causes tension. Use a one-quarter, doubly symmetric model.

E =10,000.0 ksi

Radius = 10 in

Thickness = 0.02 in

w = 0.1 psi

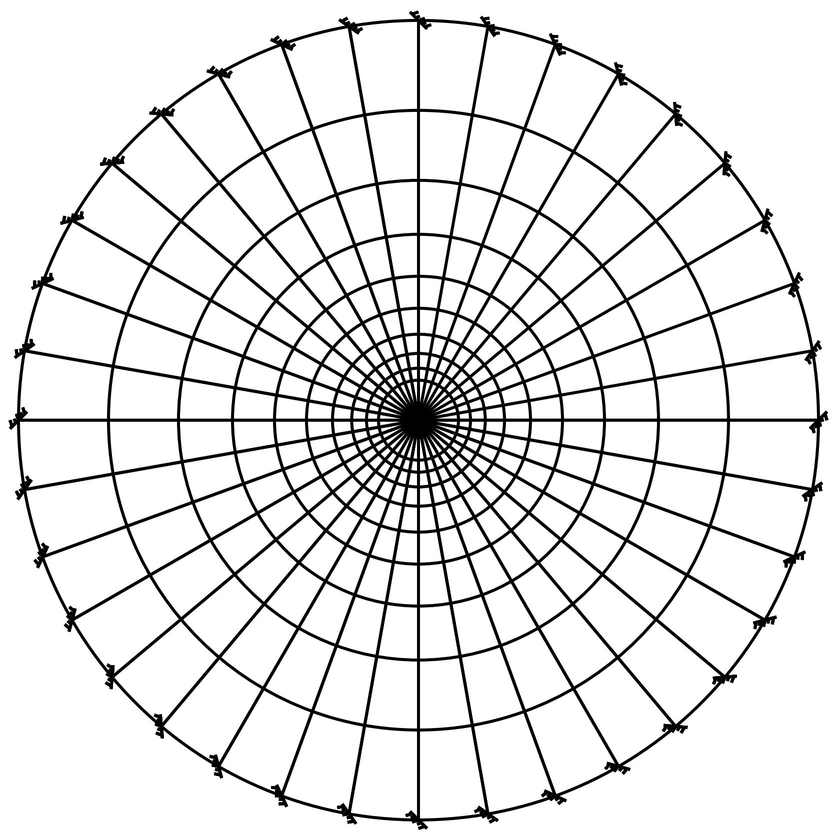

Figure 397: Model

Comparison

Table 421: Comparison of results

Result Type	Theory	STAAD.Pro	Difference	Comments
δ at node 1 (in)	2.133	2.16005	1.3%	The theoretical results from classical Plate theory was compared with the results from Finite Element model - hence the difference in results.
Moment at joint 1 (in·lbs)	0.813	0.830	2.6%	

STAAD Input

Tip: You can copy and paste this content directly into a `.std` file to run in STAAD.Pro.

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\04 Plates Shells\2D Circular Surface Edge Stress.STD` is typically installed with the program.

V. 2D Curved Beam Maximum Stress

Using plate/shell elements, find maximum bending stress due to a force couple on a curved cantilever beam.

Reference

Timoshenko, S., *Strength of Materials*, Part I, 3rd Edition, Van Nostrand Co., 1956.

Problem

Find the maximum bending stress

E = 3,000.0 ksi.

Poisson's ratio = 0.3.

t = 1.0 in.

P = 100 lbs

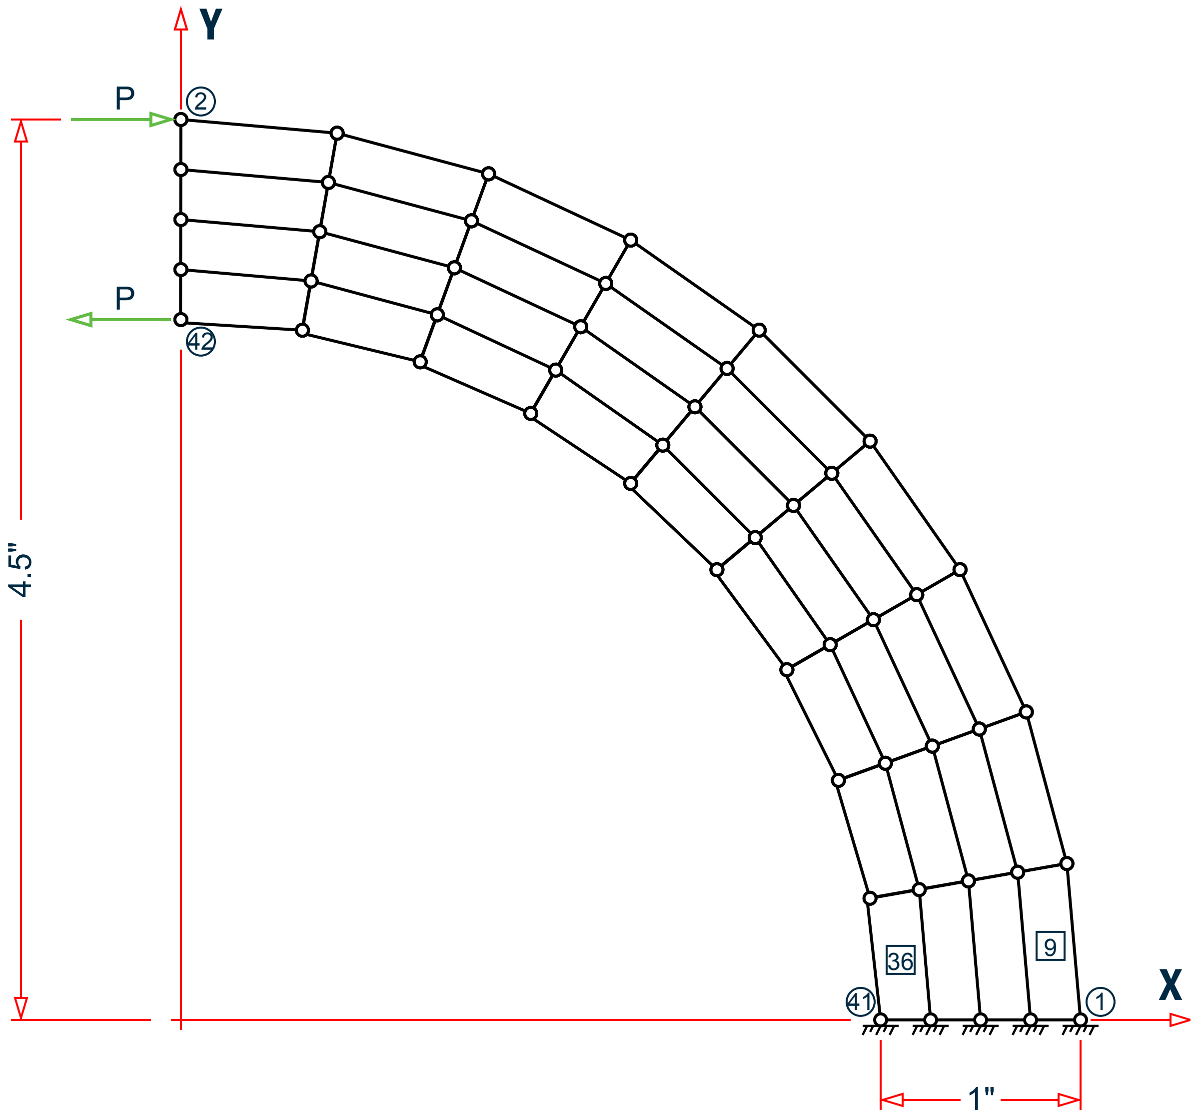

Figure 398: Cantilevered, curved plate with coupling load at free end

Comparison

Table 422: Comparison of results

Result Type	Theory	STAAD.Pro	Difference	Comments
Inside stress (psi)	655.0	636.02	2.9%	The result from the Beam theory is compared with the result from a Finite Element Model output, hence the difference in results.

Result Type	Theory	STAAD.Pro	Difference	Comments
Outside stress (psi)	555.0	556.73	negligible	

STAAD Input

Tip: You can copy and paste this content directly into a `.std` file to run in STAAD.Pro.

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\04 Plates Shells\2D Curved Beam Maximum Stress.STD` is typically installed with the program.

V. 2D Plate Thermal Moment and Stress

To find the bending moment due to thermal load through the thickness of a square plate.

Reference

Timoshenko, S., *Strength of Materials*, D. Van Nostrand Co., 3rd Edition,1956.

Problem

Temperature varies 100°F linearly through the thickness of a square plate that is fixed on the edges. Calculate the bending moment on the edges and the maximum bending stress.

E = 30,000.0 ksi

$\alpha = 70\times(10)^{-7}$ in/in/°F

Size = 5” × 5”

Thickness = 0.5 in

Poisson’s ratio = 0.3

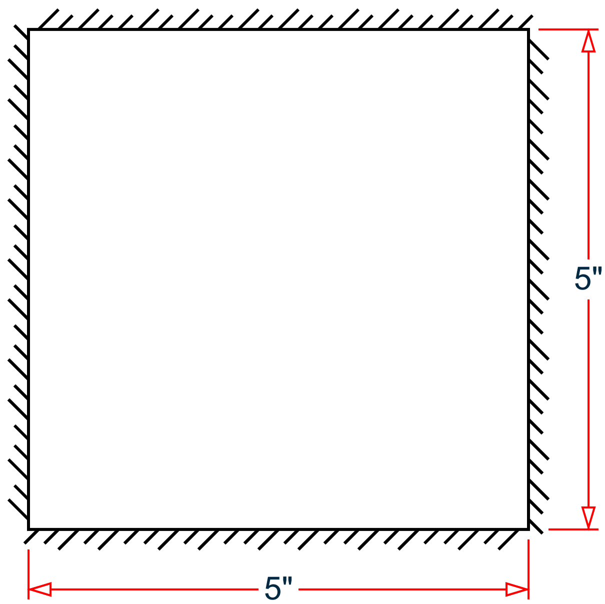

Figure 399: Model

Comparison

Table 423: Comparison of results

Result Type	Theory	STAAD.Pro	Difference
Moment (in·lb/in)	625.0	625.0	none
Maximum stress (psi)	15,000	15,000	none

STAAD Input

Tip: You can copy and paste this content directly into a `.std` file to run in STAAD.Pro.

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\04 Plates Shells\2D Plate Thermal Moment and Stress.STD` is typically installed with the program.

V. 2D Rectangular Plate with fixed edges

To find the vertical deflection and bending moments at several points due to a unit pressure on a thin rectangular plate simply supported along 4 edges.

Reference

Timoshenko, S. and Woinowsky-Kreiger, S., *Theory of Plates and Shells*, McGraw-Hill, 2nd Edition, 1959, Pages 113-117.

Problem

Loading is unit pressure (1 psi) over entire surface.

$E = 1 \times (10)^6$ psi

Poisson's ratio = 0.3

Length = 16 in.

Width = 10 in.

Thickness = 0.2 in

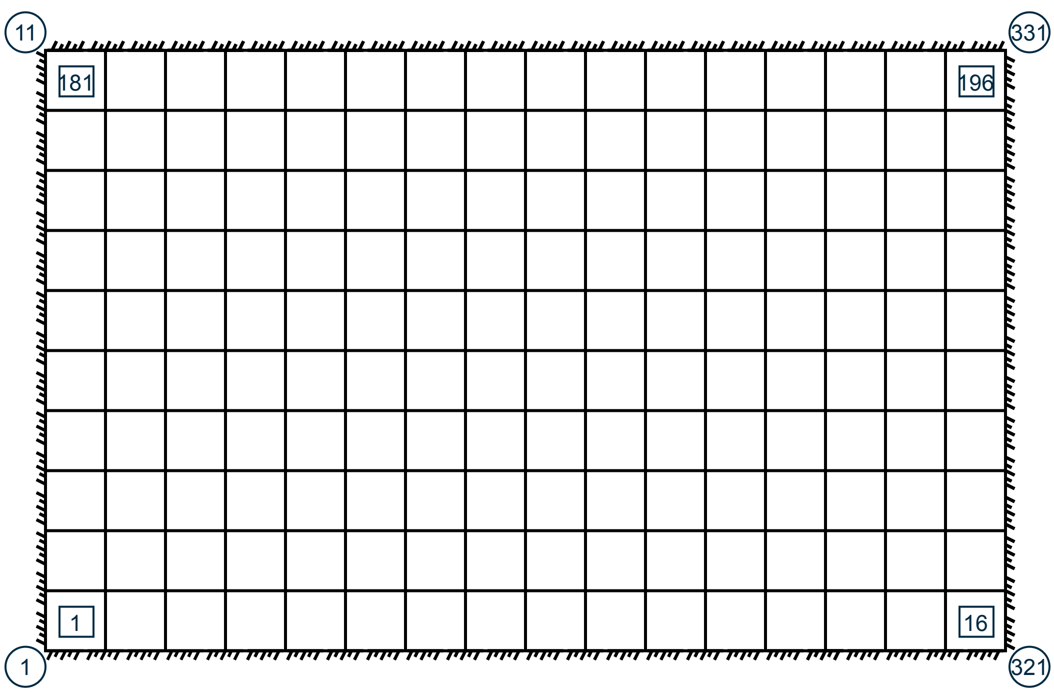

Figure 400: Model

Comparison

Table 424: Comparison of results

Result Type		Theory	STAAD.Pro	Difference
Vertical deflection, δ (in) at joint	162	0.036	0.03549	1.2%
	166	0.113	0.11230	1.0%
	306	0.025	0.02478	1.4%
Bending moment, Mx (in·lb) at joint	9	1.763	1.64	7.0%
	89	8.513	8.41	1.2%
	96	1.098	1.05	4.4%
Bending moment, My (in·lb) at joint	9	0.897	0.86	4.1%
	89	4.873	4.81	1.3%
	96	1.108	0.99	10.7%

STAAD Input

Tip: You can copy and paste this content directly into a `.std` file to run in STAAD.Pro.

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\04 Plates Shells\2D Rectangular Plate with fixed edges.std` is typically installed with the program.

V. 2D Retaining Wall

To find the bending moments at various points on a wall fixed along three edges.

Reference

Young, W. C., *Roark's Formulas for Stress and Strain*, McGraw-Hill Inc., 6th Edition, 1989.

Problem

Find the bending moment at the points circled in the figure for 2 load cases:

a. a uniform pressure over the entire wall
b. a hydrostatic pressure varying linearly from 0 at the top to maximum at the bottom.

E =3,150 ksi

Length, a = 60 ft

Height, b = 40 ft

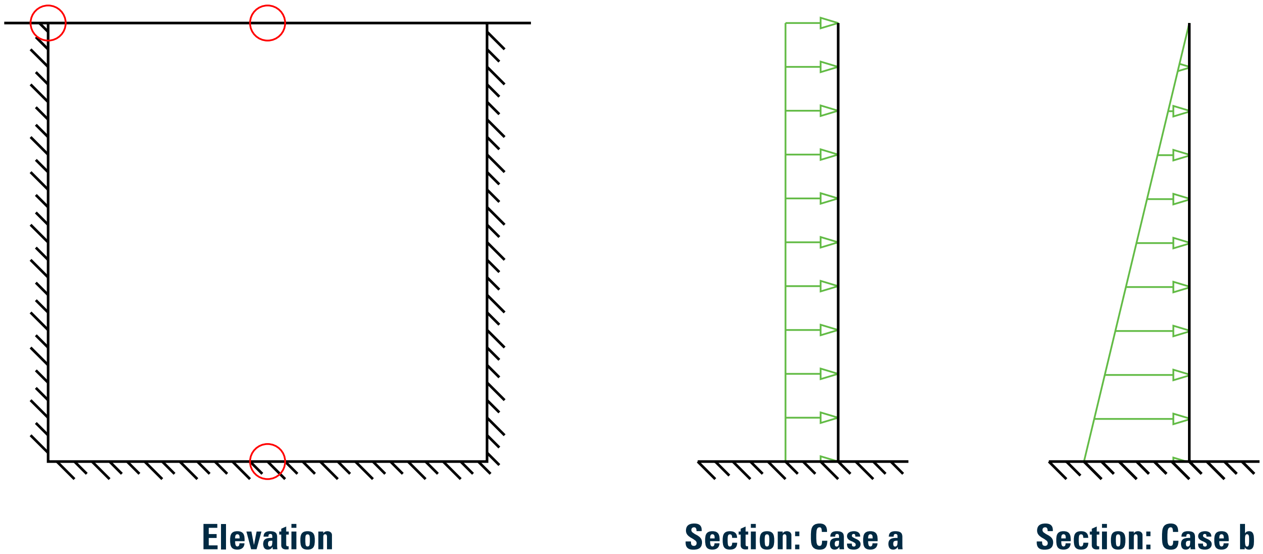

Figure 401: Model

Hand Calculation

$$\frac{a}{b} = \frac{60\text{ft}}{40\text{ft}} = 1.5$$

$$M = \frac{\beta_i q b^2}{6}$$

a. For uniform pressure (load case 1):

where

β_i = = value taken for Case 10a, Table 26, on p.469 of the reference (when a/b = 1.5):

= 0.727 for midpoint of bottom edge (moment about the horizontal axis)

= 0.484 for midpoint of top edge (free edge; moment about the horizontal axis)

= 1.073 for corner of the free edge and fixed edge (moment about the vertical axis)

q = magnitude of the pressure, 1 ksf

b. For linearly varying pressure (load case 2):

Pressure varies from zero intensity at the top to maximum at the base.

where

β_i = value taken for Case 10d, Table 26, on p.470 of the reference (when a/b = 1.5):

= 0.351 for midpoint of bottom edge (moment about the horizontal axis)

= 0.244 for corner of the free edge and fixed edge (moment about the vertical axis)

q = magnitude of the pressure at bottom, 3.5 ksf

Comparison

Table 425: Comparison of results

Result Type		Theory	STAAD.Pro	Difference	Comments
Uniform pressure load case	Bending moment at midpoint of bottom edge (ft·kip/ft)	193.9	393.25/2 = 196.6	1.4%	The theoretical results from classical Plate theory was compared with the results from Finite Element model - hence the difference in results.
	Bending moment at midpoint of top edge (ft·kip/ft)	129	130.6	1.2%	
	Bending moment at corner of free edge and fixed edge (ft·kip/ft)	286.1	294.0	2.8%	
Linearly varying pressure load case	Bending moment at midpoint of bottom edge (ft·kip/ft)	327.6	673.0/2 = 336.5	2.7%	
	Bending moment at corner of free edge and fixed edge (ft·kip/ft)	227.7	212.0	6.9%	

STAAD Input

Tip: You can copy and paste this content directly into a `.std` file to run in STAAD.Pro.

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\04 Plates Shells\2D Retaining Wall.STD` is typically installed with the program.

V. 2D Surface Displacements

To find the vertical deflection and bending moments due to an unit pressure in a rectangular plate simply supported along four edges.

Problem

Find the vertical deflection at the points shown in the sketch and the bending stress at the center of a 20 in. square plate subjected to a uniform pressure of 1 ksi. Use a quarter of the plate assuming proper boundary conditions along the lines of symmetry.

E = 10,000.0 ksi

Thickness = 5 in

Poisson's ratio = 0.4

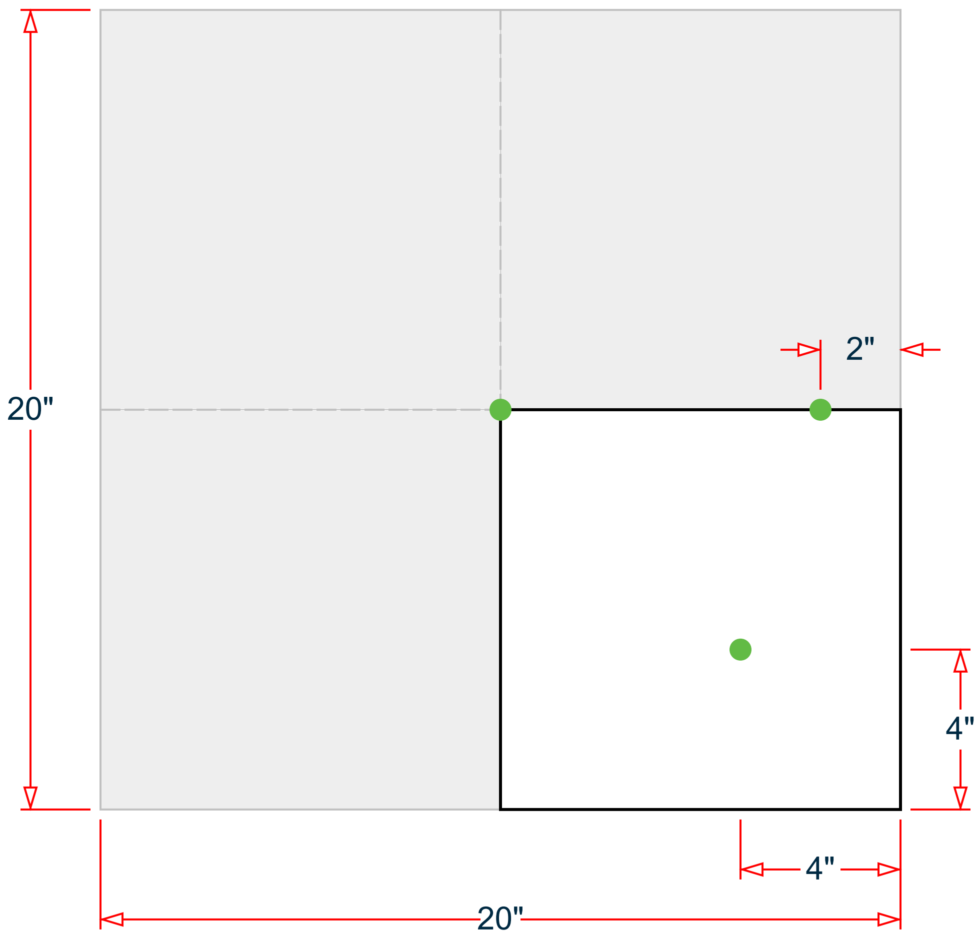

Figure 402: Model

Comparison

Table 426: Comparison of results

Result Type		Theory	STAAD.Pro	Difference	Comments
Vertical deflections due to unit pressure, 10^{-3} in	δ_1	6.826	6.864	0.6%	
	δ_9	2.322	2.343	0.9%	
	δ_{73}	2.684	2.707	0.9%	

Result Type	Theory	STAAD.Pro	Difference	Comments
Maximum bending stress due to unit pressure, σ, element 1 (psi)	5,071	4,908	3.2%	The theoretical results from classical Plate theory was compared with the results from Finite Element model - hence the difference in results.

STAAD Input

Tip: You can copy and paste this content directly into a `.std` file to run in STAAD.Pro.

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\04 Plates Shells\2D Surface Displacements.STD` is typically installed with the program.

V. 2D Surface with Hole Edge Stress

To find the normal stress on the edge of a circular hole in the center of a rectangular plate.

Reference

Young, W. C., *Roark's Formulas for Stress and Strain*, McGraw-Hill Inc., 6th Edition, 1989 (Page 732, Type 7).

Problem

Find the normal stress on the edge of the circular hole for the plate shown, when an in-plane load causes tension. Use a one-quarter, doubly symmetric model.

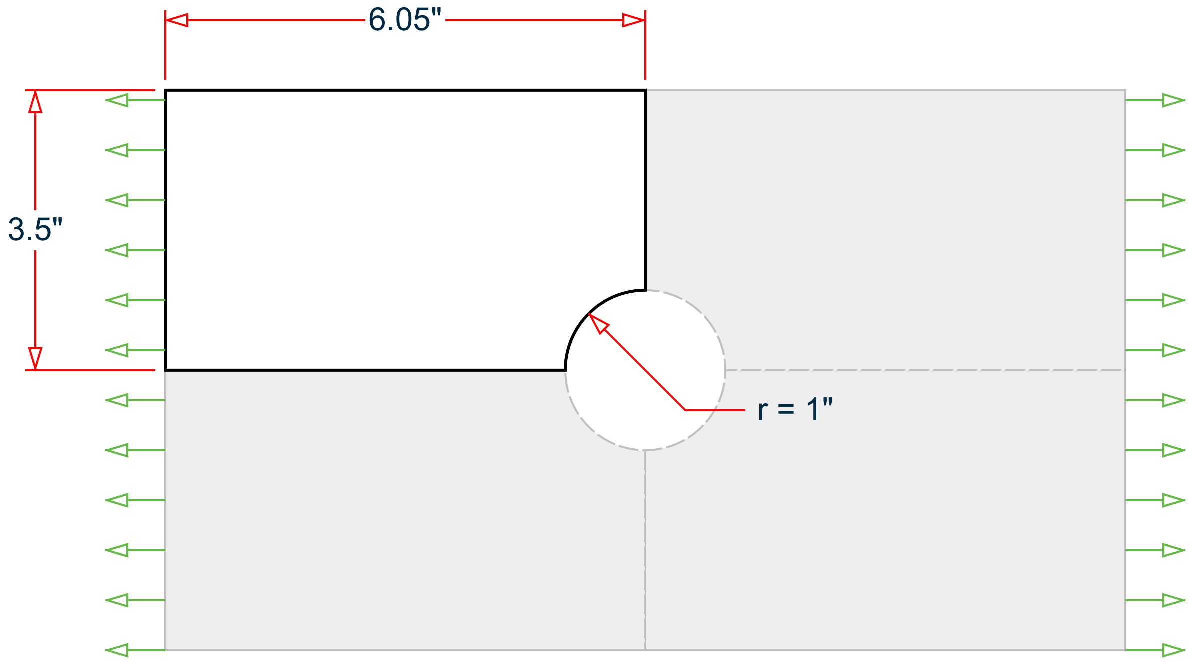

Figure 403: One quarter of rectangular plate with hole

E = 30,000.0 ksi

Size = 12.10 in × 7.0 in

Thickness = 0.1 in

Fillet radius = 1 in

Poisson's ratio = 0.3

P = 2,000 lbs

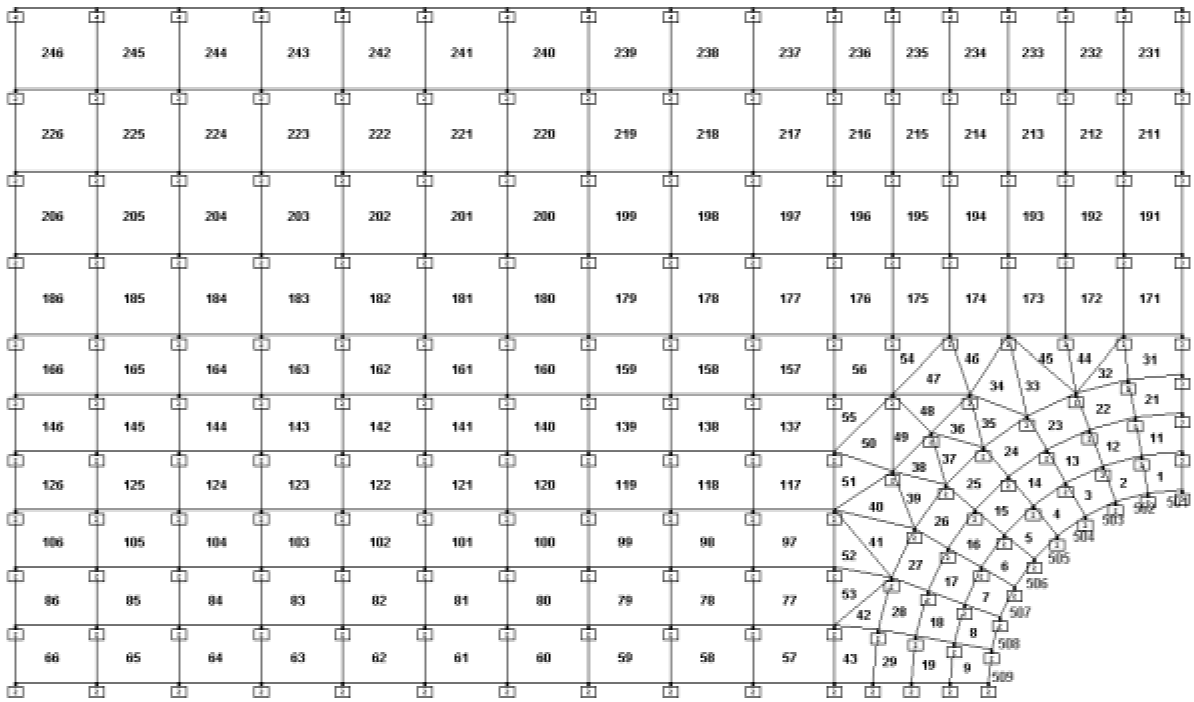

Figure 404: Model with nodes and elements labeled

Comparison

Table 427: Comparison of results

Result Type	Theory	STAAD.Pro	Difference
Stress on fillet (node 1, plate 1) (psi)	9.475	9.489	<1%

STAAD Input

Tip: You can copy and paste this content directly into a `.std` file to run in STAAD.Pro.

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\04 Plates Shells\2D Surface with Hole Edge Stress.STD` is typically installed with the program.

V. 2D Tapered Beam In-Plane Stress

To find element stress due to joint load at the fixed end of a tapered plate with one end fixed.

Reference

Crandall, S.H., & Dahl, N.C., *An Introduction to the Mechanics of Solids*, McGraw – Hill, Inc., 1959.

Problem

The tapered plate structure is loaded at the free end. Calculate the maximum stress at the midspan.

E = 30,000.0 ksi

Thickness = 2 in

Poisson's ratio = 0.2

P = 4 kips

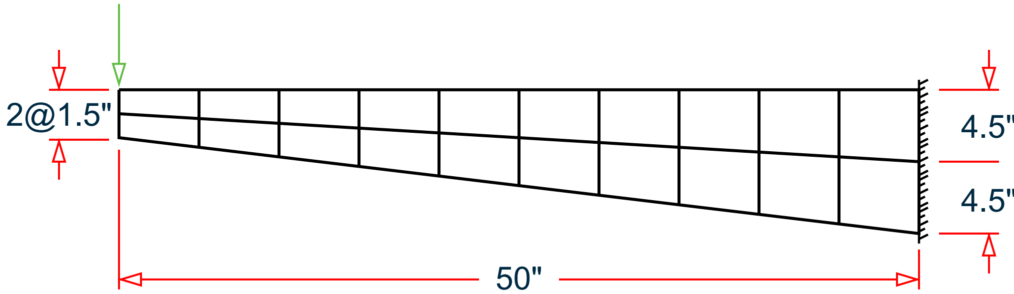

Figure 405: Model

Comparison

The STAAD.Pro result is taken as average of stress in elements 9 and 11 at node 16 = *0.5(8,333.35 + 8,359.62) = 8,346.5*.

Table 428: Comparison of results

Result Type	Theory	STAAD.Pro	Difference
Maximum stress at the center (psi)	8,333	8,346.5	0.2%

STAAD Input

Tip: You can copy and paste this content directly into a `.std` file to run in STAAD.Pro.

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\04 Plates Shells\2D Tapered Beam In-Plane Stress.STD` is typically installed with the program.

V. 2D Triangular Surface with Thermal Load

A simply-supported equilateral triangle is subjected to a linear thermal gradient. The deflections and bending moments are calculated.

Reference

Timoshenko, S. and Woinowsky-Krieger, S., *Theory of Plates and Shells*, McGraw Hill, 1959, pp. 92-97.

Problem

The purpose of this example is to demonstrate the ability of STAAD to calculate the response of a structure when thermally-loaded plate elements are utilized. The STAAD.Pro model considers one-half of the plate, modeled using 49 quad elements and seven tri plate elements. For specifying inclined supports, an auxiliary coordinate system is defined along the edge (see second figure below) not parallel to a global axis.

$E = 10\times(10)^6$ lb/in^2

$\upsilon = 0.3$

$\alpha = 12\ (10)^{-6}$ in/in °F

$\Delta T = T_{top} - T_{bottom} = 4500$

$t = 0.1$ inches

$a = 3.0$ inches

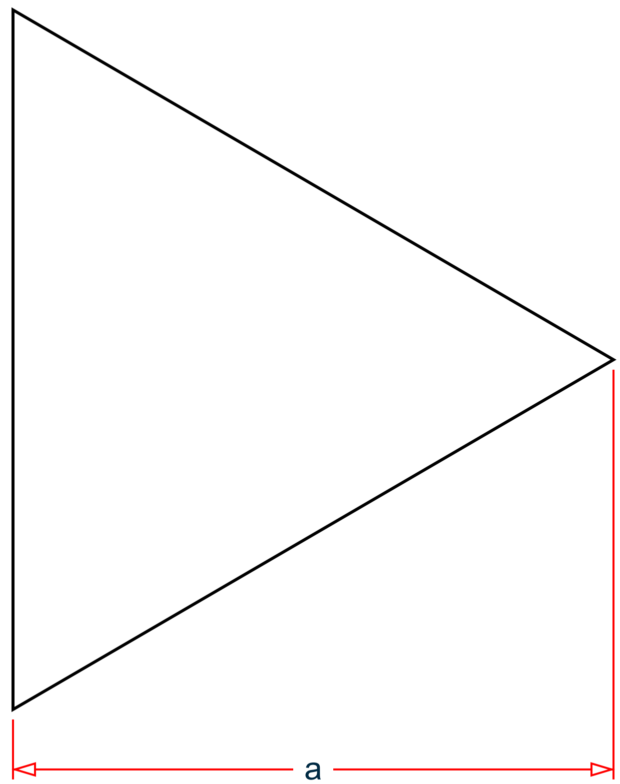

Figure 406: Simply-supported, equilateral triangle with thermal load

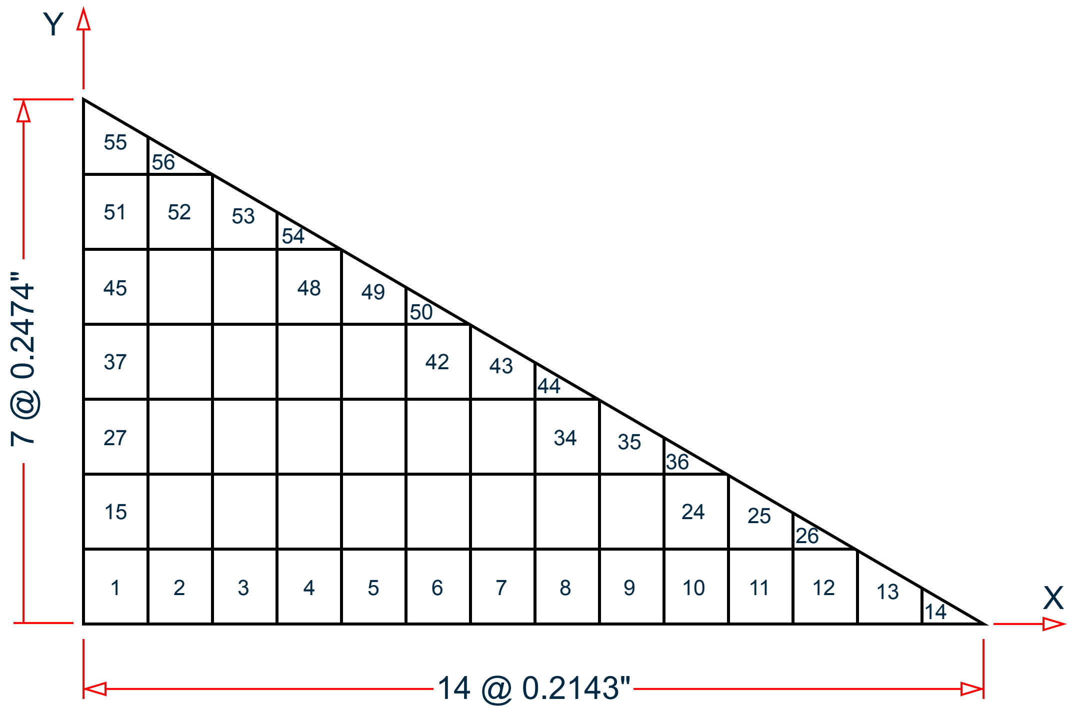

Figure 407: Finite element model of a simply-supported, equilateral triangle

Theoretical Solution

From page 96 of the reference:

$$M_x = -\frac{\alpha \Delta T E t^2}{24}\left(1 + \frac{3x'}{a}\right)$$

$$= -\frac{12(10)^{-6}(450.0)10(10)^6(0.1)^2}{24}\left(1 + \frac{3x'}{3}\right) = -22.5\left(1 + x'\right)$$

$$M_y = -\frac{\alpha \Delta T E t^2}{24}\left(1 - \frac{3x'}{a}\right) = -22.5\left(1 - x'\right)$$

$$M_{xy} = \frac{\alpha \Delta T E t^2 y}{8a}$$

$$= \frac{12(10)^{-6}(450.0)10(10)^6(0.1)^2}{8(3)}y = 22.5y$$

$$w = \frac{\alpha \Delta T(1+\nu)}{4at}\left(x'^3 - 3y^2x' - ax'^2 - ay^2 + \frac{4a^3}{27}\right)$$

$$= 0.00585\left(x'^3 - 3y^2x' - 3x'^2 - 3y^2 + 4\right)$$

The origin of the x' axis in the reference is located at a/3, or 1 inch from the edge. Therefore:

x' = x-1

Upon substitution:

Mx = -22.5x

$My = -22.5 (2 - x)$

$Mxy = 22.5y$

$w = 0.00585 (x3 – 6x^2 + 9x – 3y^2x)$

Comparison

Table 429: Comparison of results

Result Type		Theory	STAAD.Pro	Difference
Z deflection at center of element along x-axis (in)	Node 6	0.02331	0.02331	none
Maximum (magnitude) bending moment along x-axis (in·lb/in)	Mx at Element 8	-36.16	-36.15	none
	Mx at Element 14	-64.29	-65.64	2.1%
	My at Element 1	-42.59	-42.59	none
	My at Element 8	-8.839	-8.838	none
Twisting moment along y-axis at center of elements (in·lb/in)	Mxy at Element 55	36.19	36.06	none

The results show excellent agreement for displacements and for quad plate element stresses except in the few instances where the magnitude of the answers is very small. The tri plate elements are lower order elements, and it is therefore not unusual for these elements to show poorer agreement than quads where mesh size is smaller.

STAAD Input

Tip: You can copy and paste this content directly into a `.std` file to run in STAAD.Pro.

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\04 Plates Shells\2D Triangular Surface with Thermal Load.STD` is typically installed with the program.

V. Cantilever Tube Stresses and Deflection

To find deflections and element stresses due to loads at the free end of a Cantilever beam of tubular section. The beam is modeled using plate/shell elements.

Reference

Timoshenko, S., *Strength of Materials, Part I, Elementary Theory and Problems*, 2nd Edition, Van Nostrand Company, 1940.

Problem

A cantilever beam is made of a tubular section. Using plate/shell elements calculate the deflection at the free end and axial stress at the center of the beam for the following free end loads:

$P = 1{,}000$ lb

$M_x = 2{,}000$ in·lb

$M_y = 2{,}500$ in·lb

$V = 1{,}000$ lb

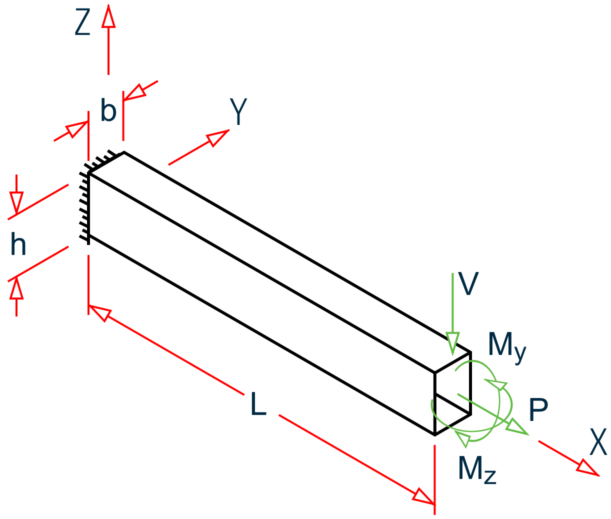

Figure 408: Cantilever beam modeled with elements

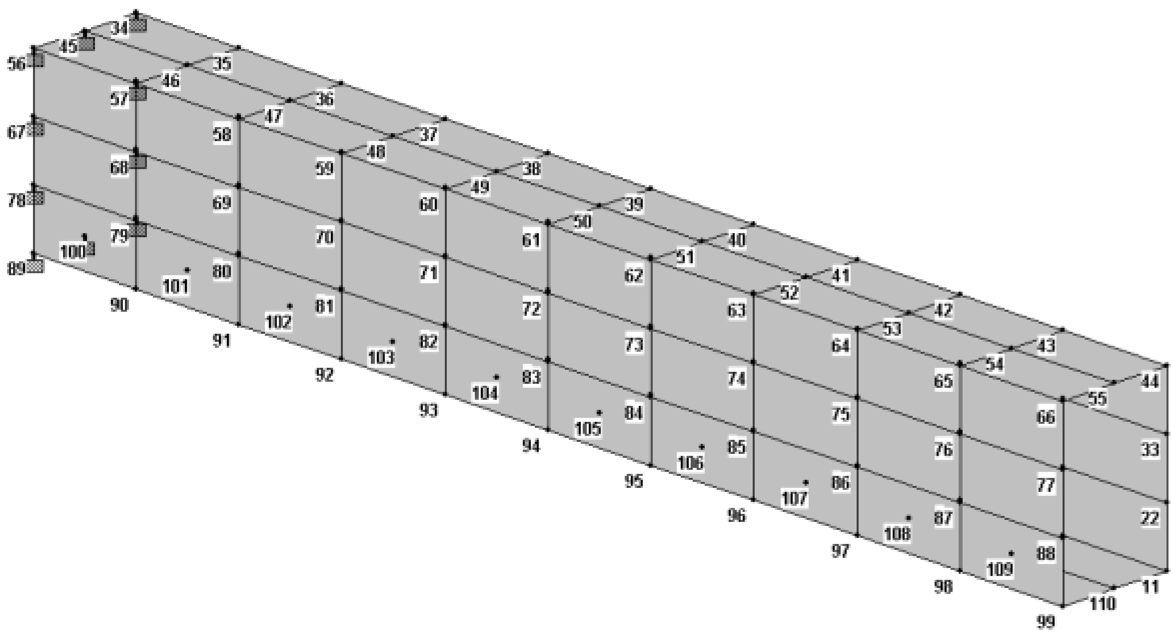

Figure 409: STAAD.Pro Model showing Node numbers

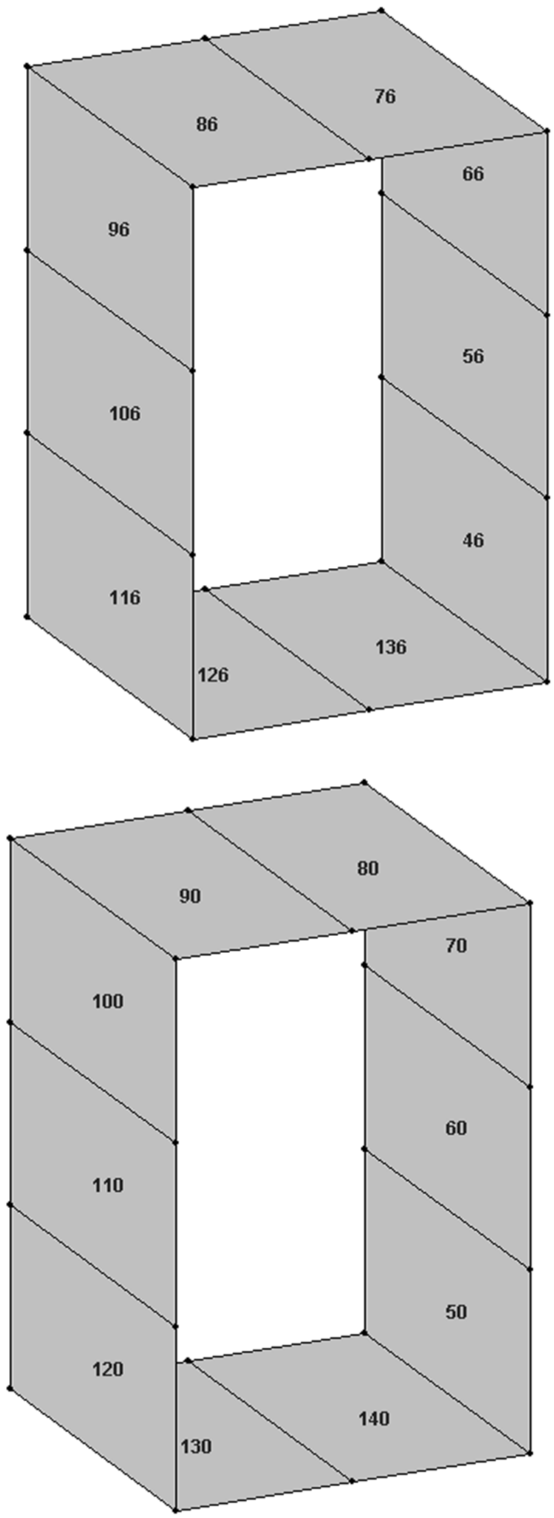

Figure 410: Element numbers at a) the middle section and b) the free end

Average deflection for nodes 11, 22, 33, 44, 55, 66, 77, 88, 99 and 10 due to load case 3 (M_y):

$$d = [4(0.07431) + 4(0.07384) + 2(0.07374)]/10 = 0.074008$$

Average deflection for nodes 11, 22, 33, 44, 55, 66, 77, 88, 99 and 10 due to load case 4 (V):

$$d = [4(-0.41123) + 4(-0.41124) + 2(-0.41057)]/10 = 0.41110$$

Average bending stress for nodes 76, 86, 126, and 136 due to load case 3 (My):

$$\sigma = 4(5551.52)/4 = 5551.52 \text{ psi}$$

Average bending stress for nodes 71, 81, 121, and 131 due to load case 4 (V):

$$\sigma = 4(42074.63)/4 = 42074.63 \text{ psi}$$

Comparison

Table 430: Comparison of results

Result Type		Theory	STAAD.Pro	Difference
Free end deflection due to axial load, P (in)	Nodes 11, 44, 66, 99	0.004	0.00410	2.5%
	Nodes 22,33, 55, 77, 88, 110	0.004	0.00401	negligible
Axial stress at the middle of the beam due to axial load, P (psi)	Elements 46, 66, 96, 116	2,000	2,000.02	negligible
	Elements 56, 106	2,000	1,991.57	negligible
	Elements 76, 86, 126, 136	2,000	2,004,19	negligible
In plane shear stress at the free end due to torque, M_x (psi)	Elements 50,70,100,120	3,333	3,333.55	negligible
	Elements 60, 110	3,333	3,325.54	negligible
	Elements 80,90,130,140	3,333	3,342.23	negligible
Avg. free end deflection at the center due to moment, M_y (in)		0.0741	0.074008	negligible
Avg. free end bending stress at the center due to moment, M_y (psi)		5,647	5,551.52	1.7%
Avg. free end deflection at the center due to shear, V (in)		0.4152	-0.41110	1.0%
Avg. free end bending stress at the center due to shear, V (psi)		42,913	42,074.63	2.0%

STAAD Input

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\04 Plates Shells\Cantilever Tube Stresses and Deflection.STD` is typically installed with the program.

V. Curved Roof Displacements and Stresses

A Cylindrical roof is supported along two circular edges. Using plate/shell elements, find the vertical deflection at the center of the free edge, principal stresses at the center of the support and center of the free edge (top and bottom of the roof plate) due to uniformly distributed gravity load.

Reference

Scordelis, A.C. and Lo, K.S., "Computer Analysis of Cylindrical Shells", *Journal of the American Concrete Institute*, Vol. 61, May 1964.

Problem

For the cylindrical roof shell calculate the following deflection and stresses due to the gravity load.

The vertical deflection, δ_y, at the center of the free edge.

Principal stresses, σ_{max} and σ_{min}, at the center line section at the vertical angle (top and bottom of the roof plate element). Principal stresses, σ_{max} and σ_{min}, at the center section of the free edge (top and bottom of the roof plate element).

$E = 4.32\times(10)^8$ psf

t = 3.0 in.

Poisson's ratio = 0.0 in theory (0.01001 in STAAD)

w = 90 psf (uniform on surface).

L = 50 feet.

r = 25 feet, 40° sector either side of vertical

Boundary conditions: simply supported on circular edges

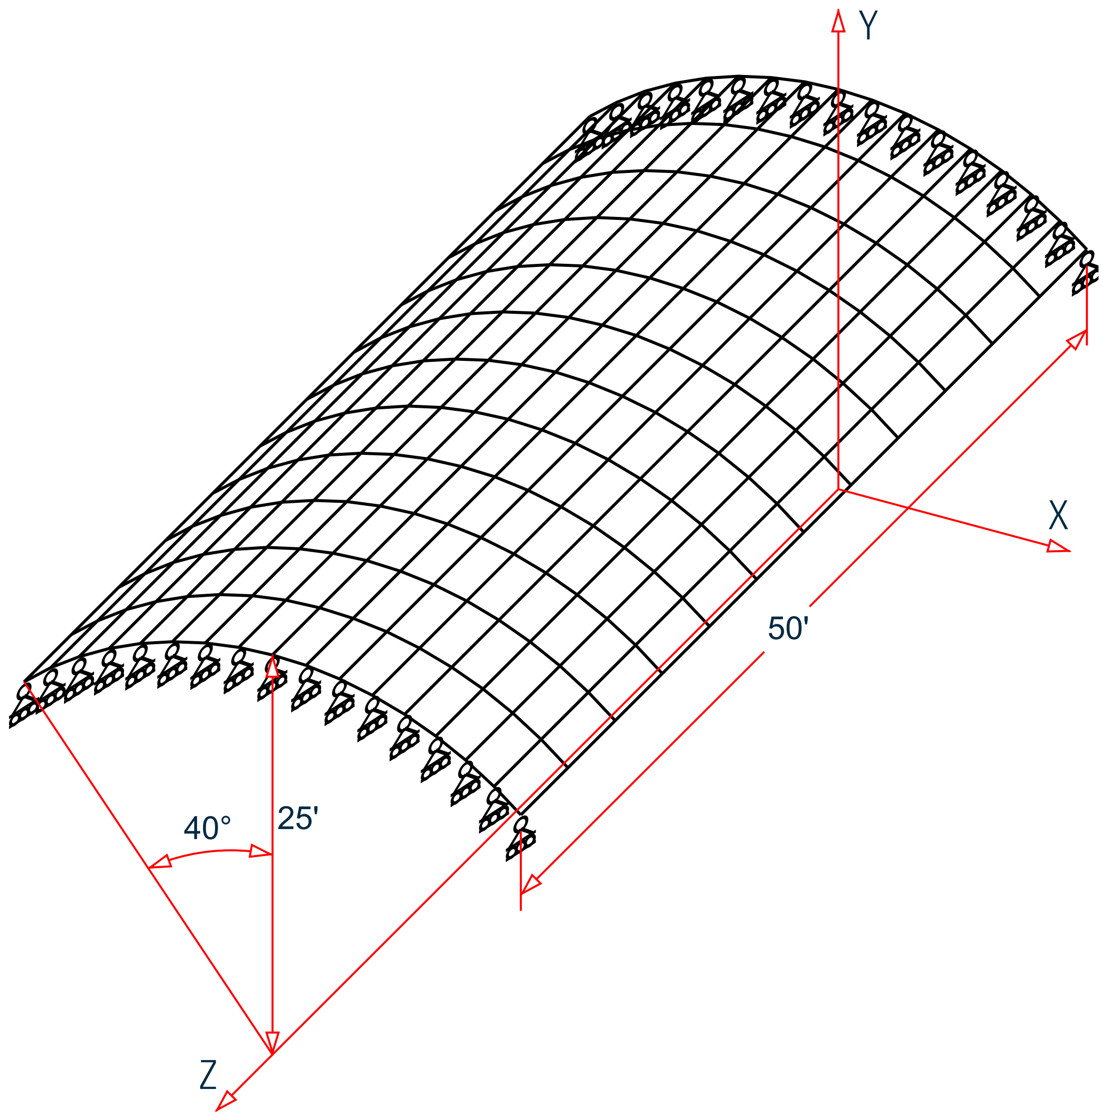

Figure 411: Finite element model of cylindrical roof structure

Comparison

Table 431: Comparison of results

Result Type		Theory	STAAD.Pro	Difference	Comments
δ_y, at the center of the free edge (in) (y translation at node 63)		-3.703	3.650	1.4%	A finer mesh may reduce the difference between the theoretical and software output.
σ at center (ft·kip)	Bottom	191.23	181.55[a]	5.1%	
	Top	218.74	209.16[a]	4.4%	

Result Type		Theory	STAAD.Pro	Difference	Comments
σ at free edge (ft·kip)	Bottom	215.57	208.33[b]	3.4%	
	Top	340.7	334.95[b]	1.7%

V. Element Offset Table Top Comparison

A simple table-like structure is composed of four column members and a single plate element. Verify that the element offset command gives similar results as those from other modeling methods.

Problem

The plate element is subjected to a pressure load acting vertically downward along global Y direction of 1 kN/m^2. Also, two concentrated point loads of 10 kN are acting laterally along global X & global Z directions at center of the plate element.

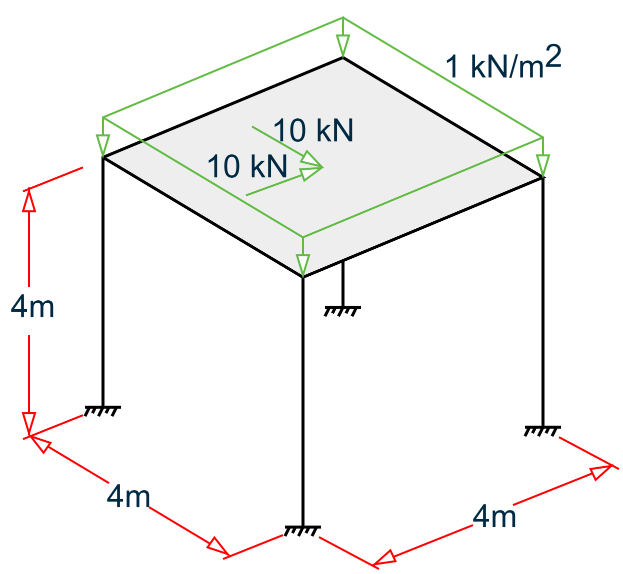

Figure 412: Loads and dimensions of the table-top structure

- Slab thickness = 20 cm
- Columns and beams = 40 cm square
- Concrete materials for all members and elements*

Offset the slab edge by 1/2 the column width (20 cm) in the plan dimensions and 1/2 the slab depth (10 cm) into the thickness of the slab.

Calculations

The model is generated with three different approaches to include the offset effect on the plate. First approach is to use `ELEMENT OFFSET` command wherein offset distances are directly assigned to corner joints of the plate without any need to manually compute co-ordinates for offset joints.

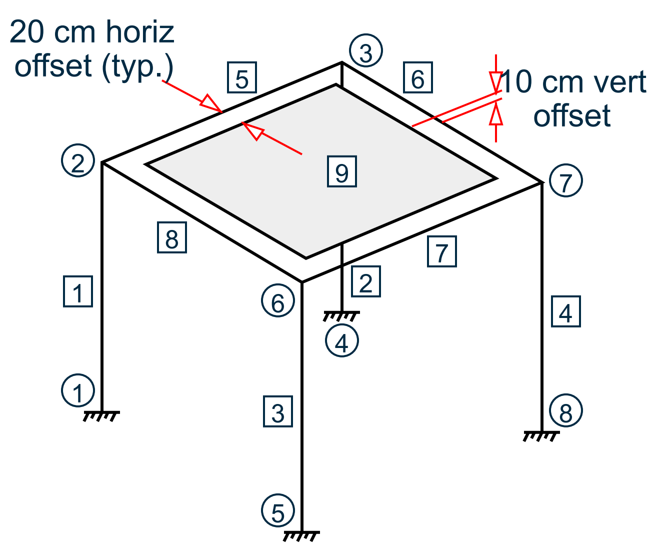

Figure 413: Nominal joint, member, and plate numbers and offset distances

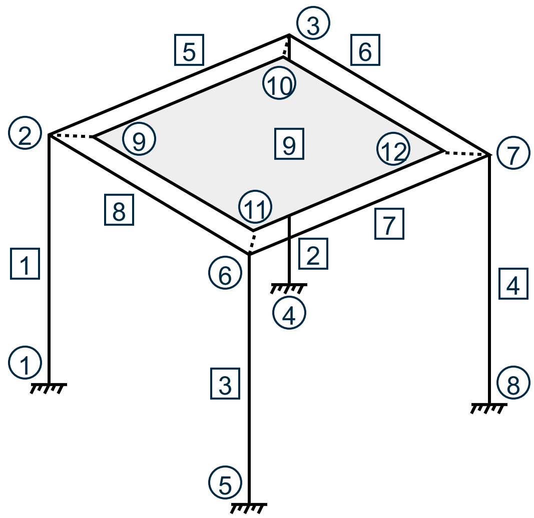
The second approach is to use control-dependent specification instead of offset commands with rigid connections between offset joints of the plate & beam-column junction for load transfer. The third approach is to use short, relatively stiff beam members (*assigned with material `STIFF` having high E & G values) instead of control-dependent specification so that offset joints of plate and beam-column junction are rigidly connected to ensure load transfer.

Note: In both control-dependent approach and short rigid beam approaches, the coordinates for plate offset joints must be manually computed.



The STAAD.Pro model includes three structures to represent these three different methods. The node numbers, member numbers, and plate numbers are prefixed with 1, 2, and 3, respectively:

1. Using element offsets in the global direction (nodes 101, 102, 103, etc.)
2. Using rigid links with a high stiffness value (nodes 201, 202, 203, etc.)
3. Using a control / dependent specification (nodes 301, 302, 303, etc.)

Figure 414: Additional node numbers added for different approaches

Comparison

Results for the model created with element offset command should be identical with the model created with control-dependent approach or short rigid beam approach. Hence, the results from control-dependent and short rigid beam models are treated as reference values against which results from model with element offset command are compared.

V. Element Offset Water Tank Comparison

A concrete water tank structure is composed of members and plate elements. Verify that the element offset command gives similar results as those from other modeling methods.

Problem

A water tank structure supported by peripheral beams & columns is to be modelled in STAAD.Pro. Objective is to introduce offsets in elevation to all four side walls of water tank so that corner joints of side walls flushes with top surface of bottom slab and offsets in plan to two side walls spanning parallel to global Z direction so that corner joints flushes with the edge of side walls spanning parallel to global X direction.

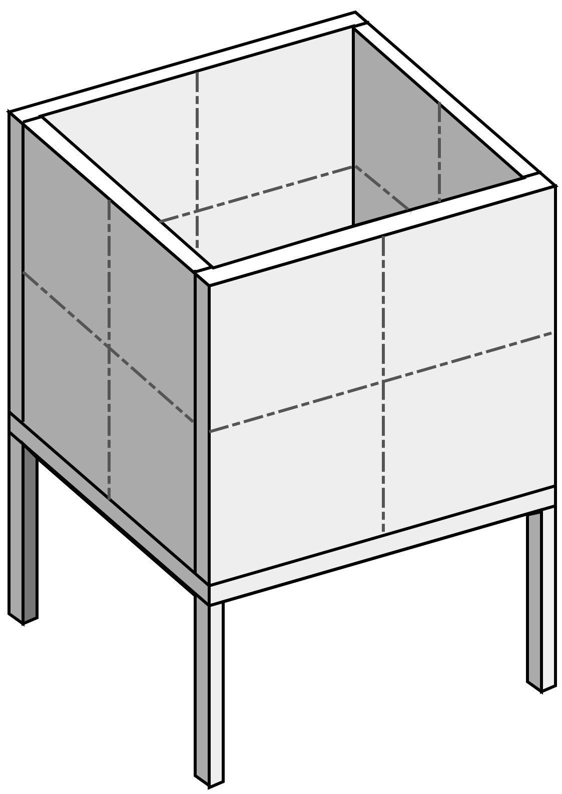

Figure 415: Concrete water tank model showing element offsets

Selfweight acting vertically downward along global Y direction.

- Tank wall and bottom thickness = 20 cm

- Columns and beams = 40 cm square
- Concrete materials for all members and elements*

Validation

The model is generated with three different approaches to include the offset effect on the plate. First approach is to use `ELEMENT OFFSET` command wherein offset distances are directly assigned to corner joints of the plate without any need to manually compute co-ordinates for offset joints.

The second approach is to use control-dependent specification instead of offset commands with rigid connections between offset joints of the plate & beam-column junction for load transfer. The third approach is to use short, relatively stiff beam members (*assigned with material `STIFF` having high E & G values) instead of control-dependent specification so that offset joints of plate and beam-column junction are rigidly connected to ensure load transfer.

Note: In both control-dependent approach and short rigid beam approaches, the coordinates for plate offset joints must be manually computed.

The STAAD.Pro model includes three structures to represent these three different methods. The node numbers, member numbers, and plate numbers are prefixed with 1, 2, and 3, respectively:

1. Using element offsets in the global direction (nodes 101, 102, 103, etc.)
2. Using rigid links with a high stiffness value (nodes 201, 202, 203, etc.)
3. Using a control / dependent specification (nodes 301, 302, 303, etc.)

Comparison

Results for the model created with element offset command should be identical with the model created with control-dependent approach or short rigid beam approach. Hence, the results from control-dependent and short rigid beam models are treated as reference values against which results from model with element offset command are compared.

V. Response Spectrum Using Element Offset

Validate the response spectrum analysis results using element offsets with a similar model that uses control-dependent connections.

Details

A 2 story building with overall dimensions of 20 m in the global X direction and 8 m in the global Z direction is modelled in STAAD.Pro.

A custom defined response spectrum loading containing time-acceleration pairs along global X, Z, & Y directions is used for the loading.

Validation

The model is generated with two different approaches to include the effect on the plate offsets. The first approach is to use the `ELEMENT OFFSET` command wherein offset distances are directly assigned to corner joints of the plate without any need to manually compute coordinates for offset joints. The second approach is to use control-dependent specification instead with rigid connections between offset joints of the plate & beam-column junction for load transfer. In the control-dependent approach, one must note that coordinates for plate offset joints need to be manually computed.

Results for the model created with `ELEMENT OFFSET` command should be identical with the model created with control-dependent approach. Hence results from control-dependent approach are treated as reference values against which results from model with element offset command will be compared.
