TRACK 2 Output

`TRACK 2` will produce the results of `TRACK 1` along with the details of the bars and their distribution at each cross section. This option will also report any of the relevant detailed design messages. The longitudinal bar details at each cross section will have information on the setting out of each bar at the specific cross section. This should serve as a useful tool to inspect the design in detail. A `TRACK 2` output would contain:

Design Summary — This section provides a summary of the design including the design status, i.e. PASS/FAIL, member type and length, the critical ratio, the critical criteria and relevant clauses.

Cross Section Details — This section provides the shape type and dimension(s) of the cross-section

Design Inputs — This section reports the material data for the steel and concrete including the yield strength for steel (FY), compressive strength of concrete (FC) and modulus of elasticity for both (Es and Ec) This section additionally includes details of the cover to the longitudinal bars from the top, bottom and side faces.

Critical Strength Results — This section reports the demand determined from the design envelope as described in D1.F.4 Beam Design (on page 1215), along with the capacity for forces applied in positive and negative directions. The ratio is then the value of the demand divided by the appropriate capacity.

Longitudinal Bar Details at Cross Sections — For each of the design cross sections, the longitudinal bars are reported for each face where they are required, top bottom and skin. Area of steel is reported as the optimum required from the design and that provided after additionally meeting the detailing requirements.

The total quantity of bars on the given face are reported as “No(s) bars,” the size of longitudinal bars and quantity of layers that the bars are to be distributed on. For example, if the number of bars reported is 10 and in 2 layers, then there will be 5 bars in each layer.

Longitudinal Bar Layout — The position and extent of the longitudinal bars will be reported along with an indication if additional anchorage is required at the start or the end of the bars. A value of “yes” in the Anchor column indicates that the bar or set of bars will need to be anchored beyond the given section distances. This can be done using hooks/bends or physical anchors as deemed fit. A value of “no” indicates that no additional extension to the bar is needed beyond the given dimension. The value given in “Distance from face”is the measurement from the face defined by the position, to the center line of the bar, measured perpendicular to the face.

Transverse Bar Layout

The transverse bar table reports the details of various shear zones (see D1.F.4.3 Shear and Torsion Design (on page 1217)) within the span for both the local Y & Z axes.

Each zone is identified by the unique start and end location reported as the distances “From” and “To.”

This provides shear densities as minimum required and as provided by the given bar details.

The value “Nums” is the number of transverse groups in the zone (this equates to the zone length/spacing +1), the center to center spacing between adjacent transverse groups along the local X axis, the size of the bar used in the transverse group, and the leg count for the bars in a transverse group. A transverse group is the collection of transverse bars at a given cross section.

D1.F.5.6 Column Design in Pre-2014 Codes

Columns design in STAAD.Pro per the ACI code is performed for axial force and uniaxial as well as biaxial moments. All active loadings are checked to compute reinforcement. The loading which produces the largest amount of reinforcement is called the critical load. Column design is done for square, rectangular and circular sections. For rectangular and circular sections, reinforcement is always assumed to be equally distributed on all faces. This means that the total number of bars for these sections will always be a multiple of four (4). If the `MMAG` parameter is specified, the column moments are multiplied by the `MMAG` value to arrive at the ultimate moments on the column. Since the ACI code no longer requires any minimum eccentricity conditions to be satisfied, such checks are not made.

Method used

Bresler Load Contour Method

Known Values

Pu, Muy, Muz, B, D, Clear cover, Fc, Fy

Ultimate Strain for concrete : 0.003

Steps involved

1. Assume some reinforcement. Minimum reinforcement (1%) is a good amount to start with.
2. Find an approximate arrangement of bars for the assumed reinforcement.
3. Calculate PNMAX = 0.85 Po, where Po is the maximum axial load capacity of the section. Ensure that the actual nominal load on the column does not exceed PNMAX. If PNMAX is less than Pu/PHI, (PHI is the strength reduction factor) increase the reinforcement and repeat steps 2 and 3. If the reinforcement exceeds 8%, the column cannot be designed with its current dimensions.
4. For the assumed reinforcement, bar arrangement and axial load, find the uniaxial moment capacities of the column for the Y and the Z axes, independently. These values are referred to as MYCAP and MZCAP respectively.
5. Solve the interaction equation:

$$\left(\frac{M_{ny}}{M_{ycap}}\right)^{a} + \left(\frac{M_{nz}}{M_{zcap}}\right)^{a} \leq 1.0$$

where

a	=	The ALPHA parameter used in ACI 318 2011, 2008, 2005, and 2002. Refer to D1.F.3.1 ACI 318-2011 Design Parameters (on page 1206) or D1.F.3.2 Pre ACI 318-2011 Design Parameters (on page 1212) for details.

If the column is subjected to a uniaxial moment, a is chosen as 1.0

6. If the Interaction equation is satisfied, find an arrangement with available bar sizes, find the uniaxial capacities and solve the interaction equation again. If the equation is satisfied now, the reinforcement details are written to the output file.
7. If the interaction equation is not satisfied, the assumed reinforcement is increased (ensuring that it is under 8%) and steps 2 to 6 are repeated.
8. The maximum spacing of reinforcement closest to the tension force, for purposes of crack control, is given by

$$s = 15\left(40,\ 000\frac{40,\ 000}{f_s}\right) - 2.5cc \leq 12\left(\frac{40,\ 000}{f_s}\right)$$

with f_s in psi and is permitted to be taken equal to (2/3) f_y, rather than 60 percent of f_y, as in ACI 318-02.

9. Section 10.9.3 has been modified to permit the use of spiral reinforcement with specified yield strength of up to 100,000 psi. For spirals with fyt greater than 60,000 psi, only mechanical or welded splices may be used.

Column Interaction

The column interaction values may be obtained by using the design parameter TRACK 1.0 or TRACK 2.0 for the column member. If a value of 2.0 is used for the TRACK parameter, 12 different Pn-Mn pairs, each representing a different point on the Pn-Mn curve are printed. Each of these points represents one of the several Pn-Mn combinations that this column is capable of carrying about the given axis, for the actual reinforcement that the column has been designed for. In the case of circular columns, the values are for any of the radial axes. The values printed for the TRACK 1.0 output are:

P0	Maximum purely axial load carrying capacity of the column (zero moment).
Pnmax	Maximum allowable axial load on the column (Section 10.3.5 of ACI 318).
P-bal	Axial load capacity at balanced strain condition.
M-bal	Uniaxial moment capacity at balanced strain condition.
e-bal	M-bal / P-bal = Eccentricity at balanced strain condition.
M0	Moment capacity at zero axial load.

P-tens Maximum permissible tensile load on the column.

Des. Pn Pu/PHI where PHI is the Strength Reduction Factor and Pu is the axial load for the critical load case.

Des. Mn $Mu \times MMAG / PHI$ where PHI is the Strength Reduction Factor and Mu is the bending moment for the appropriate axis for the critical load case.

For circular columns,

$$M_u = \sqrt{M_{uy}{}^2 + M_{uz}{}^2}$$

$$e/h = (M_n/P_n)/h$$

where

h = the length of the column

Example

Column design per the ACI 318-2005 code

```
UNIT KIP INCH
START CONCRETE DESIGN
CODE ACI 2005
FYMAIN 58 ALL
MAXMAIN 10 ALL
CLB 2.5 ALL
DESIGN COLUMN 23 25
END CONCRETE DESIGN
```

Example

Column design per the ACI 318-2002 code

```
UNIT KIP INCH
START CONCRETE DESIGN
CODE ACI 2002
FYMAIN 58 ALL
MAXMAIN 10 ALL
CLB 2.5 ALL
DESIGN COLUMN 23 25
END CONCRETE DESIGN
```

Example

Column design per the ACI 318-1999 code

```
UNIT KIP INCH
START CONCRETE DESIGN
CODE ACI 1999
FYMAIN 58 ALL
MAXMAIN 10 ALL
CLB 2.5 ALL
DESIGN COLUMN 23 25
END CONCRETE DESIGN
```

Column Design Output

The samples illustrate different levels of the column design output. The following output is generated without any TRACK definition (i.e., using the default of TRACK 0.0):

```
=====================================================================

     COLUMN  NO.     5  DESIGN PER ACI 318-05 - AXIAL + BENDING

FY - 60000  FC - 4000 PSI,  SQRE SIZE - 12.00 X 12.00 INCHES, TIED
        AREA OF STEEL REQUIRED =   7.589  SQ. IN.

BAR CONFIGURATION        REINF PCT.   LOAD   LOCATION   PHI
-----------------------------------------------------------

  8 - NUMBER  9            5.556        2      STA     0.650
(PROVIDE EQUAL NUMBER OF BARS ON EACH FACE)
TIE BAR NUMBER    4 SPACING   8.00 IN
```

TRACK 1.0 generates the following additional output:

```
    COLUMN INTERACTION: MOMENT ABOUT Z -AXIS (KIP-FT)

 --------------------------------------------------------
   P0        Pn max    P-bal.    M-bal.   e-bal.(inch)
  942.40    753.92    179.59    170.75   11.41
    M0        P-tens.   Des.Pn    Des.Mn     e/h
  148.52   -480.00    350.15     10.47    0.00249
 --------------------------------------------------------

    COLUMN INTERACTION: MOMENT ABOUT Y -AXIS (KIP-FT)

 --------------------------------------------------------
   P0        Pn max    P-bal.    M-bal.   e-bal.(inch)
  942.40    753.92    179.59    170.75   11.41
    M0        P-tens.   Des.Pn    Des.Mn     e/h
  148.52   -480.00    350.15    136.51    0.03249
 --------------------------------------------------------
```

TRACK 2.0 generates the following output in addition to the above examples:

```
                             Pn        Mn        Pn        Mn    (@ Z )

D1.F.5.6.1 Slenderness Effects and Analysis Consideration
Slenderness effects are extremely important in designing compression members. The ACI 318 code specifies two options by which the slenderness effect can be accommodated (Section 10.10 & 10.11 ACI-318). One option is to perform an exact analysis which will take into account the influence of axial loads and variable moment of inertia on member stiffness and fixed-end moments, the effect of deflections on moments and forces, and the effect of the duration of loads. Another option is to approximately magnify design moments.

STAAD.Pro uses both these options. To perform the first type of analysis, use the command `PDELTA ANALYSIS` instead of `PERFORM ANALYSIS`. This analysis method will accommodate the requirements as specified in Section 10.10 of the ACI-318 Code, except for the effects of the duration of the loads. It is felt that this effect may be safely ignored because experts believe that the effects of the duration of loads are negligible in a normal structural configuration. If it is desired, STAAD.Pro can also accommodate any arbitrary moment magnification factor (second option) as an input, in order to provide some safety due to the effects of the duration of loads.

Although ignoring load duration effects is somewhat of an approximation, it must be realized that the approximate evaluation of slenderness effects is also an approximate method. In this method, moment-magnification is based on empirical formula and assumptions on sidesway.

Considering all this information, it is our belief that a `PDELTA ANALYSIS`, as performed by STAAD.Pro , is most appropriate for the design of concrete members. However, you should note that to take advantage of this analysis, all combinations of loadings must be provided as repeat load cases and not as load combinations. This is due to the fact that load combinations are just algebraic combinations of forces and moments, whereas a repeat load case consists of one or more primary load case which are revised during the PDelta analysis based on the deflections. Also note that the you must provide the proper factored loads (e.g., 1.4 for DL etc.). STAAD.Pro does *not* factor the loads automatically.

Moment Magnification per the 2011 Editions

If the moment magnification method is used in lieu of an exact analysis, columns designed per ACI 318-11 in STAAD.Pro can consider sway using the moment magnification procedure. The second order effects are approximated by magnified moments for slender columns (as determined by clause 10.10.1) in sway and non-sway frames. The moment magnification procedure described in clause 10.10.6 of the code is used for nonsway frame columns and the procedure in clause 10.10.7 is used for sway frame columns.

The parameters `BDY`, `BDZ`, `SKY`, `SKZ`, `SLY`, `SLZ`, `SQY`, `SQZ`, `SWY`, and `TRN` apply to these calculations.

Note: You must set the `MMAG` parameter to 0 in order to consider sidesway for slender columns. Otherwise, the `MMAG` value is used directly.

D1.F.6 Slab Design

Slab design is performed only for the moments MX and MY at the center of an element. Design will not be performed for SX, SY, SXY, SQX, SQY, or MXY. Also, design is not performed at any other point on the surface of the element.

Note: Element design is only supported for ACI 318-08 and earlier editions of the code.

A typical example of element design output is shown below. The reinforcement required to resist Mx moment is denoted as longitudinal reinforcement and the reinforcement required to resist My moment is denoted as transverse reinforcement (D1.F.2 Section Types for Concrete Design (on page 1199)). The parameters FYMAIN, FC, and CLEAR listed in D1.F.3 Design Parameters (on page 1201) are relevant to slab design. Other parameters mentioned in Table 3.1 are not applicable to slab design. Please note that the default value of clear cover - parameters CLT and CLB - for plate elements is 0.75 inches, as shown in D1.F.3 Design Parameters (on page 1201).

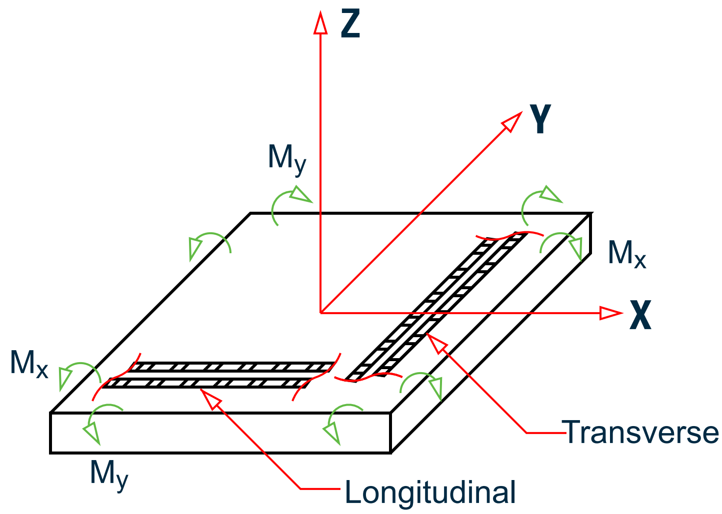

Figure 154: Sign convention of loaded plate element

Element design for flexure is done using the same rules that are used for beam design. A unit width (1 meter) is assumed as the width of the beam. This suits plate elements as MX and MY are in units of moment per unit width. Reinforcement is reported in units of mm^2 per unit width. Longitudinal direction corresponds to the direction of reinforcement for MX, transverse corresponds to that for MY. Longitudinal reinforcement is the outer layer of reinforcement and transverse is the inner layer.

Elements are *not* designed for shear forces or axial stress.

Example Element Design Output

D1.F.7 Scope of ACI 318 Code Implemented

The following describes the code clauses from ACI 318-14 implemented for beams and columns.

Note: Plate elements and deep beams cannot be designed per ACI 318-14. Use an older edition of the ACI code to design these elements if needed.

Materials

- Beams

  19.2.2
  19.2.3.1
  19.2.4.2
- Columns

  19.2.2
  19.2.4.2

Minimum Reinforcement

- Beams

  9.6.1.1
  9.6.1.2
  9.6.1.3

9.7.2.1
9.7.6.4.2
9.7.6.4.3

- Columns

  10.6.1
  10.7.2.1
  10.7.3.1
  10.7.6.1
  10.7.6.2
  25.2.3

Clauses 9.7.6.4.2 and 9.7.6.4.3 are not included in the standard design criteria of the minimum reinforcement since the design of these criteria should consider the rebar including the bar detailing and thus they should be applied in a second design after performing the strength design and the bar detailing.

Clause 9.6.1.3 is also not included in the standard criteria since the reduction of the minimum reinforcement is optional.

Service

- Beams

  9.7.2.2
  9.7.2.3

Strength

- Beams

  9.5
  9.5.1
  9.5.2
  9.5.3
  9.5.4
  9.6.3.1
  9.6.3.3
  9.6.4.2
  9.7.5.2
  9.7.6.2.2
  9.7.6.3.1
  9.7.6.3.3
  9.7.3.3
  9.6.4.3
  20.2.2.4a
  20.2.2.1
  20.2.2.2
  21.2.1
  22.2.2.2
  22.5.5

22.2.2.3
22.7.4
22.5.1.2
22.7.6.1
22.7.7.1

- Columns

  10.5
  10.5.1
  10.5.2
  10.5.3
  10.6.2
  10.7.6.5.2
  20.2.2.4a
  20.2.2.1
  20.2.2.2
  22.5
  22.2.2.2
  22.5.5
  22.2.2.3
  22.7.4
  22.5.1.2
  22.7.6.1

Ductility

- Beams

  9.3.3.1

Development Length

- Beams

  25.4.1.4
  25.4.2
  25.4.3
- Columns

  25.4.1.4
  25.4.2
  25.4.3

Span Detailing

- Beams

  9.7.3.3
  9.7.3.8

9.7.7

D1.G. American Codes - Timber Design per AITC Code

D1.G.1 Design Operations

STAAD.Pro supports timber design per two versions of the AITC code: 1985 and 1994. The implementation of both the codes is explained below.

To access the 1994 edition, specify the commands:

```
CODE AITC
```

or

```
CODE AITC 1994
```

To access the 1984 edition, specify the commands:

```
CODE AITC 1984
```

or

```
CODE TIMBER
```

D1.G.1.1 1994 AITC Code Implementation

The salient aspects of design in accordance with the 4th edition (1994) of the *Timber Construction Manual* published by the American Institute of Timber Construction are:

1. Design can be performed for two types of timber sections: dimensional timber sections (i.e., sawn lumber) and glulaminated sections.
2. The program includes a database of dimensional timber sections with this code.

Implementation of Dimensional Lumber Properties

The database of sawn lumber sections, listed in Table 8.1 of the 1994 AITC Manual, is implemented in the program. Some of the key aspects of this implementation are:

In the property tables in the AITC manual, one will find that, for any particular species of timber, the Modulus of Elasticity (E) and allowable stresses may vary with the cross-section size. For example, a 2x4 Douglas Fir-Larch, Select Structural member has an E of 1900 ksi and an allowable bending stress, F_b, of 1450 psi. A 5x5 Douglas Fir-Larch, Select Structural, Beam or Stringer member has an E of 1600 ksi and an allowable bending stress, F_b, of 1600 psi. And a 5x5 Douglas Fir-Larch, Select Structural, Post or Timbers member has an E of 1600 ksi and an allowable bending stress, F_b, of 1750 psi.

So, in the STAAD timber database for sawn lumber, for each species and grade of timber, the section size, or properties are associated with the Modulus of Elasticity and allowable stresses for the cross-section. When a section is assigned, its E and allowable stresses are automatically fetched along with its properties. The material properties of Southern Pine members were taken from Table 8.4 of the 1994 AITC manual. For all other species with section sizes 2”-4” wide, the material properties have been taken from Table 8.3. For all non-Southern Pine species with section sizes greater than 5”x5”, the material properties are obtained from Table 8.6 of the 1994 AITC Manual.

Please note that not all section sizes listed in Table 8.1 are available in every species. Some sizes are not produced for particular species. For example, the Aspen species only produces sizes from 2”-4” wide. It does not produce sizes 5”x5” and larger. This can be observed by comparing Table 8.3, where Aspen is listed as an available species, to Table 8.6, where Aspen is not listed as an available species. Also note that although 1” wide members are listed in Table 8.1, there are no values available in the species properties tables; Table 8.4, Table 8.5, and Table 8.6. AITC does not allow for the structural design of these small members.

D1.G.1.2 1985 AITC Code Implementation

STAAD's Timber design module per the 1985 AITC code (*Timber Construction Manual*, 3rd. Edition, 1985) allows design of Glulam timber sections. It also conforms to the National Design Specification for Wood Construction and Supplement (NDS) and building codes like Uniform Building Code (UBC), Basic/National Building Code and Standard Building Code. Some of the main features of the program are:

1. This feature is for Glulam Timber only (design of dimensional lumber are available for 1994 AITC only).
2. Code check and design of members as per TCM - AITC.
3. Design values for Structural Glued Laminated Timber tables are in-built into the program. The program accepts Table no., Combination and Species specifications as inputs (e.g., 1:16F-V3-SP/SP) and reads design values from in-built tables.
4. Incorporates all the following Allowable stress modifiers:

   i. Duration of Load Factor
   ii. Size Factor
   iii. Form Factor
   iv. Lateral stability of Beams and Columns
   v. Moisture Content Factor
   vi. Temperature and Curvature factors.

   The allowable stresses for bending, tension, compression, shear and Moduli of elasticities are modified accordingly.
5. Determines slenderness for beams and columns (Short, intermediate and long) and checks for min. eccentricity, lateral stability, buckling, bending and compression, bending and tension and horizontal shear against both axes.
6. The output results show sections provided or chosen, actual and allowable stresses, governing condition and ratios of interaction formulae and the relevant AITC clause nos. etc for each individual member.

D1.G.2 Allowable Stress per AITC Code

Explanation of terms and symbols used in this section

Table 93: Timber design nomenclature

Symbols	Description
f_a	Actual compression or tension stress (in PSI). For tension, the axial load is divided by net sectional area (i.e, NSF x X-area).
FA	Allowable design value for compression or tension (in PSI) modified with applicable modifiers or calculated based on slenderness in case of compression.

Symbols	Description
f_{bz} f_{by}	Actual bending stresses about local Z and Y axis (in PSI).
FBZ FBY	Allowable design values for bending stresses about local Z and Y axis (in PSI) modified by the applicable modifiers.
JZ JY	Modifier for P-DELTA effect about the Z and Y axis respectively as explained in formula 5-18 of TCM.
f_{vz} f_{vy}	Actual horizontal shear stresses.
FVZ FVY	Allowable horizontal shear stresses.
VZ VY	Shear in local Z and local Y direction.
ZD YD	Depth of section in local Z and Y axis.
EZ EY	Minimum eccentricity along Z and Y axis.
CFZ CFY	Values of the size factors in the z-axis and y-axis, respectively.
CLZ CLY	Represent the factors of lateral stability for beams about the z-axis and y-axis, respectively.
RATIO	Permissible ratio of stresses. The default value is 1.0.

D1.G.2.1 Combined Bending and Axial Tension

The following interaction formulae are checked :

$$f_a/FA + f_{bz}/(FBZ \times CFZ) + f_{by}/(FBY \times CFY) \leq$$

Lateral stability check with Net compressive stress:

$$f_a/FA + f_{bz}/(FBZ \times CLZ) + f_{by}/(FBY \times CLY) \leq$$

D1.G.2.2 Combined Bending and Axial Compression

$$f_a/FA + f_{bz}/(FBZ\text{-}JZ \times f_a) + f_{by}/(FBY\text{-}JY \times f_a) \leq$$

Applicability of the size factor:

a. When CF < 1.00,

if fa > FBZ x (1-CFZ), FBZ is not modified with CFZ. if fa > FBY x (1-CFY), FBY is not modified with CFY.

if fa < FBZ x (1-CFZ) FBZ is taken as FBZ x CFZ + fa but shall not exceed FBZ x CLZ

if fa < FBY x (1-CFY) FBY is taken as FBY x CFY + fa but shall not exceed FBY x CLY

b. When CF ≥ 1.00, the effect of CF and CL are cumulative FBZ is taken as FBZ x CFZ x CLZ FBY is taken as FBY x CFY x CLY

D1.G.2.3 Minimum Eccentricity

The program checks against min. eccentricity in following cases:

a. The member is a FRAME member and not a truss member and under compression.
b. The value of actual axial compressive stress does not exceed 30% of the allowable compressive stress.
c. The actual moments about both axes are less than moments that would be caused due to min. eccentricity. In this approach, the moment due to min. eccentricity is taken as the compressive load times an eccentricity of 1 in. or 0.1 x depth whichever is larger.

In case of min. eccentricity,

$$f_{bz} = f_a \times (6+1.5 \times JZ)/(EZ/ZD)$$

$$f_{by} = f_a \times (6+1.5 \times JY)/ (EY/YD)$$

the following conditions are checked :

$$f_a/FA + f_{bz}/(FBZ\text{-}JZ \times f_a) \leq$$

$$f_a/FA + f_{by}/(FBY\text{-}JY \times f_a) \leq$$

D1.G.2.4 Shear Stresses

Horizontal stresses are calculated and checked against allowable values:

$$f_{vz} = 3 \times VY /(2 \times Area \times NSF) \leq FVZ$$

$$f_{vy} = 3 \times VZ /(2 \times Area \times NSF) \leq FVY$$

D1.G.3 Input Specification

A typical set of input commands for STAAD.Pro timber design per AITC 1984 is listed below:

```
UNIT KIP INCH
PARAMETER
CODE TIMBER
GLULAM  1:16F-V3-DF/DF MEMB 1 TO 14
GLULAM  1:24F-V5-SP/SP MEMB 15 TO 31
```

```
GLULAM  20F-V1-DF/WW MEMB 32 TO 41
LAMIN  1.375 LY 168.0 MEMB 5 9 15 TO 31
LZ  176.0 MEMB 1 TO 4 6 7 8 10 TO 14
LUZ 322.6 ALL
LUY 322.6 ALL
WET  1.0 ALL
CDT  1.33
NSF  0.85
BEAM  1.0 ALL
CHECK  CODE 1 TO 14
SELECT  MEMB 15 TO 31
```

D1.G.3.1 Explanation of Input Commands and Parameters

Specify `PARAMETER` and then `CODE TIMBER` to start `TIMBER DESIGN` before specifying the input parameters. The user must provide the timber grade (`GLULAM GRADE`) for each member he intends to design. The parameters can be specified for all or specified list of members. If a parameter is not specified, the default value is assigned to it. See following `INPUT PARAMETERS LIST TABLE` for description and default values of the parameters.

D1.G.3.2 Glulam Grade and Allowable Stresses from Table

The allowable stresses for `GLULAM` members are read in from Table-1 and Table-2 of AITC for design values for Structural Glued Laminated Timber. The structural members are to be specified in the following manner:

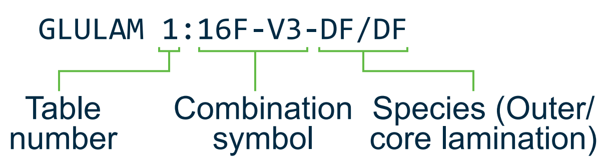

Figure 155: AITC Table-1 glulam members

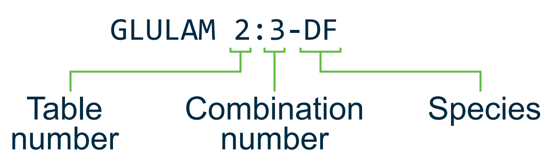

Figure 156: AITC Table-2 glulam members

For TABLE-2 members, the applicable stress values are selected based on the depth and the number of laminations.

Note: The lamination thickness (in inches) can be specified. Typical values are 1 3/8 inches or 1 1/2 inches. If not specified, a default value of 1 1/2 inches assumed by the program.

- *TR.52.1 Timber Design Parameter Specifications* (on page 2683)

D1.G.4 Naming Conventions for Sections

The following conventions are used to describe timber sections in STAAD.Pro

D1.G.4.1 Dimensional Lumber sections

As can be seen from Tables 8.3 through 8.6 of the AITC 1994 manual, one or more of the following attributes have to be considered while choosing a section :

- Species
- Commercial Grade
- Size classification
- Nominal size of the section
- Grading rules agency

STAAD.Pro uses a naming convention that incorporates all of the above. Shown below is the name of a section that has characteristics as shown. It may be found on page 8-637 of the AITC 1994 manual.

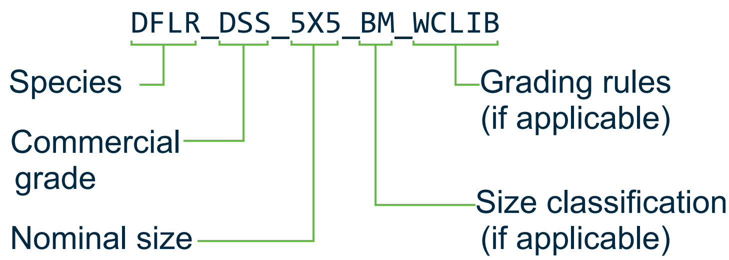

Figure 157: Timber naming conventions

Species: Douglas Fir Larch
Commercial Grade: Dense Select Structural
Size Classification: Beams
Nominal size: 5"x 5"
Grading Rules Agency: WCLIB

D1.G.4.2 Implementation of Glulam Properties

For glulam sections, each glulam designation has an associated value of modulus of elasticity and a set of allowable stresses. However, these values are not dependent on the size of the cross section. For example, a 3-1/8"x 6" 24F-V8 DF/DF beam and a 6-3/4" x 30" 24F-V8 DF/DF beam both have an E of 1,600 ksi and an allowable bending stress in the tension zone, F_{bx}, of 2,400 psi.

Therefore, in STAAD.Pro’s glulam database, the section sizes are not linked to the glulam type. Users may specify any cross-section size they choose and pick the desired glulam type. The Modulus of Elasticity and allowable stresses associated with that glulam are assigned to the member. The material properties for the glulam database are taken from Table 1 of AITC 117-93 – *Design Standard Specifications for Structural Glued Laminated Timber of Softwood Species*. This publication has been reproduced in the AITC 1994 manual starting from page 8-843.

Example for Dimensional Timber

```
UNIT FEET KIP
DEFINE MATERIAL START
ISOTROPIC DFLN_SS_4X4
```

```
E 273600
POISSON 0.15
DENSITY 0.025
ALPHA 5.5e-006
END DEFINE MATERIAL
MEMBER PROPERTY AITC
3 4 7 8 TABLE ST DFLN_SS_4X4
CONSTANTS
MATERIAL DFLN_SS_4X4 MEMB 3 4 7 8
```

D1.G.4.3 Glulam Sections

The STAAD.Pro name for glulam sections incorporates

- Combination Symbol
- Species-Outer Laminations/Core Laminations

Shown here is a typical section listed in page 8-854 of the AITC manual.

```
GLT-24F-V11_DF/DFS
```

Implementation of Material Constants

As explained in the previous paragraphs, for sawn lumber as well as glulam sections, E is built into the database and gets automatically assigned to the member along with the section dimensions. Density, Poisson's ratio and Alpha (coefficient of thermal expansion) have to be assigned separately. If they are not assigned, the analysis engine will use default values for those.

Example for Glulam Timber

```
UNIT FEET KIP
DEFINE MATERIAL START
ISOTROPIC GLT-24F-V8_WET_DF/DF
E 191923
POISSON 0.15
DENSITY 0.025
ALPHA 5.5e-006
END DEFINE MATERIAL
MEMBER PROPERTY AITC
8 PRIS YD 1.5 ZD 0.427083
CONSTANTS
MATERIAL GLT-24F-V8_WET_DF/DF MEMB 8
```

D1.G.5 Design Parameters

The timber design parameters for the AITC codes.

D1.G.5.1 AITC 1994 Parameters

Table 94: AITC 1994 Timber Design Properties

Parameter Name		Default Value	Description
STAAD	AITC 1994 Code		
CB	C_b	1.0	Bearing Area Factor, Table 4.13
CFB	C_F	1.0	Size Factor for Allowable Bending Stress, see Table 8.3, 8.4, 8.5, 8.6, 8.7
CFC	C_F	1.0	Size Factor for Allowable Compression Parallel to Grain, see Table 8.3, 8.4, 8.5, 8.6, 8.7
CFT	C_F	1.0	Size Factor for Allowable Tension Parallel to Grain, see Table 8.3, 8.4, 8.5, 8.6, 8.7
CFU	C_{fu}	1.0	Flat Use Factor, see Table 4.9
CSS	C_H	1.0	Shear Stress Factor, Section 4.5.14
CMB	C_M	1.0	Wet service Factor for Allowable Bending Stress, see Table 4.8
CMC	C_M	1.0	Wet service Factor for Allowable Compression Parallel to Grain, see Table 4.8
CME	C_M	1.0	Wet service Factor for Modulus of Elasticity, see Table 4.8
CMP	C_M	1.0	Wet service Factor for Allowable Compression Perpendicular to Grain, see Table 4.8

Parameter Name		Default Value	Description
STAAD	**AITC 1994 Code**		
CMT	C_M	1.0	Wet service Factor for Allowable Tension Parallel to Grain, see Table 4.8
CMV	C_M	1.0	Wet service Factor for Allowable Shear Stress Parallel to Grain, see Table 4.8
CR	C_r	1.0	Repetitive Member Factor, see Section 4.5.10
CSF	C_F	1.0	Form Factor, see Section 4.5.12
CTM	C_t	1.0	Temperature Factor, see Table 4.11
CTT	C_T	1.0	Buckling Stiffness Factor, see Section 4.5.15
KB	K_b	1.0	Buckling Length Coefficient to calculate Effective Length
KBD	K_{bd}	1.0	Buckling Length Coefficient for Depth to calculate Effective Length
KBE	K_{bE}	0.609	Euler Buckling Coefficient for Beams, see Section 5.4.11
KCE	K_{cE}	1.0	Euler Buckling Coefficient for Columns, see Section 5.8.2
KEY	K_{ey}	1.0	Buckling Length Coefficient in Y Direction
KEZ	K_{ez}	1.0	Buckling Length Coefficient in Z Direction
KL	K_l	1.0	Load Condition Coefficient, Table 4.10

Parameter Name		Default Value	Description
STAAD	AITC 1994 Code		
LZ	LZ	Member Length	Effective shear length in the z direction for Column Stability Check, Le=Ke*L
LY	LY	Member Length	Effective shear length in the y direction for Column Stability Check, Le=Ke*L
LUZ	LUZ	Member Length	Member length in the z direction for Beam Stability Check, Lu=Kb*l +Kbd*d
LUY	LUY	Member Length	Member length in the y direction for Beam Stability Check, Lu=Kb*l +Kbd*d
CDT	CDT	1.0	Load Duration Factor
CCR	CCR	1.0	Curvature factor (Section 4.5.11)
INDEX	INDEX	10	Exponent value in the Volume Factor Equation (Section 4.5.6)
CV	CV	1.0	Volume Factor (Section 4.5.6)
CC	CC	0.8	Variable in Column Stability Factor, Cp (Section 5.8.2, Eqn 5-14)
SRC	SRC	1.0	Slenderness ratio of Compression member
SRT	SRT	1.0	Slenderness ratio of Tension member
RATIO		1.0	Permissible ratio of actual to allowable stress

Parameter Name		Default Value	Description
STAAD	AITC 1994 Code		
BEAM		1.0	0.0 = design at start and end nodes and those locations specified by the SECTION command. 1.0 = design at 13 evenly spaced points (i.e., 1/12th points) along member length, including start and end nodes. **Note:** See D1.A.6 Design Parameters (on page 1100).

D1.G.5.2 AITC 1984 Parameters

Table 95: AITC 1985 Timber Design Parameters

Parameter Name	Default Value	Description
BEAM	1.0	0.0 = design at start and end nodes and those locations specified by the SECTION command. 1.0 = design at 13 evenly spaced points (i.e., 1/12th points) along member length, including start and end nodes. **Note:** See D1.A.6 Design Parameters (on page 1100).
CCR	1.0	Curvature factor
CDT	1.0	Duration of load factor
CSF	1.0	Form factor
CTM	1.0	Temp. factor
LAMINATION	1.50 inch	Thickness of lamination in inch (1.50 or 1.375)

Parameter Name	Default Value	Description
LUZ	1.92*L	Unsupported effective length for beam in z.
LUY	1.92*L	Unsupported effective length for beam in y.
LY	Member Length	Same as above in y-axis.
LZ	Member Length	Effective length of the column in z-axis.
NSF	1.0	Net section factor for tension members. (both shear and tension stresses are based on sectional area x nsf)
RATIO	1.0	Permissible ratio of actual to allowable stresses.
WET	0.0	0.0 - dry condition 1.0 - wet condition wet use factors are in-built

D1.G.6 Member Design Capabilities

STAAD.Pro is capable of performing member design functions for both 1984 and 1994 editions of AITC.

Tip: The User Interface can be used to easily assign design commands to members.

D1.G.6.1 Code Checking

The `CHECK CODE` command enables the user to check the adequacy of the size (`YD` X `ZD`) provided in the `MEMBER PROPERTIES` for the most critical forces and moments. The program prints whether the member has passed or failed, the critical conditions and the value of the ratio.

D1.G.6.2 Member Selection

Member selection is limited to AITC 1994.

The `SELECT MEMBER` command starts with the min. permissible depth (or min. depth provided thru `DMIN` parameter) and checks the code. If the member fails with this depth, the thickness is increased by one lamination thickness and the code requirements are checked again. The process is continued till the section passes all the code requirements. This ensures the least weight section for the member. If the depth of the section reaches max. allowable or available depth and the member still fails, you can have the following options for redesign:

a. Change the width or increase the max. allowable depth (`DMAX`)
b. Change the timber grade
c. Change the design parameters

Related Links

- *TR.52.2 Code Checking Specification* (on page 2684)

D1.G.7 Orientation of Lamination

Laminations are always assumed to lie along the local Z-plane of the member. In the `MEMBER PROPERTIES` section, YD always represents the depth of the section across the grain and ZD represents the width along the grain. This is in accordance with the sign convention conforming to `SET Y UP` (default).

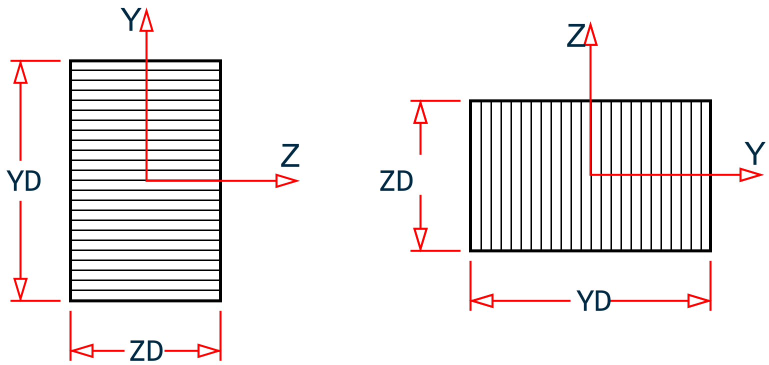

Figure 158: Orientation of lamination

D1.G.8 Tabulated Results of Member Design

For `CODE CHECKING` and/or `MEMBER SELECTION` the output results are printed as shown in the previous section. The items are explained as follows:

a. MEMBER refers to the member number for which the design is performed.

b. TABLE refers to the size of the `PRISMATIC` section (B X D or ZD X YD).

c. RESULT prints whether the member has PASSed or FAILed.

d. CRITICAL COND refers to the CLAUSE or FORMULA NO. from the TIMBER CONSTRUCTION MANUAL (3rd. Edition, AITC-1985) which governed the design. See following table:

Table 96: Critical conditions evaluated per AITC code

Critical Condition	Governing Criteria
Clause 5-19	Axial Compression and Bending with MINIMUM ECCENTRICITY.
Clause 5-18	Axial Compression and Bending
Clause 5-42	Axial Tension and Bending
Clause 5-24	Horizontal Shear
Clause 5.40	Lateral stability for net compressive stress in case of Tension and Bending.

e. RATIO prints the ratio of the actual stresses to allowable stresses for the critical condition. This ratio is usually the cumulative ratio of stresses in the interaction formula. In case of shear governing the design, it means the ratio of the actual shear stress to allowable shear stress. If this value exceeds the allowable ratio (default 1.0) the member is FAILed.

f. LOADING provides the load case number that governed.
g. FX, MY and MZ provide the design axial force, moment in local Y axes and moment in local Z axes respectively. FX value is followed by a letter C or T to denote COMPRESSION or TENSION.
h. LOCATION specifies the actual distance from the start of the member to the section where design forces govern in case BEAM command or SECTION command is specified.

OUTPUT parameters that appear within the box are explained as follows:

a. MEMB refers to the same member number for which the design is performed.
b. GLULAM GRADE refers to the grade of the timber.
c. LAM refers to lamination thickness provided in the input or assumed by the program. See INPUT PARAMETERS section.
d. LZ, LY, LUZ and LUY are the effective lengths as provided or calculated. See INPUT PARAMETERS section.
e. JZ and JY are the modifiers for the P-DELTA effect about Z-axis and Y-axis respectively. These are calculated by the program.
f. CDT, CSF, WET, CCR, CTM are the allowable stress modifiers explained in the INPUT PARAMETERS section.
g. CFZ and CFY are values of the size factors in the Z-axis and Y-axis respectively. CLZ and CLY represent the factors of lateral stability for beams about Z-axis and Y-axis respectively. These values are printed to help the user see the intermediate design values and re-check the design calculations.
h. f_a, f_{bz}, f_{by}, f_{vz} and f_{vy} are the actual axial stress, bending stresses about Z and Y axes and horizontal shear stresses about Z and Y axes respectively. If the bending moments about both axes are less then the eccentric moments based on min. eccentricity then bending stresses are calculated based on the min. eccentricity . Refer DESIGN OPERATIONS section for details.
i. FA, FBZ, FBY, FVZ, and FVY are the final allowable axial, bending (Z and Y axes) and horizontal shear (Z and Y axes) stresses. See D1.G.2 Allowable Stress per AITC Code (on page 1249) for details.

D1.H. American Codes - Aluminum Design per 1994 ADM

STAAD.Pro is capable of performing aluminum member design based on the ASD 1994 *Specifications for Aluminum Structures*, Sixth Edition (October, 1994) included in the *Aluminum Design Manual* 1994.

D1.H.1 Member Properties

In order to do this design in STAAD.Pro, the members in the structure must have their properties specified from Section VI of the above-mentioned manual. The section names are mentioned in Tables 5 through 28 of that manual. All of those tables except Table 10 (Wing Channels) and Table 20 (Bulb Angles) are available in STAAD.Pro.

Described below is the command specification for various sections:

D1.H.1.1 Standard single section

```
memb-list  TA ST section-name
```

Example

```
1 TO 5 TA ST CS12X11.8
9 TA ST I8.00X13.1
11 33 45 67 TA ST LS8.00X8.00X0.625
18 TA ST 1.50PipeX160
15 TA ST T(A-N)6.00X8.00X11.2
23 25 29 TA ST 20X12RectX.500Wall
```

D1.H.1.2 Double channel back-to-back

```
memb-list  TA BACK section-name  SPACING value
```

Example

```
3 TA BACK C(A-N)7X3.61 SPACING 1.5
5 TA BACK C15X17.33 SP 0.75
```

D1.H.1.3 Double channel front-to-front

```
memb-list  TA FRONT section-name  SPACING value
```

Example

```
2 TA FRONT CS12X10.3 SP 1.0
4 TA FR CS10X10.1 SP 0.5
```

D1.H.1.4 Double angle long leg back-to-back

```
memb-list  TA LD section-name  SPACING value
```

Example

```
14 TA LD LS4.00X3.00X0.375 SP 1.5
```

D1.H.1.5 Double angle short leg back-to-back

```
memb-list  TA SD section-name  SPACING value
```

Example

```
12 TA SD L3.5X3X0.5 SP 0.25
13 TA SD L8X6X0.75 SP 1.0
```

D1.H.2 Design Procedure

The design is done according to the rules specified in Sections 4.1, 4.2 and 4.4 on pages I-A-41 and I-A-42 of the Aluminum code. The allowable stresses for the various sections are computed according to the equations shown in Section 3.4.1 through 3.4.21 on pages I-A-27 through I-A-40. The adequacy of the member is checked by calculating the value of the left-hand side of equations 4.1.1-1, 4.1.1-2, 4.1.1-3, 4.1.2-1, 4.4-1 and 4.4-2. This left-hand side value is termed as RATIO. If the highest RATIO among these equations turns out to be less than or equal to 1.0, the member is declared as having PASSed. If it exceeds 1.0, the member has FAILed the design requirements.

Note: The check for torsion per Clause 4.3 for open sections is currently not implemented in STAAD.Pro.

D1.H.3 Design Parameters

The following are the parameters for specifying the values for variables associated with the design.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 97: Aluminum Design Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as ALUMINUM Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
ALCLAD	0	Defines if material is Alclad. 0 - Material used in the section is not an Alclad. 1 - Material used in the section is an Alclad.

Parameter Name	Default Value	Description
ALLOY	34	This variable can take on a value from 1 through 40. The default value represents the alloy 6061-T6. See Table 14A.2 below for a list of values for this parameter and the alloy they represent. Table 3.3-1 in Section I-B of the Aluminum specifications provides information on the properties of the various alloys.
BEAM	0.0	If this parameter is set to 1.0, the adequacy of the member is determined by checking a total of 13 equally spaced locations along the length of the member. If the BEAM value is 0.0, the 13 location check is not conducted, and instead, checking is done only at the locations specified by the SECTION command (See STAAD manual for details). If neither the BEAM parameter nor any SECTION command is specified, STAAD will terminate the run and ask the user to provide one of those 2 commands. This rule is not enforced for TRUSS members.
DMAX	1000 in.	Maximum depth permissible for the section during member selection. This value must be provided in the current units.
DMIN	0.0 in	Minimum depth required for the section during member selection. This value must be provided in the current units.

Parameter Name	Default Value	Description
KT	1.0	Effective length factor for torsional buckling. It is a fraction and is unit-less. Values can range from 0.01 (for a column completely prevented from torsional buckling) to any user specified large value. It is used to compute the KL/R ratio for twisting for determining the allowable stress in axial compression. See Equation 3.4.7.2-6 on page I-A-28 of the Aluminum specifications for details.
KY	1.0	Effective length factor for overall column buckling in the local Y-axis. It is a fraction and is unit-less. Values can range from 0.01 (for a column completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the allowable stress in axial compression.
KZ	1.0	Effective length factor for overall column buckling in the local Z-axis. It is a fraction and is unit-less. Values can range from 0.01 (for a column completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the allowable stress in axial compression.
LT	Member length	Unbraced length for twisting. It is input in the current units of length. Values can range from 0.01 (for a column completely prevented from torsional buckling) to any user specified large value. It is used to compute the KL/R ratio for twisting for determining the allowable stress in axial compression. See Equation 3.4.7.2-6 on page I-A-28 of the Aluminum specifications for details.

Parameter Name	Default Value	Description
LY	Member length	Effective length for overall column buckling in the local Y-axis. It is input in the current units of length. Values can range from 0.01 (for a column completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the allowable stress in axial compression.
LZ	Member length	Effective length for overall column buckling in the local Z-axis. It is input in the current units of length. Values can range from 0.01 (for a column completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the allowable stress in axial compression.
PRODUCT	1	This variable can take on a value from 1 through 4. They represent: 1 - All 2 - Extrusions 3 - Drawn Tube 4 - Pipe The default value stands for All. The PRODUCT parameter finds mention in Table 3.3-1 in Section I-B of the Aluminum specifications.

Parameter Name	Default Value	Description
SSY	0.0	Factor that indicates whether or not the structure is subjected to sidesway along the local Y axis of the member. The values are: 0 - Sidesway is present along the local Y-axis of the member 1 - There is no sidesway along the local Y-axis of the member. The sidesway condition is used to determine the value of Cm explained in Section 4.1.1, page I-A-41 of the Aluminum specifications.
SSZ	0.0	Factor that indicates whether or not the structure is subjected to sidesway along the local Z axis of the member. The values are: 0 - Sidesway is present along the local Z-axis of the member 1 - There is no sidesway along the local Z-axis of the member. The sidesway condition is used to determine the value of Cm explained in Section 4.1.1, page I-A-41 of the Aluminum specifications.
STIFF	Member length	Spacing in the longitudinal direction of shear stiffeners for stiffened flat webs. It is input in the current units of length. See section 3.4.21 on page I-A-40 of the Aluminum specifications for information regarding this parameter.

Parameter Name	Default Value	Description
STRUCTURE	1	In Table 3.4-1 in Section I-A of the Aluminum specifications, it is mentioned that the value of coefficients nu, ny and na are dependent upon whether the structure being designed is a building or a bridge. Users may convey this information to STAAD using the parameter STRUCTURE. The values that can be assigned to this parameter are: 1 - Buildings and similar type structures 2 - Bridges and similar type structures
TRACK	2	This parameter is used to control the level of detail in which the design output is reported in the output file. The allowable values are: 1 - Prints only the member number, section name, ratio, and PASS/FAIL status. 2 - Prints the design summary in addition to that printed by TRACK 1 3 - Prints the member properties and alloy properties in addition to that printed byTRACK 2. 4 - Prints the values of variables used in design in addition to that printed by TRACK 3.
UNL	Member length	Distance between points where the compression flange is braced against buckling or twisting. This value must be provided in the current units. This value is used to compute the allowable stress in bending compression.

Parameter Name	Default Value	Description
<u>WEL</u>D	0	In Table 3.4-2 in Section I-A of the Aluminum specifications, it is mentioned that the value of coefficients Kt and Kc are dependent upon whether or not, the location of the section where design is done is within 1.0 inch of a weld. The WELD parameter is used in STAAD for this purpose. The values that can be assigned to this parameter are: 0 - Region is farther than 1.0in from a weld 1 - Region is within 1.0in from a weld

D1.H.4 Code Checking

The purpose of code checking is to determine whether the initially specified member properties are adequate to carry the forces transmitted to the member due to the loads on the structure. Code checking is done at the locations specified by either the `SECTION` command or the `BEAM` parameter described above.

See T.1 – Steel Portal Frame (on page 387) for STAAD provides an example on the usage of the `CHECK CODE` command.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

D1.H.4.1 Example

Sample input data for Aluminum Design

```
PARAMETER
CODE ALUMINUM
BEAM 1 ALL
KY 1.2 MEMB 3 4
ALLOY 35 ALL
PRODUCT 2 ALL
TRACK 3 ALL
SELECT ALL
PARAMETER
CODE ALUMINUM
ALCLAD 1 ALL
STRUCT 1 ALL
CHECK CODE ALL
```

D1.H.5 Member Selection

The member selection process involves the determination of the least weight member that PASSes the code checking procedure based on the forces and moments of the most recent analysis. The section selected will be of the same type as that specified initially. For example, a member specified initially as a channel will have a channel selected for it.

See T.1 – Steel Portal Frame (on page 387) for STAAD provides an example on the usage of the `SELECT MEMBER` command.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D1.I. American Codes - Steel Design per ASCE Transmission Tower Codes

D1.I.1. American Transmission Tower Code - Steel Design per ASCE 10-97

STAAD.Pro is capable of performing steel design based on the American Transmission Tower code ASCE 10-97 *Design of Latticed Steel Transmission Structures*.

D1.I.1.1 General Comments

The ASCE 10-97 code is meant to supercede the older edition of the code, available under the name ASCE Publication 52. However, in the interests of backward compatibility, both codes are currently accessible in STAAD.Pro.

Design is available for all standard sections listed in the AISC ASD 9th edition manual, namely, Wide Flanges, S, M, HP, Tees, Channels, Single Angles, Double Angles, Tubes and Pipes. Design of HSS sections (those listed in the 3rd edition AISC LRFD manual) and Composite beams (I shapes with concrete slab on top) is not supported.

To use the ASCE 52 code, use the commands

```
PARAMETER
CODE ASCE 52
```

To use the ASCE 10-97 code, use the commands

```
PARAMETER
CODE ASCE
```

The detailing requirements, such as provisioning of stiffeners and checking the local effects like flange buckling, web crippling, etc. must be performed manually. It is assumed that you are familiar with the basic concepts of Steel Design facilities available in STAAD. Please refer to D. Steel Design (on page 969) for detailed information on this topic.

D1.I.1.2 Allowable Stresses per ASCE 10-97

Member selection and code checking operations in the STAAD implementation of ASCE 10-97 are done to resist loads at stresses approaching yielding, buckling, fracture and other limiting conditions specified in the standard. Those stresses are referred to in the standard as Design Stresses. The appropriate sections of the ASCE standard where the procedure for calculating the design stresses is explained are as follows.

D1.I.1.2.1 Design Axial Tensile Stress

Design tensile stresses are calculated on the basis of the procedure described in section 3.10. The NSF parameter (see the Parameters table shown later in this section) may be used if the section area needs to be reduced to account for bolt holes.

D1.I.1.2.2 Design Axial Compressive Stress

Design compressive stress calculation is based on the procedures of section 3.6 through 3.9. For angle members under compression, the procedures of sections 3.7 and 3.8 have been implemented. Capacity of the section is computed for column buckling and wherever applicable, torsional buckling. The user may control the effective lengths for buckling using the LT, LY, LZ and/or KT, KY, KZ parameters (see the Parameters table shown later in this section).

D1.I.1.2.3 Design Bending Compressive Stress

Calculations for design bending compressive stress about the major axis and minor axis are based on the procedures of section 3.14. Procedures outlined in sections 3.14.1 through 3.14.6 have been implemented.

D1.I.1.2.4 Design Bending Tensile Stress

Calculations for design bending tensile stress about the major and minor axis are based on the procedures of section 3.14.2.

D1.I.1.2.5 Design Shear Stress

Calculation of the design shear stress is based on the procedure outlined in section 3.15 of the ASCE 10-97. The procedure of section 3.15.2 is followed for angles and the procedure of section 3.15.1 is followed for all other sections.

D1.I.1.3 Critical Conditions used as criteria to determine Pass/Fail status

These are Clause 3.4 for slenderness limits, Clause 3.12 for Axial Compression and Bending, Clause 3.13 for Axial Tension and Bending, Clause 3.9.2 for Maximum w/t ratios and Clause 3.15 for Shear.

D1.I.1.4 Design Parameters

Design parameters are summarized in the table shown later in this section. These parameters may be used to control the design process to suit specific modeling needs. The default parameter values have been selected such that they are frequently used numbers for conventional design.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 99: Steel Design Parameters for ASCE 10-97

Parameter Name	Default Value	Description
CODE	-	Must be specified as ASCE to design per ASCE 10-97. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
BEAM	1.0	0 = Perform design at beam ends and section locations specified according to the SECTION command 1 = Perform design at the ends and eleven intermediate sections of the beam
CMY CMZ	0.85 for sidesway and calculated for no sidesway	Cm value in local y and z axes as defined in equation 3.12-1 on p.10 of ASCE 10-97.
DMAX	45.0 in.	Maximum allowable depth for member selection

Parameter Name	Default Value	Description
DBL	0.75 in.	Diameter of bolt for calculation of number of bolts required and the net section factor.
DMIN	0.0 in.	Minimum allowable depth for member selection
ELA	4	Indicates what type of end conditions are to be used from among Equations 3.7-4 thru 3.7-7 to determine the KL/R ratio. 1. EQN.3.7-4, Page 4 2. EQN.3.7-5, Page 4 3. EQN.3.7-6, Page 4 4. EQN.3.7-7, Page 5 **Note:** Value 1 is valid for leg members only.
ELB	1	Indicates what type of end conditions are to be used from among Equations. 3.7-8 thru 3.7-10 and 3.7-12 thru 3.7-14 to determine the KL/R ratio. 1. EQN.3.7-8, Page 5, EQN. 3.7-12, Page 5 2. EQN.3.7-9, Page 5, EQN. 3.7-13, Page 5 3. EQN.3.7-10, Page 5, EQN. 3.7-14,Page 5
FVB	30 KSI	Shear strength of bolt.
FYB	36 KSI	Yield strength of bolt.
FYLD	36.0 KSI	Yield Strength of steel
KT	1.0	Effective length coefficient for warping restraint (clause 3.14.4, p. 11)
KY	1.0	Effective length factor (K) for compression buckling about the Y-axis (minor axis)

Parameter Name	Default Value	Description
KZ	1.0	Effective length factor (K) for compression buckling about the Z-axis (major axis)
LEG	0.0	This parameter is meant for plain angles. 0. indicates that the angle is connected by both legs and allowable stress in axial tension is 1.0FYLD. 1. indicates that the angle is connected only by the shorter leg and allowable tensile stress is computed per clause 3.10.2 as 0.9FYLD. 2. indicates that the angle is connected by the longer leg.
LT	Member Length	Effective length for warping.
LY	Member Length	Length to calculate slenderness ratio for buckling about the Y-axis (minor axis)
LZ	Member Length	Length to calculate slenderness ratio for buckling about the Z-axis (major axis)
MAIN	2	Parameter that indicates the member type for the purpose of calculating the KL/R ratio (see clause 3.4, PAGE 3, ASCE 10-97) 1. Leg member, KL/R ≤ 150 2. Compression member, KL/R ≤ 250 3. Tension member, KL/R ≤ 500 4. Hanger member, KL/R ≤ 375 (Clause 3C.4, page 31) 5. Redundant member, KL/R ≤ 250 10. Do not perform the KL/R Check

Parameter Name	Default Value	Description
NHL	0	Number of bolt holes on the cross section that should be used to determine the net section factor for tension capacity.
NSF	1.0	Net section factor for tension members
RATIO	1.0	Permissible ratio that determines the cut off point for pass/fail status. A value below this quantity indicates PASS while a value greater than this quantity indicates FAILURE.
SSY	0.0	0.0 = Sidesway in local y-axis 1.0 = No sidesway
SSZ	0.0	Same as above except in local z-axis
TRACK	0.0	0.0 = Suppresses printing of allowable stresses 1.0 = Prints all allowable stresses
UNB	Member Length	Unsupported length of the bottom flange for calculating flexural strength. Will be used only if flexural compression is on the bottom flange.
UNF	1.0	Same as UNL, but provided as a fraction of the member length
UNL	Member Length	Unsupported length of member for calculation of allowable bending stress
UNT	Member Length	Unsupported length of the top flange for calculating flexural strength. Will be used only if flexural compression is on the top flange.

Notes:

- All values must be provided in the current unit system.

- If ELA and ELB are both defined for a member, only one of them will be used for the slenderness calculation depending on the member type (as defined by the MAIN parameter) for that member.

D1.I.1.5 Code Checking and Member Selection

Both code checking and member selection options are available in the ASCE 10-97 implementation. In general, it may be noted that the concepts followed in MEMBER SELECTION and CODE CHECKING procedures are similar to that of the AISC based design.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D1.I.2. American Transmission Tower Code - Steel Design per ASCE Manuals and Reports

STAAD.Pro is capable of performing steel design based on the ASCE Manuals and Reports on Engineering Practice No. 52 – *Guide for Design of Steel Transmission Towers*, Second Edition

D1.I.2.1 General Comments

The design philosophy and procedural logistics for member selection and code checking is based upon the principles of allowable stress design. Two major failure modes are recognized: failure by overstressing and failure by stability considerations.

The following sections describe the salient features regarding the process of calculation of the relevant allowable stresses and the stability criteria being used. Members are proportioned to resist the design loads without exceeding the allowable stresses and the most economical section is selected based on the least weight criteria. The code checking part of the program also checks the slenderness requirements, the minimum metal thickness requirements, and the width-thickness requirements.

The detailing requirements, such as provisioning of stiffeners and checking the local effects like flange buckling, web crippling, etc. must be performed manually. It is assumed that you are familiar with the basic concepts of Steel Design facilities available in STAAD. Please refer to D. Steel Design (on page 969) for detailed information on this topic.

D1.I.2.2 Allowable Stresses per ASCE (Pub. 52)

The member design and code checking in the STAAD implementation of ASCE (Pub. 52) is based upon the allowable stress design method. Appropriate sections of this publication are referenced below.

D1.I.2.2.1 Allowable Axial Tensile Stress

Allowable tensile stresses are calculated on the basis of the procedure described in section 4.10. The NSF parameter (Refer to D1.I.2.3 Design Parameters (on page 1280)) may be used if the net section area needs to be used.

D1.I.2.2.2 Allowable Axial Compressive Stress

Allowable compressive stress calculation is based on the procedures of section 4.6 through 4.9. For angle members under compression, the procedures of sections 4.7 and 4.8 have been implemented. Capacity of the section is computed for column buckling and wherever applicable, torsional buckling. The user may control the effective lengths for buckling using the LX, LY, LZ and/or KX, KY, KZ parameters (Refer to D1.I.2.3 Design Parameters (on page 1280)).

D1.I.2.2.3 Allowable Bending Compressive Stress

Calculations for allowable bending compressive stress about the major axis and minor axis are based on the procedures of section 4.14. Procedures outlined in sections 4.14.1 through 4.14.6 have been implemented.

D1.I.2.2.4 Allowable Bending Tensile Stress

Calculations for allowable bending tensile stress about the major and minor axis are based on the procedures of Section 4.14.2.

D1.I.2.2.5 Allowable Shear Stress

Calculation of the allowable shear stress is based on the procedure outlined in section 4.15 of the ASCE Pub. 52. The procedure of section 4.15.2 is followed for angles and the procedure of section 4.15.1 is followed for all other sections.

D1.I.2.2.6 Critical Conditions used as criteria to determine Pass/Fail status

These are Clause 4.4 for slenderness limits, Equation 4.12-1 for Axial Compression and Bending, Equation 4.13-1 for Axial Tension and Bending, Clause 4.9.2 for Maximum w/t ratios and Clause 4.15 for Shear.

D1.I.2.3 Design Parameters

These parameters may be used to control the design process to suit specific modeling needs. The default parameter values have been selected such that they are frequently used numbers for conventional design.

Table 100: Steel Design Parameters for ASCE (Pub. 52) Based Design

Parameter Name	Default Value	Description
CODE	-	Must be specified as ASCE 52. Design code to follow. See TR.53.2 Concrete Design-Parameter Specification (on page 2685).
BEAM	0.0	Specifies locations along member length at which member design is designed. 2.0 = use the section locations specified according to the SECTION command 3.0 = at the ends and eleven intermediate sections of the beam
DBL	0.75 in.	Diameter of bolt for calculation of number of bolts required and the net section factor.

Parameter Name	Default Value	Description
DMAX	45.0 in.	Maximum allowable depth for member selection
DMIN	0.0 in.	Minimum allowable depth for member selection
ELA	4	Indicates what type of end conditions are to be used from among Equations 4.7-4 thru 4.7-7 to determine the KL/R ratio. 1 = EQN.4.7-4, Page 26 (Valid for leg members only) 2 = EQN.4.7-5, Page 27 3 = EQN.4.7-6, Page 27 4 = EQN.4.7-7, Page 27
ELB	1	Indicates what type of end conditions are to be used from among Equations. 4.7-8 thru 4.7-10 to determine the KL/R ratio. 1 = EQN.4.7-8, Page 27, EQN. 4.7-12, Page 28 2 = EQN.4.7-9, Page 27, EQN. 4.7-13, Page 28 3 = EQN.4.7-10, Page 27, EQN. 4.7-14,Page28
FVB	30 KSI	Shear strength of bolt.
FYB	36 KSI	Yield strength of bolt.
FYLD	36.0 KSI	Yield Strength of steel
KT	1.0	Effective length coefficient for warping restraint (clause 4.14.4, pg 36)
KY	1.0	Effective length factor (K) for compression buckling about the Y-axis (minor axis)
KZ	1.0	Effective length factor (K) for compression buckling about the Z-axis (major axis)

Parameter Name	Default Value	Description
LEG	0.0	This parameter is meant for plain angles. 3.0 = the angle is connected by both legs and allowable stress in axial tension is 1.0Â·FYLD 4.0 = the angle is connected only by the shorter leg and allowable tensile stress is computed per Cl. 4.10.2 as 0.9Â·FYLD 5.0 = the angle is connected by the longer leg
LT	Member Length	Effective length for warping.
LY	Member Length	Length to calculate slenderness ratio for buckling about the Y-axis (minor axis)
LZ	Member Length	Length to calculate slenderness ratio for buckling about the Z-axis (major axis)
MAIN	2	Parameter that indicates the member type for the purpose of calculating the KL/R ratio (See Cl. 4.4, p. 25) 1 = Leg member (KL/r ≤ 150) 2 = Compression member (KL/r ≤ 200) 3 = Tension member (KL/r ≤ 500) 4 = Hanger member per Cl. 4C.4, p. 43 (KL/r ≤ 375) 5 = Redundant member (KL/r ≤ 250) 10 = Do *not* perform the slenderness (KL/r) check
NHL	0	Number of bolt holes on the cross section that should be used to determine the net section factor for tension capacity.
NSF	1.0	Net section factor for tension members

Parameter Name	Default Value	Description
RATIO	1.0	Permissible ratio that determines the cut off point for pass/fail status. A value below this quantity indicates PASS while a value greater than this quantity indicates FAILURE.
TRACK	0.0	Level of detail in output 0.0 = Suppresses printing of allowable stresses 1.0 = Prints all allowable stresses
UNF	1.0	Same as `UNL`, but provided as a fraction of the member length
UNL	Member Length	Unsupported length of member for calculation of allowable bending stress

D1.I.2.4 Code Checking and Member Selection

Both code checking and member selection options are available in the ASCE Pub. 52 implementation. In general, it may be noted that the concepts followed in `MEMBER SELECTION` and `CODE CHECKING` procedures are similar to that of the AISC based design.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D1.J. American Codes - Steel Design per API 2A-WSD 2000

The API Steel Design facility in STAAD.Pro is based on the API 2A-WSD standard, titled *Recommended Practice for Planning, Design and Constructing Fixed Offshore Platforms-Working Stress Design*, 21st Edition (December 2000). Joint checks includes “Errata and Supplements” 1, 2 & 3 of the code.

D1.J.1 Design Operations

STAAD.Pro contains a broad set of facilities for the design of structural members as individual components of an analyzed structure. The member design facilities provide the user with the ability to carry out a number of different design operations. These facilities may be used selectively in accordance with the requirements of the design problem. The operations to perform a design are:

- Specify the members and the load cases to be considered in the design;
- Specify whether to perform code checking or member selection;

- Specify design parameter values, if different from the default values; and
- Specify design parameters to carry out joint checks.

These operations may be repeated any number of times depending upon the design requirements.

The basic process is as follows:

1. Define the STAAD model geometry, loading, and analysis.
2. Run the analysis and API design which creates the Geometry file (file extension `.PUN`) and give preliminary design results.
3. Check and modify the Geometry file as necessary.
4. Re-run the analysis to read the modified Geometry file for the final design results.

D1.J.1.1 Limitations

The parameter `SELECT 1.0` should not be used while carrying out punching shear checks. It can be used in initial runs for member selection.

No classification of the joint is performed using the loading. For the initial run of an API code check, all joints will be assumed to be a T/Y joint. Refer to D1.J.8 Joint Design (on page 1293) for details.

No hydrostatic checks are performed.

D1.J.1.2 Truss Members

A truss member is capable of carrying only axial force. So in design, no time is wasted calculating the allowable bending or shear stresses, thus reducing design time considerably. Therefore, if there is any truss member in an analysis (like bracing or strut, etc.), it is wise to declare it as a truss member rather than as a regular frame member with both ends pinned.

D1.J.2 Allowables per API Code

For steel design, STAAD.Pro compares the actual stresses with the allowable stresses as defined by the American Petroleum Institute (API-RP2A) Code. The 21st edition of API Code, as published in 2007, is used as the basis of this design (except for tension stress).

Note: Open sections are not applicable to API code. Therefore, any open sections added to API Code design block will be designed per the D1.B. American Codes - Steel Design per AISC 9th Edition (on page 1130).

D1.J.2.1 Tension Stress

Allowable tension stresses, as calculated in STAAD, are based on the API Code, clause (3.2.1-1).

Allowable tension stress on the net section

$$F_t = 0.60 \cdot F_y$$

D1.J.2.2 Shear Stress

Beam Shear Stress

Allowable beam shear stress on the gross section must conform to Clause 3.2.4-2 of the API code:

$$F_v = 0.4 \cdot F_y$$

The maximum applied beam shear stress is per Eqn 3.2.4-1:

$f_v = V / 0.5\ A$

Torsional Shear Stress

Allowable torsional shear stress per Eqn. 3.2.4-4:

$F_{vt} = 0.4 \cdot F_y$

F_{vt} is the maximum torsional shear stress per Clause 3.2.4-3 of the API code.

D1.J.2.3 Stress Due to Compression

The allowable compressive stress on the gross section of axially loaded compression members is calculated based on the formula 3.2.2-1 in the API Code when the largest effective slenderness ratio, Kl/r is less than or equal to C_c. If Kl/r exceeds C_c, then the allowable compressive stress is increased as per formula (3.2.2-2) of the Code.

Where:

$$C_c = \sqrt{2\pi^2 \frac{E}{F_y}}$$

For $D/t > 60$, the lesser of F_{xe} or F_{xc} is substituted for F_{xy}.

Where:

F_{xe} = the elastic local buckling stress calculated with C, the critical elastic buckling coefficient = 0.3 (3.2.2-3)
F_{xc} = the inelastic local buckling stress. (3.2.2-4)

D1.J.2.4 Combined Compression and Bending

Members subjected to both axial compression and bending stresses are proportioned to satisfy API formula 3.3.1-1 and 3.3.1-2 when $f_a/F_a > 0.15$, otherwise formula 3.3.1-3 applies. It should be noted that during code checking or member selection, if $f_a/F_a > 1.0$, the program does not compute the second 3.3.1-1/2.

D1.J.2.5 Bending Stress

The allowable bending stress for tension and compression for a symmetrical member loaded in the plane of its minor axis, as given in Clause 3.2.3 of the API code, is:

a. When $D/t \le 1{,}500/F_y$ (Imperial Units),

$F_b = 0.75F_y$

b. When $1{,}500/F_y < D/t \le 3{,}000/F_y$ (Imperial Units),

$F_b = [0.84 - 1.74\ F_y D/(Et)]F_y$

c. When $3{,}000/F_y < D/t \le 300$ (Imperial Units),

$F_b = [0.72 - 0.58\ F_y D/(Et)]F_y$

D1.J.2.6 Simple Joints: Capacity Checks

A typical joint and the terms involved with the joint checks are given below:

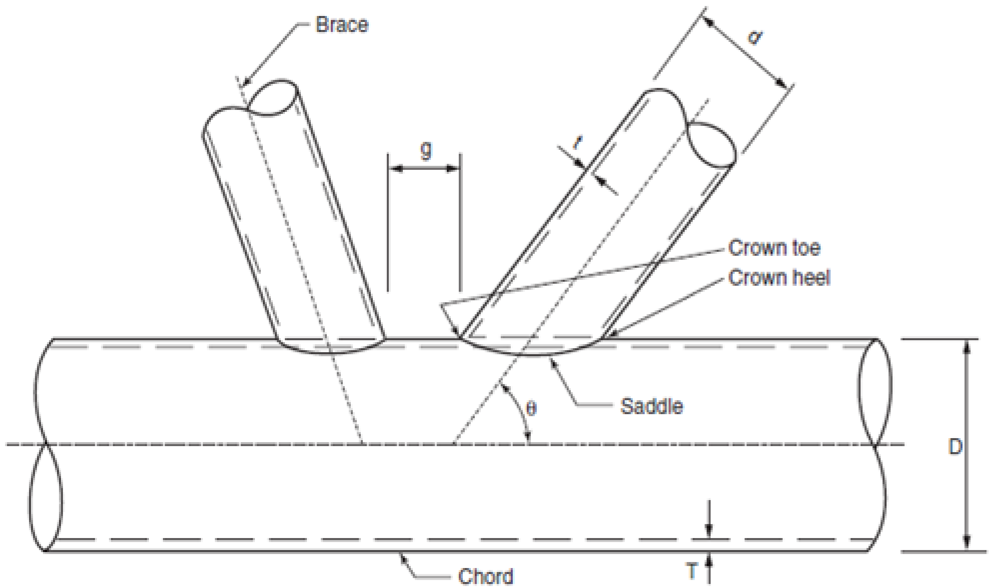

Figure 159: Simple joint diagram

Definitions

θ = Brace included rage
g = Gap between braces
t = Brace wall thickness at intersection
T = Chord wall thickness at intersection
d = Brace outside diameter
D = Chord outside diameter

$$\beta = d/D$$

$$\gamma = D/(2T)$$

$$\tau = t/T$$

Joint Validity

The validity range of the joints that are identified will be checked as per Cl. 4.3.1 of the code. The conditions to be checked for each joint are as given below:

$$0.2 \leq \beta \leq 1.0$$

$$10 \leq \gamma \leq 50$$

$$30° \leq \theta \leq 90°$$

F_y = 90 ksi (500 MPa)
g/D > -0.6 (for K joints)

If any of these conditions are not satisfied for the joint under consideration, the programissues a warning message corresponding to the invalid parameter(s). The program will, however, perform the joint checks as the code allows for the design of such joints with modified values of yield strength. You can use the FYLD parameter to reset the yield strength.

Joint Capacity

The capacity of the joint, both the axial capacity and the moment capacity is

The allowable capacity for brace axial load, P_a, is evaluated as:

$$P_a = Q_u Q_f \frac{F_{yc} T^2}{\mathrm{FSJ} \sin\theta}$$

The allowable capacity for brace bending moment, M_a, is evaluated as:

$$M_a = Q_u Q_f \frac{F_{yc} T^2 d}{\mathrm{FSJ} \sin\theta}$$

Where:

F_y = the yield stress of the chord member at the joint (or 0.8 of the tensile stress, if less)
FSJ = the factor of safety parameter (1.6 by default)

Q_u and Q_f are the strength factor and the Chord factor that are to be determined based on the joint type. The strength factor, Q_u, is to be determined as given in Section 4.3.3 of the code (ref. Table. 4.3-1 of the API code).

$$Q_f = \left[1 + C_1 \left(\frac{FSJP_c}{P_y} \right) - C_2 \left(\frac{FSJM_c}{M_p} \right) - C_3 A^2 \right]$$

$$A = \sqrt{ \left(\frac{FSJP_c}{P_y} \right)^2 + \left(\frac{FSJM_c}{M_p} \right)^2 }$$

P_c = axial load

$$M_c = \sqrt{M_{ipb}^2 + M_{opb}^2}$$

C_1, C_2, and C_3 are factors determined by the following table:

Joint Type		C_1	C_2	C_3
K joints under brace axial loading		0.2	0.2	0.3
T/Y joints under brace axial loading		0.3	0	0.8
X joints under brace axial loading	β ≤ 0.9	0.2	0	0.5
	β = 1.0	-0.2	0	0.4
All joints under brace moment loading		0.2	0	0.4

Note: For values of β between 0.9 and 1.0, coefficients are linearly interpolated between listed values.

For joints that are a mixture of K, X, or Y joints, the capacity of the joint is evaluated as a weighted average of the capacities of each joint.

In case the joint is subjected to combined axial load and bending moments (in-plane and/or out-of-plane), the program performs the following interaction check as given by Cl 4.3.6 of the code:

$$\left| \frac{P}{P_a} \right| + \left(\frac{M}{M_a} \right)_{ipb}^2 + \left| \frac{M}{M_a} \right|_{opb} \le 1.0$$

D1.J.3 Design Parameters

The program contains a large number of parameter names which are required to perform design and code checks. These parameter names, with their default values, are listed in Table 22A.1. These parameters communicate design decisions from the engineer to the program.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements for an analysis, some or all of these parameter values may have to be changed to exactly model the physical structure. For example, by default the `KZ` value (k value in local z-axis) of a member is set to 1.0, wile in the real structure it may be 1.5. In that case, the `KZ` value in the program can be changed to 1.5, as shown in the input instruction (Section 5). Similarly, the `TRACK` value of a member is set to 0.0, which means no allowable stresses of the member will be printed.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 101: American (API) Steel Design Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `API` Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
BEAM	1.0	Beam parameter: 0.0 = design only for end moments or those at locations specified by the SECTION command. 1.0 = calculate moments at twelfth points along the beam, and use the maximum Mz location for design. 2.0 = Same for `BEAM 1.0`, but additional check is made at each end.
CB	1.0	Cb value as used in Section 1.5 of AISC 0.0 = Cb value to be calculated Any other value will mean the value to be used in design
CMY CMZ	0.85 for sidesway and calculated for no sidesway	Cm value in local y & z axes

Parameter Name	Default Value	Description
DMAX	100.0 in	Maximum allowable depth
DMIN	0.0	Minimum allowable depth
FSJ	1.6	Factor of safety used for joint checks.
FYLD	36 ksi	Yield strength of steel.
KY	1.0	K value in local y-axis. Typically the minor axis.
KZ	1.0	K value in local z-axis. Typically the major axis.
LY	Member Length	Length in local Y-axis to calculate slenderness ratio.
LZ	Member Length	Length in local Z-axis to calculate slenderness ratio.
MAIN	0.0	Design for slenderness. 1.0 = Main member 2.0 = Secondary member
NSF	1.0	Net section factor for tension members.
RATIO	1.0	Permissible ratio of the actual to allowable stresses
SSY	0.0	Design for sidesway. 0.0 = Sidesway in local y-axis 1.0 = No sidesway
SSZ	0.0	Design for sidesway in local z-axis
TRACK	0.0	Controls the level of detail in the output: 0.0 = Print design output at the minimum level of detail. 1.0 = Print design output at an intermediate level of detail. 2.0 = Print design output at the maximum level of detail.

Parameter Name	Default Value	Description
UNF	1.0	Unsupported length provided as a fraction of actual member length used for lateral-torsional buckling calculation. **Note:** If both UNF and UNL parameters are specified, the effective length used is UNF×UNL.
UNL	Member Length	Unsupported length for calculating allowable bending stress. Used for the lateral-torsional buckling calculation. Value should be in the current units of length.
WELD	1	Weld type, as explained in section 3.1.1 of the API code. 1.0 = Welding is one side only except for wide flange or tee sections, where the web is always assumed to be welded on both sides. 2. 0 = Welding is both sides. For closed sections like pipe or tube, the welding will be only on one side.
WMIN	1.16 in.	Minimum thickness
WSTR	0.4 X FLYD	Allowable welding stress

Note: The parameters DMAX and DMIN are only used for member selection.

D1.J.4 Code Checking

The purpose of code checking is to ascertain whether the provided section properties of the members are adequate as per API. Code checking is done using the forces and moments at specific sections of the members. If no sections are specified, the program uses the start and end forces for code checking.

When code checking is selected, the program calculates and prints whether the members have passed or failed the checks, the critical condition of API code (like any of the API specifications for compression, tension, shear, etc.), the value of the ratio of the critical condition (overstressed for value more than 1.0 or any other specified RATIO value), the governing load case, and the location (distance from the start of the number of forces in the member) where the critical condition occurs.

Code checking can be done with any type of steel section listed in D1.A.3 Member Properties (on page 1088) .

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

D1.J.5 Member Selection

The program is capable of performing design operations on specified members. Once an analysis has been performed, the program can select the most economical section, i.e., the lightest section which fulfills the code requirements for the specified member. The section selected will be of the same type section as originally designated for the member being designed. Member selection can also be constrained by the parameters `DMAX` and `DMIN` which limits the maximum and minimum depth of the members.

- Member selection can be performed with all types of hollow steel sections.
- Selection of members whose properties are originally input from a user created table will be limited to sections in the user table.
- Member selection cannot be performed on members whose section properties are input as prismatic.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D1.J.6 Chord Selection and Q_f Parameter

Q_f is a factor to account for the presence of nominal longitudinal stress in the chord. When calculating Q_f for the joints, the moments used in the chord stress calculation will be from the computer node results and not the representative moments underneath the brace. If the moment varies significantly along the chord, it is more accurate to use the actual chord moment in the middle of the brace foot print. The tests reported in Reference I[1] were performed with a constant moment along the chord. Thus for a local joint check, the local chord moment (under the brace) should be used.

STAAD calculates Q_f based on the moment at the chord member. The chord member can be selected automatically by initial screening by the program (based on geometry and independent of loading) or specified in the External file.

In the automatic selection of the chord two collinear members (5 degree tolerance) are used to identify the chord. The chord is then selected from one of the two members based on the larger diameter then thickness or then by the minimum framing angle; for T joints the first member modeled will be selected as the chord.

You should confirm that the chord either be assigned by the program or the user is representative of the local chord moment for the brace in question.

D1.J.6.1 Reference

1 Ref I: Boone, TJ. Yura, JA. and Hoadley, PW. *Ultimate Strength if Tubular Joints – Chord Stress Effects*, OTC 4828, 1984

D1.J.7 Tabulated Results of Steel Design

For code checking or member selection, the program produces the results in a tabulated fashion. The items in the output table are explained as follows:

Member	the member number for which the design is performed.
TABLE	AISC steel section name which has been checked against the steel code or has been selected.

RESULTS prints whether the member has PASSed or FAILed. If the RESULT is FAIL, there will be an asterisk (*) mark on front of the member.

CRITICAL COND the section of the AISC code which governs the design.

RATIO prints the ratio of the actual stresses to allowable stresses for the critical condition. Normally a value of 1.0 or less will mean the member has passed.

LOADING provides the load case number which governed the design.

FX, MY, and MZ provide the axial force, moment in local Y-axis, and the moment in local Z-axis respectively. Although STAAD does consider all the member forces and moments (except torsion) to perform design, only FX, MY and MZ are printed since they are the ones which are of interest, in most cases.

LOCATION specifies the actual distance from the start of the member to the section where design forces govern.

Note: If the parameter TRACK is set to 1.0, the program will block out part of the table and will print the allowable bending stressed in compression (FCY & FCZ) and tension (FTY & FTZ), allowable axial stress in compression (FA), and allowable shear stress (FV).

D1.J.7.1 Example of Member Code Check output

For `TRACK 0.0` output:

```
                         STAAD.Pro CODE CHECKING - (API )
                         ***********************

D1.J.8 Joint Design

D1.J.8.1 Joint Checking

The design of joints is based on Section 4 of the API code.

The program only checks simple joints and overlapping joints formed between circular hollow section members. Any other type of joint within the structure or joint cans will not be considered for API joint checks. Other types of joints (such as grouted joints, joints with ring stiffeners, etc.) are not considered.

Material Strength

The API code states in Cl. 4.2.1 that the value of yield stress of the chord member to be used in the calculation of the joint capacity should be limited to 0.8 times the tensile strength of the chord for materials with a yield stress less than or equal to 500 MPa.

The yield stress to be used in the joint capacity checks value is specified in the joint data file (*filename* .PUN). For every joint, the value specified in the FYLD column will be used as the yield strength to be used for the joint capacity checks. When the file is created for the first time by the program, a default value of 36 ksi is used for all joints. The value used for each joint check will also be reported in the output file.

Note: All the fields in the joint data file (`*.PUN` file) are to be in imperial units.

Minimum Joint Capacity

Clause 4.2.3 of the code specifies a minimum capacity for any joint as follows:

The connections at the ends of a member should develop the strength required by the design loads, but should not be less than 50% of the effective strength of the member. The effective strength is defined as the buckling load for a compression member or the yield load for members in tension. You, however, must ensure that this condition is satisfied even if the joint strength indicates a PASS status.

The program checks to see if the capacity of a joint as calculated by the methods in the code satisfies this requirement. If not the program issues a warning to that effect and marks the joint as FAILED. The program calculates the axial and/or bending moment capacities of the joint and reports the load/capacity ratio for each condition. The program also reports a “critical ratio” along with the condition that induces this ratio. Note that the maximum among the various individual ratios will be reported as the ‘critical ratio’. The program also reports a PASS/FAIL status for the joint.

Refer to D1.J.2.6 Simple Joints: Capacity Checks (on page 1285) for details of capacity checks performed.

Joint Classification

Clause of 4.2.4 of the API code essentially classifies a joint into one of the three basic types: K, X, and Y. Joint classification is the process whereby the axial load in a given brace is subdivided into its K, X, and Y components corresponding to the three joint types. A joint—as considered in the code—is the connection between a "chord" and a "brace" that are in the same plane. The program considers any two members to be in the same plane if they lie in planes that are within ±15 degrees of each other. The classification of a joint can also be a mixture of any of the basic types mentioned above. Once the classification of a joint has been identified, the capacity of that joint is then evaluated per Section 4.3 of the code.

The program automatically identifies the joints in a structure and identifies the chord and the brace members. The program applies the ±15° rule to determine the members in a plane and then determines the joint as being the intersection point of these members. Since a joint is between a chord and a brace member, the program considers two members at a time and then proceeds to identify the chord and the brace member at that joint. The program assumes the member with the larger diameter among the two members as the chord member and the other is considered as the brace. If both members have the same diameter, the chord is assumed to be the member with the thicker wall. If both the diameter and thickness of the members are identical, the program will assume the most horizontal member to be the chord. To be automatically considered as a chord member, the member has to be continuous across the joint. The user can always edit the joint data file (*.PUN) to add or delete new BRACE-CHORD joints.

The chord and brace member numbers (from the STAAD input file) are saved under the `CHORD` and `BRACE` columns in the *filename* .PUN file.

When the joint data file (`.PUN`) is created by the program, a default joint Class Y is assumed for the initial joint checks. This is indicated by the `K`, `X`, and `Y` column values being set to 0, 0, and 1 respectively. Since the API code allows for a mixed joint classification, you must manually vary the contribution factors for K, X, and Y joint classes for a given joint. For example, if a joint is to be 25% K, 25% X, and 50% Y, then you must assign K column value of 0.25, X column value of 0.25, and a Y column value of 0.50 for that joint. The program will verify that the supplied contributions sum to 1.0.

If the joint has a gap (i.e., a K-GAP joint), the gap distance (in inches) must be supplied in the `GAP` column. The value to be provided will be the actual gap between the brace members at the joint. An overlap can be specified by setting the gap to a negative value. The overlapping brace in this case can then be indicated by specifying the member number at the `OBRACE` (Overlapping brace) column in the data file.

Overlapping Joints

Clause 4.4 of the API discusses overlapping joints. Checks for overlapping joints will be performed as described D1.J.2.6 Simple Joints: Capacity Checks (on page 1285). The difference will be in that the gap value, g, will be taken as negative in evaluating the various factors.

If the axial loads in the overlapping brace and the through brace have the same sign, the axial load in the through brace will be increased to allow for the loads in the overlapping brace. This will be achieved by allowing a portion of the overlapping brace load equal to the proportion of the overlapping brace area to be added to the axial load in the through brace.

Note: The program issues a warning for any joint overlap is less than $0.25 \cdot \beta \cdot D$.

D1.J.8.2 Joint File Format

The data contained in the *`filename`* `.PUN` file should meet the following format. The overall process of performing punching shear checks consists of two steps which are explained in D1.J.8.1 Joint Checking (on page 1293).

When the API design module is invoked, the program will initially check for the presence of a *`filename`* `.PUN` file (where *`filename`* is the name of the `.std` file) in the same folder as the input file. If the program does not find such a file, it assumes that the joint design is being run for the first time and will create this file. If the program does find this file, it will assume that the joint design has been run at least once and will attempt to read the input data from this file. Not that modifying and saving the main structure (i.e., any changes to the main model using GUI or text editor) will invalidate all design results and the program will automatically delete all design related files including the `*.PUN` file. Hence if the user wises to keep an existing version of the *.PUN file, he/she must make a separate copy of this file before making any changes to the model.

Note: Units used in this file must be kips and inches.

General Format

```
*BRACE CHORD K X Y D T d t GAP FYLD OBRACE TW SWAP
```

```
 b# c# K% X% Y% Dc Tc db tb gap fy ob tw swap
```

Where:

b# = the brace member number
c# = the chord member number

K%, X%, and Y% = The fractional contributions of K-type, X type and Y-type, respectively. Initially the joints will be classed as Y (i.e., K=0, X=0 and Y=1).

db, tb = Diameter and thickness of BRACE member

Dc, Tc = Diameter and thickness of CHORD member

gap = Distance required to calculate gap factor for K bracing. Initially, the value of GAP is assumed as 0. An overlap can be specified by setting the gap to a negative value.

fy = the yield stress to be used in the joint capacity checks

ob = member number of the overlapping brace in an overlap joint (i.e., a gap value less than zero)

tw = Used in overlap K-joint, taken as the lesser of the weld throat thickness or thickness t of the thinner brace in inches

swap = If parameter SWAP 0 is used then major moment Mz is taken for In Plane Bending (IPB). SWAP 1 uses the minor moment My as the IPB.

Example

```
*BRACE  CHORD   K      X      Y       D       T       d       t      GAP   FYLD OBRACE TW SWAP

```

D1.K. American Codes - Steel Design per ANSI/AISC N690 Design Codes

D1.K.1. ANSI/AISC N690-1994 Code

STAAD.Pro is capable of performing steel design based on ANSI/AISC N690-1994 and as amended by *Supplement No. 2 to the Specification of the Design, Fabrication and Erection of Steel Safety-Related Structures for Nuclear Facilities* (ANSI/AISC N690 1994(R2004)s2).

Design of members per ANSI/AISC N690-1994 requires the *STAAD Nuclear Design Codes* SELECT Code Pack.

D1.K.1.1 General Comments

For steel design, STAAD compares the actual stresses with the allowable stresses as defined by ANSI/AISC N690-1994 and as amended by ANSI/AISC N690 1994(R2004)s2.

All the design steps are done as described in D1.B.1.1 Allowables per AISC Code (on page 1130) except for allowable stress in compression for `AUSTENITIC STAINLESS STEEL`. Section Q1.5.9 is used to calculate allowable compressive stress for Austenitic Stainless Steel. Correction made in Supplementary s1 published in April 15, 2002 has been applied.

Note: By default, N690 code uses Stainless Steel material in the design. Care should be taken to assign the proper Stainless Steel material properties to the members for the analysis. There is a parameter – `STYPE` – to change material type to either Stainless Steel (STYPE=1) or Carbon Steel (STYPE=0).

D1.K.1.1.1 Design Process

Members subjected to both axial compression and bending stresses are proportioned to satisfy equation Q1.6-1a:

$$\frac{f_a}{\mathrm{SFC} \cdot F_a} + \frac{C_{my} f_{by}}{\mathrm{SMY} \cdot F_{by}\left(1 - \frac{f_a}{F'_{ey}}\right)} + \frac{C_{mz} f_{bz}}{\mathrm{SMZ} \cdot F_{bz}\left(1 - \frac{f_a}{F'_{ez}}\right)} \le 1.0$$

and Q1.6-1b:

$$\frac{f_a}{\mathrm{SFC} \cdot 0.6F_y} + \frac{f_{by}}{\mathrm{SMY} \cdot F_{by}} + \frac{f_{bz}}{\mathrm{SMZ} \cdot F_{bz}} \le 1.0$$

when, $f_a/F_a > 0.15$, as per section Q1.6.1 of the code.

Otherwise, equation Q1.6-2 must be satisfied:

$$\frac{f_a}{\mathrm{SFC} \cdot F_a} + \frac{f_{by}}{\mathrm{SMY} \cdot F_{by}} + \frac{f_{bz}}{\mathrm{SMZ} \cdot F_{bz}} \le 1.0$$

It should be noted that during code checking or member selection, if f_a/F_a exceeds unity, the program does not compute the second and third part of the formula, because this would result in a misleadingly liberal ratio. The value of the coefficient Cm is taken as 0.85 for side-sway and $[0.6 - 0.4 \cdot (M1/M2)]$, but not less than 0.4 for no side-sway.

Members subjected to both axial tension and bending stress are proportioned to satisfy equation Q1.6-3:

$$\frac{f_a}{\mathrm{SFT} \cdot 0.6F_y} + \frac{f_{by}}{\mathrm{SMY} \cdot F_{by}} + \frac{f_{bz}}{\mathrm{SMZ} \cdot F_{bz}} \le 1.0$$

Where:

`SFC`, `SFT`, `SMZ`, and `SMY` are stress limit coefficient parameters used to control the components of the interaction equations. Refer to D1.K.1.2 Design Parameters (on page 1297) for details.

D1.K.1.2 Design Parameters

The program contains a large number of parameter names which are required to perform design and code checks. These parameter names, with their default values, are listed in the following table.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements for an analysis, some or all of these parameter values may have to be changed to exactly model the physical structure

Table 102: Design Parameters for ANSI/AISC N690-1994

Parameter Name	Default Value	Description
CODE	-	Must be specified as `AISC N690` Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).

Parameter Name	Default Value	Description
BEAM	1	Beam parameter 0. Perform design at ends and those locations in the SECTION command. 1. Perform design at ends and at 1/12th section locations along the member length.
CAN	0	Used for Deflection Check only (i.e., when DFF is specified). 0. Deflection check based on the principle that maximum deflection occurs within the span between DJ1 and DJ2. 1. Deflection check based on the principle that maximum deflection is of the cantilever type
CB	1.0	Bending coefficient dependent upon moment gradient, as specified in Chapter F of AISC ASD. 0.0 = CB is calculated itself Any other user-defined value is accepted.
CMY CMZ	0.85 for sidesway and calculated for no sidesway	Cm value in local y & z axes
COMPOSITE	0	Composite action with connectors (CMP) 0. No composite action 1. Composite action 2. Ignore positive moments during design
CONDIA	0.625 in	Diameter of shear connectors (DIA), in current units.
CONHEIGHT	2.5 in	Height of shear connectors after welding (HGT), in current units.

Parameter Name	Default Value	Description
CYCLES	500,000	Cycles of maximum stress to which the shear connector is subject (CYC).
DFF	None(Mandatory for deflection check)	"Deflection Length" / Maximum allowable local deflection
DJ1	Start Jointof member	Joint No. denoting starting point for calculation of "Deflection Length"
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length"
DLR2	0.4	Ratio of moment due to dead load applied after the concrete hardens to the total moment (DR2).
DLRATIO	0.4	Ratio of moment due to dead load applied before the concrete hardens to the total moment (DR1).
DMAX	45 inch	Maximum allowable depth
DMIN	0.0 inch	Minimum allowable depth
EFFWIDTH	1/4 Member Length	Effective width of concrete slab (WID).
FYLD	36 KSI	Yield strength of steel in current units.
FPC	3 KSI	Compressive strength of concrete at 28 days, in current units.
FSS	1	Full section shear for welding. 0. False 1. True
FU	60 KSI	Ultimate tensile strength of steel, in current units.
FYLD	46 KSI	Yield strength of steel, in current units.
KX	1.0	Effective length factor for flexural torsional buckling.

Parameter Name	Default Value	Description
KY	1.0	Effective Length Factor for Compression in local y-axis. Usually, this is minor axis.
KZ	1.0	Effective Length Factor for Compression in local z-axis. Usually, this is major axis.
LX	Member Length	Length for flexural torsional buckling.
LY	Member Length	Length to calculate slenderness ratio (KL/r) for buckling about local Y axis.
LZ	Member Length	Same as above except in z-axis (major).
MAIN	0.0	Design for slenderness: 0. check for slenderness 1. suppress slenderness check
NSF	1.0	Net section Factor for tension members
OVR	1.0	Factor by which all allowable stresses/capacities should be multiplied. Default of 1.0 indicates that no overstressing is allowed.
PLTHICK	0	Thickness of the cover plate welded to the bottom flange of the composite beam (PLT), in current units.
PLTWIDTH	0	Width of the cover plate welded to the bottom flange of the composite beam (PLT), in current units.
PROFILE	None	Used to search for the lightest section for the profile(s) specified for member selection. See TR.48.1 Parameter Specifications (on page 2676) for details.
RATIO	1.0	Permissible ratio of the actual to allowable stresses.

Parameter Name	Default Value	Description
RIBHEIGHT	0	Height of ribs of form steel deck (RBH), in current units.
RIBWIDTH	0	Width of ribs of form steel deck (RBW), in current units.
SFC	1.0	Stress limit coefficient for compression (SLC) as found in Table Q 1.5.7.1.
SFT	1.0	Stress limit coefficient for tension (SLC) as found in Table Q 1.5.7.1.
SHE	0	Shear stress calculation option 0. Computes the actual shear stress using VQ/It 1. Computes the actual shear stress using V(Ay or Az)
SHORING	0	Temporary shoring during construction 0. Without shoring 1. With shoring
SLABTHICK	4 in	Thickness of concrete slab or thickness of concrete slab above the form steel deck (THK), in current units.
SMY	1.0	Stress limit coefficient for minor axis bending (SLC) as found in Table Q 1.5.7.1.
SMZ	1.0	Stress limit coefficient for major axis bending (SLC) as found in Table Q 1.5.7.1.
SSY	0	Design for sidesway in the local y axis. 0. Sidesway 1. No sidesway

Parameter Name	Default Value	Description
SSZ	0	Design for sidesway in the local z axis. 0. Sidesway 1. No sidesway
STIFF	Member length or depth whichever is greater	Spacing of stiffeners for plate girder design, in current units.
STYPE	0.0	Type of steel material 0. Normal Steel 1. Austenitic Stainless Steel
TAPER	1	Design for tapered member. 0. Design for tapered I-section based on rules in Chapter F and Appendix B. 1. Design for tapered section based on Appendix F.
TMAIN	240 for main member 300 for "Truss" member	Slenderness limit under tension
TORSION	0	Design for torsion. 0. Do not design for torsion. 1. Design for torsion.
TRACK	0.0	Controls the levels of detail to which results are reported. 0. Minimum detail 1. Intermediate detail level 2. Maximum detail
UNB	Member Length	Unsupported length of the bottom* flange for calculating allowable bending compressive stress. Will be used only if flexural compression on the bottom flange.

Parameter Name	Default Value	Description
UNT	Member Length	Unsupported length of the top* flange for calculating allowable bending compressive stress. Will be used only if flexural compression on the top flange.
WELD	1	Design for weld. 0. Closed sections. 1. Open sections.
WMAX	1 in	Maximum weld thickness, in current units.
WMIN	0.625 in	Minimum weld thickness, in current units.
WSTR	0.4·Fyld	Allowable welding stress, in current units.

D1.K.1.2.1 Notes

1. All values are entered in the current units
2. parameters `DMAX` and `DMIN` are only used with the `MEMBER SELECTION` command

D1.K.2. ANSI/AISC N690-1984 Code

For code checking of steel members, STAAD compares the actual stresses with the allowable stresses as defined by ANSI/AISC N690-1984: *Nuclear Facilities - Steel Safety-Related Structures for Design, Fabrication, and Erection.*

A brief description of some of the major allowable stresses is described herein.

D1.K.2.1 Design Process

The following Checks are to be performed on a Steel Member as per this AISC N690 – 1984 Code. When a design is performed, the output file the reports the maximum utilization from all of the checks.

D1.K.2.1.1 Slenderness

The maximum allowable slenderness ratio in Compression (K·L/r_min), as per clause Q1.8.4 of the code shall not exceed 200. And the maximum allowable slenderness ratio in Tension (L/r_min) shall not exceed 240 for main members and 300 for bracing members and other secondary members.

This can be controlled by using the existing `MAIN` and `TMAIN` parameters respectively.

The default value of `MAIN` is `200` and for `TMAIN` is `240`.

D1.K.2.1.2 Check for Element Slenderness and Stress Reduction Factors

The permissible Width-to-Thickness Ratio of “Un-stiffened Elements under Compression” is determined as per section Q1.9.1 and that of “Stiffened Elements under Compression” is determined as per section Q1.9.2 of the code.

The permissible Width–Thickness Ratio of web is determined as per section Q1.10.2.

D1.K.2.1.3 Tension

Allowable tensile stress on the Net section is calculated as $0.60 \cdot F_y$, but not more than $0.5 \cdot F_u$ on the Effective Net area, as per section Q1.5.1.1.

The Net Area (An) shall be determined in accordance with Q1.14, and the `NSF` parameter can be utilized for that.

The Effective Net Area (Ae) of axially loaded tension members, where the load is transmitted by bolts through some but not all of the cross-sectional elements of the member, shall be computed from the formula (ref. Q1.14),

$$A_e = C_t \cdot A_n$$

Unless otherwise specified, the default value of the `CT` parameter is set as 0.75.

The value of `CT` parameter for other conditions is described at section Q1.14.

The provisions for Pin-connected and Threaded tensile member are not implemented in STAAD.

D1.K.2.1.4 Compression

The allowable compressive stress for columns which meet the provisions of section Q1.9, except those fabricated from austenitic stainless steel shall be as required by Q1.5.1.3. The allowable compressive stress for columns fabricated from austenitic stainless steel shall be in accordance to section Q1.5.9.

A. Gross Sections of Columns, except those fabricated of austenitic stainless steel:

  a. On gross section of axially loaded compression members, when $(Kl/r) \le C_c$,

$$F_a = [1 - (Kl/r)^2/(2 \cdot C_c{}^2)]F_y / \{5/3 + [3(Kl/r)/(8 \cdot C_c)] - [(Kl/r)^3/(8 \cdot C_c{}^3)]\}$$

  Where:

$$C_c = [(2 \cdot \pi^2 E)/F_y]^{1/2}$$

  b. When $(Kl/r) > C_c$,

$$F_a = 12 \cdot \pi^2 E/[23(kL/r)^2]$$

B. Gross sections of columns fabricated from Austenitic Stainless steel:

  a. When $(Kl/r) \le 120$,

$$F_a = F_y/2.15 - [(F_y/2.16 - 6)/120](kL/r)$$

  b. When $(Kl/r) > 120$,

$$F_a = 12 - (KL/r)/20$$

If the provisions of the section Q1.9 are not satisfied,

A. For un-stiffened compression element, a reduction factor Q_s is introduced. Detailed values of Qs for different shapes are given in Section QC2.

B. For stiffened compression element, a reduced effective width b_e is introduced.

a. For the flanges of square and rectangular sections of uniform thickness:

$$b_e = 253 \cdot t/\sqrt{F_y}\{1 - (50.3/[(b/t)\sqrt{F_y}]\} \leq b$$

b. For other uniformly compressed elements:

$$b_e = 253 \cdot t/\sqrt{F_y}\{1 - (44.3/[(b/t)\sqrt{F_y}]\} \leq b$$

Consequently, a reduction factor Q_a is introduced and is equal to the effective area divided by the actual area. Combining both these factors, allowable stress for axially loaded compression members containing stiffened or unstiffened elements shall not exceed

$$F_a = Q_s Q_a[1 - (Kl/r)^2/(2 \cdot C_c^{\ 2})]F_y / \{5/3 + [3(Kl/r)/(8 \cdot C_c)] - [(Kl/r)^3/(8 \cdot C_c^{\ 3})]\}$$

Where:

$$C'_c = [(2 \cdot \pi^2 E)/(Q_s Q_a F_y)]^{1/2}$$

D1.K.2.1.5 Bending Stress

Allowable bending stress for tension and compression for a structural member, as given in section Q1.5.1.4 is:

A. Along Major Axis:

a. Tension and compression on extreme fibers of compact hot rolled or built-up members symmetrical about and loaded in the plane of their minor axes and meeting the requirements of Subsection Q1.5.1.4.1.1 to 7, shall result in a maximum bending stress:

$$F_b = 0.66 \cdot F_y$$

If meeting the requirements of this member of:

a. Width-thickness ratio of unstiffened projecting elements of the compression flange shall not exceed $65/\sqrt{F_y}$.

b. Width-thickness ratio of stiffened elements of the compression flange shall not exceed $190/\sqrt{F_y}$.

c. The depth-thickness ratio of the web shall not exceed

$d/t = (640/\sqrt{F_y})[1 - 3.74(f_a/F_y)]$ when $f_a/F_y \leq 0.16$

$d/t = 257/\sqrt{F_y}$ when $f_a/F_y > 0.16$

d. The laterally unsupported length of the compression flange of members other than box-shaped members shall not exceed the value of $76b_f/\sqrt{F_y}$ nor $20000/(d/A_f)F_y$.

b. For noncompact and slender elements, section Q1.5.1.4.2 is followed.

c. For box-type flexural members, maximum bending stress is:

$$F_b = 0.60 \cdot F_y$$

B. Along Minor Axis:

a. For doubly symmetrical members (I shaped) meeting the requirements of section Q1.5.1.4.1, maximum tensile and compressive bending stress shall not exceed the following value as per section Q1.5.1.4.3:

$$F_b = 0.75 \cdot F_y$$

b. For doubly symmetrical members (I shaped) meeting the requirements of section Q1.5.1.4.1, except where $b_f/2t_f > 65/\sqrt{F_y}$ but is less than $95/\sqrt{F_y}$, maximum tensile and compressive bending stress shall not exceed:

$$F_b = F_y[0.79 - 0.002(b_f/2t_f)\sqrt{F_y}]$$

D1.K.2.1.6 Combined Interaction Check

Members subjected to both axial compression and bending stresses are proportioned to satisfy equation Q1.6-1a:

$$\frac{f_a}{\mathrm{SFC} \cdot F_a} + \frac{C_{my} f_{by}}{\mathrm{SMY} \cdot F_{by}\left(1 - \frac{f_a}{F'_{ey}}\right)} + \frac{C_{mz} f_{bz}}{\mathrm{SMZ} \cdot F_{bz}\left(1 - \frac{f_a}{F'_{ez}}\right)} \le 1.0$$

and Q1.6-1b

$$\frac{f_a}{\mathrm{SFC} \cdot 0.6F_y} + \frac{f_{by}}{\mathrm{SMY} \cdot F_{by}} + \frac{f_{bz}}{\mathrm{SMZ} \cdot F_{bz}} \le 1.0$$

when, $f_a/F_a > 0.15$, as per section Q1.6.1 of the code.

Otherwise, equation Q1.6-2 must be satisfied:

$$\frac{f_a}{\mathrm{SFC} \cdot F_a} + \frac{f_{by}}{\mathrm{SMY} \cdot F_{by}} + \frac{f_{bz}}{\mathrm{SMZ} \cdot F_{bz}} \le 1.0$$

It should be noted that during code checking or member selection, if f_a/F_a exceeds unity, the program does not compute the second and third part of the formula, because this would result in a misleadingly liberal ratio. The value of the coefficient Cm is taken as 0.85 for side-sway and $[0.6 - 0.4 \cdot (M1/M2)]$, but not less than 0.4 for no side-sway.

Members subjected to both axial tension and bending stress are proportioned to satisfy equation Q 1.6-1b:

$$\frac{f_a}{\mathrm{SFT} \cdot 0.6F_y} + \frac{f_{by}}{\mathrm{SMY} \cdot F_{by}} + \frac{f_{bz}}{\mathrm{SMZ} \cdot F_{bz}} \le 1.0$$

Where `SFC`, `SFT`, `SMZ`, and `SMY` are stress limit coefficient parameters used to control the components of the interaction equations. Refer to D1.K.2.3 Design Parameters (on page 1307) for details.

D1.K.2.1.7 Shear Stress

Allowable shear stress on the gross section [ref. section Q1.10.5.2] is calculated as

$$F_v = (F_y/2.89)C_v \le 0.4 \cdot F_y$$

Where:

$C_v = (45{,}000 \cdot k)/[F_y(h/t)^2]$, when $h/t \le 0.8$
$C_v = [190/(h/t)]\sqrt{(k/F_y)}$, when $h/t > 0.8$
$k = 4.00 + [5.34/(a/h)^2]$, when $a/h \le 1.0$
$k = 5.34 + [4.00/(a/h)^2]$, when $a/h > 1.0$

For actual shear on the web, the gross section is taken as the product of the total depth and the web thickness. For shear on the flanges, the gross section is taken as the total flange areas.

D1.K.2.2 Member Property Specification

For specification of member properties, the specified steel section available in Steel Section Library of STAAD may be used, namely: I-shaped section, Channel, Tee, HSS Tube, HSS Pipe, Angle, Double Angle, and Double Channel sections.

Member properties may also be specified using the User Table facility except for the General and Prismatic member.

For more information on these facilities, refer to G.6 Member Properties (on page 2113) .

D1.K.2.3 Design Parameters

The program contains a large number of parameter names which are required to perform design and code checks. These parameter names, with their default values, are listed in the following table.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements for an analysis, some or all of these parameter values may have to be changed to exactly model the physical structure

Table 103: Design Parameters for ANSI/AISC N690-1984

Parameter Name	Default Value	Description
CODE	-	Must be specified as `AISC N690 1984` to use the ANSI/AISC N690-1984 code for checking purposes. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
CAN	0	Used for Deflection Check only. 0 = Deflection check based on the principle that maximum deflection occurs within the span between DJ1 and DJ2. 1 = Deflection check based on the principle that maximum deflection is of the cantilever type
CB	1.0	Bending coefficient dependent upon moment gradient 0.0 = CB is calculated itself Any other user-defined value is accepted.
CMY CMZ	0.85 for sidesway and calculated for no sidesway	Cm value in local y & z axes
CT	0.75	Reduction Coefficient in computing net effective net area of an axially loaded tension member.
DFF	None(Mandatory for deflection check)	"Deflection Length" / Maximum allowable local deflection

Parameter Name	Default Value	Description
DJ1	Start Jointof member	Joint No. denoting starting point for calculation of "Deflection Length"
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length"
DMAX	45 inch	Maximum allowable depth
DMIN	0.0 inch	Minimum allowable depth
FU	60 KSI	Ultimate tensile strength of steel in current units.
FYLD	36 KSI	Yield strength of steel in current units.
KY	1.0	Effective Length Factor for Compression in local y-axis. Usually, this is minor axis.
KZ	1.0	Effective Length Factor for Compression in local z-axis. Usually, this is major axis.
LY	Member Length	Length to calculate slenderness ratio for buckling about local Y axis.
LZ	Member Length	Same as above except in z-axis (major).
MAIN	0.0	Design for slenderness. 0. Check for slenderness 1. Suppress slenderness check
NSF	1.0	Net section Factor for tension members
PROFILE	None	Used to search for the lightest section for the profile(s) specified for member selection. See TR.48.1 Parameter Specifications (on page 2676) for details.
RATIO	1.0	Permissible ratio of the actual to allowable stresses.

Parameter Name	Default Value	Description
SFC	1.0	Stress limit coefficient for compression (SLC) as found in Table Q 1.5.7.1.
SFT	1.0	Stress limit coefficient for tension (SLC) as found in Table Q 1.5.7.1.
SMY	1.0	Stress limit coefficient for minor axis bending (SLC) as found in Table Q 1.5.7.1.
SMZ	1.0	Stress limit coefficient for major axis bending (SLC) as found in Table Q 1.5.7.1.
STIFF	Member length or depth whichever is greater	Spacing of stiffeners for plate girder design
STYPE	0.0	Steel type: 0.0 = Normal Steel 1.0 = Austenitic Stainless Steel
TMAIN	240 for main member 300 for “Truss” member	Slenderness limit under tension
TRACK	0.0	Controls the levels of detail to which results are reported. 0 = Minimum detail 1 = Intermediate detail level 2 = Maximum detail
UNB	Member Length	Unsupported length of the bottom* flange for calculating allowable bending compressive stress. Will be used only if flexural compression on the bottom flange.
UNT	Member Length	Unsupported length of the top* flange for calculating allowable bending compressive stress. Will be used only if flexural compression on the top flange.

D1.K.2.3.1 Notes

1. All values are entered in the current units

2. parameters DMAX and DMIN are only used with the MEMBER SELECTION command

D1.K.2.4 Code Checking and Member Selection

Both code checking and member selection options are available with the AISC N690 1984 code.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D1.L. American Codes - Steel Design per ASME NF Codes

The following American Society of Mechanical Engineers – Nuclear Facility codes are available.

D1.L.1. ASME NF 3000 - 1974 & 1977 Codes

STAAD.Pro is capable of performing steel design based on the American Society of Mechanical Engineers *Nuclear Facility Code*, ASME NF 3000 - 1974 & 1977 .

Note: From design point of view, there are no major differences between NF-3000 1974 and NF-3000 1977 version of codes.

Design of members per ASME NF 3000 - 1974 & 1977 requires the *STAAD Nuclear Design Codes* SELECT Code Pack.

D1.L.1.1 Design Process

The design process follows the following design checks

Each one of the checks are described in the following sections.

When a design is performed, the output file the reports the maximum utilization from all of the checks.

D1.L.1.1.1 Slenderness
As per clause XVII-2223 of NF-3000 1974, the slenderness ratio KL/r of compression members shall not exceed 200, and the slenderness ratio L/r of tension members, preferably should not exceed 240 for main members and 300 for lateral bracing members and other secondary members. The default limit for TRUSS members in Tension is set at 300.

D1.L.1.1.2 Tension

Allowable tensile stress on the Net section is calculated as ($0.60 \times F_y$), but not more than ($0.5 \times F_u$) on the Net area.

The Net Area (A_n) shall be determined in accordance with the clause XVII-2283 of NF-3000 1974, and the `NSF` parameter can be utilized for that.

The provisions for Pin-connected and Threaded tensile member are not implemented in STAAD.Pro.

D1.L.1.1.3 Compression

The allowable compressive stress for columns shall be as required by clause XVII-2213 of NF-3000 1974.

a. Gross Sections of Columns:

  a. On gross section of axially loaded compression members, when $(Kl/r) < C_c$,

$$F_a = F_y \frac{\left[1 - \frac{(KL/r)^2}{2C_c^2}\right]}{5\left/3 + \frac{3(KL/r)}{8C_c} - \frac{(KL/r)^3}{8C_c^3}\right.}$$

  Where:

$$C_c = \sqrt{\frac{2\pi^2 E}{F_y}}$$

  b. When $(Kl/r) > C_c$,

$$F_a = \frac{12\pi^2 E}{23(KL/r)^2}$$

  c. When $(Kl/r) > 120$,

$$F_{as} = \frac{F_a\left[Eq.(a1) \text{ or } Eq.(a2)\right]}{1.6 - \left(\frac{l}{200r}\right)}$$

b. Member elements other than columns:

  a. For Plate Girder Stiffeners, $F_a = 0.60 \cdot F_y$

  b. For webs of rolled shapes, $F_a = 0.75 \cdot F_y$

The above clauses are applicable only when the width-thickness ratio of the element satisfies all the sub-sections of clause XVII-2224 of NF-3000 1974.

If the above-mentioned clauses are not satisfied,

a. For un-stiffened compression element, a reduction factor, Q_s, is introduced. Detailed values of Q_s for different shapes are given in the clause XVII-2225.2 of NF-3000 1974.

b. For stiffened compression element, a reduced effective width, b_e, is introduced.

  a. For the flanges of square and rectangular sections of uniform thickness:

$$b_e = \frac{253t}{\sqrt{f}}\left[1 - \left(\frac{50.3}{(b/t)\sqrt{f}}\right)\right] \le b$$

  b. For other uniformly compressed elements:

$$b_e = \frac{253t}{\sqrt{f}}\left[1 - \left(\frac{44.3}{(b/t)\sqrt{f}}\right)\right] \le b$$

Consequently, a reduction factor, Q_a, equal to the effective area divided by the actual area is introduced.

Combining both these factors, allowable stress for axially loaded compression members containing stiffened or un-stiffened elements shall not exceed

$$F_a = F_y \frac{Q_s Q_a \left[1 - \frac{(KL\ / r)^2}{2C'^2_c} \right]}{5 \Big/ 3 + \frac{3(KL\ / r)}{8C'_c} - \frac{(KL\ / r)^3}{8C'^3_c}}$$

Where:

$$C'_c = \sqrt{\frac{2\pi^2 E}{Q_s Q_a F_y}}$$

The section is also checked that the stress is less than 2/3× the critical buckling stress, which is taken as the Euler critical buckling load divided by the cross sectional area:

$$F = \frac{2}{3}\frac{P_{\text{cr}}}{A}$$

where

P_{cr} = the Euler critical buckling load of the column: $\frac{\pi^2 EI}{(KL\ )^2}$

D1.L.1.1.4 Bending Stress

Allowable bending stress for tension and compression for a structural member, as given in XVII-2214 of NF-3000 1974 is:

a. Along Major Axis:

b. For Compact Sections, tension and compression on extreme fibers of compact hot rolled or built-up members symmetrical about and loaded in the plane of their minor axes and meeting the requirements of Subsection NF shall result in a maximum bending stress:

$$F_b = 0.66 \times F_y$$

If meeting the requirements of this member of:

a. Width-thickness ratio of un-stiffened projecting elements of the compression flange shall not exceed $52.2/\sqrt{F_y}$.

b. Width-thickness ratio of stiffened elements of the compression flange shall not exceed $190/\sqrt{F_y}$.

c. The depth-thickness ratio of the web shall not exceed

$$d/t = (412/\sqrt{F_y})[1 - 2.33(F_a/F_y)]$$

except that it need not be less than $257/\sqrt{F_y}$.

d. The laterally unsupported length of the compression flange of members other than box-shaped members shall not exceed the value of $76b_f/\sqrt{F_y}$ nor $20000/(d/A_f)F_y$.

e. For noncompact and slender elements, clause XVII-2214.2 and XVII-2214.5 of NF-3000 1974 are followed respectively.

f. For box-type flexural members, maximum bending stress is:

$$F_b = 0.60 \times F_y$$

g. Along Minor Axis:

For doubly symmetrical members (I shaped) meeting the requirements of XVII-2214.1(a) and (b) of NF-3000 1974, maximum tensile and compressive bending stress shall not exceed:

$$F_b = 0.75 \times F_y$$

D1.L.1.1.5 Combined Interaction Check

Members subjected to both axial compression and bending stresses are proportioned to satisfy

$$\frac{f_a}{F_a} + \frac{C_{mz} f_{bz}}{\left(1 - f_a / F'_{ex}\right) F_{bx}} + \frac{C_{my} f_{by}}{\left(1 - f_a / F'_{ey}\right) F_{by}} \le 1.0$$

and

$$\frac{f_a}{0.60 F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} \le 1.0$$

when $f_a / F_a > 0.15$, otherwise

$$\frac{f_a}{F_a} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} \le 1.0$$

It should be noted that during code checking or member selection, if f_a / F_a exceeds unity, the program does not compute the second and third part of the formula, because this would result in a misleadingly liberal ratio. The value of the coefficient Cm is taken as 0.85 for side-sway and $0.6 - 0.4 \cdot (M1/M2)$, but not less than 0.4 for no side-sway.

Members subjected to both axial tension and bending stress are proportioned to satisfy

$$\frac{f_a}{0.60 F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} \le 1.0$$

D1.L.1.1.6 Shear Stress
Allowable shear stress on the gross section [ref. XVII-2263.2 of NF-3000 1974] is calculated as

$$F_v = \left(F_y / 2.89\right) C_v \le 0.4 F_y$$

where

C_v = $\frac{45,\ 000k}{F_y (h\ /\ t)^2}$ when $h/b \le 0.8$

= $\frac{190}{h\ /\ t} \sqrt{\frac{k}{F_y}}$ when $h/b > 0.8$

k = $4.00 + 5.34/(a/h)^2$ when $a/h \le 1.0$

= $5.34 + 4.00/(a/h)^2$ when $a/h > 1.0$

For actual shear on the web, the gross section is taken as the product of the total depth and the web thickness. For shear on the flanges, the gross section is taken as the total flange areas.

D1.L.1.1 Member Property Specification

For specification of member properties, the specified steel section available in Steel Section Library of STAAD may be used namely — I-shaped section, Channel, Tee, HSS Tube, HSS Pipe, Angle, Double Angle, Double Channel section.

Member properties may also be specified using the User Table facility except for the General and Prismatic member.

For more information on these facilities, refer to G.6 Member Properties (on page 2113) .

D1.L.1.3 Design Parameters

The program contains a large number of parameter names which are required to perform design and code checks. These parameter names, with their default values, are listed in the following table.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements for an analysis, some or all of these parameter values may have to be changed to exactly model the physical structure. For example, by default the KZ value (k value in local z-axis) of a member is set to 1.0, while in the real structure it may be 1.5. In that case, the KZ value in the program can be changed to 1.5, as shown in the input instruction (Section 5). Similarly, the TRACK value of a member is set to 0.0, which means no allowable stresses of the member will be printed. If the allowable stresses are to be printed, the TRACK value must be set to 1.0.

Note: Unlike many other design codes available in STAAD.Pro (which use the `BEAM` parameter), design per ASME NF 3000 codes in STAAD.Pro is *always* performed based on forces calculated at 13 sections, including ends.

Table 104: ASME NF 3000 Design Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `CODE NF3000 1974` or `CODE NF3000 1977` Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
CAN	0	Used for Deflection Check only. 0 = Deflection check based on the principle that maximum deflection occurs within the span between DJ1 and DJ2. 1 = Deflection check based on the principle that maximum deflection is of the cantilever type
CB	1.0	Bending coefficient dependent upon moment gradient 0.0 = CB is calculated itself Any other user-defined value is accepted.
CMY CMZ	0.85 for sidesway and calculated for no sidesway	Cm value in local y & z axes

Parameter Name	Default Value	Description
CT	0.75	Reduction Coefficient in computing effective net area of an axially loaded tension member. [Refer NF-3322.8(c)(1)(d)]
DFF	None(Mandatory for deflection check)	"Deflection Length" / Maximum allowable local deflection
DJ1	Start Jointof member	Joint No. denoting starting point for calculation of "Deflection Length"
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length"
DMAX	45 inch	Maximum allowable depth. Used only with the MEMBER SELECTION command.
DMIN	0.0 inch	Minimum allowable depth. Used only with the MEMBER SELECTION command.
FYLD	36 KSI	Yield strength of steel at temperature in current units.
FU	60 KSI	Ultimate tensile strength of steel in current units.
KBK	1.0	Stress Limit Factor applicable to the Design Allowable Compressive Axial and Bending stresses to determine the Buckling Limit. **Note:** Ignored unless SRL is set to D.
KS	1.0	Stress Limit Factor applicable to the Design Allowable Tensile and Bending Stresses. **Note:** Ignored unless SRL is set to D.
KV	1.0	Stress Limit Factor applicable to the Design Allowable Shear Stresses. **Note:** Ignored unless SRL is set to D.

Parameter Name	Default Value	Description
KY	1.0	K value in local y-axis. Usually, this is minor axis.
KZ	1.0	K value in local z-axis. Usually, this is major axis.
LY	Member Length	Length to calculate slenderness ratio for buckling about local Y axis.
LZ	Member Length	Same as above except in z-axis (major).
MAIN	0.0	0.0 = check for slenderness 1.0 = suppress slenderness check
NSF	1.0	Net Section Factor for tension member.
PROFILE	None	Used in member selection. See TR. 48.1 Parameter Specifications (on page 2676) for details.
RATIO	1.0	Permissible ratio of the actual to allowable stresses.
SRL	A	Service level, which defines the service level factors to use for modifying stress values for the service level conditions. **A.** Normal Conditions **B.** Upset **C.** Emergency **D.** Faulted - If any of KS, KV, or KBK parameters are not set, a warning is issued that these must be user-defined. Refer to D1.L.5. ASME NF 3000 Service Level Conditions (on page 1348) for additional information.
STIFF	Member length or depth whichever is greater	Spacing of stiffeners for plate girder design
TMAIN	240 for main member 300 for "Truss" member	Slenderness limit under tension

Parameter Name	Default Value	Description
TRACK	0.0	Controls the levels of detail to which results are reported. 0. Minimum detail 1. Intermediate detail level 2. Maximum detail
UNB	Member Length	Unsupported length of the bottom* flange for calculating allowable bending compressive stress. Will be used only if flexural compression on the bottom flange.
UNT	Member Length	Unsupported length of the top* flange for calculating allowable bending compressive stress. Will be used only if flexural compression on the top flange.

Related Links

- *D1.L.5. ASME NF 3000 Service Level Conditions* (on page 1348)

D1.L.1.4 Code Checking and Member Selection

Both code checking and member selection options are available with the ASME NF-3000 1974 and ASME NF-3000 1977 codes.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D1.L.1.5 Example

A cantilever beam of length 30 inch is loaded at its free end with 5 kip compressive load and 5 kip lateral load. The beam is assigned with W24X104 steel member and is designed in accordance with ASME NF3000 1974.

The corresponding input of STAAD input editor file is shown as below:

D1.L.2. ASME NF 3000 - 1989 Code

For steel design, STAAD.Pro compares the actual stresses with the allowable stresses as defined by the American Society of Mechanical Engineers — Nuclear Facility (ASME NF) Code. The ASME NF-3000 1989 Code is used as the basis of this design.

A brief description of some of the major allowable stresses is described herein.

D1.L.2.1 Design Process

The design process follows the following design checks.

Each one of the checks are described in the following sections.

When a design is performed, the output file the reports the maximum utilization from all of the checks.

D1.L.2.1.1 Slenderness

As per NF-3322.2(c), the slenderness ratio KL/r of compression members shall not exceed 200, and the slenderness ratio L/r of tension members, preferably should not exceed 240 for main members and 300 for lateral bracing members and other secondary members. The default limit for TRUSS members in Tension is set at 300.

D1.L.2.1.2 Tension

Allowable tensile stress on the Net section is calculated as ($0.60 \times F_y$), but not more than ($0.5 \times F_u$) on the Effective Net area.

The Net Area (A_n) shall be determined in accordance with NF-3322.8(c)(1) - (a), (b) and (c), and the NSF parameter can be utilized for that.

The Effective Net Area (A_e) of axially loaded tension members, where the load is transmitted by bolts through some but not all of the cross-sectional elements of the member, shall be computed from the formula (ref. NF-3322.8(c)(1)(d)),

$$A_e = C_t \times A_n$$

Unless otherwise specified, the default value of the CT parameter is set as 0.75.

The value of CT parameter for other conditions is described at section NF-3322.8(c)(1)(d)(1), (2) and (3).

The provisions for Pin-connected and Threaded tensile member are not implemented in STAAD.

D1.L.2.1.3 Compression

The allowable compressive stress for columns, except those fabricated from austenitic stainless steel shall be as required by NF-3322.1(c)(1). The allowable compressive stress for columns fabricated from austenitic stainless steel shall be as required by NF-3322.1(c)(2). The allowable compressive stress for member elements other than columns constructed by any material, including austenitic stainless steel, shall be as required by NF-3322.1(c)(3).

a. Gross Sections of Columns, except those fabricated of austenitic stainless steel:

   a. On gross section of axially loaded compression members, when $(Kl/r) < C_c$,

$$F_a = F_y \frac{\left[1 - \frac{(KL / r)^2}{2C_c^2}\right]}{5/3 + \frac{3(KL / r)}{8C_c} - \frac{(KL / r)^3}{8C_c^3}}$$

   Where:

$$C_c = \sqrt{\frac{2\pi^2 E}{F_y}}$$

   b. When $(Kl/r) > C_c$,

$$F_a = \frac{12\pi^2 E}{23(KL / r)^2}$$

   c. When $(Kl/r) > 120$,

$$F_{as} = \frac{F_a\left[Eq.(a1) \text{ or } Eq.(a2)\right]}{1.6 - \left(\frac{l}{200r}\right)}$$

b. Gross sections of columns fabricated from Austenitic Stainless steel:

  a. When $(Kl/r) \leq 120$,

$$F_a = F_y\left(0.47 - \frac{KL\ /r}{444}\right)$$

  b. When $(Kl/r) > 120$,

$$F_a = F_y\left(0.40 - \frac{KL\ /r}{600}\right)$$

c. Member elements other than columns:

  a. For Plate Girder Stiffeners, $F_a = 0.60 \cdot F_y$

  b. For webs of rolled shapes, $F_a = 0.75 \cdot F_y$

The above clauses are applicable only when the width-thickness ratio of the element satisfies all the sub-sections of NF-3322.2(d).

If the above-mentioned clauses are not satisfied,

a. For un-stiffened compression element, a reduction factor, Q_s, is introduced. Detailed values of Q_s for different shapes are given in NF-3322.2(e)(2)(a) to NF-3322.2(e)(2)(d).

b. For stiffened compression element, a reduced effective width, b_e, is introduced.

  a. For the flanges of square and rectangular sections of uniform thickness:

$$b_e = \frac{253t}{\sqrt{f}}\left[1 - \left(\frac{50.3}{(b\ /\ t)\sqrt{f}}\right)\right] \leq b$$

  b. For other uniformly compressed elements:

$$b_e = \frac{253t}{\sqrt{f}}\left[1 - \left(\frac{44.3}{(b\ /\ t)\sqrt{f}}\right)\right] \leq b$$

Consequently, a reduction factor, Q_a, equal to the effective area divided by the actual area is introduced.

Combining both these factors, allowable stress for axially loaded compression members containing stiffened or un-stiffened elements shall not exceed

$$F_a = F_y \frac{Q_s Q_a\left[1 - \frac{(KL\ /r)^2}{2C'^2_c}\right]}{5\Big/3 + \frac{3(KL\ /r)}{8C'_c} - \frac{(KL\ /r)^3}{8C'^3_c}}$$

Where:

$$C'_c = \sqrt{\frac{2\pi^2 E}{Q_s Q_a F_y}}$$

The section is also checked that the stress is less than 2/3× the critical buckling stress, which is taken as the Euler critical buckling load divided by the cross sectional area:

$$F = \frac{2}{3}\frac{P_{\text{cr}}}{A}$$

where

P_{cr} = the Euler critical buckling load of the column: $\frac{\pi^2 EI}{(KL)^2}$

D1.L.2.1.4 Bending Stress

Allowable bending stress for tension and compression for a structural member, as given in NF-3322.1(d) is:

A. Along Major Axis:

a. For Compact Sections, tension and compression on extreme fibres of compact hot rolled or built-up members symmetrical about and loaded in the plane of their minor axes and meeting the requirements of Subsection NF shall result in a maximum bending stress:

$$F_b = 0.66 \times F_y$$

If meeting the requirements of this member of:

a. Width-thickness ratio of unstiffened projecting elements of the compression flange shall not exceed $65/\sqrt{F_y}$.

b. Width-thickness ratio of stiffened elements of the compression flange shall not exceed $190/\sqrt{F_y}$.

c. The depth-thickness ratio of the web shall not exceed

$$d \Big/ t = \left(\frac{640}{\sqrt{F_y}}\right)\left[1 - 3.74\left(\frac{f_a}{F_y}\right)\right] \text{ when } f_a/F_y \leq 0.16$$

$$d \Big/ t = \left(\frac{257}{\sqrt{F_y}}\right) \text{ when } f_a/F_y > 0.16$$

d. The laterally unsupported length of the compression flange of members other than box-shaped members shall not exceed the value of $76b_f/\sqrt{F_y}$ nor $20000/(d/A_f)F_y$.

b. For noncompact and slender elements, NF-3322.1(d)(5) and NF-3322.1(d)(3) are followed respectively.

c. For box-type flexural members, maximum bending stress is:

$$F_b = 0.60 \times F_y$$

B. Along Minor Axis:

a. For doubly symmetrical members (I shaped) meeting the requirements of NF-3322.1(d)(1)(a) and (b), maximum tensile and compressive bending stress shall not exceed:

$$F_b = 0.75 \times F_y$$

b. For doubly symmetrical members (I shaped) meeting the requirements of NF-3322.1(d)(1)(a), *except where* $b_f/2t_f$ exceeds $65/\sqrt{F_y}$ but is less than $95/\sqrt{F_y}$, maximum tensile and compressive bending stress shall not exceed:

$$F_b = F_y[1.075 - 0.005(b_f/2t_f)\sqrt{F_y}]$$

D1.L.2.1.5 Combined Interaction Check

Members subjected to both axial compression and bending stresses are proportioned to satisfy

$$\frac{f_a}{F_a} + \frac{C_{mz} f_{bz}}{(1 - f_a / F'_{ex})F_{bx}} + \frac{C_{my} f_{by}}{(1 - f_a / F'_{ey})F_{by}} \leq 1.0$$

and

$$\frac{f_a}{0.60F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} \leq 1.0$$

when $f_a/F_a > 0.15$, otherwise

$$\frac{f_a}{F_a} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} \le 1.0$$

It should be noted that during code checking or member selection, if f_a/F_a exceeds unity, the program does not compute the second and third part of the formula, because this would result in a misleadingly liberal ratio. The value of the coefficient Cm is taken as 0.85 for side-sway and $0.6 - 0.4 \cdot (M1/M2)$, but not less than 0.4 for no side-sway.

Members subjected to both axial tension and bending stress are proportioned to satisfy

$$\frac{f_a}{0.60F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} \le 1.0$$

D1.L.2.1.6 Shear Stress

Allowable shear stress on the gross section [ref. NF-3322.6(e)(2)] is calculated as

$$F_v = (F_y/2.89)C_v \le 0.4F_y$$

where

C_v = $\frac{45,\ 000k}{F_y(h\ /\ t)^2}$ when $h/b \le 0.8$

= $\frac{190}{h\ /\ t}\sqrt{\frac{k}{F_y}}$ when $h/b > 0.8$

k = $4.00 + 5.34/(a/h)^2$ when $a/h \le 1.0$

= $5.34 + 4.00/(a/h)^2$ when $a/h > 1.0$

For actual shear on the web, the gross section is taken as the product of the total depth and the web thickness. For shear on the flanges, the gross section is taken as the total flange areas.

D1.L.2.2 Member Property Specification

For specification of member properties, the specified steel section available in Steel Section Library of STAAD may be used namely — I-shaped section, Channel, Tee, HSS Tube, HSS Pipe, Angle, Double Angle, Double Channel section.

Member properties may also be specified using the User Table facility except for the General and Prismatic member.

For more information on these facilities, refer to G.6 Member Properties (on page 2113) .

D1.L.2.3 Design Parameters

The program contains a large number of parameter names which are required to perform design and code checks. These parameter names, with their default values, are listed in the following table.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements for an analysis, some or all of these parameter values may have to be changed to exactly model the physical structure. For example, by default the KZ value (k value in local z-axis) of a member is set to 1.0, while in the real structure it may be 1.5. In that case, the KZ value in the program can be changed to 1.5, as shown in the input instruction (Section 5). Similarly, the TRACK value of a member is set to 0.0, which means no allowable stresses of the member will be printed. If the allowable stresses are to be printed, the TRACK value must be set to 1.0.

Note: Unlike many other design codes available in STAAD.Pro (which use the BEAM parameter), design per ASME NF 3000 codes in STAAD.Pro is *always* performed based on forces calculated at 13 sections, including ends.

Table 105: ASME NF 3000 Design Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as NF3000 1989. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
CAN	0	Used for Deflection Check only. 0 = Deflection check based on the principle that maximum deflection occurs within the span between DJ1 and DJ2. 1 = Deflection check based on the principle that maximum deflection is of the cantilever type
CB	1.0	Bending coefficient dependent upon moment gradient 0.0 = CB is calculated itself Any other user-defined value is accepted.
CT	0.75	Reduction Coefficient in computing effective net area of an axially loaded tension member. [Refer NF-3322.8(c)(1)(d)]
CMY CMZ	0.85 for sidesway and calculated for no sidesway	Cm value in local y & z axes
DFF	None(Mandatory for deflection check)	"Deflection Length" / Maximum allowable local deflection
DJ1	Start Jointof member	Joint No. denoting starting point for calculation of "Deflection Length"
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length"

Parameter Name	Default Value	Description
DMAX	45 inch	Maximum allowable depth, in current units. Used only with the MEMBER SELECTION command.
DMIN	0.0 inch	Minimum allowable depth, in current units. Used only with the MEMBER SELECTION command.
FYLD	36 KSI	Yield strength of steel at temperature in current units.
FU	60 KSI	Ultimate tensile strength of steel in current units.
KBK	1.0	Stress Limit Factor applicable to the Design Allowable Compressive Axial and Bending stresses to determine the Buckling Limit. **Note:** Ignored unless SRL is set to D.
KS	1.0	Stress Limit Factor applicable to the Design Allowable Tensile and Bending Stresses. **Note:** Ignored unless SRL is set to D.
KV	1.0	Stress Limit Factor applicable to the Design Allowable Shear Stresses. **Note:** Ignored unless SRL is set to D.
KY	1.0	K value in local y-axis. Usually, this is minor axis.
KZ	1.0	K value in local z-axis. Usually, this is major axis.
LY	Member Length	Length to calculate slenderness ratio for buckling about local Y axis.
LZ	Member Length	Same as above except in z-axis (major).

Parameter Name	Default Value	Description
MAIN	0.0	0.0 = check for slenderness 1.0 = suppress slenderness check
NSF	1.0	Net Section Factor for tension member.
PROFILE	None	Used in member selection. See TR. 48.1 Parameter Specifications (on page 2676) for details.
RATIO	1.0	Permissible ratio of the actual to allowable stresses.
SRL	A	Service level, which defines the service level factors to use for modifying stress values for the service level conditions. **A.** Normal Conditions **B.** Upset **C.** Emergency **D.** Faulted - If any of KS, KV, or KBK parameters are not set, a warning is issued that these must be user-defined. Refer to D1.L.5. ASME NF 3000 Service Level Conditions (on page 1348) for additional information.
STIFF	Member length or depth whichever is greater	Spacing of stiffeners for plate girder design
STYPE	0.0	0.0 = Normal Steel 1.0 = Austenitic Stainless Steel
TMAIN	240 for main member 300 for "Truss" member	Slenderness limit under tension
TRACK	0.0	Controls the levels of detail to which results are reported. 0 = Minimum detail 1 = Intermediate detail level 2 = Maximum detail

Parameter Name	Default Value	Description
UNB	Member Length	Unsupported length of the bottom* flange for calculating allowable bending compressive stress. Will be used only if flexural compression on the bottom flange.
UNT	Member Length	Unsupported length of the top* flange for calculating allowable bending compressive stress. Will be used only if flexural compression on the top flange.

D1.L.2.4 Code Checking and Member Selection

Both code checking and member selection options are available with the ASME NF-3000 1989 code.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D1.L.2.5 Example

A cantilever beam of length 100 inch is loaded at its free end with 5 kip compressive load and a uniformly distributed load of 1 kip/inch over the whole span. The beam is assigned with B571806 steel member and is designed in accordance with ASME NF3000 1989.

D1.L.3. ASME NF 3000 - 1998 Code

For steel design, STAAD.Pro compares the actual stresses with the allowable stresses as defined by the American Society of Mechanical Engineers — Nuclear Facility (ASME NF) Code. The ASME NF-3000 1998 Code is used as the basis of this design.

A brief description of some of the major allowable stresses is described herein.

D1.L.3.1 Design Process

The design process follows the following design checks.

Each one of the checks are described in the following sections.

When a design is performed, the output file the reports the maximum utilization from all of the checks.

D1.L.3.2.1 Slenderness

As per NF-3322.2(c), the slenderness ratio KL/r of compression members shall not exceed 200, and the slenderness ratio L/r of tension members, preferably should not exceed 240 for main members and 300 for lateral bracing members and other secondary members. The default limit for TRUSS members in Tension is set at 300.

D1.L.3.2.2 Tension

Allowable tensile stress on the Net section is calculated as ($0.60 \times F_y$), but not more than ($0.5 \times F_u$) on the Effective Net area.

The Net Area (A_n) shall be determined in accordance with NF-3322.8(c)(1) - (a), (b) and (c), and the `NSF` parameter can be utilized for that.

The Effective Net Area (A_e) of axially loaded tension members, where the load is transmitted by bolts through some but not all of the cross-sectional elements of the member, shall be computed from the formula (ref. NF-3322.8(c)(1)(d)),

$$A_e = C_t \times A_n$$

Unless otherwise specified, the default value of the `CT` parameter is set as 0.75.

The value of `CT` parameter for other conditions is described at section NF-3322.8(c)(1)(d)(1), (2) and (3).

The provisions for Pin-connected and Threaded tensile member are not implemented in STAAD.

D1.L.3.2.3 Compression

The allowable compressive stress for columns, except those fabricated from austenitic stainless steel shall be as required by NF-3322.1(c)(1). The allowable compressive stress for columns fabricated from austenitic stainless steel shall be as required by NF-3322.1(c)(2). The allowable compressive stress for member elements other than columns constructed by any material, including austenitic stainless steel, shall be as required by NF-3322.1(c)(3).

a. Gross Sections of Columns, except those fabricated of austenitic stainless steel:

  a. On gross section of axially loaded compression members, when $(Kl/r) < C_c$,

$$F_a = F_y \frac{\left[1 - \frac{(KL/r)^2}{2C_c^2}\right]}{5 / 3 + \frac{3(KL/r)}{8C_c} - \frac{(KL/r)^3}{8C_c^3}}$$

  Where:

$$C_c = \sqrt{\frac{2\pi^2 E}{F_y}}$$

  b. When $(Kl/r) > C_c$,

$$F_a = \frac{12\pi^2 E}{23(KL/r)^2}$$

  c. When $(Kl/r) > 120$,

$$F_{as} = \frac{F_a\left[Eq.(a1) \text{ or } Eq.(a2)\right]}{1.6 - \left(\frac{l}{200r}\right)}$$

b. Gross sections of columns fabricated from Austenitic Stainless steel:

  a. When $(Kl/r) \le 120$,

$$F_a = F_y\left(0.47 - \frac{KL/r}{444}\right)$$

  b. When $(Kl/r) > 120$,

$$F_a = F_y\left(0.40 - \frac{KL/r}{600}\right)$$

c. Member elements other than columns:

  a. For Plate Girder Stiffeners, $F_a = 0.60 \cdot F_y$

  b. For webs of rolled shapes, $F_a = 0.75 \cdot F_y$

The above clauses are applicable only when the width-thickness ratio of the element satisfies all the sub-sections of NF-3322.2(d).

If the above-mentioned clauses are not satisfied,

a. For un-stiffened compression element, a reduction factor, Q_s, is introduced. Detailed values of Q_s for different shapes are given in NF-3322.2(e)(2)(a) to NF-3322.2(e)(2)(d).

In the case for angles or plates projecting from compression members and for projecting elements of compression flanges of girder,

When $95 / \sqrt{F_y / kc} < b / t < 195 / \sqrt{F_y / kc}$, $Q_s = 1.293 - 0.00309(b / t)\sqrt{F_y / kc}$

When $b / t > 195 / \sqrt{F_y / kc}$,

$$Q_s = \frac{26,\ 200kc}{F_y(b/t)^2}$$

Where:

$$kc = \frac{4.05}{(h\ /\ t)^{0.46}}$$ when $h/t > 70$, otherwise, kc = 1.0.

b. For stiffened compression element, a reduced effective width, b_e, is introduced.

a. For the flanges of square and rectangular sections of uniform thickness:

$$b_e = \frac{253t}{\sqrt{f}}\left[1 - \left(\frac{50.3}{(b/t)\sqrt{f}}\right)\right] \leq b$$

b. For other uniformly compressed elements:

$$b_e = \frac{253t}{\sqrt{f}}\left[1 - \left(\frac{44.3}{(b/t)\sqrt{f}}\right)\right] \leq b$$

Consequently, a reduction factor, Q_a, equal to the effective area divided by the actual area is introduced.

Combining both these factors, allowable stress for axially loaded compression members containing stiffened or un-stiffened elements shall not exceed

$$F_a = F_y \frac{Q_s Q_a\left[1 - \frac{(KL\ /r)^2}{2C'^2_c}\right]}{5\Big/3 + \frac{3(KL\ /r)}{8C'_c} - \frac{(KL\ /r)^3}{8C'^3_c}}$$

Where:

$$C'_c = \sqrt{\frac{2\pi^2 E}{Q_s Q_a F_y}}$$

The section is also checked that the stress is less than 2/3× the critical buckling stress, which is taken as the Euler critical buckling load divided by the cross sectional area:

$$F = \frac{2}{3}\frac{P_{\mathrm{cr}}}{A}$$

where

P_{cr} = the Euler critical buckling load of the column: $\frac{\pi^2 EI}{(KL)^2}$

D1.L.3.2.4 Bending Stress

Allowable bending stress for tension and compression for a structural member, as given in NF-3322.1(d) is:

A. Along Major Axis:

1. For Compact Sections, tension and compression on extreme fibres of compact hot rolled or built-up members symmetrical about and loaded in the plane of their minor axes and meeting the requirements of Subsection NF shall result in a maximum bending stress:

$$F_b = 0.66 \times F_y$$

If meeting the requirements of this member of:

   a. Width-thickness ratio of unstiffened projecting elements of the compression flange shall not exceed $65/\sqrt{F_y}$.
   b. Width-thickness ratio of stiffened elements of the compression flange shall not exceed $190/\sqrt{F_y}$.
   c. The depth-thickness ratio of the web shall not exceed

      $d/t = (640/\sqrt{F_y})[1 - 3.74(f_a/F_y)]$ when $f_a/F_y \le 0.16$

      $d/t = 257/\sqrt{F_y}$ when $f_a/F_y > 0.16$

   d. The laterally unsupported length of the compression flange of members other than box-shaped members shall not exceed the value of $76b_f/\sqrt{F_y}$ nor $20,000/(d/A_f)F_y$.

2. For noncompact and slender elements, NF-3322.1(d)(5) and NF-3322.1(d)(3) are followed respectively.
3. For box-type flexural members, maximum bending stress is:

   $F_b = 0.60 \times F_y$

B. Along Minor Axis:

   a. For doubly symmetrical members (I shaped) meeting the requirements of NF-3322.1(d)(1)(a) and (b), maximum tensile and compressive bending stress shall not exceed:

      $F_b = 0.75 \times F_y$

   b. For doubly symmetrical members (I shaped) meeting the requirements of NF-3322.1(d)(1)(a), except where $b_f/2t_f$ exceeds $65/\sqrt{F_y}$ but is less than $95/\sqrt{F_y}$, maximum tensile and compressive bending stress shall not exceed:

      $F_b = F_y[1.075 - 0.005(b_f/2t_f)\sqrt{F_y}]$

D1.L.3.2.5 Combined Interaction Check

Members subjected to both axial compression and bending stresses are proportioned to satisfy

$$\frac{f_a}{F_a} + \frac{C_{mz} f_{bz}}{(1 - f_a/F'_{ex})F_{bx}} + \frac{C_{my} f_{by}}{(1 - f_a/F'_{ey})F_{by}} \le 1.0$$

and

$$\frac{f_a}{0.60F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} \le 1.0$$

when $f_a/F_a > 0.15$, otherwise

$$\frac{f_a}{F_a} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} \le 1.0$$

It should be noted that during code checking or member selection, if f_a/F_a exceeds unity, the program does not compute the second and third part of the formula, because this would result in a misleadingly liberal ratio. The value of the coefficient Cm is taken as 0.85 for side-sway and $0.6 - 0.4 \cdot (M1/M2)$, but not less than 0.4 for no side-sway.

Members subjected to both axial tension and bending stress are proportioned to satisfy

$$\frac{f_a}{0.60F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} \le 1.0$$

D1.L.3.2.6 Shear Stress

Allowable shear stress on the gross section [ref. NF-3322.6(e)(2)] is calculated as

$$F_v = (F_y/2.89)C_v \le 0.4F_y$$

where

C_v = $\frac{45,000k}{F_y(h/t)^2}$ when $h/b \leq 0.8$

$= \frac{190}{h/t}\sqrt{\frac{k}{F_y}}$ when $h/b > 0.8$

k = $4.00 + 5.34/(a/h)^2$ when $a/h \leq 1.0$

$= 5.34 + 4.00/(a/h)^2$ when $a/h > 1.0$

For actual shear on the web, the gross section is taken as the product of the total depth and the web thickness. For shear on the flanges, the gross section is taken as the total flange areas.

D1.L.3.3 Member Property Specification

For specification of member properties, the specified steel section available in Steel Section Library of STAAD.Pro may be used namely — I-shaped section, Channel, Tee, HSS Tube, HSS Pipe, Angle, Double Angle, Double Channel section.

Member properties may also be specified using the User Table facility except for the General and Prismatic member.

For more information on these facilities, refer to G.6 Member Properties (on page 2113) .

D1.L.3.4 Design Parameters

The program contains a large number of parameter names which are required to perform design and code checks. These parameter names, with their default values, are listed in the following table.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements for an analysis, some or all of these parameter values may have to be changed to exactly model the physical structure. For example, by default the KZ value (k value in local z-axis) of a member is set to 1.0, while in the real structure it may be 1.5. In that case, the KZ value in the program can be changed to 1.5, as shown in the input instruction (Section 5). Similarly, the TRACK value of a member is set to 0.0, which means no allowable stresses of the member will be printed. If the allowable stresses are to be printed, the TRACK value must be set to 1.0.

Note: Unlike many other design codes available in STAAD.Pro (which use the `BEAM` parameter), design per ASME NF 3000 codes in STAAD.Pro is *always* performed based on forces calculated at 13 sections, including ends.

Table 106: ASME NF 3000 1998 Design Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `NF3000 1998`. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).

Parameter Name	Default Value	Description
CAN	0	Used for Deflection Check only. 0 = Deflection check based on the principle that maximum deflection occurs within the span between DJ1 and DJ2. 1 = Deflection check based on the principle that maximum deflection is of the cantilever type
CB	1.0	Bending coefficient dependent upon moment gradient 0.0 = CB is calculated itself Any other user-defined value is accepted.
CMY CMZ	0.85 for sidesway and calculated for no sidesway	Cm value in local y & z axes
CT	0.75	Reduction Coefficient in computing effective net area of an axially loaded tension member. [Refer NF-3322.8(c)(1)(d)]
DFF	None(Mandatory for deflection check)	"Deflection Length" / Maximum allowable local deflection
DJ1	Start Jointof member	Joint No. denoting starting point for calculation of "Deflection Length"
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length"
DMAX	45 inch	Maximum allowable depth, in current units. Used only with the MEMBER SELECTION command.
DMIN	0.0 inch	Minimum allowable depth, in current units. Used only with the MEMBER SELECTION command.
FYLD	36 KSI	Yield strength of steel at temperature in current units.
FU	60 KSI	Ultimate tensile strength of steel in current units.

Parameter Name	Default Value	Description
KBK	1.0	Stress Limit Factor applicable to the Design Allowable Compressive Axial and Bending stresses to determine the Buckling Limit. **Note:** Ignored unless SRL is set to D.
KS	1.0	Stress Limit Factor applicable to the Design Allowable Tensile and Bending Stresses. **Note:** Ignored unless SRL is set to D.
KV	1.0	Stress Limit Factor applicable to the Design Allowable Shear Stresses. **Note:** Ignored unless SRL is set to D.
KY	1.0	K value in local y-axis. Usually, this is minor axis.
KZ	1.0	K value in local z-axis. Usually, this is major axis.
LY	Member Length	Length to calculate slenderness ratio for buckling about local Y axis.
LZ	Member Length	Same as above except in z-axis (major).
MAIN	0.0	0.0 = check for slenderness 1.0 = suppress slenderness check
NSF	1.0	Net Section Factor for tension member.
PROFILE	None	Used in member selection. See TR. 48.1 Parameter Specifications (on page 2676) for details.
RATIO	1.0	Permissible ratio of the actual to allowable stresses.

Parameter Name	Default Value	Description
SRL	A	Service level, which defines the service level factors to use for modifying stress values for the service level conditions. **A.** Normal Conditions **B.** Upset **C.** Emergency **D.** Faulted - If any of KS, KV, or KBK parameters are not set, a warning is issued that these must be user-defined. Refer to D1.L.5. ASME NF 3000 Service Level Conditions (on page 1348) for additional information.
STIFF	Member length or depth whichever is greater	Spacing of stiffeners for plate girder design
STYPE	0.0	0.0 = Normal Steel 1.0 = Austenitic Stainless Steel
TMAIN	240 for main member 300 for "Truss" member	Slenderness limit under tension
TRACK	0.0	Controls the levels of detail to which results are reported. 0 = Minimum detail 1 = Intermediate detail level 2 = Maximum detail
UNB	Member Length	Unsupported length of the bottom* flange for calculating allowable bending compressive stress. Will be used only if flexural compression on the bottom flange.
UNT	Member Length	Unsupported length of the top* flange for calculating allowable bending compressive stress. Will be used only if flexural compression on the top flange.

Notes

1. All values are entered in the current units.

2. The parameters DMAX and DMIN are only used with the MEMBER SELECTION command.

D1.L.3.5 Code Checking and Member Selection

Both code checking and member selection options are available with the ASME NF-3000 1998 code.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D1.L.3.6 Example

A cantilever beam of length 100 inch is loaded at its free end with 5 kip compressive load and a uniformly distributed load of 1 kip/inch over the whole span. The beam is assigned with B571806 steel member and is designed in accordance with ASME NF3000 1998.

D1.L.4. ASME NF 3000 - 2001 & 2004 Codes

STAAD.Pro is capable of performing steel design based on the American Society of Mechanical Engineers *Nuclear Facility Code*, ASME NF 3000 - 2004.

Note: Use of 2004 edition requires STAAD.Pro V8i (SELECTseries 2) NRC (build 20.07.07.30) or higher. Use of 2001 edition requires STAAD.Pro V8i (SELECTseries 3) NRC (build 20.07.08.22) or higher.

Design of members per ASME NF 3000 - 2001 & 2004 requires the *STAAD Nuclear Design Codes* SELECT Code Pack.

Related Links

D1.L.4.1 Design Process

The design process follows the following design checks.

Each one of the checks is described in the following sections.

When a design is performed, the output file the reports the maximum utilization from all of the checks.

D1.L.4.1.1 Slenderness

As per NF-3322.2(c), the slenderness ratio KL/r of compression members shall not exceed 200, and the slenderness ratio L/r of tension members, preferably should not exceed 240 for main members and 300 for lateral bracing members and other secondary members. The default limit for TRUSS members in Tension is set at 300.

D1.L.4.1.2 Tension

Allowable tensile stress on the Net section is calculated as ($0.60 \times F_y$), but not more than ($0.5 \times F_u$) on the Effective Net area.

The Net Area (A_n) shall be determined in accordance with NF-3322.8(c)(1) - (a), (b) and (c), and the NSF parameter can be utilized for that.

The Effective Net Area (A_e) of axially loaded tension members, where the load is transmitted by bolts through some but not all of the cross-sectional elements of the member, shall be computed from the formula (ref. NF-3322.8(c)(1)(d)),

$$A_e = C_t \times A_n$$

Unless otherwise specified, the default value of the CT parameter is set as 0.75.

The value of CT parameter for other conditions is described at section NF-3322.8(c)(1)(d)(1), (2) and (3).

The provisions for Pin-connected and Threaded tensile member are not implemented in STAAD.

D1.L.4.1.3 Compression

The allowable compressive stress for columns, except those fabricated from austenitic stainless steel shall be as required by NF-3322.1(c)(1). The allowable compressive stress for columns fabricated from austenitic stainless steel shall be as required by NF-3322.1(c)(2). The allowable compressive stress for member elements other than columns constructed by any material, including austenitic stainless steel, shall be as required by NF-3322.1(c)(3).

A. Gross Sections of Columns, except those fabricated of austenitic stainless steel:

a. On gross section of axially loaded compression members, when $(Kl/r) < C_c$,

$$F_a = F_y \frac{\left[1 - \frac{(KL/r)^2}{2C_c^2}\right]}{5/3 + \frac{3(KL/r)}{8C_c} - \frac{(KL/r)^3}{8C_c^3}}$$

Where:

$$C_c = \sqrt{\frac{2\pi^2 E}{F_y}}$$

b. When $(Kl/r) > C_c$,

$$F_a = \frac{12\pi^2 E}{23(KL/r)^2}$$

c. When $(Kl/r) > 120$,

$$F_{as} = \frac{F_a\left[Eq.(a1) \text{ or } Eq.(a2)\right]}{1.6 - \left(\frac{l}{200r}\right)}$$

B. Gross sections of columns fabricated from Austenitic Stainless steel:

a. When $(Kl/r) \leq 120$,

$$F_a = F_y[0.47 - (Kl/r)/444]$$

b. When $(Kl/r) > 120$,

$$F_a = F_y[0.40 - (Kl/r)/600]$$

C. Member elements other than columns:

a. For Plate Girder Stiffeners,

$$F_a = 0.60 \cdot F_y$$

b. For webs of rolled shapes,

$$F_a = 0.75 \cdot F_y$$

The above clauses are applicable only when the width-thickness ratio of the element satisfies all the sub-sections of NF-3322.2(d)..

If the above-mentioned clauses are not satisfied,

a. For un-stiffened compression element,

A reduction factor Q_s is introduced. Detailed values of Q_s for different shapes are given in NF-3322.2(e)(2)(a) to NF-3322.2(e)(2)(d).

In the case for angles or plates projecting from compression members and for projecting elements of compression flanges of girder,

When $95/(F_y/kc)^{1/2} < b/t < 195/(F_y/kc)^{1/2}$, $Q_s = 1.293 - 0.00309 \cdot (b/t) \cdot (F_y/kc)^{1/2}$

When $b/t > 195/(F_y/kc)^{1/2}$, $Q_s = 26{,}200 \cdot kc/[F_y(b/t)^2)]$

Where:

$kc = 4.05/[(h/t)^{0.46}]$ if $h/t > 70$, otherwise $kc = 1.0$.

b. For stiffened compression element,

A reduced effective width b_e is introduced.

a. For the flanges of square and rectangular sections of uniform thickness:

$$b_e = \frac{253t}{\sqrt{f}}\left[1 - \left(\frac{50.3}{(b/t)\sqrt{f}}\right)\right] \leq b$$

b. For other uniformly compressed elements:

$$b_e = \frac{253t}{\sqrt{f}}\left[1 - \left(\frac{44.3}{(b/t)\sqrt{f}}\right)\right] \leq b$$

Consequently, a reduction factor Q_a is introduced and is equal to the effective area divided by the actual area. Combining both these factors, allowable stress for axially loaded compression members containing stiffened or unstiffened elements shall not exceed

$$F_a = F_y \frac{Q_s Q_a\left[1 - \frac{(KL/r)^2}{2C'^2_c}\right]}{5\Big/3 + \frac{3(KL/r)}{8C'_c} - \frac{(KL/r)^3}{8C'^3_c}}$$

Where:

$$C'_c = \sqrt{\frac{2\pi^2 E}{Q_s Q_a F_y}}$$

The section is also checked that the stress is less than 2/3× the critical buckling stress, which is taken as the Euler critical buckling load divided by the cross sectional area:

$$F = \frac{2}{3}\frac{P_{\mathrm{cr}}}{A}$$

where

P_{cr} = the Euler critical buckling load of the column: $\frac{\pi^2 EI}{(KL)^2}$

D1.L.4.1.4 Bending Stress

Allowable bending stress for tension and compression for a structural member, as given in NF-3322.1(d) is:

A. Along Major Axis:

a. For Compact Sections, tension and compression on extreme fibres of compact hot rolled or built-up members symmetrical about and loaded in the plane of their minor axes and meeting the requirements of Subsection NF shall result in a maximum bending stress:

$F_b = 0.66 \times F_y$

If meeting the requirements of this member of:

a. Width-thickness ratio of unstiffened projecting elements of the compression flange shall not exceed $65/\sqrt{F_y}$.

b. Width-thickness ratio of stiffened elements of the compression flange shall not exceed $190/\sqrt{F_y}$.

c. The depth-thickness ratio of the web shall not exceed

$d/t = (640/\sqrt{F_y})[1 - 3.74(f_a/F_y)]$ when $f_a/F_y \le 0.16$

$d/t = 257/\sqrt{F_y}$ when $f_a/F_y > 0.16$

d. The laterally unsupported length of the compression flange of members other than box-shaped members shall not exceed the value of $76b_f/\sqrt{F_y}$ nor $20{,}000/(d/A_f)F_y$.

b. For noncompact and slender elements, NF-3322.1(d)(5) and NF-3322.1(d)(3) are followed respectively.

c. For box-type flexural members, maximum bending stress is:

$F_b = 0.60 \times F_y$

B. Along Minor Axis:

a. For doubly symmetrical members (I shaped) meeting the requirements of NF-3322.1(d)(1)(a) and (b), maximum tensile and compressive bending stress shall not exceed:

$F_b = 0.75 \times F_y$

b. For doubly symmetrical members (I shaped) meeting the requirements of NF-3322.1(d)(1)(a), except where $b_f/2t_f$ exceeds $65/\sqrt{F_y}$ but is less than $95/\sqrt{F_y}$, maximum tensile and compressive bending stress shall not exceed:

$F_b = F_y[1.075 - 0.005(b_f/2t_f)\sqrt{F_y}]$

D1.L.4.1.5 Combined Interaction Check

Members subjected to both axial compression and bending stresses are proportioned to satisfy

$$\frac{f_a}{F_a} + \frac{C_{mz} f_{bz}}{(1 - f_a/F'_{ex})F_{bx}} + \frac{C_{my} f_{by}}{(1 - f_a/F'_{ey})F_{by}} \le 1.0$$

and

$$\frac{f_a}{0.60F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} \le 1.0$$

when $f_a/F_a > 0.15$, otherwise

$$\frac{f_a}{F_a} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} \le 1.0$$

It should be noted that during code checking or member selection, if f_a/F_a exceeds unity, the program does not compute the second and third part of the formula, because this would result in a misleadingly liberal ratio. The value of the coefficient Cm is taken as 0.85 for side-sway and $0.6 - 0.4 \cdot (M1/M2)$, but not less than 0.4 for no side-sway.

Members subjected to both axial tension and bending stress are proportioned to satisfy

$$\frac{f_a}{0.60F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} \le 1.0$$

D1.L.4.1.6 Shear Stress

Allowable shear stress on the gross section [ref. NF-3322.6(e)(2)] is calculated as

$$F_v = (F_y/2.89)C_v \le 0.4F_y$$

where

C_v = $\frac{45,000k}{F_y(h/t)^2}$ when $h/b \le 0.8$

$$= \frac{190}{h/t}\sqrt{\frac{k}{F_y}} \text{ when } h/b > 0.8$$

$$k = 4.00 + 5.34/(a/h)^2 \text{ when } a/h \leq 1.0$$

$$= 5.34 + 4.00/(a/h)^2 \text{ when } a/h > 1.0$$

For actual shear on the web, the gross section is taken as the product of the total depth and the web thickness. For shear on the flanges, the gross section is taken as the total flange areas.

D1.L.4.2 Member Property Specification

For specification of member properties, the specified steel section available in Steel Section Library of STAAD.Pro may be used namely — I-shaped section, Channel, Tee, HSS Tube, HSS Pipe, Angle, Double Angle, Double Channel section.

Member properties may also be specified using the User Table facility except for the General and Prismatic member.

For more information on these facilities, refer to G.6 Member Properties (on page 2113) .

D1.L.4.3 Design Parameters

The program contains a large number of parameter names which are required to perform design and code checks. These parameter names, with their default values, are listed in the following table.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements for an analysis, some or all of these parameter values may have to be changed to exactly model the physical structure. For example, by default the KZ value (k value in local z-axis) of a member is set to 1.0, while in the real structure it may be 1.5. In that case, the KZ value in the program can be changed to 1.5, as shown in the input instruction (Section 5). Similarly, the `TRACK` value of a member is set to 0.0, which means no allowable stresses of the member will be printed. If the allowable stresses are to be printed, the `TRACK` value must be set to 1.0.

Note: Unlike many other design codes available in STAAD.Pro (which use the `BEAM` parameter), design per ASME NF 3000 codes in STAAD.Pro is *always* performed based on forces calculated at 13 sections, including ends.

Table 107: ASME NF 3000 2001 & 2004 Design Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `NF3000 2001` or `NF3000 2004` Specified design code is followed for code checking purpose. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).

Parameter Name	Default Value	Description
CAN	0	Used for Deflection Check only. 0 = Deflection check based on the principle that maximum deflection occurs within the span between DJ1 and DJ2. 1 = Deflection check based on the principle that maximum deflection is of the cantilever type
CB	1.0	Bending coefficient dependent upon moment gradient 0.0 = CB is calculated itself Any other user-defined value is accepted.
CMY CMZ	0.85 for sidesway and calculated for no sidesway	Cm value in local y & z axes
CT	0.75	Reduction Coefficient in computing effective net area of an axially loaded tension member. [Refer NF-3322.8(c)(1)(d)]
DFF	None (Mandatory for deflection check)	"Deflection Length" / Maximum allowable local deflection
DJ1	Start Joint of the member	Joint No. denoting starting point for calculation of "Deflection Length"
DJ2	End Joint of the member	Joint No. denoting end point for calculation of "Deflection Length"
DMAX	45 inch	Maximum allowable depth
DMIN	0.0 inch	Minimum allowable depth
FYLD	36 KSI	Yield strength of steel at temperature in current units.
FU	60 KSI	Ultimate tensile strength of steel in current units.

Parameter Name	Default Value	Description
KBK	1.0	Stress Limit Factor applicable to the Design Allowable Compressive Axial and Bending stresses to determine the Buckling Limit. **Note:** Ignored unless SRL is set to D.
KS	1.0	Stress Limit Factor applicable to the Design Allowable Tensile and Bending Stresses. **Note:** Ignored unless SRL is set to D.
KV	1.0	Stress Limit Factor applicable to the Design Allowable Shear Stresses. **Note:** Ignored unless SRL is set to D.
KY	1.0	K value in local y-axis. Usually, this is minor axis.
KZ	1.0	K value in local z-axis. Usually, this is major axis.
LY	Member Length	Length to calculate slenderness ratio for buckling about local Y axis.
LZ	Member Length	Same as above except in z-axis (major).
MAIN	0.0	0.0 = check for slenderness 1.0 = suppress slenderness check
NSF	1.0	Net Section Factor for tension member.
PROFILE	None	Used in member selection. See TR. 48.1 Parameter Specifications (on page 2676) for details.
RATIO	1.0	Permissible ratio of the actual to allowable stresses.

Parameter Name	Default Value	Description
SRL	A	Service level, which defines the service level factors to use for modifying stress values for the service level conditions. **A.** Normal Conditions **B.** Upset **C.** Emergency **D.** Faulted - If any of KS, KV, or KBK parameters are not set, a warning is issued that these must be user-defined. Refer to D1.L.5. ASME NF 3000 Service Level Conditions (on page 1348) for additional information.
STIFF	Member length or depth whichever is greater	Spacing of stiffeners for plate girder design
STYPE	0.0	0.0 = Normal Steel 1.0 = Austenitic Stainless Steel
TMAIN	240 for main member 300 for "Truss" member	Slenderness limit under tension
TRACK	0.0	Controls the levels of detail to which results are reported. • Minimum detail • Intermediate detail level • Maximum detail
UNB	Member Length	Unsupported length of the bottom* flange for calculating allowable bending compressive stress. Will be used only if flexural compression on the bottom flange.
UNT	Member Length	Unsupported length of the top* flange for calculating allowable bending compressive stress. Will be used only if flexural compression on the top flange.

Notes

1. All values are entered in the current units.

2. The parameters DMAX and DMIN are only used with the MEMBER SELECTION command.

D1.L.5. ASME NF 3000 Service Level Conditions

Service Level Conditions are basically the loading conditions for which the plant structure and its components are to be designed. The same primary load can be multiplied by different factors to signify the different service levels. Also the load combinations for various service levels are different and pre-defined by the code.

D1.L.5.1 Service Levels

The following is a short overview of each of the service levels specified by the code:

Condition	Description
A. Normal Working	
B. Upset	This situation can be termed as a short term failure or a local failure, and the repairing or modification of the structure can be done without shutting the entire plant.
C. Emergency	This situation can be termed as a major failure, and the repairing of the structure can be done only after shutting down the entire plant.
D. Faulted	This situation can be termed as devastation, and the main objective of this level is to have sufficient time for safe relocation of human life and valuable properties, and to initiate the controlled failure of the plant structure. The plant is already at an unusable state and a rare chance to repair it back into the operation.

These Service Levels are the attribute of the whole structure or the structural system. So, the existence of different Service Levels to the different parts of the structure at the same point of time is totally ruled out.

The Service Level Factors are basically few multiplying factor by which the Allowable Stress values are to be multiplied based on the Service Level. The different actions (e.g., Tension, Compression, Bending, Shear etc.) have different Service Level Factors.

However, this is to be noted, the stipulated multiplying factors for creating load combinations for Service Level B, C, and D are to be user defined in this case. The facility of creating Auto Load Combination for different Service Levels is out of the scope of this implementation. The user has to take care of this.

D1.L.5.2 Stress Level Factors

For the Member Design, as per Clause NF-3321.1, the Allowable Stresses may be increased by the Factors as per Table NF-3523(b)-1 and NF-3623(b)-1. Table NF-3523(b)-1 is applicable to Component Support Structures and Table NF-3623(b)-1 is applicable to Piping Support Structures. However, as the values are the same for the service level factors in each table, STAAD.Pro does not make any differentiation between component and piping supports.

Note: Clause NF-3321.1 also indicates that the allowable stress shall be limited to two-thirds (2/3x) the critical buckling stress. However, the critical buckling stress is not clearly defined so it is left to the user to ensure that this code requirement is met.

The values used for the stress level factors in STAAD.Pro are as follows:

Service Level	Ks	Kv	Kbk
A	1.0	1.0	1.0

Service Level	Ks	Kv	Kbk
B	1.33	1.33	1.33
C	1.50	1.50	1.50
D*	KS	KV	KBK

* It is evident from the Table NF-3523(b)-1, that there are no predefined Stress Limit Factors for Service Level D. So, for Service Level D, the Factors Ks, Kv and Kbk are to be user defined. Refer to Appendix F in the code for guidance on values to specify in the design parameters.

where

Ks Stress Limit Factor applicable to the Design Allowable Tensile and Bending Stresses.

Kv Stress Limit Factor applicable to the Design Allowable Shear Stresses

Kbk Stress Limit Factor applicable to the Design Allowable Compressive Axial and Bending stresses to determine the Buckling Limit.

The program uses the service level factors —either those specified for levels A through C or the user defined values in level D— as follows:

- The Allowable Axial Tensile Stress is to be multiplied by Ks
- The Allowable Axial Compressive Stress is to be multiplied by Kbk
- The Allowable Bending Stress is to be multiplied by Ks
- The Allowable Shear Stress is to be multiplied by Kv
- As per NF-3322.1.(e), for checking Combined Stresses as per equation 20, the value of $F'ey$ and $F'ez$ — the Euler Stress divided by the factor of safety, may also be multiplied by the appropriate Stress Limit Factor. This is also implemented. $F'e$ is to be multiplied by Kbk.

D2. Australian Codes

D2.A. Australian Codes - Concrete Design per AS 3600 - 2001

STAAD.Pro is capable of performing concrete design based on the Australian code AS 3600-2001 *Australian Standard-Concrete Structures*.

D2.A.1 Section Types for Concrete Design

The following types of cross sections for concrete members can be designed.

- For Beams: Prismatic (Rectangular & Square)
- For Columns: Prismatic (Rectangular, Square, and Circular)

D2.A.2 Member Dimensions

Concrete members which will be designed by the program must have certain section properties input under the `MEMBER PROPERTY` command. The following example shows the required input:

```
UNIT MM
MEMBER PROPERTY
1 3 TO 7 9 PRISM YD 450. ZD 250.
11 13 PR YD 350.
```

In the above input, the first set of members are rectangular (450 mm depth and 250mm width) and the second set of members, with only depth and no width provided, will be assumed to be circular with 350 mm diameter. It is absolutely imperative that the user not provide the cross section area (AX) as an input.

D2.A.3 Design Parameters

The program contains a number of parameters which are needed to perform the design. Default parameter values have been selected such that they are frequently used numbers for conventional design requirements. These values may be changed to suit the particular design being performed. Table 1A.1 of this manual contains a complete list of the available parameters and their default values. It is necessary to declare length and force units as Millimeter and Newton before performing the concrete design.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 108: Australian Concrete Design per AS 3600 Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `AUSTRALIAN` to invokes design per AS 3600 - 2001. Design code to follow. See TR.53.2 Concrete Design-Parameter Specification (on page 2685).
CLB	40 mm	Clear cover for outermost bottom reinforcement.
CLS	40 mm	Clear cover for outermost side reinforcement.
CLT	40 mm	Clear cover for outermost top reinforcement.
DEPTH	YD	Total depth to be used for design. This value defaults to YD as provided under `MEMBER PROPERTIES`.

Parameter Name	Default Value	Description
EFACE	0	Distance from end node of beam to face of support used for shear design; used for shear and torsion calculations.
FC	30 N/mm^2	Compressive strength of concrete.
FYMAIN	400 N/mm^2	Yield Stress for main reinforcing steel. Applicable values per Table 6.2.1 of AS 3600-2001: 250 400 450 500
FYSEC	400 N/mm^2	Yield Stress for secondary reinforcing steel. Applicable values per Table 6.2.1 of AS 3600-2001: 250 400 450 500
MAXMAIN	12 mm	Maximum main reinforcement bar size.
MINMAIN	12 mm	Minimum main reinforcement bar size.
MINSEC	12 mm	Minimum secondary reinforcement bar size.
MMAG	1	Factor by which column design moments are magnified.
RATIO	4.0	Maximum percentage of longitudinal reinforcement in columns.
NSECTION	12	Number of equally spaced sections for design.
SFACE	0	Distance from start node of beam to face of support used for shear design; used for shear and torsion calculations.

Parameter Name	Default Value	Description
TRACK	0.0	For beam design: 0.0 = output consists of reinforcement details at the member start, middle, and end 1.0 = critical moments are printed in addition to `TRACK 0.0` output 2.0 = required steel for intermediate sections defined by `NSECTION` are printedin addition to `TRACK 0.0` output For column design: 0.0 = reinforcement details are printed
WIDTH	ZD	Width to be used for design. This value defaults to ZD as provided under MEMBER PROPERTIES.

D2.A.4 Slenderness Effects and Analysis Consideration

Slenderness effects are extremely important in designing compression members. There are two options by which the slenderness effect can be accommodated. One option is to perform an exact analysis which will take into account the influence of axial loads and variable moment of inertia on member stiffness and fixed end moments, the effect of deflections on moment and forces and the effect of the duration of loads. Another option is to approximately magnify design moments.

STAAD.Pro has been written to allow the use of the first option. To perform this type of analysis, use the command `PDELTA ANALYSIS` instead of `PERFORM ANALYSIS`. The `PDELTA ANALYSIS` will accommodate the requirements of the second- order analysis described by AS 3600, except for the effects of the duration of the loads. It is felt that this effect may be safely ignored because experts believe that the effects of the duration of loads are negligible in a normal structural configuration.

Although ignoring load duration effects is somewhat of an approximation, it must be realized that the evaluation of slenderness effects is also by an approximate method. In this method, additional moments are calculated based on empirical formula and assumptions on sidesway.

Considering all of the above information, a P-Delta analysis —as performed by STAAD— may be used for the design of concrete members. However the user must note that to take advantage of this analysis, all the combinations of loading must be provided as primary load cases and not as load combinations. This is due to the fact that load combinations are just algebraic combinations of forces and moments, whereas a primary load case is revised during the P-delta analysis based on the deflections. Also, note that the proper factored loads (like 1.5 for dead load etc.) should be provided by the user. STAAD.Pro does *not* factor the loads automatically.

D2.A.5 Beam Design

Beams are designed for flexure, shear and torsion. For all these forces, all active beam loadings are prescanned to identify the critical load cases at different sections of the beams. The total number of sections considered is 13 (e.g., 0., .1, .2, .25, .3, .4, .5, .6, .7, .75, .8, .9, and 1). All of these sections are scanned to determine the design force envelopes.

D2.A.5.1 Design for Flexure

Maximum sagging (creating tensile stress at the bottom face of the beam) and hogging (creating tensile stress at the top face) moments are calculated for all active load cases at each of the above mentioned sections. Each of these sections is designed to resist both of these critical sagging and hogging moments. Currently, design of singly reinforced sections only is permitted. If the section dimensions are inadequate as a singly reinforced section, such a message will be permitted in the output. Flexural design of beams is performed in two passes. In the first pass, effective depths of the sections are determined with the assumption of single layer of assumed reinforcement and reinforcement requirements are calculated. After the preliminary design, reinforcing bars are chosen from the internal database in single or multiple layers. The entire flexure design is performed again in a second pass taking into account the changed effective depths of sections calculated on the basis of reinforcement provided after the preliminary design. Final provisions of flexural reinforcements are made then. Efforts have been made to meet the guideline for the curtailment of reinforcements as per AS 3600. Although exact curtailment lengths are not mentioned explicitly in the design output (finally which will be more or less guided by the detailer taking into account of other practical consideration), user has the choice of printing reinforcements provided by STAAD at 13 equally spaced sections from which the final detailed drawing can be prepared.

D2.A.5.2 Design for Shear

Shear reinforcement is calculated to resist both shear forces and torsional moments. Shear design is performed at 13 equally spaced sections (0. to 1.) for the maximum shear forces amongst the active load cases and the associated torsional moments. Shear capacity calculation at different sections without the shear reinforcement is based on the actual tensile reinforcement provided by STAAD. Two-legged stirrups are provided to take care of the balance shear forces acting on these sections.

Example of Input Data for Beam Design:

```
UNIT NEWTON MMS
START CONCRETE DESIGN
CODE AUSTRALIAN
FYMAIN 415 ALL
FYSEC 415 ALL
FC 35 ALL
CLEAR 25 MEM 2 TO 6
MAXMAIN 40 MEMB 2 TO 6
TRACK 1.0 MEMB 2 TO 9
DESIGN BEAM 2 TO 9
END CONCRETE DESIGN
```

D2.A.6 Column Design

Columns are designed for axial forces and biaxial moments at the ends. All active load cases are tested to calculate reinforcement. The loading which yields maximum reinforcement is called the critical load. Column design is done for square, rectangular and circular sections. By default, square and rectangular columns are designed with reinforcement distributed on each side equally. That means the total number of bars will always be a multiple of four (4). This may cause slightly conservative results in some cases. All major criteria for selecting longitudinal and transverse reinforcement as stipulated by AS 3600 have been taken care of in the column design of STAAD.

Example of Input Data for Column Design:

```
UNIT NEWTON MMS
START CONCRETE DESIGN
CODE AUSTRALIAN
FYMAIN 415 ALL
FC 35 ALL
CLEAR 25 MEMB 2 TO 6
MAXMAIN 40 MEMB 2 TO 6
DESIGN COLUMN 2 TO 6
END CONCRETE DESIGN
```

D2.A.7 Slab or Wall Design

To design a slab or wall, it must be modeled using finite elements. The command specifications are in accordance with Chapter 2 and Chapter 6 of the specification.

Elements are designed for the moments Mx and My. These moments are obtained from the element force output. The reinforcement required to resist Mx moment is denoted as longitudinal reinforcement and the reinforcement required to resist My moment is denoted as transverse reinforcement. The parameters `FYMAIN`, `FC`, `MAXMAIN`, `MINMAIN`, and `CLEAR` listed in D2.A.3 Design Parameters (on page 1351) are relevant to slab design. Other parameters mentioned in Table 1A.1 are not applicable to slab design.

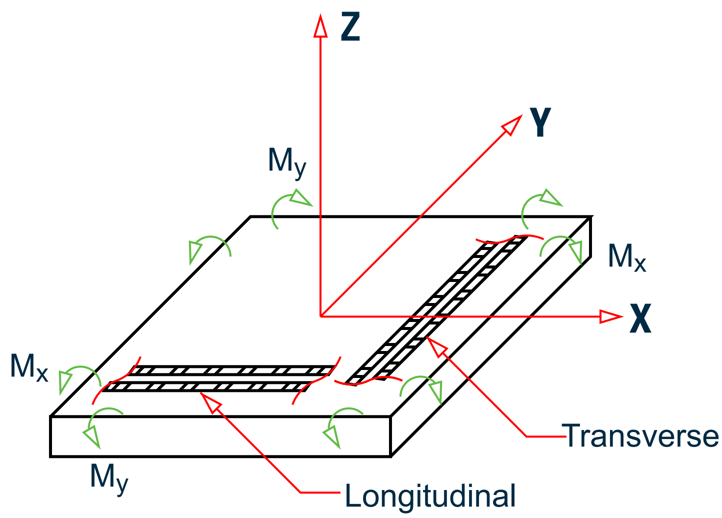

Figure 160: Element moments: Longitudinal (L) and Transverse (T)

Example of Input Data for Slab/Wall Design

```
UNIT NEWTON MMS
START CONCRETE DESIGN
CODE AUSTRALIAN
FYMAIN 415 ALL
```

```
FC 25 ALL
CLEAR 40 ALL
DESIGN ELEMENT 15 TO 20
END CONCRETE DESIGN
```

D2.B. Australian Codes - Steel Design per AS 4100 - 1998

STAAD.Pro is capable of performing steel design based on the Australian code AS 4100-1998 *Standards Australia - Steel Structural Design* , including Amendment 1 (2012).

Related Links

- *V. AS4100 1998 - Bending Capacity* (on page 3803)
- *V. AS4100 1998 - Single Angle Section in Tension* (on page 3836)

D2.B.1 General

The design philosophy embodied in this specification is based on the concept of limit state design. Structures are designed and proportioned taking into consideration the limit states at which they would become unfit for their intended use. Two major categories of limit-state are recognized - ultimate and serviceability. The primary considerations in ultimate limit state design are strength and stability, while that in serviceability is deflection. Appropriate load and resistance factors are used so that a uniform reliability is achieved for all steel structures under various loading conditions and at the same time the chances of limits being surpassed are acceptably remote.

In the STAAD implementation, members are proportioned to resist the design loads without exceeding the limit states of strength, stability, and serviceability. Accordingly, the most economic section is selected on the basis of the least weight criteria as augmented by the designer in specification of allowable member depths, desired section type, or other such parameters. The code checking portion of the program checks whether code requirements for each selected section are met and identifies the governing criteria.

The following sections describe the salient features of the STAAD implementation of AS 4100. A detailed description of the design process along with its underlying concepts and assumptions is available in the specification document.

D2.B.1.1 Strength Limit States

Strength design capacities (ϕRu) are calculated and compared to user-defined design action effects ($S*$), so as to ensure that $S* \leq \phi Ru$ in accordance with AS 4100 3.4. Details for design capacity calculations are outlined in the sections that follow.

D2.B.1.2 Deflection Limit States

STAAD.Pro’s AS 4100 implementation does not generally check deflections. It is left to the user to check that both local member and frame deflections are within acceptable limits.

Note: Local member deflections parallel to the local member y-axis can be checked against a user-defined maximum “span / deflection” ratio. This can be performed using the `DFF`, `DJ1`, and `DJ2` design parameters, however this is only available for `MEMBER` Design. Details are provided in the sections that follow.

D2.B.1.3 Eccentric Beam Reactions

STAAD.Pro does not automatically account for minimum eccentricity distances for beam reactions being transferred to columns as per AS 4100 4.3.4. However member offsets can be used to model these eccentricities.

Refer to TR.25.1 Member Offset Specification (on page 2296) for further information on the Member Offset feature.

D2.B.1.4 Limit States Not Considered

The following limit states are not directly considered in STAAD.Pro's implementation of AS 4100.

Table 109: Limit States Not Considered in STAAD.Pro AS 4100 Design

Limit State	Code Reference
Stability	AS 4100 3.3
Serviceability	AS 4100 3.5
Brittle Fracture	AS 4100 3.7
Fire	AS 4100 3.9
Other Design Requirements	AS 4100 3.11

D2.B.1.5 Connection Design

STAAD.Pro and Bentley's RAM Connection program currently do *not* support design of connections in accordance with AS 4100. In some cases connection design may govern the size of members. Such considerations are not considered in STAAD.Pro's AS 4100 and should be checked by separately.

D2.B.1.6 Bolts and Welds

Bolt holes and welds are not generally considered in STAAD.Pro's AS 4100 member design.

Note: NSC and NSF D2.B.8 Design Parameters (on page 1364) are used to manually specify a reduction in net section area for compression or tension capacity calculations. These can be used to account for bolt hole area reductions. Further details are provided in the sections that follow.

D2.B.2 Analysis Methodology

Either the elastic or dynamic analysis methods may be used to obtain the forces and moments for design as per AS 4100 section 4.4. Analysis is done for the specified primary and repeat loading conditions. Therefore, it is your responsibility to enter all necessary loads and load combination factors for design in accordance with the AS/NZS 1170 Series or other relevant design codes. You are allowed complete flexibility in providing loading specifications and using appropriate load factors to create necessary loading situations. Depending upon the analysis requirements, regular stiffness analysis or P-Delta analysis may be specified. Dynamic analysis may also be performed and the results combined with static analysis results.

Note: Plastic analysis and design in accordance with AS 4100 section 4.5 is not implemented in STAAD.Pro.

D2.B.2.1 Elastic Analysis

Two types of elastic analysis can be performed using STAAD.Pro in accordance with AS 4100:

i. First Order Linear, Elastic Analysis - used to perform a regular elastic stiffness analysis as per AS 4100 4.4.2.1. Refer to TR.37.1 Linear Elastic Analysis (on page 2620) for additional details on this feature.
ii. Second Order PDelta Linear, Elastic Analysis - Depending on the type of structure, a PDelta analysis may be required in order to capture second-order effects as per AS 4100 4.4.1.2. Second-order effects can be captured in STAAD.Pro by performing a PDelta second-order elastic analysis as per AS 4100 Appendix E. Refer to TR.37.2 P-Delta Analysis Options (on page 2621) for additional details on this feature.

> **Note:** Moment amplification as per AS 4100 clause 4.4.2 is not considered.

> **Tip:** In order to correctly capture second-order effects for combination load cases using a PDelta Analysis, the Repeat Load feature must be used. Second-order effects will not be correctly evaluated if the Load Combination feature is used. Load Combinations are combinations of results where Repeat Loads instruct the program to perform the analysis on the combined load actions. Refer to TR.32.11 Repeat Load Specification (on page 2595) for additional details on using Repeat Loads.

D2.B.2.2 Dynamic Analysis

Dynamic analysis may also be performed and the results combined with static analysis results. Refer TR.32.10 Dynamic Loading Specification (on page 2498) for further information on Dynamic Loading and Analysis features.

D2.B.3 Member Property Specifications

For specification of member properties, either the steel section library available in STAAD or the User Table facility may be used. The next section describes the syntax of commands used to assign properties from the built-in steel table. For more information on these facilities, refer to G.6 Member Properties (on page 2113) .

D2.B.4 Built-in Steel Section Library

The following information is provided for use when the built-in steel tables are to be referenced for member property specification. These properties are stored in a database file. If called for, the properties are also used for member design. Since the shear areas are built into these tables, shear deformation is always considered during the analysis of these members. An example of the member property specification in an input file is provided at the end of this section.

A complete listing of the sections available in the built-in steel section library may be obtained by using the tools of the graphical user interface.

Table 110: Available Australian Sections for STAAD.Pro AS 4100 Design

General Profile Type	Australian Sections	Description
I-SECTION	WB, WC	Welded beams and columns
	UB, UC	Universal beams and columns
T-SECTION	BT, CT	Tees cut from universal beams and columns

General Profile Type	Australian Sections	Description
CHANNEL	PFC	Parallel flange channels
ANGLE	EA, UA	Equal and unequal angles
TUBE	SHS, RHS	Square and rectangular hollow sections
PIPE	CHS	Circular hollow sections

Note: STAAD.Pro will not design the following section types to AS 4100: Double Profiles (D), Composite Sections (C), Top Cover Plates (TC), Bottom Cover Plates (BC), and Top & Bottom Cover Plates (TB), Double Channels (D, BA, & FR) and Double Angles (LD & SD). Refer to Section Profile Tables in the Graphical Environment for these options.

Tip: When adding and assigning sections using the built-in steel section library through the Graphical Environment, STAAD.Pro's default tables are American. To change the default tables to Australian, select **File** > **Configuration** from the STAAD.Pro Start page (no input file open). Set the Default Profile Table to Australian on the Configure Program dialog Section Profile Table.

Following are the descriptions of different types of sections.

Refer to G.6.2 Built-In Steel Section Libraries (on page 2116) for additional information.

D2.B.4.1 UB Shapes

These shapes are designated in the following way.

```
20 TO 30 TA ST UB150X14.0
36 TO 46 TA ST UB180X16.1
```

D2.B.4.2 UC Shapes

The designation for the UC shapes is similar to that for the UB shapes.

```
25 TO 35 TA ST UC100X14.8
23 56 TA ST UC310X96.8
```

D2.B.4.3 Welded Beams

Welded Beams are designated in the following way.

```
25 TO 35 TA ST WB700X115
23 56 TA ST WB1200X455
```

D2.B.4.4 Welded Columns

Welded Columns are designated in the following way.

```
25 TO 35 TA ST WC400X114
23 56 TA ST WC400X303
```

D2.B.4.5 Parallel Flange Channels

Shown below is the syntax for assigning names of channel sections.

```
1 TO 5 TA ST PFC75
6 TO 10 TA ST PFC380
```

D2.B.4.6 Double Channels

Back-to-back double channels, with or without a spacing between them, are available. The letter D in front of the section name will specify a double channel.

```
11 TA D PFC230
17 TA D C230X75X25 SP 0.5
```

In the above set of commands, member 11 is a back-to-back double channel PFC230 with no spacing in between. Member 17 is a double channel PFC300 with a spacing of 0.5 length units between the channels.

D2.B.4.7 Angles

Two types of specification may be used to describe an angle. The standard angle section is specified as follows:

```
16 20 TA ST A30X30X6
```

The above section signifies an angle with legs of length 30 mm and a leg thickness of 6 mm. This specification may be used when the local Z axis corresponds to the z-z axis specified in Chapter 2. If the local Y axis corresponds to the z-z axis, type specification "RA" (reverse angle) may be used.

```
17 21 TA RA A150X150X16
```

Note: Single angles must be specified with an “RA” (Single Angle w/Reverse Y-Z Axis) in order to be designed to AS 4100. This is to ensure that the major and minor principal axes align with the local member z and y axes respectively, similar to other section profiles.

D2.B.4.8 Double Angles

Short leg back-to-back or long leg back-to-back double angles can be specified by means of input of the words SD or LD, respectively, in front of the angle size. In case of an equal angle, either SD or LD will serve the purpose.

```
33 35 TA SD A65X50X5 SP 0.6
37 39 TA LD A75X50X6
43 TO 47 TA LD A100X75X10 SP 0.75
```

D2.B.4.9 Tubes (Rectangular or Square Hollow Sections)

Tubes can be assigned in 2 ways. In the first method, the designation for the tube is as shown below. This method is meant for tubes whose property name is available in the steel table. In these examples, members 1 to 5 consist of a 2X2X0.5 inch size tube section, and members 6 to 10 consist of 10X5X0.1875 inch size tube section. The name is obtained as 10 times the depth, 10 times the width, and 16 times the thickness.

```
1 TO 5 TA ST TUB20202.5
6 TO 10 TA ST TUB100503.0
```

In the second method, tubes are specified by their dimensions. For example,

```
6 TA ST TUBE DT 8.0 WT 6.0 TH 0.5
```

is a tube that has a height of 8 length units, width of 6 length units, and a wall thickness of 0.5 length units. Only code checking, no member selection, will be performed for TUBE sections specified in this latter manner.

D2.B.4.10 Pipes (Circular Hollow Sections)

Pipes can be assigned in 2 ways. In the first method, the designation for the pipe is as shown below. This method is meant for pipes whose property name is available in the steel table.

```
1 TO 5 TA ST PIP180X5
6 TO 10 TA ST PIP273X6.5
```

In the second method, pipe sections may be provided by specifying the word PIPE followed by the outside and inside diameters of the section. For example,

```
1 TO 9 TA ST PIPE OD 25.0 ID 20.0
```

specifies a pipe with outside diameter of 25 length units and inside diameter of 20 length units. Only code checking, no member selection, will be performed on pipes specified in this latter manner.

D2.B.4.11 Sample File Containing Australian Shapes

D2.B.5 Section Classification

The AS 4100 specification allows inelastic deformation of section elements. Thus, local buckling becomes an important criterion. Steel sections are classified as compact, noncompact, or slender; depending upon their local buckling characteristics. This classification is a function of the geometric properties of the section. The design procedures are different depending on the section class. STAAD determines the section classification for the standard shapes and user specified shapes. Design is performed for all three categories of section described above.

D2.B.6 Material Properties

For specification of material properties, the user can use either:

a. built-in material constants
b. user-defined materials

Refer TR.26.2 Specifying Constants for Members and Elements (on page 2305) for further information on the Built-in Material Constants feature.

Refer TR.26.1 Define Material (on page 2303) for further information on the Define Material feature.

D2.B.6.1 Young's Modulus of Elasticity (E)

STAAD.Pro's default steel material's E value is 205,000 MPa. However AS 4100 section 1.4 states that the modulus of elasticity should be taken as 200,000 MPa. There are a number of options to change this value:

- change the steel material through the input file or GUI for each file created
- define a new steel material for each file created
- change the default STAAD.Pro metric E value in the file `C:/Windows/StaadPro20070.ini`, going to the "[Material-Metric]" section, and changing `E1=205.0e6` to `E1=200.0e6`. Restart STAAD.Pro for this to take effect.

> **Caution:** Virtualization features of Windows 7, Windows 8, and Windows 10 may require additional files to be modified. Contact Bentley Technical Support for assistance.

D2.B.7 Member Resistances

The member resistance is calculated in STAAD according to the procedures outlined in AS 4100. Calculated design capacities are compared to corresponding axial, bending moment, and shear forces determined from the STAAD.Pro analysis. These are used to report the fail or pass status for the members designed.

Two types of design checks are typically performed per AS 4100:

- Nominal section checks
- Nominal member checks

The nominal section capacity refers to the capacity of a cross-section to resists applied loads, and accounts for cross-section yielding and local buckling effects. The nominal member capacity on the other hand refers to the capacity of a member to resist applied loads, and includes checks for global member buckling effects including Euler buckling, lateral-torsional buckling, etc.

D2.B.7.1 Axial Tension

The criteria governing the capacity of tension members are based on two limit states per AS 4100 Section 7. The limit state of yielding of the gross section is intended to prevent excessive elongation of the member.

The second limit state involves fracture at the section with the minimum effective net area φN_t section axial tension capacities are calculated (Cl.7.2). Through the use of the `NSF` parameter (see D2.B.8 Design Parameters (on page 1364)), you may specify the net section area. STAAD calculates the tension capacity of a member based on these two limit states per Cl.7.1 and Cl.7.2 respectively of AS 4100. Eccentric end connections can be taken into account using the `KT` correction factor, perCl.7.3. The f_y yield stress is based on the minimum plate yield stress. Parameters `FYLD`, `FU`, and `NSF` are applicable for these calculations.

D2.B.7.2 Axial Compression

The compressive strength of members is based on limit states per AS 4100 Section 6. It is taken as the lesser of nominal section capacity and nominal member capacity. Nominal section capacity, φN_s , is a function of form factor (Cl.6.2.2), net area of the cross section, and yield stress of the material. Through the use of the `NSC` parameter (see D2.B.8 Design Parameters (on page 1364)), you may specify the net section area. Note that this parameter is different from that corresponding to tension. The program automatically calculates the form factor. The k_f form factors are calculated based on effective plate widths per Cl.6.2.4, and the f_y yield stress is based on the minimum plate yield stress.

Nominal member capacity, φN_c , is a function of nominal section capacity and member slenderness reduction factor (Cl.6.3.3). This value is calculated about both principal x and y axes. Here, you are required to supply the value of α_b (Cl.6.3.3) through the `ALB` parameter (see D2.B.8 Design Parameters (on page 1364)). The effective length for the calculation of compressive strength may be provided through the use of the parameters `KY`, `KZ`, `LY`, and `LZ` (see D2.B.8 Design Parameters (on page 1364)).

D2.B.7.3 Bending

Bending capacities are calculated to AS 4100 Section 5. The allowable bending moment of members is determined as the lesser of nominal section capacity and nominal member capacity (ref. Cl.5.1).

The nominal section moment capacity, φM_s, is calculated about both principal x and y axes and is the capacity to resist cross-section yielding or local buckling and is expressed as the product of the yield stress of the material and the effective section modulus (ref. Cl.5.2). The effective section modulus is a function of D2.B.5 Section Classification (on page 1361) (i.e., compact, noncompact, or slender) and minimum plate yield stress f_y. The nominal member capacity depends on overall flexural-torsional buckling of the member (ref.Cl.5.3).

Note: For sections where the web and flange yield stresses ($f^{y,web}$ and $f_{y.flange}$ respectively) are different, the lower of the two yield stresses is applied to both the web and flange to determine the slenderness of these elements.

Member moment capacity, φM_b , is calculated about the principal x axis only (ref. Cl.5.6). Critical flange effective cross-section restraints and corresponding design segment and sub-segments are used as the basis for calculating capacities.

D2.B.7.4 Interaction of Axial Force and Bending

Combined section bending and shear capacities are calculated using the shear and bending interaction method as per Cl.5.12.3.

Note: This check is only carried out where φV_v section web shear capacities are calculated. Refer Table 1B.6-1 for details.

The member strength for sections subjected to axial compression and uniaxial or biaxial bending is obtained through the use of interaction equations. Here, the adequacy of a member is also examined against both section (ref. Cl.8.3.4) and member capacity (ref.Cl.8.4.5). These account for both in-plane and out-of-plane failures. If the summation of the left hand side of the equations, addressed by the above clauses, exceeds 1.0 or the allowable value provided using the `RATIO` parameter (see D2.B.8 Design Parameters (on page 1364)), the member is considered to have FAILed under the loading condition.

D2.B.7.5 Shear

Section web shear capacity, φV_v , is calculated per Cl.5.11, including both shear yield and shear buckling capacities. Once the capacity is obtained, the ratio of the shear force acting on the cross section to the shear capacity of the section is calculated. If any of the ratios (for both local Y & Z-axes) exceed 1.0 or the allowable value provided using the `RATIO` parameter (see D2.B.8 Design Parameters (on page 1364)), the section is considered to have failed under shear.

Table 1B.6-1 below highlights which shear capacities are calculated for different profile types.

Table 111: Section Type Shear Checks

General Profile Type	Australian Section	Shear Checks
I-SECTION (i.e., parallel to minor principal y-axis)	WB, WC, UB, UC	Calculated for web only
T-SECTION	BT, CT	
CHANNEL	PFC	
ANGLE	EA, UA	No checks performed
TUBE	SHS, RHS	Calculated parallel to both x & y principal axes
PIPE	CHS	Per AS 4100 5.11.4

Note: Only unstiffened web capacities are calculated. Stiffened webs are not considered. Bearing capacities are not considered.

D2.B.7.6 Torsion

STAAD.Pro does *not* design sections or members for torsion for AS 4100.

D2.B.7.7 Slenderness

The slenderness check is *not* used as a critical member ratio check. If a slenderness check is included and exceed unity (1.0), then it may be reported as the governing criteria. However, if it is less than unity, it will be reported but will not be used as the governing ratio.

D2.B.8 Design Parameters

The design parameters outlined in the following table are used to control the design procedure. These parameters communicate design decisions from the engineer to the program and thus allow the engineer to control the design process to suit an application's specific needs. The design scope indicates whether design parameters are applicable for `MEMBER` Design, `PMEMBER` Design, or both.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements, some or all of these parameter values may be changed to exactly model the physical structure.

Table 112: Australian Steel Design Parameters

Parameter Name	Default Value	Design Scope	Description
CODE	-		Must be specified as AUSTRALIAN to invoke design per AS 4100 - 1998. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
ALB	2.0		Member section constant (refer cl. 6.3.3) If ALB is 2.0, it is automatically calculated based on TABLE 6.3.3(1), 6.3.3(2); otherwise the input value is used.
ALM	0.0		Moment modification factor (refer cl. 5.6.1.1) If ALM is 0.0, it is automatically calculated based cl. 5.6.1.1; otherwise the input value is used.
BEAM	0.0		0.0 = design only for end moments and those at locations specified by SECTION command. 1.0 = Perform design for moments at twelfth points along the beam.
DFF	None (Mandatory for deflection check)	Analytical members only	"Deflection Length"/ Maximum Allowable local deflection.
DJ1	Start Joint of member	Analytical members only	Joint No. denoting start point for calculation of "deflection length"
DJ2	End Joint of member	Analytical members only	Joint No. denoting end point for calculation of "deflection length"
DMAX	45.0 [in.]		Maximum allowable depth (Applicable for member selection)
DMIN	0.0 [in.]		Minimum required depth (Applicable for member selection)
FU	500.0 [MPa]		Ultimate strength of steel.
FYLD	250.0 [MPa]		Yield strength of steel.
IST	1		Steel type - 1 - SR, 2 - HR, 3 - CF, 4 - LW, 5 - HW **Note:** See p.47 of AS 4100-1998.

Parameter Name	Default Value	Design Scope	Description
KT	1.0		Correction factor for distribution of forces (refer cl. 7.2)
KY	1.0		K value for general column flexural buckling about the local Y-axis. Used to calculate slenderness ratio.
KZ	1.0		K value for general column flexural buckling about the local Z-axis. Used to calculate slenderness ratio.
LHT	0	Physical members only	Load height position as described in Table 5.6.3(2) of AS 4100:1998 0) at Shear center 1) At top flange
LX	see desc.		Unbraced length between torsional restraints. The default is the distance between partial or full restraints which effectively prevent twist of the section about its centroid as per Sec. 8.4.4.1.2.
LY	Member Length		Length for general column flexural buckling about the local Y-axis. Used to calculate slenderness ratio.
LZ	Member Length		Length for general column flexural buckling about the local Z-axis. Used to calculate slenderness ratio.
MAIN	0.0		Slenderness checks for compression. Checks are not explicitly required per AS 4100. A value of either 0.0 or 1.0 suppresses the slenderness ratio check. Any value greater than 1.0 is used as the limit for slenderness in compression.
NSC	1.0		Net section factor for compression members = An / Ag (refer cl. 6.2.1)
NSF	1.0		Net section factor for tension members.
PBRACE	None	Physical members only	Refer to D2.B.12 Physical Member Design (on page 1372) for details on the PBRACE parameter.
PHI	0.9		Capacity reduction factor
RATIO	1.0		Permissible ratio of actual load effect to the design strength.

Parameter Name	Default Value	Design Scope	Description
SGR	0		Steel Grade. Refer to Note c (on page 1368) below. 0) Default (see note below) 2) AS/NZS 3679.1 350 3) AS/NZS 3679.1 300 4) AS/NZS 1163 C450 5) AS/NZS 1163 C350 6) AS/NZS 1163 C250 7) AS/NZS 3678 450 8) AS/NZS 3678 400 9) AS/NZS 3678 350 10) AS/NZS 3678 WR350 11) AS/NZS 3678 300 12) AS 3597 500 13) AS 3597 600 14) AS 3597 700
SKL	1.0		A load height factor given in Table 5.6.3(2)
SKR	1.0		A lateral rotation restraint factor given in Table 5.6.3(3)
SKT	1.0		A twist restraint factor given in Table 5.6.3(1)
TMAIN	400		Slenderness limit for tension. Checks are not explicitly required per AS 4100. Any value greater than 1.0 is used as the limit for slenderness in tension.
TRACK	0		Output detail 0) report only minimum design results 1) report design strengths in addition to `TRACK 0` output 2) = provide full details of design
TSP	Member web depth		Spacing of the transverse stiffeners.
UNB	Member Length		Unsupported length in bending compression of the bottom flange for calculating moment resistance.
UNT	Member Length		Unsupported length in bending compression of the top flange for calculating moment resistance.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

D2.B.8.1 Notes

a. DFF, DJ1, and DJ2 – Deflection calculations

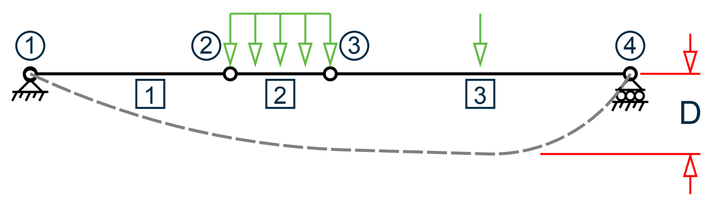
Compute Delta = $SQRT((DX2 - DX1)^2 + (DY2 - DY1)^2 + (DZ2 - DZ1)^2)$

Compute Length = distance between DJ1 and DJ2 or, between start node and end node, as the case may be.

Note: Deflection calculations are not applicable to PMEMBERs.

i. A straight line joining DJ1 and DJ2 is used as the reference line from which local deflections are measured.

For example, refer to the figure below where a beam has been modeled using four joints and three members. The "Deflection Length" for all three members will be equal to the total length of the beam in this case. The parameters DJ1 and DJ2 should be used to model this situation. Thus, for all three members here, DJ1 should be 1 and DJ2 should be 4.



D = Maximum local deflection for members 1, 2, and 3.

```
PARAMETERS
DFF 300. ALL
DJ1 1 ALL
DJ2 4 ALL
```

ii. If DJ1 and DJ2 are not used, "Deflection Length"will default to the member length and local deflections will be measured from original member line.

iii. It is important to note that unless a DFF value is specified, STAAD.Pro will not perform a deflection check. This is in accordance with the fact that there is no default value for DFF.

b. LHT Parameter

If the shear force is constant within the segment, longitudinal position of the load is assumed to be at the segment end.

If there is any variation of the shear force and the load is acting downward determined from shear force variation and load height parameter indicates the load is acting on top flange (flange at the positive local y axis) and restraints at the end of the segment is not FU (FRU) or PU (PRU) Kl is assumed to be 1.4.

If there is any variation of the shear force and the load is acting upward determined from shear force variation and load height parameter indicates the load is acting on top flange (flange at the positive local y axis) and restraints at the end of the segment is not FU (FRU) or PU (PRU) Kl is assumed to be 1.0 as the load acting at the top flange is contributing to stabilize against local torsional buckling.

c. SGR Parameter

Rolled profiles typically use an AS/NZS 3679.1 grade (i.e., SGR 2 or SGR 3), hollow profiles typically use an AS/NZS 1163 grade (i.e., SGR 4 to SGR 6), welded profiles typically use an AS/NZS 3678 grade (i.e., SGR 7 to SGR 11), and pressure vessels typically use an AS/NZS 3597 grade (i.e., SGR 12 to SGR 14).

When an explicit grade has not been specified or the option `SGR 0` has been specified, the program determines the steel grade as follows:

Table 113: Default steel grades used for the SGR parameter

Section Type	Steel Grade Used
WB, WC, Tee section cut from WB and WC, other welded and UPT sections	AS 3678 300
UB, UC, Tee section cut from UB and UC, EA, UA and all UPT sections UB, UC, Tee section cut from UB and UC, EA, UA and all other rolled sections	AS 3679.1 300
Pipe, Tube, CHS, RHS, SHS Pipe, Tube, CHS, RHS, SHS	AS 1163 C250

Note: If a value for the FYLD parameter has been specified, then that value will be used. Otherwise, the SGR value will be used to determine the yield strength and tensile strength values for the steel. based on maximum thickness of the individual elements of the section. Only for shear capacity calculation web thickness is used. Similarly, Tensile Strength is determined either from FU parameter or from SGR parameter.

Caution: A check is introduced to see if yield stress is more than 450 MPa or not. If it is, a warning is issued and the yield stress is set to 450 MPa.

D2.B.8.2 Example

The following example uses the member design facility in STAAD.Pro. However, it is strongly recommended to use the Physical member design capabilities for AS 4100:

```
PARAMETER 1
CODE AUSTRALIAN
ALB 0.0 MEMBER ALL
ALM 1.13 MEMBER ALL
BEAM 1.0 MEMBER ALL
DFF 250.0 MEMBER ALL
DMAX 0.4 MEMBER ALL
DMIN 0.25 MEMBER ALL
FU 400.0 MEMBER ALL
FYLD 310.0 MEMBER ALL
IST 2.0 MEMBER ALL
KT 0.85 MEMBER ALL
KX 0.75 MEMBER ALL
KY 1.0 MEMBER ALL
LX 4.5 MEMBER ALL
LY 6.0 MEMBER ALL
MAIN 1.0 MEMBER ALL
NSC 0.9 MEMBER ALL
NSF 1.0 MEMBER ALL
PHI 0.9 MEMBER ALL
RATIO 0.9 MEMBER ALL
SGR 1.0 MEMBER ALL
SKT 1.0 MEMBER ALL
SKL 1.0 MEMBER ALL
SKR 1.0 MEMBER ALL
TRACK 2.0 MEMBER ALL
UNB 3.4 MEMBER ALL
```

```
UNT 6.8 MEMBER ALL
CHECK CODE MEMBER ALL
```

D2.B.9 Code Checking

The purpose of code checking is to evaluate whether the provided section properties of the members are adequate for the specified loads as per AS 4100 requirements.

Tip: The D2.B.10 Member Selection (on page 1371) facility can be used to instruct the program to select a different section if the specified section is found to be inadequate.

Code checking for an analytical member is done using forces and moments at every twelfth point along the beam. The code checking output labels the members as PASSed or FAILed. In addition, the critical condition, governing load case, location (distance from the start joint) and magnitudes of the governing forces and moments are also printed. The extent of detail of the output can be controlled by using the `TRACK` parameter.

Note: Code checking cannot be performed on composite and prismatic sections.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

Example of commands for code checking:

```
UNIT NEWTON METER
PARAMETER
CODE AUSTRALIAN
FYLD 330E6 MEMB 3 4
NSF 0.85 ALL
KY 1.2 MEMB 3 4
RATIO 0.9 ALL
CHECK CODE MEMB 3 4
```

D2.B.9.1 Physical Members

For physical members (`PMEMBER`s), code checks are performed at section stations positioned at $1/12^{th}$ points along each analytical member included in the `PMEMBER`. It is up to you to determine if these locations cover critical sections for design, and adjust as necessary. The number of stations for `PMEMBER` Design cannot be altered, however the analytical members can be split so that in effect more stations are checked for a `PMEMBER`.

For each section station along a `PMEMBER`, section capacity checks are carried for design actions at that station location. Member capacity checks are also carried out for each station. For these the program searches each side of the station to find adjacent effective restraints and design forces and moments. This allows the program to determine the segment / sub-segment that the section station resides in, and then proceeds to calculate the member capacities. Enough section stations should be included to capture all segments / sub-segments for checking.

Note: When checking combined actions for the section capacities, the design actions at the section station are used. However when checking combined actions for the member capacities, the maximum forces from anywhere along the segment / sub-segment being considered are used. This is as stipulated in AS 4100 8.2.

The output reports whether the member has PASSed or FAILed the design checks, as well as the critical condition, critical load case, magnitudes of design actions for the most critical cross-section location (distance from the start joint), and complete calculations for design. The TRACK design parameter can be used to control the level of detail provided in the output.

Tip: You can use the **Utilization Ratio** tool in the graphical user interface **Postprocessing** workflow to view color-coded results.

In some cases some of the output will report “N/A” values. This occurs where a calculation does not apply to a member. For example if a member never goes into tension then no values can be reported in the tension capacity output sections.

Note: As per AS 4100 1.4, the `TRACK 2.0` detailed level of output for PMEMBER Design uses x and y subscripts to refer to major and minor principal axes respectively. These differ to STAAD.Pro local member axes, where z and y refer to major and minor principal axes.

D2.B.10 Member Selection

This process incrementally checks increasing section profile sizes until a size is found that is AS 4100 compliant, or the largest section has been checked. Only section profiles of the same type as modeled are incrementally checked, with the increasing sizes based on a least weight per unit length criteria.

For example, a member specified initially as a channel will have a channel selected for it. Selection of members whose properties are originally provided from a user table will be limited to sections in the user table.

The design calculations for Member Selection are the same as for D2.B.9 Code Checking (on page 1370).

Tip: A Fixed Group command is also available, and can be used to force all members within a user-defined group to take the same section size based on the most critical governing design criteria for all members within that group. This is particularly useful when you want to use the Member Selection feature, but want a group of elements to have the same size. Refer to TR.50 Group Specification (on page 2680) for information on using this feature.

Note: Member Selection will change member sizes, and hence will change the structure’s stiffness matrix. In order to correctly account for this, a subsequent analysis and Code Check should be performed to ensure that the final structure is acceptable. This may need to be carried out over several iterations.

Note: Composite and prismatic sections cannot be selected.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

Example of commands for member selection:

```
UNIT NEWTON METER
PARAMETER
FYLD 330E6 MEMB 3 4
NSF 0.85 ALL
KY 1.2 MEMB 3 4
RATIO 0.9 ALL
SELECT MEMB 3 4
```

D2.B.11 Tabulated Results of Steel Design

Results of code checking and member selection are presented in a tabular format. The term `CRITICAL COND` refers to the section of the AS 4100 specification which governs the design.

D2.B.12 Physical Member Design

There are two methods available in STAAD.Pro for checking members against the requirements of AS 4100:

a. Analytical member method
b. Physical member method

Herein these are referred to as `MEMBER` Design and `PMEMBER` Design respectively.

Traditionally STAAD.Pro performed code checks based on single analytical members (i.e., single members between two nodes). This implementation remains in place as shown in the example in D2.B.8 Design Parameters (on page 1364). Physical Member (`PMEMBER`) Design on the other hand allows you to group single or multiple analytical members into a single physical design member for the purposes of design to AS 4100.

`PMEMBER` Design also has additional features, including:

- automated steel grades based on section type;
- automated tensile stress (f_u) and yield stress (f_y) values based on plate thicknesses;
- automated segment / sub-segment design;
- improved detailed design calculation output; and

Thus, it is strongly recommended that `PMEMBER` Design be used, even for the design of single analytical members.

D2.B.12.1 Modeling with Physical Members

Physical Members may be grouped by either of the following methods:

- STAAD.Pro Editor - Directly specify physical members in the input file. Refer to TR.16.2 Physical Members (on page 2238) for additional information.
- Graphical Environment - Using the tools in the **Physical Member** group on the **Geometry** ribbon tab, members can be manually or automatically formed.

Note: When creating PMEMBERs for AS 4100, this must be performed in STAAD.Pro's M. Creating Model Objects (on page 653) . Do *not* use the Steel Design workflow.

D2.B.12.2 Segment and Sub-Segment Layout

For calculation of member bending capacities about the principal x-axis, the PMEMBER Design uses the concept of segment / sub-segment design. By default PMEMBERs are automatically broken up into design segments and sub-segments based on calculated effective restraints. User-defined restraints assigned using the PBRACE design parameter are checked to see if they are effective (i.e., if they are placed on the critical flange as per AS 4100 5.5). Restraints not applied to the critical flange are ineffective and hence are completely ignored.

Refer to Section 1B.7 for further information on how user-defined restraints are applied using the `PBRACE` design parameter, including available restraint types, and restraint layout rules.

Note: Segment and sub-segment layouts for PMEMBERs may change for different load cases considered for design. Some restraints may be effective for one particular load case as they are found to apply to the critical flange, however for another load case may be found not to act on the critical flange, and found to be ineffective. In other words the critical flange can change for each load case considered.

Typically the critical flange will be the compression flange, except for segments with a “U” restraint at one end, in which case it will be the tension flange (as is the case for a cantilever).

The PMEMBER Design uses the following routine to determine effective cross-section restraints for each load case considered:

i. first all user-defined restraints are checked to see if they are applied to the compression flange, with those that aren’t ignored;
ii. next a check is made to see if a “U” type restraint is found at either end of the PMEMBER. If this is the case then any adjacent “L” restraints up to the next “F”, “FR”, “P” or “PR” restraint are also ignored, regardless of whether they are placed on the critical or non-critical flange. Refer AS 4100 5.4.2.4.

The compression flange in step 1 of the routine above is calculated based on the bending moments at the locations of the restraints being considered. If the bending moment is zero at the same location as a restraint then the following method is used to determine which flange is critical at the zero moment location:

a. If the zero moment is at the end of the PMEMBER, then the compression flange is based on the bending moment at a small increment from then end;
b. If the zero moment is along the PMEMBER and is a peak value, then the compression flange is based on the bending moment at a small increment from that location;
c. If neither 1 or 2 above is valid, then the stiffer of the restraints at that location is taken. The stiffness of different restraint types from the most stiff to least stiff are taken as outlined in Table 1B.9-3.

Table 114: Assumed Order of Restraint Stiffness for Zero Moment Critical Flange

Stiffness	Restraint Type
Most Stiff	FR
↓	F
↓	PR
↓	P
↓	L
↓	U
Least Stiff	None

Once the effective restraints have been determined, the PMEMBER is divided into segments bounded by “F”, “P”, “FR”, “PR” or “U” effective restraints. These segments are then further divided into sub-segments by effective “L” restraints.

Note: Sub-segment lengths are not automatically checked to determine if they provide full lateral restraint as per AS 4100 5.3.2.4.

For design of cantilevers, the free tip should have user-defined “U” restraints applied to both top and bottom flanges.

Note: If the effective restraints for any load case consist of "U" or "L" restraints only, an error will be reported.

D2.B.12.3 Automated PMEMBER Design Calculations

The AS 4100 PMEMBER Design automates many design calculations, including those required for segment / sub-segment design.

Table 115: Automated PMEMBER AS 4100 Design Parameters and Calculations

Automated Design Calculations	PMEMBER Design Parameter	Comments
α_b compression member section constant per AS 4100 6.3.3.	ALB	
α_m moment modification factor per AS 4100 5.6.1.1.	ALM	Calculated based on moments distribution for individual segments and sub-segments.
f_u tensile strength per AS 4100 2.1.2.	FU	Based on nominal steel grade specified using SGR design parameter and section type.
f_y yield stress per AS 4100 2.1.1.	FYLD	Based on nominal steel grade specified using SGR design parameter and section type.
residual stress category for AS 4100 Table 5.2 and AS 4100 Table 6.2.4.	IST	Based on section type.
correction factor for distribution of forces in a tension member per AS 4100 7.3.	KT	Based on section type and eccentric end connection specified using EEC design parameter.
Load height position for automated calculation of the kl load height factor per AS 4100 Table 5.6.3(2).	LHT	LHT is used for automating calculation of kl load height factors for segments and sub-segments, per AS 4100 Table 5.6.3(2). See D2.B.12.4 Load Height Position (on page 1375) for details.
Segment and sub-segment layout.	PBRACE	Refer to the Segment and Sub-Segment Layout section above for details.
Nominal steel grade.	SGR	Based on section types.
k_t twist restraint factor as per AS 4100 Table 5.6.3(1).	SKT	Based on effective end restraints for each segment / sub-segment.

Automated Design Calculations	`PMEMBER` Design Parameter	Comments
k_l load height factor as per AS 4100 Table 5.6.3(2).	SKL	Based on effective end restraints for each segment / sub-segment, and LHT design parameter (refer above).
k_r lateral rotation restraint factor as per AS 4100 Table 5.6.3(3).	SKR	Based on effective end restraints for each segment / sub-segment. This is where the distinction between "F" and "FR", as well as "P" and "PR" is used.

D2.B.12.4 Load Height Position

When LHT is set to 1.0 to specify a top flange load height position, STAAD.Pro takes the top to be the positive local y-axis of the member.

Note: This may not literally be the top flange for say a column or beam with a beta angle. The local member axes can be viewed in the user interface by selecting **Beam Orientation** in the Diagrams Labels dialog (or by pressing **<Ctrl+O>**).

To automate kl using AS 4100 Table 5.6.3(2), the longitudinal position of the load also needs to be considered, i.e., as either "within segment" or "at segment end".

To determine which of these applies, the shear forces at the ends of each design segment / sub-segment is considered. If the shear force is found to have the same direction and magnitude at both ends, it is assumed that loads act at the segment end.

If on the other hand the shear force at each end is found to have different directions or magnitudes, loads are assumed to act within the segment.

Note: The above method includes an allowance for the self-weight of the member to be considered, as the self-weight always acts through the shear center.

The net sum of the end shears is also used to determine if the load is acting in the positive or negative local member y-axis direction. If LHT is set to 1.0 for top flange loading, the net sum is used to determine whether the top flange loading is acting to stabilise or destabilise the member for lateral torsional buckling. Negative local y-axis net loads act to destabilise the segments / sub-segments, whereas positive local y-axis net loads act to stabilise segments / sub-segments.

D2.B.12.5 Example

```
PARAMETER 1

TRACK 2.0 PMEMBER 1 TO 42
CHECK CODE PMEMBER 1 TO 42
```

D2.B.12.6 Physical Member Restraints Specification

The PBRACE parameter is used to specify the restraint condition along the top and bottom flange of a PMEMBER.

General Format

```
PBRACE { TOP | BOTTOM } f1 r1 f2 r2 … f52 r52 (PMEMB pmember-list)
```

fn a fraction of the PMEMBER length where restraint condition is being specified. This value is any ratio between 0.0 and 1.0.

rn one of the possible restraint conditions as follows:

Table 116: Physical Member Restraint Types

Designation, *rn*	Restraint Type	Description
F	Fully restrained	
P	Partially restrained	
L	Laterally restrained	Cannot be specified at the ends of design members.
U	Unrestrained	Can only be applied at the ends of design members, and must be applied to both flanges to be effective. **Caution:** Both top and bottom flanges can not be unrestrained at the same location (as this is unstable).
FR	Fully and rotationally restrained	
PR	Partially and rotationally restrained	
C	Continuously restrained	The flange is assumed to be continuously supported at that flange up to next restraint location. For continuously supported flange unbraced length is assumed to be zero.

Example

```
PBRACE TOP 0.85 FR 0.33 PR 0.33 PR 0.25 F 0.75 L 0.5 PR 1.0 U 0.0 U
PBRACE BOTTOM 0.75 L 0.0 U 0.25 P 0.5 L -
1.0 U PMEMB 3 7
```

Description

Refer to AS 4100 Section 5.5 for a full definition of the critical flange. Typically this will be the compression flange, except for segments with U restraint at one end, then it will be the tension flange (as is the case for cantilever portion at the end).

- when gravity loads are dominant (i.e., negative local y-axis direction), the critical flange of a segment shall be the top flange (i.e., tension).
- when upward wind loads are dominant (i.e., positive local y-axis direction), the critical flange shall be the bottom flange (i.e., tension).

Design physical members are divided into segments by “F”, “P”, “FR”, “PR” or “U” effective section restraints. Segments are further broken down into sub-segments by “L” restraints, but only if the “L” restraints are deemed to be “effective”. “L” restraints are only considered to be effective when positioned on the “critical” flange between “F”, “P”, “FR” or “FP” restraints. If an “L” restraint is positioned on the non-critical flange it shall be completely ignored. Further, if an “L” restraint is positioned between a “U” and an “F”, “P”, “FR” or “PR” restraint, it shall be ignored (regardless of whether it is on the critical or non-critical flange).

Design members must have either a F, P, FR, PR, or U restraint specified at both ends, for both flanges.

- If UNL is not specified, segment length is used as UNL and used as L in effective length calculation as per 5.6.3.
- If ALM i.e., α_m is not provided, automatic calculation of ALM is done based on moments within the segment.
- If SKR i.e., Kr is not provided, it is automatically calculated based on table 5.6.3(3) considering restraint conditions are the end of the segment. If FR or PR is found at only one of the end, Kr is assumed to be 0.85; if FR or PR is found at both the ends, 0.70 is used as Kr.
- If SKT i.e., Kt is not provided, it is automatically calculated based on Table 5.6.3(1) considering end restraints of the segment and section geometric information and segment length.
- If SKL i.e., Kl is not provided, it is automatically calculated based on Table 5.6.3(2) considering end restraints of the segment, Load Height Position parameter, LHT and shear force variation within the segment.

Notes

a. If PMEMBER list is not provided, all the PMEMBERS are restrained by same configuration.
b. It is not necessary to provide the restraint locations in sequence as the program sorts them automatically.
c. Unless specified, PMEMBER ends are assumed to be Fully Restrained (F).
d. While designing any section of the member, effective restraints are searched on each side of the section along the critical flange.
e. The types of restraints applied to the top and bottom flanges at each location determines the effective section restraints. These are outlined in the table below:

Table 117: Restraint Meanings in Critical and Noncritical Flanges

Case	Flange	Restraint on a Critical Flange	Restraint on a Non-Critical Flange	Effective Section Restraint
I		U	U	U
II	1	L	Nothing	L
	2	Nothing	L	None
III	1	P or F	Nothing or U	F

Case	Flange	Restraint on a Critical Flange	Restraint on a Non-Critical Flange	Effective Section Restraint
	2	Nothing or U	P or F	P
IV	1	PR or FR	Nothing or U	FR
	2	Nothing or U	PR or FR	PR
V	1	L, P or F	L, P, F, FR or PR	F
	2	FR or PR	L, P, F, FR or PR	FR

Note: The critical flange can change for each load case considered.

f. If a C-type restraint is defined to a flange at a particular location of the PMEMBER, program will consider that continuous restraint to be effective up to the next bracing point of the point of contraflexure whichever is nearer to the continuous restraint.

D3. British Codes

D3.A. British Codes - Concrete Design per BS8110

Note: This code has been removed from the batch design. To perform design to the current BS 8110 design code, please use the D. Advanced Concrete Design (on page 1071).

D3.B. British Codes - Steel Design per BS5950:2000

STAAD.Pro is capable of performing steel design based on the British code BS 5950-1:2000 *Structural use of steelwork in building - Part 1: Code of practice for design - Rolled and welded sections*, Incorporating Corrigendum No. 1.

D3.B.1 General

The design philosophy embodied in BS5950:2000 is built around the concept of limit state design, used today in most modern steel design codes. Structures are designed and proportioned taking into consideration the limit states at which they become unfit for their intended use.

Two major categories of limit state are recognized - serviceability and ultimate. The primary considerations in ultimate limit state design are strength and stability while that in serviceability limit state is deflection. Appropriate safety factors are used so that the chances of limits being surpassed are acceptably remote.

In the STAAD.Pro implementation of BS5950:2000, members are proportioned to resist the design loads without exceeding the limit states of strength and stability. Accordingly, the most economic section is selected on the basis of the least weight criteria. This procedure is controlled by the designer in specification of allowable member depths, desired section type or other such parameters. The code checking portion of the program checks that code requirements for each selected section are met and identifies the governing criteria.

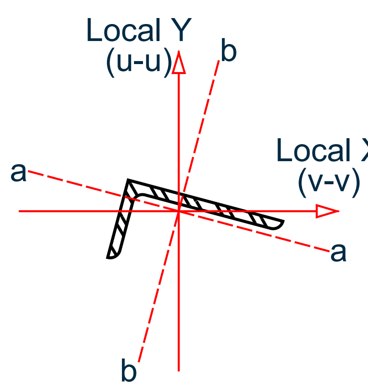
The complete B.S.C. steel tables for both hot rolled and hollow sections are built into the program for use in specifying member properties as well as for the actual design process. See D3.B.4 Built-In Steel Section Library (on page 1380) for information regarding the referencing of these sections. In addition to universal beams, columns, joists, piles, channels, tees, composite sections, beams with cover plates, pipes, tubes, and angles, there is a provision for user provided tables.

The program designs tapered I shaped beams according to Annex G of BS5950. See D3.B.13 Design of Tapered Beams (on page 1398) for a complete description.

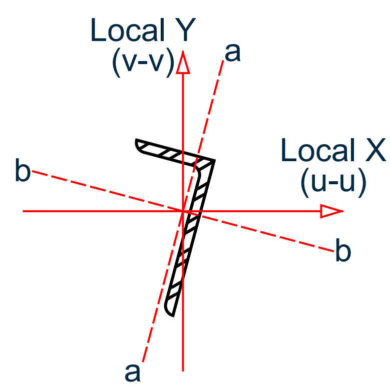
Single Angle Sections

Angle sections are unsymmetric and when using BS 5950:2000 table 25, you must consider four axes: two principal, u-u and v-v and two geometric, a-a and b-b. The effective length for the v-v axis, Lvv, is taken as the LVV parameter or $LY \cdot KY$, if not specified. The a-a and b-b axes are determined by which leg of the angle is fixed by the connection and should be specified using the LEG parameter, see section 5B.6 for more information on the LEG parameter. The effective length in the a-a axis is taken as $LY \cdot KY$ and the effective length in the b-b axis as $LZ \cdot KZ$.

The following diagram shows the axes for angles which have been defined with either an ST or RA specification and is connected by its longer leg (i.e., a-a axis is parallel to the longer leg).



ST angle and USER table angles



RA angle

D3.B.2 Analysis Methodology

Elastic analysis method is used to obtain the forces and moments for design. Analysis is done for the primary and combination loading conditions provided by the user. The user is allowed complete flexibility in providing loading specifications and using appropriate load factors to create necessary loading situations. Depending upon the analysis requirements, regular stiffness analysis or P-Delta analysis may be specified. Dynamic analysis may also be performed and the results combined with static analysis results.

D3.B.3 Member Property Specifications

For specification of member properties, the steel section library available in STAAD may be used. The next section describes the syntax of commands used to assign properties from the built-in steel table. Member properties may also be specified using the User Table facility. Any user-defined section may be specified, except for `GENERAL` or `PRISMATIC` sections. For more information on these facilities, refer to G.6 Member Properties (on page 2113) .

D3.B.4 Built-In Steel Section Library

The following information is provided for use when the built-in steel tables are to be referenced for member property specification. These properties are stored in a database file. If called for, the properties are also used for member design. Since the shear areas are built into these tables, shear deformation is always considered during the analysis of these members.

Almost all BSI steel sections are available for input. A complete listing of the sections available in the built-in steel section library may be obtained by using the tools of the graphical user interface.

Following are the descriptions of different types of sections available:

Refer to G.6.2 Built-In Steel Section Libraries (on page 2116) for additional information.

D3.B.4.1 Universal Beams, Columns, and Piles

All rolled universal beams, columns and pile sections are available. The following examples illustrate the designation scheme.

```
20 TO  30 TA ST UB305X165X54
33 36  TA ST UC356X406X287
100  102 106 TA ST UP305X305X186
```

D3.B.4.2 Rolled Steel Joists

Joist sections may be specified as they are listed in BSI-80 with the weight omitted. In those cases where two joists have the same specifications but different weights, the lighter section should be specified with an "A" at the end.

```
10 TO  20 TA ST JO152X127
1 2  TA ST JO127X114A
```

D3.B.4.3 Channels

All rolled steel channel sections from the BSI table have been incorporated in STAAD. The designation is similar to that of the joists. The same designation scheme as in BSI tables may be used with the weight omitted.

```
10 TO  15 TA ST CH305X102
55 57 59 61 TA ST CH178X76
```

D3.B.4.4 Double Channels

Back-to-back double channels, with or without spacing between them, are available. The letter "D" in front of the section name will specify a double channel (e.g., D CH102X51, D CH203X89, etc.)

```
51 52  53 TA D CH152X89
70 TO 80 TA D CH305X102 SP 5.
```

(specifies a double channel with a spacing of 5 length units)

Note: Face-to-face double channels can not be used in a `CHECK CODE` command.

D3.B.4.5 Tee Sections

Tee sections are not input by their actual designations, but instead by referring to the universal beam shapes from which they are cut. For example,

```
54 55  56 TA T UB254X102X22
```

(tee cut from UB254X102X22)

D3.B.4.6 Angles

All equal and unequal angles are available for analysis.Note, however, that only angles specified with an RA specification can be designed.

The standard angle section is specified as follows:

```
15 20  25 TA ST UA200X150X18
```

Note: This specification is for "standard" angles, designated by ST. In this specification, the local z-axis corresponds to the Y'-Y' axis shown in the section table. Another common practice of specifying angles assumes the local y-axis to correspond to the Y'-Y' axis. To specify angles in accordance with this convention, use the reverse angle designation, RA. Refer to G.4.2 Local Coordinate System (on page 2088) for details on the local axis systems for standard (ST) and reverse (RA) angles.

```
35 TO  45 TA RA UA200X150X18
```

D3.B.4.7 Double Angles

Short leg back-to-back or long leg back-to-back double angles can be specified by inputting the word SD or LD, respectively, in front of the angle size. In case of an equal angle, either LD or SD will serve the purpose. For example,

```
14 TO  20 TA LD UA200X200X16 SP 1.5
23 27 TA SD UA80X60X6
```

"SP" denotes spacing between the individual angle sections.

Note: If the section is defined from a double angle user table, then the section properties must be defined with an 11th value which defines the radius of gyration about an individual sections' principal v-v axis (refer to TR.19.4 Double Angle (on page 2248))

D3.B.4.8 Pipes (Circular Hollow Sections)

To designate circular hollow sections from BSI tables, use PIP followed by the numerical value of diameter and thickness of the section in mm omitting the decimal section of the value provided for diameter. The following example will illustrate the designation.

```
10 15  TA ST PIP213.2
```

(specifies a 21.3 mm dia. pipe with 3.2 mm wall thickness)

Circular hollow sections may also be provided by specifying the outside and inside diameters of the section. For example,

```
1 TO  9 TA ST PIPE OD 25.0 ID 20.0
```

(specifies a pipe with outside dia. of 25 and inside dia. of 20 in current length units)

Only code checking and no member selection will be performed if this type of specification is used.

D3.B.4.9 Rectangular or Square Hollow Sections (Tubes)

Designation of tubes from the BSI steel table is illustrated below:

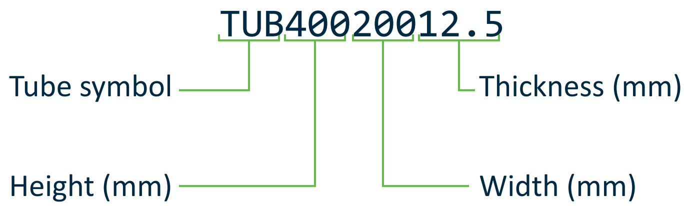


Figure 161: BSI tube nomenclature

Example:

```
15 TO 25 TA ST TUB160808.0
```

Tubes, like pipes, can also be input by their dimensions (Height, Width and Thickness) and not by any table designations.

```
6 TA  ST TUBE DT 8.0 WT 6.0 TH 0.5
(a tube  that has a height of 8, a width of 6, and a wall thickness of 0.5 length
units)
```

Note: Only code checking and no member selection is performed for TUBE sections specified this way.

D3.B.5 Member Capacities

The basic measure of capacity of a beam is taken as the plastic moment of the section. This is a significant departure from the standard practice followed in BS449, in which the limiting condition was attainment of yield stress at the extreme fibers of a given section. With the introduction of the plastic moment as the basic measure of capacity, careful consideration must be given to the influence of local buckling on moment capacity. To assist this, sections are classified as either Class 1, plastic, Class 2, compact, Class 3, semi-compact or Class 4, slender, which governs the decision whether to use the plastic or the elastic moment capacity. The section classification is a function of the geometric properties of the section. STAAD is capable of determining the section classification for both hot rolled and built up sections. In addition, for slender sections, BS5950 recommends the use of a 'stress reduction factor' to reduce the design strength. This factor is again a function of the geometry of the section and is automatically determined by STAAD for use in the design process.

D3.B.5.1 Axial Tension

In members with axial tension, the tensile load must not exceed the tension capacity of the member. The tension capacity of the member is calculated on the basis of the effective area as outlined in Section 4.6 of the code. STAAD calculates the tension capacity of a given member per this procedure, based on a user supplied net section factor (NSF-a default value of 1.0 is present but may be altered by changing the input value - see D3.B.6 Design Parameters (on page 1384)), proceeding with member selection or code check accordingly. BS5950 does not have any slenderness limitations for tension members.

D3.B.5.2 Compression

Compression members must be designed so that the compression resistance of the member is greater than the axial compressive load. Compression resistance is determined according to the compressive strength, which is a function of the slenderness of the gross section, the appropriate design strength and the relevant strut characteristics. Strut characteristics take into account the considerable influence residual rolling and welding stresses have on column behavior. Based on data collected from extensive research, it has been determined that sections such as tubes with low residual stresses and Universal Beams and Columns are of intermediate performance. It has been found that I-shaped sections are less sensitive to imperfections when constrained to fail about an axis parallel to the flanges. These research observations are incorporated in BS5950 through the use of four strut curves together with a selection of tables to indicate which curve to use for a particular case. Compression strength for a particular section is calculated in STAAD according to the procedure outlined in Annex C of BS5950 where compression strength is seen to be a function of the appropriate Robertson constant (representing Strut Curve) corresponding Perry factor, limiting slenderness of the member and appropriate design strength.

A departure from BS5950:1990, generally compression members are no longer required to be checked for slenderness limitations, however, this option can be included by specifying a MAIN parameter. Note, a slenderness limit of 50 is still applied on double angles checked as battened struts as per clause 4.7.9.

D3.B.5.3 Axially Loaded Members With Moments

In the case of axially loaded members with moments, the moment capacity of the member must be calculated about both principal axes and all axial forces must be taken into account. If the section is plastic or compact, plastic moment capacities will constitute the basic moment capacities subject to an elastic limitation. The purpose of this elastic limitation is to prevent plasticity at working load. For semi-compact or slender sections, the elastic moment is used. For plastic or compact sections with high shear loads, the plastic modulus has to be reduced to accommodate the shear loads. The STAAD implementation of BS5950 incorporates the procedure outlined in section 4.2.5 and 4.2.6 to calculate the appropriate moment capacities of the section.

For members with axial tension and moment, the interaction formula as outlined in section 4.8.2 is applied based on effective tension capacity.

For members with axial compression and moment, two principal interaction formulae must be satisfied – *Cross Section Capacity* check (4.8.3.2) and the *Member Buckling Resistance* check (4.8.3.3). Three types of approach for the member buckling resistance check have been outlined in BS5950:2000 - the simplified approach (4.8.3.3.1), the more exact approach (4.8.3.3.2) and Annex I1 for stocky members. As noted in the code, in cases where neither the major axis nor the minor axis moment approaches zero, the more exact approach may be more conservative than the simplified approach. It has been found, however, that this is not always the case and STAAD therefore performs both checks, comparing the results in order that the more appropriate criteria can be used.

Additionally the equivalent moment factors, m_x m_y and m_{yx}, can be specified by the user or calculated by the program.

Members subject to biaxial moments in the absence of both tensile and compressive axial forces are checked using the appropriate method described above with all axial forces set to zero. STAAD also carries out cross checks for compression only, which for compact/plastic sections may be more critical. If this is the case, COMPRESSION will be the critical condition reported despite the presence of moments.

D3.B.5.4 Shear

A member subjected to shear is considered adequate if the shear capacity of the section is greater than the shear load on the member. Shear capacity is calculated in STAAD using the procedure outlined in section 4.2.3, also 4.4.5 and Annex H3 if appropriate, considering the appropriate shear area for the section specified.

Since plastic moment capacity is the basic moment capacity used in BS5950, members are likely to experience relatively large deflections. This effect, coupled with lateral torsional buckling, may result in severe serviceability limit state. Hence, lateral torsional buckling must be considered carefully.

The procedure to check for lateral torsional buckling as outlined in section 4.3 has been incorporated in the STAAD implementation of BS5950. According to this procedure, for a member subjected to moments about the major axis, the 'equivalent uniform moment' on the section must be less than the lateral torsional buckling resistance moment. For calculation of the buckling resistance moment, the procedure outlined in Annex B.2 has been implemented for all sections with the exception of angles. In Annex B.2., the resistance moment is given as a function of the elastic critical moment, Perry coefficient, and limiting equivalent slenderness, which are calculated within the program; and the equivalent moment factor, m_{LT}, which is determined as a function of the loading configuration and the nature of the load (stabilizing, destabilizing, etc).

D3.B.5.6 RHS Sections - Additional Provisions

Rectangular Hollow sections are treated in accordance with S.C.I. recommendations in cases when the plastic axis is in the flange. In such cases, the following expressions are used to calculate the reduced plastic moduli:

For $n \geq 2t(D-2t)/A$

$$S_{rx} = \frac{A^2}{4(B-t)}\left(1-n\right)\left[\frac{2D(B-t)}{A} + n - 1\right]$$

For $n \geq 2t(B-2t)/A$

$$S_{ry} = \frac{A^2}{4(D-t)}\left(1-n\right)\left[\frac{2B(D-t)}{A} + n - 1\right]$$

D3.B.6 Design Parameters

Available design parameters to be used in conjunction with BS5950 are listed in table 2B.1 along with their default values.

Note: Once a parameter is specified, its value stays at that specified number till it is specified again. This is the way STAAD works for all codes.

Table 118: British Steel Design BS5950:2000 Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `BS5950` Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).

Parameter Name	Default Value	Description
AD	Depth at end/2	Distance between the reference axis and the axis of restraint. See G. 2.3
BEAM	3.0	Beam divisions 0. Design only for end moments or those locations specified by the SECTION command. 1. Calculate forces and moments at 12th points along the member. Establish the location where Mz is the maximum. Use the forces and moments at that location. Clause checks at one location. 2. Same as `BEAM = 1.0` but additional checks are carried out for each end. 3. Calculate moments at 12th points along the member. Clause checks at each location including the ends of the member.
CAN	0	Deflection check method. See Note 1 below. 0. Deflection check based on the principle that maximum deflection occurs within the span between DJ1 and DJ2. 1. Deflection check based on the principle that maximum deflection is of the cantilever type (see note below)
CB	1	Specifies the method used to calculate Mb. 1. Value of Mb from Clause 4.3.6 is used (default). 2. Value of Mbs from Clause 4.7.7 is used.
DFF	None(Mandatory for deflection check, TRACK 4.0)	"Deflection Length" / Maxm. allowable local deflection See Note 1d below.

Parameter Name	Default Value	Description
DJ1	Start Jointof member	Joint No. denoting starting point for calculation of "Deflection Length." See Note 1 below.
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length." See Note 1 below.
DMAX *	100.0cm	Maximum allowable depth
DMIN *	0.0 cm	Minimum allowable depth
ESTIFF	0.0	Clauses 4.8.3.3.1 and 4.8.3.3.2 0.0 = Fail ratio uses MIN of 4.8.3.3.1, 4.8.3.3.2. and Annex I1 checks. 1.0 = Fail ratio uses MAX of 4.8.3.3.1, 4.8.3.3.2. and Annex I1 checks.
KY	1.0	K factor value in local y - axis. Usually, this is the minor axis.
KZ	1.0	K factor value in local z - axis. Usually, this is the major axis.
LEG	0.0	Valid range from 0 – 7 and 10. The values correspond to table 25 of BS5950 for fastener conditions. See note 2 below.
LVV *	Maximum of Lyy and Lzz(Lyy is a term used by BS5950)	Used in conjunction with LEG for Lvv as per BS5950 table 25 for double angles. See note 6 below.
LY *	Member Length	Length in local y - axis (current units) to calculate (KY)(LY)/Ryy slenderness ratio.
LZ *	Member Length	Length in local z - axis (current units) to calculate (KZ)(LZ)/Rzz slenderness ratio.

Parameter Name	Default Value	Description
MLT	1.0	Equivalent moment factor for lateral torsional buckling as defined in clause 4.8.3.3.4
MX	1.0	Equivalent moment factor for major axis flexural buckling as defined in clause 4.8.3.3.4
MY	1.0	Equivalent moment factor for minor axis flexural buckling as defined in clause 4.8.3.3.4
MYX	1.0	Equivalent moment factor for minor axis lateral flexural buckling as defined in clause 4.8.3.3.4
NSF	1.0	Net section factor for tension members.
PNL *	0.0	Transverse stiffener spacing (“a” in Annex H1) 0.0 = Infinity Any other value used in the calculations.
PY *	Set according to steel grade (SGR)	Design strength of steel
MAIN	0.0	Slenderness limit for members with compression forces, effective length/ radius of gyration, for a given axis: 0.0 = Slenderness not performed. 1.0 = Main structural member (180) 2.0 = Secondary member. (250) 3.0 = Bracing etc (350)
RATIO	1.0	Permissible ratio of the actual capacities.

Parameter Name	Default Value	Description
SAME**	0.0	Controls the sections to try during a SELECT process. 0.0 = Try every section of the same type as original 1.0 = Try only those sections with a similar name as original, e.g., if the original is an HEA 100, then only HEA sections will be selected, even if there are HEM's in the same table.
SBLT	0.0	Identify Section type for section classification 0.0 = Rolled Section 1.0 = Built up Section 2.0 = Cold formed section
SWAY	none	Specifies a load case number to provide the sway loading forces in clause 4.8.3.3.4 (See additional notes)
SGR	0.0	Steel Grade per BS4360 0.0 = Grade S 275 1.0 = Grade S 355 2.0 = Grade S 460 3.0 = As per GB 1591 – 16 Mn
TB	0.0	LImit of moment capacity in Cl 4.2.5.1: 0 = Mc limit 1.5pyZ 1= Mc limit 1.2 pyZ

Parameter Name	Default Value	Description
TRACK	0.0	Output details 0.0 = Suppress all member capacity info. 1.0 = Print all member capacities. 2.0 = Print detailed design sheet. 4.0 = Deflection Check (separate check to main select / check code)
UNF	1.0	Unsupported length factor applied to the member length for the lateral torsional-buckling effective length per section 4.3.6.7 of BS5950. **Note:** If both UNF and UNL parameters are specified, the effective length used is UNF×UNL.
UNL *	Member Length	Unsupported length for calculating lateral torsional-buckling resistance moment section 4.3.6.7 of BS5950. Given in current length units.
WELD	1.0 closed 2.0 open	Weld Type 1.0 = Closed sections. Welding on one side only (except for webs of wide flange and tee sections) 2.0 = Open sections. Welding on both sides (except pipes and tubes)

* current units must be considered.

**For angles, if the original section is an equal angle, then the selected section will be an equal angle and vice-versa for unequal angles.

Note: There was an NT parameter in STAAD.Pro 2005 build 1003 which is now automatically calculated during the design as it is load case dependent.

D3.B.6.1 Notes

1. CAN, DJ1, and DJ2 – Deflection

a. When performing the deflection check, you can choose between two methods. The first method, defined by a value 0 for the `CAN` parameter, is based on the local displacement. Refer to TR.44 Printing Section Displacements for Members (on page 2672) for details on local displacement.

   If the `CAN` parameter is set to 1, the check will be based on cantilever style deflection. Let (DX1, DY1, DZ1) represent the nodal displacements (in global axes) at the node defined by DJ1 (or in the absence of DJ1, the start node of the member). Similarly, (DX2, DY2, DZ2) represent the deflection values at DJ2 or the end node of the member.

   Compute Delta = SQRT((DX2 - DX1)^2 + (DY2 - DY1)^2 + (DZ2 - DZ1)^2)

   Compute Length = distance between DJ1 & DJ2 or, between start node and end node, as the case may be.

   Then, if CAN is specified a value 1, dff = L/Delta

   Ratio due to deflection = DFF/dff

b. If `CAN` = 0, deflection length is defined as the length that is used for calculation of local deflections within a member. It may be noted that for most cases the “Deflection Length” will be equal to the length of the member. However, in some situations, the “Deflection Length” may be different. A straight line joining `DJ1` and `DJ2` is used as the reference line from which local deflections are measured.

   For example, refer to the figure below where a beam has been modeled using four joints and three members. The “Deflection Length” for all three members will be equal to the total length of the beam in this case. The parameters `DJ1` and `DJ2` should be used to model this situation. Thus, for all three members here, `DJ1` should be `1` and `DJ2` should be `4`.

   D = Maximum local deflection for members 1, 2, and 3.

DJ2 4 ALL
```

c. If `DJ1` and `DJ2` are not used, "Deflection Length" will default to the member length and local deflections will be measured from original member line.

d. It is important to note that unless a `DFF` value is specified, STAAD will not perform a deflection check. This is in accordance with the fact that there is no default value for `DFF`.

e. The above parameters may be used in conjunction with other available parameters for steel design.

2. `LEG` – follows the requirements of BS5950 table 28. This table concerns the fastener restraint conditions for angles, double angles, tee sections and channels for slenderness. The following values are available:

Table 119: LEG Parameter values

Clause	Bold Configuration	Leg	LEG Parameter
4.7.10.2 Single Angle	(a) - 2 bolts	short leg	1.0
		long leg	3.0
	(b) - 1 bolts	short leg	0.0

Clause	Bold Configuration	Leg	LEG Parameter
		long leg	2.0
4.7.10.3 Double Angles	(a) - 2 bolts	short leg	3.0
		long leg	7.0
	(b) - 1 bolts	short leg	2.0
		long leg	6.0
	(c) - 2 bolts	long leg	1.0
		short leg	5.0
	(d) - 1 bolts	long leg	0.0
		short leg	4.0
4.7.10.4 Channels	(a) - 2 or more rows of bolts		1.0
	(b) - 1 row of bolts		0.0
4.7.10.5 Tee Sections	(a) - 2 or more rows of bolts		1.0
	(b) - 1 row of bolts		0.0

The slenderness of single and double angle, channel and tee sections are specified in BS 5950 table 25 depending on the connection provided at the end of the member. To define the appropriate connection, a LEG parameter should be assigned to the member.

The following list indicates the value of the LEG parameter required to match the BS5950 connection definition:

Clause 4.7.10.2 Single Angle:

a. 2 Bolts: Short leg = 1.0, Long Leg = 3.0
b. 1 Bolt: Short Leg = 0.0, Long Leg = 2.0

For single angles, the slenderness is calculated for the geometric axes, a-a and b-b as well as the weak v-v axis. The effective lengths of the geometric axes are defined as:

$$La = KY \times LY$$

$$Lb = KZ \times LZ$$

The slenderness calculated for the v-v axis is then used to calculate the compression strength p_c for the weaker principal axis (z-z for ST angles or y-y for RA specified angles). The maximum slenderness of the a-a and b-b axes is used to calculate the compression strength p_c for the stronger principal axis.

Alternatively for single angles where the connection is not known or Table 25 is not appropriate, by setting the LEG parameter to 10, slenderness is calculated for the two principal axes y-y and z-z only. The LVV parameter is not used.

For double angles, the LVV parameter is available to comply with note 5 in table 25. In addition, if using double angles from user tables, (refer to TR.19.4 Double Angle (on page 2248)) an eleventh value, r_{vv}, should be supplied at the end of the ten existing values corresponding to the radius of gyration of the single angle making up the pair.

3. PY – Steel Design Strength

   The design parameter PY should only be used when a uniform design strength for an entire structure or a portion thereof is required. Otherwise the value of PY will be set according to the stipulations of BS5950 table 9 in which the design strength is seen as a function of cross sectional thickness for a particular steel grade (SGR parameter) and particular element considered. Generally speaking this option is not required and the program should be allowed to ascertain the appropriate value.

4. UNL, LY, and LZ – Relevant Effective Length

   The values supplied for UNL, LY and LZ should be real numbers greater than zero in current units of length. They are supplied along with or instead of UNF, KY and KZ (which are factors, not lengths) to define lateral torsional buckling and compression effective lengths respectively. Please note that both UNL or UNF and LY or KY values are required even though they are often the same values. The former relates to compression flange restraint for lateral torsional buckling while the latter is the unrestrained buckling length for compression checks.

5. TRACK – Control of Output Formats

   When the `TRACK` parameter is set to 0.0, 1.0, or 2.0, member capacities will be printed in design related output (code check or member selection) in kilonewtons per square meter.

   `TRACK 4.0` causes the design to carry out a deflection check, usually with a different load list to the main code check. The members that are to be checked must have the parameters `DFF`, `DJ1`, and `DJ2` set.

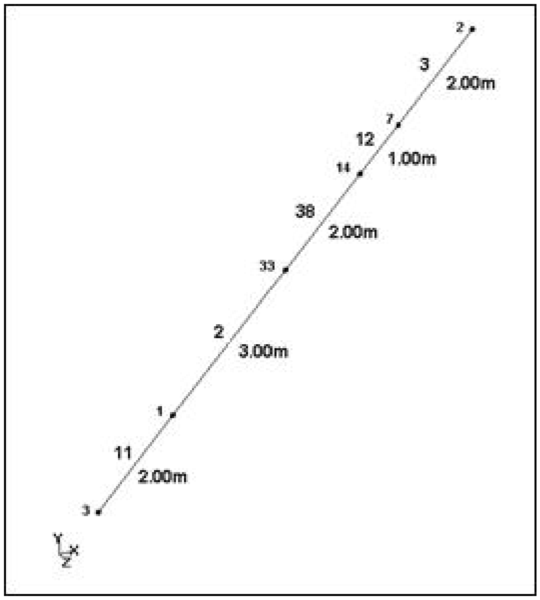
6. MX, MY, MYX, and MLT – Equivalent Moment Factors

   The values for the equivalent moment factors can either be specified directly by the user as a positive value between 0.4 and 1.0 for MX, MY and MYX and 0.44 and 1.0 for MLT.

   The program can be used to calculate the values for the equivalent moment factors by defining the design member with a GROUP command (refer to TR.16.1 Listing of Entities by Specifying Groups (on page 2235)). The nodes along the beam can then be defined as the location of restraint points with J settings.

   Additionally for the MLT parameter, the joint can be defined as having the upper flange restrained (positive local Y) with the a U setting or the lower flange restrained (negative local Y) with a L setting.

   For example, consider a series of 5 beam elements as a single continuous member as shown below:



To enable the steel design, the beam needs to be defined as a group, called MainBeam:

```
START  GROUP DEFINITION
MEMBER
_MainBeam  11 2 38 12 3
END  GROUP DEFINITION
```

Note: This can be done in the User Interface by selecting **Tools** > **Create New Group…**.

Therefore, this 5 beam member has 6 joints such that:

Joint 1 = Node 3
Joint 2 = Node 1
Joint 3 = Node 33
Joint 4 = Node 14
Joint 5 = Node 7
Joint 6 = Node 2

a. Consider MX, MY and MYX

Say that this member has been restrained in its' major axis (local Y) only at the ends. In the minor axis (local Z) it has been restrained at the ends and also at node number 33 (joint 3). For local flexural buckling, it has only been restrained at its ends. Hence:

For the major axis, local Y axis:

MX _MainBeam J1 J6

For the minor axis, local Z axis:

MY _ MainBeam J1 J3 J6

For the lateral flexural buckling, local X axis:

MYX _ MainBeam J1 J6

b. Consider MLT

Say that this member has been restrained at its' ends against lateral torsional buckling and the top flange has been restrained at node number 33 (joint 3) and only the lower flange at node number 7, (joint 5). Hence:

MLT _MainBeam J1 T3 L5 J6

To split the beam into two buckling lengths for L_y at joint 14:

MY _groupname J1 J4 J6

7. SWAY – Sway Loadcase

   This parameter is used to specify a load case that is to be treated as a sway load case in the context of clause 4.8.3.3.4. This load case would be set up to represent the $k_{am\ p}M_s$ mentioned in this clause and the steel design module would add the forces from this load case to the forces of the other load case it is designed for.

   Note that the load case specified with this parameter will not be designed as a separate load case. The following is the correct syntax for the parameter:

Parameter Name	Default Value	Description
SWAY	(load case number)	ALL MEMBER (member list) _(group name)

   Example

```
SWAY  5 MEM 1 to 10
SWAY  6 _MainBeams
```

D3.B.7 Design Operations

STAAD.Pro contains a broad set of facilities for the design of structural members as individual components of an analyzed structure. The member design facilities provide the user with the ability to carry out a number of different design operations. These facilities may be used selectively in accordance with the requirements of the design problem.

The operations to perform a design are:

- Specify the load cases to be considered in the design; the default is all load cases.
- Specify design parameter values, if different from the default values.
- Specify whether to perform code checking or member selection along with the list of members.

These operations may be repeated by the user any number of times depending upon the design requirements.

D3.B.8 Code Checking

The purpose of code checking is to ascertain whether the provided section properties of the members are adequate. The adequacy is checked as per BS5950. Code checking is done using the forces and moments at specific sections of the members. If no sections are specified, the program uses the start and end forces for code checking.

When code checking is selected, the program calculates and prints whether the members have passed or failed the checks; the critical condition of BS5950 code (like any of the BS5950 specifications for compression, tension, shear, etc.); the value of the ratio of the critical condition (overstressed for value more than 1.0 or any other specified RATIO value); the governing load case, and the location (distance from the start of the member of forces in the member where the critical condition occurs).

Code checking can be done with any type of steel section listed in D3.B.4 Built-In Steel Section Library (on page 1380) or any of the user defined sections as described in G.6.3 User-Provided Steel Table (on page 2117) , except profiles defined in GENERAL and ISECTION tables.

Note: PRISMATIC sections are also not acceptable steel sections for design per BS5950 in STAAD.Pro.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

D3.B.9 Member Selection

STAAD.Pro is capable of performing design operations on specified members. Once an analysis has been performed, the program can select the most economical section, i.e., the lightest section, which fulfills the code requirements for the specified member. The section selected will be of the same type section as originally designated for the member being designed. Member selection can also be constrained by the parameters DMAX and DMIN, which limits the maximum and minimum depth of the members.

Member selection can be performed with all the types of steel sections with the same limitations as defined in D3.B.8 Code Checking (on page 1394).

Selection of members, whose properties are originally input from a user created table, will be limited to sections in the user table.

Member selection cannot be performed on members whose section properties are input as prismatic or as above limitations for code checking.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D3.B.10 Tabulated Results of Steel Design

For code checking or member selection, the program produces the results in a tabulated fashion. The items in the output table are explained as follows:

MEMBER	refers to the member number for which the design is performed.
TABLE	refers to steel section name, which has been checked against the steel code or has been selected.
RESULTS	prints whether the member has PASSED or FAILED. If the RESULT is FAIL, there will be an asterisk (*) mark on front of the member.
CRITICAL COND	refers to the section of the BS5950 code which governs the design.
RATIO	prints the ratio of the actual stresses to allowable stresses for the critical condition. Normally a value of 1.0 or less will mean the member has passed.
LOADING	provides the load case number, which governed the design
FX, MY, and MZ	provide the axial force, moment in local Y-axis and the moment in local z-axis respectively. Although STAAD does consider all the member forces and moments (except torsion) to perform design, only FX, MY and MZ are printed since they are the ones which are of interest, in most cases.

LOCATION specifies the actual distance from the start of the member to the section where design forces govern.

TRACK If the parameter TRACK is set to 1.0, the program will block out part of the table and will print the allowable bending capacities in compression (MCY & MCZ) and reduced moment capacities (MRY & MRZ), allowable axial capacity in compression (PC) and tension (PT) and shear capacity (PV). TRACK 2.0 will produce the design results as shown in D3.B.9 Member Selection (on page 1395).

An example of each TRACK setting follows:

D3.B.10.1 Example output for TRACK 0.0

```

    Torsion and deflections have not been considered in the design.
```

D3.B.11 Plate Girders

Sections will be considered for the Plate Girder checks (BS 5950 Section 4.4) if d/t > 70 ε for “rolled sections” or d/t >62 ε for ‘welded sections’. The parameter SBLT should be used to identify sections as rolled or welded; see the parameter list for more information.

If the plate girder has intermediate stiffeners, the spacing is set with the PNL parameter. These are then used to check against the code clauses “4.4.3.2 - Minimum web thickness for serviceability” and ‘4.4.3.3 - Minimum web thickness to avoid compression flange buckling’. The following printout is then included if a TRACK 2.0 output is selected:

```
Shear  Buckling check is required: Vb = 1070 kN : qw    = 118  N/mm2
d   = 900 mm  :   t  =  10 mm   : a  =  200 mm : pyf = 275 N/mm2
BS-4.4.3.2  status = PASS        : BS-4.4.3.3 status  = PASS
```

The section is then checked for shear buckling resistance using clause “4.4.5.2 - Simplified method” and the result is included in the ratio checks.

D3.B.12 Composite Sections

Sections that have been defined as acting compositely with a concrete flange either from a standard database section using the CM option, or from a modified user WIDE FLANGE database with the additional composite parameters, cannot be designed with BS5950:2000.

D3.B.13 Design of Tapered Beams

Sections will be checked as tapered members provided that are defined either as a Tapered I section or from a USER table.

Example using a Tapered I section:

```
UNIT CM
MEMBER PROPERTY
1 TO 5 TAPERED 100 2.5  75 25 4 25 4
```

Example using a USER table:

```
START USER TABLE
TABLE 1
UNIT CM
ISECTION
1000mm_TAPER
100 2.5 75 25 4 25 4 0  0 0
750mm_TAPER
75 2.5 50 25 4 25 4 0  0 0
END
```

You must specify the effective length of unrestrained compression flange using the parameter `UNL`.

The program compares the resistance of members with the applied load effects, in accordance with BS 5950-1:2000. Code checking is carried out for locations specified by the user via the `SECTION` command or the `BEAM` parameter. The results are presented in a form of a PASS/FAIL identifier and a RATIO of load effect to resistance for each member checked. The user may choose the degree of detail in the output data by setting the `TRACK` parameter.

The beam is designed as other wide flange beams apart from the Lateral Torsional Buckling check which is replaced by the Annex G.2.2. check.

D3.B.13.1 Design Equations

A beam defined with tapered properties as defined above will be checked as a regular wide flange (e.g., UB or UC), except that the following is used in place of clause 4.3.6, the lateral torsional buckling check.

D3.B.13.2 Check Moment for Taper Members as per clause G.2.2

The following criterion is checked at each defined check position in the length of the member defined by the BEAM parameter.

$$M_{xi} \leq M_{bi} (1 - F_c/P_c)$$

where

F_c	=	the longitudinal compression at the check location
M_{bi}	=	the buckling resistance moment M_b from 4.3.6 for an equivalent slenderness λ_{TB}, see G.2.4.2, based on the appropriate modulus S, S_{eff}, Z or Z_{eff} of the cross-section at the point i considered
M_{xi}	=	the moment about the major axis acting at the point i considered

P_c	=	the compression resistance from 4.7.4 for a slenderness $\lambda_{TC \cdot y}$, see G.2.3, based on the properties of the minimum depth of cross-section within the segment length L

D3.B.13.2 G.2.3 Slenderness ITC

$\lambda_{TC} = y\lambda$

where

y	=	$\left[\frac{1 + (2a / h_s)^2}{1 + (2a / h_s)^2 + 0.05(\lambda / x)^2} \right]^{0.5}$
λ	=	L_y / r_y
a	=	the distance between the reference axis and the axis of restraint,
h_s	=	the distance between the shear centers of the flanges
L_y	=	the length of the segment
r_y	=	the radius of gyration for buckling about the minor axis
x	=	is the torsional index

D3.B.13.4 G.2.4.2 Equivalent slenderness ITB for tapered members

$\lambda_{TB} = cn_t v_t \lambda$

Where, for a two-flange haunch:

$$v_t = \left[\frac{4a / h_s}{1 + (2a / h_s)^2 + 0.05(\lambda / x)^2} \right]^{0.5}$$

where

C	=	the taper factor, see G.2.5

D3.B.13.5 G.2.5 Taper factor

For an I-section with $D \geq 1.2B$ and $x \geq 20$, the taper factor, c, is as follows:

$$c = 1 + \frac{3}{x - 9}\left(\frac{D_{max}}{D_{min}} - 1\right)^{2/3}$$

where

D_{max}	=	the maximum depth of cross-section within the length Ly, see Figure G.3
D_{min}	=	the minimum depth of cross-section within the length Ly, see Figure G.3
x	=	the torsional index of the minimum depth cross-section, see 4.3.6.8

Otherwise, c is taken as 1.0 (unity).

D3.C. British Codes - Design per BS5400

STAAD.Pro is capable of performing steel design based on the British code BS 5400:Part 3:1982 *Steel, concrete and composite bridges Part 3. Code of practice for design of steel bridges* and Amd No. 4051 and Amd No. 6488.

D3.C.1 General Comments

The British Standard, BS5400 adopts the limit state design philosophy and is applicable to steel, concrete, and composite construction. The code is in ten parts covering various aspects of bridge design. The implementation of part 3, Code of practice for design of steel bridges, in STAAD is restricted in its scope to simply supported spans. It is assumed that the depth remains constant and both construction and composite stages of steel I-Sections can be checked. The following sections describe in more detail features of the design process currently available in STAAD.

D3.C.2 Shape Limitations

The capacity of sections could be limited by local buckling if the ratio of flange outstand to thickness is large. In order to prevent this, the code sets limits to the ratio as per clause 9.3.2. In the event of exceeding these limits, the design process will terminate with reference to the clause.

D3.C.3 Section Class

Sections are further defined as compact or noncompact. In the case of compact sections, the full plastic moment capacity can be attained. In the case of noncompact sections, local buckling of elements may occur prior to reaching the full moment capacity and for this reason the extreme fibre stresses are limited to first yield. In STAAD, section types are determined as per clause 9.3.7 and the checks that follow will relate to the type of section considered.

D3.C.4 Moment Capacity

Lateral torsional buckling may occur if a member has unrestrained elements in compression. The code deals with this effect by limiting the compressive stress to a value depending on the slenderness parameter which is a modified form of the ratio Le/Ry. Le is the effective length governed by the provision of lateral restraints satisfying the requirements of clause 9.12.1. Once the allowable compressive stress is determined then the moment capacity appropriate to the section type can be calculated. STAAD takes the effective length as that provided by the user, defaulting to the length of the member during construction stage and as zero, assuming full restraint throughout, for the composite stage. The program then proceeds to calculate the allowable compressive stress based on appendix G7 from which the moment capacity is then determined.

D3.C.5 Shear Capacity

The shear capacity, as outlined in clause is a function of the limiting shear strength, l, which is dependent on the slenderness ratio. STAAD.Pro follows the iterative procedure of appendix G8 to determine the limiting shear strength of the web panel. The shear capacity is then calculated based on the formula given under clause 9.9.2.2.

D3.C.6 Design Parameters

Available design parameters to be used in conjunction with BS5400 are listed in table 2C.1. Depending on the value assigned to the `WET` parameter, you can determine the stage under consideration. For a composite design check, taking into consideration the construction stage, two separate analyses are required. In the first, member properties are non-composite and the WET parameter is set to 1.0 . In the second, member properties should be changed to composite and the `WET` parameter set to 2.0. Member properties for composite or non-composite sections should be specified from user provided tables (refer to section 5.19 of the manual for specification of user tables). Rolled sections, composite or non-composite, come under WIDE FLANGE section-type and built-up sections under ISECTION. When specifying composite properties the first parameter is assigned a negative value and four additional parameters provided giving details of the concrete section. See user table examples provided.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 120: BS5400 Design Parameters

Parameter Name	Default Value	Description
ESTIFF	0	Specify the criteria used for the design of compression members with moments. 0. Member passes if *either* Cl. 4.8.3.3.1 *or* Cl. 4.8.3.3.2 check. 1. Member passes if *both* Cl. 4.8.3.3.1 *and* Cl. 4.8.3.3.2 check.
KY	1.0	K value for bending about Y-axis. Usually this is minor axis.
KZ	1.0	K value for bending about Z-axis. Usually this is major axis.
LY	Member Length	Length to calculate slenderness ratio for bending about Y-axis, in current units of length.
LZ	Member Length	Length to calculate slenderness ratio for bending about Z-axis, in current units of length.
MAIN	1.0	Grade of concrete: 1. 30 N/mm2 2. 40 N/mm2 3. 50 N/mm2
NSF	1.0	Net section factor for tension members.
PY	*	Yield stress of steel. Set according to Design Strength of steel SGR
RATIO	1	Permissible ratio of actual to allowable stresses.

Parameter Name	Default Value	Description
SBLT	0.0	Steel 0.0 = Rolled Section 1.0 = Built up Section
SGR	0.0	Steel Grade per BS4360 0. Grade 43 1. Grade 50 2. Grade 55
TRACK	1.0	Used to control the level of detail in the output 0. Suppress all member capacities 1. Print all member capacities
UNL	Member Length	Unsupported length for calculating allowable compressive bending stress, in current units of length.
WET	0.0	Used to specify the stage of construction. 0. Wet stage with no data saved for composite stage 1. Wet stage with data saved for composite stage 2. Composite and wet stage combined 3. Composite stage only

D3.C.7 Composite Sections

The definition of composite sections has been provided for in the standard sections definition (refer to TR.20.1 Assigning Properties from Steel Tables (on page 2257) for details). This is purely for analysis and for obtaining the right section properties. It uses the American requirement of 18 times depth (CT) as the effective depth. For more control with British sections two new options are available in user provided tables.

D3.C.7.1 Wide Flange Composite

Using the standard definition of I sections in WIDE FLANGE, 4 additional values can now be provided. The first is the width of concrete to the left of center of the steel web (b1). The second is the concrete width to the right (b2). The third is the concrete depth (d1) to be considered. The last is the modular ratio. The above values are accepted in the program by adding a '-' at the first position on the first line of data. The program now awaits four extra values on line 2 as described above. If (-) is provided on the second line the program requires another 2 breadths + 1 thickness for the bottom plate.

D3.C.7.2 I Section

The same is true for ISECTION definition in user table.

D3.C.7.3 Example

```
UNIT  CM
WIDE  FLANGE
C45752
-66.5  44.98 .76 15.24 1.09 21345 645 21.3 34.185 33.223
150  150 30 10
ISECTION
PG9144
-92.05  2.15 92.05 42.05 3.66 42.05 3.66 197.9 153.9 1730
40 40  12 1
```

The larger British sections have been coded as USER TABLES under wide flange and are available on request to any existing user. Please note however that composite design is *not* available in this portion of STAAD.

D3.D. British Codes - Design per BS8007

STAAD.Pro is capable of performing concrete design based on the British code BS8007:1987 *Design of concrete structures for retaining aqueous liquids*. It is recommended that the design of the structure is carried out according to BS8110, unless modified by the recommendations given in BS8007.

The information in this section is to be used in conjunction with the BS8110. Refer to D3.A. British Codes - Concrete Design per BS8110 (on page 1378)

D3.D.1 Design Process

The design process is carried out in three stages.

1. Ultimate Limit States

   The program is structured so that ultimate design is first carried out in accordance with recommendations given in BS8110. All active design load cases are considered in turn and a tabulated output is printed showing possible reinforcement arrangements. 12, 16, and 20 mm bars are considered with possible spacings from 100,125,150,175, and 200 mm. Within these spacings, the layout providing the closest area of steel is printed under each bar size. Longitudinal and transverse moments together with critical load cases for both hogging and sagging moments are also printed. Minimum reinforcement is in any case checked and provided in each direction. Wood & Armer moments may also be included in the design.
2. Serviceability Limit States

   In the second stage, flexural crack widths under serviceability load cases are calculated. The *first* and *every other occurring* design load case is considered as a serviceability load case and crack widths are calculated based on bar sizes and spacings proposed at the ultimate limit state check.
3. Thermal crack widths

   Crack widths due to longitudinal and transverse moments are calculated directly under bars, midway between and at corners. A tabulated output indicating critical serviceability load cases and moments for top and bottom of the slab is then produced.

Finally thermal, crack width calculations are carried out. Through available parameters, the user is able to provide information on the type of slab, temperature range and crack width limits.

Surface zone depths are determined based on the type of slab and critical areas of reinforcements are calculated and printed in a tabulated form.

Four bar sizes are considered and for each, max crack spacing, Smax and crack widths are calculated for the critical reinforcements and printed under each bar size.

Maximum bar spacing to limit crack widths to the user's limit is also printed under each bar size.

D3.D.2 Design Parameters

The program contains a number of parameters which are needed to perform and control the design to BS8007.

These parameters not only act as a method to input required data for code calculations but give the Engineer control over the actual design process. Default values of commonly used values for conventional design practice have been chosen as the basis. Table 2D.1 contains a complete list of available parameters with their default values.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 121: BS8007 Design Parameters

Parameter Name	Default Value	Description
FC	30 N/mm^2	Concrete grade, in current units of length and force.
CLEAR	20 mm	Distance from the outer surface to the edge of the bar, in current units of length. This is considered the same on both surfaces.
SRA	0.0	Orthogonal reinforcement layout without considering torsional moment Mxy - slabs on -500.orthogonal reinforcement layout with Mxy used to calculate Wood & Armer moments for design. A* Skew angle considered in Wood & Armer equations. A* is any angle in degrees.
SCON	1	Parameter which indicates the type of slab ee. ground or suspended as defined in BS8007 1 = Suspended Slab 2 = Ground Slab

Parameter Name	Default Value	Description
TEMP	30°C	Temperature range to be considered in thermal crack width calculations
CRACK *	0.2 mm	Limiting thermal crack width, in current units of length.

* Provided in current unit systems

D3.D.3 Structural Model

Structural slabs that are to be designed to BS8007 must be modeled using finite elements. Refer to G.5 Finite Element Information (on page 2099) for information on the sign convention used in the program for defining elements

It is recommended to connect elements in such a way that the positive local z axis points outwards away, from the center of the container. In this manner the "Top" of elements will consistently fall on the outer surface and internal pressure loads will act in the positive direction of the local z axis.

An example of a rectangular tank is provided to demonstrate the above procedure.

Element properties are based on the thickness given under `ELEMENT PROPERTIES` command. The following example demonstrates the required input for a 300 mm slab modeled with ten elements.

```
UNIT  MM
ELEMENT  PROPERTIES
1 TO  10 THI 300.0
```

D3.D.4 Wood & Armer Moments

This is controlled by the SRA parameter. If the default value of zero is used, the design will be based on the Mx and My moments which are the direct results of STAAD analysis. The SRA parameter (Set Reinforcement Angle) can be manipulated to introduce Wood & Armer moments into the design replacing the pure Mx, My moments. These new design moments allow the Mxy moment to be considered when designing the section. Orthogonal or skew reinforcement may be considered. SRA set to -500 will assume an orthogonal layout. If however a skew is to be considered, an angle is given in degrees, measured between the local element x axis anti-clockwise (positive). The resulting Mx* and My* moments are calculated and shown in the design format.

D3.E. British Codes - Design per British Cold Formed Steel Code

STAAD.Pro is capable of performing steel design based on the British code BS 5950-5:1998 *Structural use of steelwork in building - Part 5: Code of practice for design of cold formed thin gauge sections* . The program allows design of single (non-composite) members in tension, compression, bending, shear, as well as their combinations. Cold work of forming strengthening effects have been included as an option.

D3.E.1 Cross-Sectional Properties

You specify the geometry of the cross-section by selecting one of the section shape designations from the Gross Section Property Tables published in the “The Steel Construction Institute”, (*Design of Structures using Cold Formed Steel Sections*).

The Tables are currently available for the following shapes:

- Channel with Lips
- Channel without Lips
- Z with Lips
- Pipe
- Tube

Shape assignment may be done using the Properties - Whole Strucutre dialog (on page 2793) of the graphical user interface (GUI) or by specifying the section designation symbol in the input file.

The properties listed in the tables are gross section properties. STAAD.Pro uses unreduced section properties in the structure analysis stage. Both unreduced and effective section properties are used in the design stage, as applicable.

D3.E.2 Design Procedure

The following two design modes are available:

D3.E.2.1 Code Checking

The program compares the resistance of members with the applied load effects, in accordance with BS 5950-5:1998. Code checking is carried out for locations specified by the user via the `SECTION` command or the BEAM parameter. The results are presented in a form of a PASS/FAIL identifier and a RATIO of load effect to resistance for each member checked. The user may choose the degree of detail in the output data by setting the TRACK parameter.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

D3.E.2.2 Member Selection

The user may request that the program search the cold formed steel shapes database (BS standard sections) for alternative members that pass the code check and meet the least weight criterion. In addition, a minimum and/or maximum acceptable depth of the member may be specified. The program will then evaluate all database sections of the type initially specified (i.e., channel, angle, etc.) and, if a suitable replacement is found, presents design results for that section. If no section satisfying the depth restrictions or lighter than the initial one can be found, the program leaves the member unchanged, regardless of whether it passes the code check or not.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

The program calculates effective section properties in accordance with Section 4 of the subject code. Cross-sectional properties and overall slenderness of members are checked for compliance with:

- Clause 6.2.2, Maximum Effective Slenderness Ratio for members in Compression
- Clause 4.2, Maximum Flat Width Ratios for Elements in Compression

D3.E.3 Design Equations

D3.E.3.1 Tensile Strength

The allowable tensile strength, as calculated in STAAD as per BS5950-5, section 7 is described below.

The tensile strength, P_t of the member should be determined from clause 7.2.1

$$P_t = A_e p_y$$

where

A_e	=	the net area An determined in accordance with cl.3.5.4
p_y	=	the design strength

D3.E.3.2 Combined bending and tension

As per clause 7.3 of BS 5950-5:1998 members subjected to both axial tension and bending should be proportioned such that the following relationships are satisfied at the ultimate limit state

$$F_t/P^t + M_z/M_{cz} + M_y/M_{cy} \le 1$$

$$M_z/M_{cz} \le 1$$

and

$$M_y/M_{cy} \le 1$$

where

F_t	=	the applies tensile strength
P_t	=	the tensile capacity determined in accordance with clause 7.2.1 of the subject code
M_z,M_y,M_{cz},M_{cy}	=	as defined in clause 6.4.2 of the subject code

D3.E.3.3 Compressive Strength

The allowable Compressive strength, as calculated in STAAD as per BS5950-5, section 6 is described below

For sections symmetrical about both principal axes or closed cross-sections which are not subjected to torsional flexural buckling, the buckling resistance under axial load, Pc, may be obtained from the following equation as per clause 6.2.3 of the subject code

$$P_c = \frac{P_E P_{cs}}{\phi + \sqrt{\phi^2 - P_E P_{cs}}}$$

For sections symmetrical about a single axis and which are not subject to torsional flexural buckling, the buckling resistance under axial load, P_c, may be obtained from the following equation as per clause 6.2.4 of the subject code

$$P'_c = \frac{M_c P_c}{(M_c + P_c e_s)}$$

Where the meanings of the symbols used are indicated in the subject clauses.

D3.E.3.4 Torsional flexural buckling

Design of the members which have at least one axis of symmetry, and which are subject to torsional flexural buckling should be done according to the stipulations of the clause 6.3.2 using factored slenderness ratio $\alpha L_E/r$ in place of actual slenderness ratio while reading Table 10 for the value of Compressive strength(p_c).

where

α	=	(P_E/P_{TF}) when $P_E > P_{TF}$
α	=	1, otherwise

Where the meanings of the symbols used are indicated in the subject clause.

D3.E.3.5 Combined bending and compression

Members subjected to both axial compression and bending should be checked for local capacity and overall buckling

Local capacity check as per clause 6.4.2 of the subject code

$$F_c/P^{cs} + M_z/M_{cz} + M_y/M_{cy} \leq 1$$

D3.E.3.6 Overall buckling check as per clause 6.4.3 of the subject code

For beams not subjected to lateral buckling, the following relationship should be satisfied

$$\frac{F_c}{P_c} + \frac{M_z}{C_{bx} M_{cz}\left(1 - \frac{F_c}{P_{Ez}}\right)} + \frac{M_y}{C_{by} M_{cy}\left(1 - \frac{F_c}{P_{Ey}}\right)} \leq 1$$

For beams subjected to lateral buckling, the following relationship should be satisfied:

$$\frac{F_c}{P_c} + \frac{M_z}{M_b} + \frac{M_y}{C_{by} M_{cy}\left(1 - \frac{F_c}{P_{Ey}}\right)} \leq 1$$

where

F_c	=	the applied axial load
P_{cs}	=	the short strut capacity as per clause 6.2.3
M_z	=	the applied bending moment about z axis
M_y	=	the applied bending moment about y axis
M_{cz}	=	the moment capacity in bending about the local Z axis in the absence of F_c and M_y, as per clause 5.2.2 and 5.6
M_{cy}	=	the moment capacity in bending about the local Y axis, in the absence of F_c and M_z,as per clause 5.2.2 and 5.6
M_b	=	the lateral buckling resistance moment as per clause 5.6.2
P_{Ez}	=	the flexural buckling load in compression for bending about the local Z axis
P_{Ey}	=	the flexural buckling load in compression for bending about the local Y axis
C_{bz}, C_{by}	=	taken as unity unless their values are specified by the user

M_{cz}, M_{cy}, and M_b are calculated from clause numbers 5.2.2 and 5.6 in the manner described herein below.

For restrained beams, the applied moment based on factored loads should not be greater then the bending moment resistance of the section, M_c

$$M_{cz} = S_{zz} \text{ x } p_o$$

$$M_{cy} = S_{yy} \text{x } p_o$$

$$p_o = \left(1.13 - 0.0019\frac{D_w}{t}\sqrt{\frac{Y_s}{280}}\right)p_y$$

Where

where

M_{cz}	=	the Moment resistance of the section in z axis
M_{cz}	=	the Moment resistance of the section in z axis
p_o	=	the limiting stress for bending elements under stress gradient and should not greater then design strength p_y

For unrestrained beams the applied moment based on factored loads should not be greater than the smaller of the bending moment resistance of the section , M_c , and the buckling resistance moment of the beam, M_b

Then buckling resistance moment, M_b, may be calculated as follows

$$M_b = \frac{M_E M_y}{\phi_B + \sqrt{\phi_B^2 - M_E M_y}} \leq M_c$$

$$\varphi_B = [M_y + (1 + \eta)M_E]/2$$

where

M_Y	=	the yield moment of the section , product of design strength p_y and elastic modules of the gross section with respect to the compression flange Zc
M_E	=	the elastic lateral buckling resistance as per clause 5.6.2.2
η	=	the Perry coefficient

Please refer clause numbers 5.2.2 and 5.6 of the subject code for a detailed discussion regarding the parameters used in the above mentioned equations.

The maximum shear stress should not be greater then 0.7 ´ p_y as per clause 5.4.2

The average shear stress should not exceed the lesser of the shear yield strength, p_v or the shear buckling strength, q_{cr} as stipulated in clause 5.4.3 of the subject code.

The parameters are calculated as follows:

$$p_v = 0.6 \cdot p_y$$

$$q_{cr} = (1000 \cdot t/D)^2 \text{ N/mm}^2$$

$$P_v = A \cdot \min(p_v,\ q_{cr})$$

where

P_v	=	the shear capacity in N/mm^2
p_y	=	the design strength in N/mm^2
t	=	the web thickness in mm
D	=	the web depth in mm

For beam webs subjected to both bending and shear stresses the member should be designed to satisfy the following relationship as per the stipulations of clause 5.5.2 of the subject code

$$(F_v/P_v)^2 + (M/M_c)^2 \leq 1$$

where

F_v	=	the shear force
M	=	the bending moment acting at the same section as F_v
M_c	=	the moment capacity determined in accordance with 5.2.2

D3.E.4 Design Parameters

The design parameters outlined in Table 2E.1 are used to control the design procedure. These parameters communicate design decisions from the engineer to the program and thus allow the engineer to control the design process to suit an application's specific needs.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements, some or all of these parameter values may be changed to exactly model the physical structure.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 122: British Cold Formed Steel Design Parameters

Parameter Name	Default Value	Description
CODE	BS5950 COLD	Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
BEAM	1.0	When this parameter is set to 1.0 (default), the adequacy of the member is determined by checking a total of 13 equally spaced locations along the length of the member. If the BEAM value is 0.0, the 13 location check is not conducted, and instead, checking is done only at the locations specified by the SECTION command (See STAAD manual for details. For TRUSS members only start and end locations are designed.
CMZ	1.0	Coefficient of equivalent uniform bending C_b. See BS: 5950-5:1998,5.6. Used for Combined axial load and bending design.
CMY	1.0	Coefficient of equivalent uniform bending C_b. See BS: 5950-5:1998,5.6. Used for Combined axial load and bending design.
CWY	1.0	Specifies whether the cold work of forming strengthening effect should be included in resistance computation. See BS: 5950-5:1998,3.4 0 – effect should not be included 1 – effect should be included

Parameter Name	Default Value	Description
FLX	1	Specifies whether torsional-flexural buckling restraint is provided or is not necessary for the member. See BS:5950-5:1998, 5.6 Values: 0 – Section subject to torsional flexural buckling 1 – Section *not* subject to torsional flexural buckling
FU	430 MPa	Ultimate tensile strength of steel in current units.
FYLD	250 MPa	Yield strength of steel in current units.
KX	1.0	Effective length factor for torsional buckling. It is a fraction and is unit-less. Values can range from 0.01 (for a column completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for twisting for determining the capacity in axial compression.
KY	1.0	Effective length factor for overall buckling about the local Y-axis. It is a fraction and is unit-less. Values can range from 0.01 (for a column completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the capacity in axial compression.
KZ	1.0	Effective length factor for overall buckling in the local Z-axis. It is a fraction and is unit-less. Values can range from 0.01 (for a member completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the capacity in axial compression.

Parameter Name	Default Value	Description
LX	Member length	Unbraced length for twisting. It is input in the current units of length. Values can range from 0.01 (for a member completely prevented from torsional buckling) to any user specified large value. It is used to compute the KL/R ratio for twisting for determining the capacity in axial compression.
LY	Member length	Effective length for overall buckling in the local Y-axis. It is input in the current units of length. Values can range from 0.01 (for a member completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the capacity in axial compression.
LZ	Member length	Effective length for overall buckling in the local Z-axis. It is input in the current units of length. Values can range from 0.01 (for a member completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the capacity in axial compression.
MAIN	0	Specify the design for slenderness against the maximum slenderness as per Clause 6.2.2: 0 – Do not check slenderness ratio 1 – Check members resisting normal loads (180) 2 - Check members resisting self-weight and wind loads (250) 3 - Check members resisting reversal of stress (350)
NSF	1.0	Net section factor for tension members

Parameter Name	Default Value	Description
DMAX	2540.0 cm.	Maximum allowable depth. It is input in the current units of length.
RATIO	1.0	Permissible ratio of actual to allowable stresses
TRACK	0	This parameter is used to control the level of detail in which the design output is reported in the output file. The allowable values are: 0 - Prints only the member number, section name, ratio, and PASS/FAIL status. 1 - Prints the design summary in addition to that printed by TRACK 1 2 - Prints member and material properties in addition to that printed by TRACK 2.

D4. Canadian Codes

D4.A. Canadian Codes - Concrete Design per CSA Standard A23.3-94

STAAD.Pro is capable of performing concrete design based on the Candadian code CSA A23.3 1994 *Design of Concrete Structures*. Given the width and depth (or diameter for circular columns) of a section, the program will calculate the required reinforcement to resist the forces and moments.

D4.A.1 Section Types for Concrete Design

The following types of cross sections for concrete members can be designed.

- For Beams - Prismatic (Rectangular, Square & Tee)
- For Columns - Prismatic (Rectangular, Square and Circular)
- For Slabs - 4-noded Plate Elements

D4.A.2 Member Dimensions

Concrete members that are to be designed by STAAD must have certain section properties input under the `MEMBER PROPERTIES` command. The following example demonstrates the required input:

```
UNIT  MM
MEMBER  PROPERTIES
1 3  TO 7 9 PRISM YD 450. ZD 300.
11 14  PR YD 300.
```

In the above input, the first set of members are rectangular (450mm depth and 300mm width) and the second set of members, with only depth and no width provided, will be assumed to be circular with a 300mm diameter

D4.A.3 Slenderness Effects and Analysis Considerations

STAAD.Pro provides the user with two methods of accounting for the slenderness effect in the analysis and design of concrete members. The first method is equivalent to the procedure presented in CSA Standard A23.3-94 Clause 10.13. STAAD.Pro accounts for the secondary moments, due to axial loads and deflections, when the `PDELTA ANALYSIS` command is used. After solving for the joint displacements of the structure, the program calculates the additional moments induced in the structure due to the P-Delta effect. Therefore, by performing a P-Delta analysis, member forces are calculated which will require no user modification before beginning member design. Refer to TR.37.2 P-Delta Analysis Options (on page 2621) for additional details on this analysis facility.

The second method by which STAAD allows the user to account for the slenderness effect is through user supplied moment magnification factors (see the parameter `MMAG` in D4.A.4 Design Parameters (on page 1414)). Here the user approximates the additional moment by supplying a factor by which moments will be multiplied before beginning member design. This second procedure allows slenderness to be considered in accordance with Clause 10.14 of the code.

Note: STAAD.Pro does not factor loads automatically for concrete design. All the proper factored loads must be provided by the user before the `ANALYSIS` specification.

While performing a P-Delta analysis, all load cases must be defined as primary load cases. If the effects of separate load cases are to be combined, it should be done either by using the `REPEAT LOAD` command or by specifying the load information of these individual loading cases under one single load case. Usage of the `LOAD COMBINATION` command will yield incorrect results for P-Delta Analysis in STAAD.Pro.

D4.A.4 Design Parameters

The program contains a number of parameters which are needed to perform design per CSA Standard A23.3-94. These parameters not only act as a method to input required data for code calculations but give the engineer control over the actual design process.

Default values, which are commonly used numbers in conventional design practice, have been used for simplicity. The following table contains a list of available parameters and their default values. It is necessary to declare length and force units as Millimeter and Newton before performing the concrete design.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 123: Canadian Concrete Design CSA-A23.3-94 Parameters

Parameter Name	Default Value	Description
CLB	40	Clear cover to reinforcing bar at bottom of cross section, in mm.
CLS	40	Clear cover to reinforcing bar along the side of the cross section, in mm.

Parameter Name	Default Value	Description
CLT	40	Clear cover to reinforcing bar at top of cross section, in mm.
DEPTH	YD	Depth of the concrete member. This value defaults to YD as provided in the `MEMBER PROPERTIES`.
EFACE	0.0 (Face of Support)	Distance of face of support from end node of beam. Used for shear and torsion calculation. **Note:** Both `SFACE` & `EFACE` must be positive numbers.
FC	30	Specified compressive strength of concrete, in N/mm^2.
FYMAIN	400	Yield Stress for main reinforcing steel, in N/mm^2.
FYSEC	400	Yield Stress for secondary reinforcing steel, in N/mm^2.
MAXMAIN	7 (Number 55 bar)	Maximum main reinforcement bar size. The parameter values for metric bar sizes are: 0) 10 mm 1) 15 mm 2) 20 mm 3) 25 mm 4) 30 mm 5) 35 mm 6) 45 mm 7) 55 mm

Parameter Name	Default Value	Description
MINMAIN	0 (Number 10 bar)	Minimum main reinforcement bar size. The parameter values for metric bar sizes are: 0) 10 mm 1) 15 mm 2) 20 mm 3) 25 mm 4) 30 mm 5) 35 mm 6) 45 mm 7) 55 mm
MINSEC	0 (Number 10 bar)	Minimum secondary (stirrup) reinforcement bar size. The parameter values for metric bar sizes are: 0) 10 mm 1) 15 mm 2) 20 mm 3) 25 mm 4) 30 mm 5) 35 mm 6) 45 mm 7) 55 mm
MMAG	1.0	A factor by which the column design moments will be magnified.
NSECTION	12	Number of equally-spaced sections to be considered in finding critical moments for beam design.
REINF	0	Column comfining reinforcement type: 0) Tied column 1) Spiral reinforcement

Parameter Name	Default Value	Description
SFACE	0.0	Distance of face of support from start node of beam. Used for shear and torsion calculation. **Note:** Both SFACE & EFACE must be positive numbers.
TRACK	0	Specify the level of detail in the output: 0) Critical Moment will not be printed out with beam design report. 1) Moments will be printed.
WIDTH	ZD	Width of the concrete member. This value defaults to ZD as provided in the MEMBER PROPERTIES.

D4.A.5 Beam Design

Beams are designed for flexure, shear and torsion. For all these forces, all active beam loadings are scanned to create moment and shear envelopes, and locate critical sections. The total number of sections considered is thirteen (start, end, and 11 intermediate), unless that number is redefined with the NSECTION parameter.

D4.A.5.1 Design for Flexure

Design for flexure is performed per the rules of Chapter 10 of CSA Standard A23.3-94. Maximum sagging (creating tensile stress at the bottom face of the beam) and hogging (creating tensile stress at the top face) moments are calculated for all active load cases at each of the thirteen sections. Each of these sections are designed to resist the critical sagging and hogging moments. Currently, design of singly reinforced sections only is permitted. If the section dimensions are inadequate as a singly reinforced section, such a message will be printed in the output. Flexural design of beams is performed in two passes. In the first pass, effective depths of the sections are determined with the assumption of single layer of assumed reinforcement and reinforcement requirements are calculated. After the preliminary design, reinforcing bars are chosen from the internal database in single or multiple layers. The entire flexure design is performed again in a second pass taking into account the changed effective depths of sections calculated on the basis of reinforcement provided after the preliminary design. Final provision of flexural reinforcements are made then. Efforts have been made to meet the guideline for the curtailment of reinforcements as per CSA Standard A23.3-94. Although exact curtailment lengths are not mentioned explicitly in the design output (which finally will be more or less guided by the detailer taking into account other practical considerations), the user has the choice of printing reinforcements provided by STAAD at 13 equally spaced sections from which the final detailed drawing can be prepared.

The following annotations apply to the output for Beam Design.

LEVEL	Serial number of bar level which may contain one or more bar group.
HEIGHT	Height of bar level from the bottom of beam.
BAR INFOrmation	Reinforcement bar information specifying number of bars and size.

FROM	Distance from the start of the beam to the start of the rebar.
TO	Distance from the start of the beam to the end of the rebar.
ANCHOR(STA,END)	States whether anchorage, either a hook or continuation, is needed at start (STA) or at the end (END) of the bar.

D4.A.5.2 Design for Shear and Torsion

Design for shear and torsion is performed per the rules of Chapter 11 of CSA Standard A23.3-94. Shear reinforcement is calculated to resist both shear forces and torsional moments. Shear design is performed at the start and end sections. The location along the member span for design is chosen as the effective depth + SFACE at the start, and effective depth + EFACE at the end. The load case which gives rise to the highest stirrup area for shear & torsion is chosen as the critical one. The calculations are performed assuming 2-legged stirrups will be provided. The additional longitudinal steel area required for torsion is reported.

The stirrups are assumed to be U-shaped for beams with no torsion, and closed hoops for beams subjected to torsion.

D4.A.5.3 Example of Input

Example of Input Data for Beam Design

END  CONCRETE DESIGN
```

D4.A.6 Column Design

Column design is performed per the rules of Chapters 7 & 8 of the CSA Standard A23.3-94. Columns are designed for axial force and biaxial moments at the ends. All active loadings are tested to calculate reinforcement. The loading which produces maximum reinforcement is called the critical load. Column design is done for square, rectangular and circular sections. For rectangular and square sections, the reinforcement is always assumed to be equally distributed on each side. That means the total number of bars will always be a multiple of four (4). This may cause slightly conservative results in some cases.

```

D4.A.7 Slab and Wall Design

To design a slab or wall, it must be modeled using finite elements. The commands for specifying elements are in accordance with the relevant sections of the Technical Reference Manual.

Elements are designed for the moments Mx and My using the same principles as those for beams in flexure. The width of the beam is assumed to be unity for this purpose. These moments are obtained from the element force output. The reinforcement required to resist Mx moment is denoted as longitudinal reinforcement and the reinforcement required to resist My moment is denoted as transverse reinforcement. The effective depth is calculated assuming #10 bars are provided. The parameters `FYMAIN`, `FC`, `CLT`, and `CLB` listed in D4.A.4 Design Parameters (on page 1414) are relevant to slab design. Other parameters mentioned in Table 3A.1 are not applicable to slab design. The output consists only of area of steel required. Actual bar arrangement is not calculated because an element most likely represents just a fraction of the total slab area.

D4.B.1 General Comments

The design of structural steel members in accordance with the specification CAN/CSA S16-01 Limit States Design of Steel Structures is can be used in STAAD.Pro. This code supercedes the previous edition of the code CAN/CSA – S16.1-94.

The design philosophy embodied in this specification is based on the concept of limit state design. Structures are designed and proportioned taking into consideration the limit states at which they would become unfit for their intended use. Two major categories of limit-states are recognized - ultimate and serviceability. The primary considerations in ultimate limit state design are strength and stability, while that in serviceability is deflection. Appropriate load and resistance factors are used so that a uniform reliability is achieved for all steel structures under various loading conditions and at the same time the probability of limits being surpassed is acceptably low.

In the STAAD.Pro implementation, members are proportioned to resist the design loads without exceeding the limit states of strength, stability and serviceability. Accordingly, the most economic section is selected on the basis of the least weight criteria as augmented by the designer in specification of allowable member depths, desired section type, or other such parameters. The code checking portion of the program checks whether code requirements for each selected section are met and identifies the governing criteria.

The following sections describe the salient features of the STAAD.Pro implementation of CAN/CSA-S16-01. A detailed description of the design process along with its underlying concepts and assumptions is available in the specification document.

D4.B.2 Analysis Methodology

The elastic analysis method is used to obtain the forces and moments for design. Analysis is done for the specified primary and combination loading condition. You are allowed complete flexibility in providing loading specifications and using appropriate load factors to create necessary loading situations. Depending upon the analysis requirements, regular stiffness analysis or P-Delta analysis may be specified. Dynamic analysis may also be performed and the results combined with static analysis results.

D4.B.3 Member Property Specifications

For specification of member properties, the steel section library available in STAAD.Pro may be used. The next section describes the syntax of commands used to assign properties from the built-in steel table. Member properties may also be specified using the User Table facility. For more information on these facilities, refer to the STAAD.Pro Technical Reference Manual.

D4.B.4 Built-in Steel Section Library

The following information is provided for use when the built-in steel tables are to be referenced for member property specification. These properties are stored in a database file. If called for, the properties are also used for member design. Since the shear areas are built into these tables, shear deformation is always considered during the analysis of these members.

Almost all Canadian steel sections are available for input. A complete listing of the sections available in the built-in steel section library may be obtained by using the tools of the graphical user interface.

Following is the description of the different types of sections available:

D4.B.4.1 Welded Wide Flanges (WW shapes)

Welded wide flange shapes listed in the CSA steel tables can be designated using the same scheme used by CSA. The following example illustrates the specification of welded wide flange shapes.

```
100 TO 150 TA ST WW400X444
34 35 TA ST WW900X347
```

D4.B.4.2 Wide Flanges (W shapes)

Designation of wide flanges in STAAD is the same as that in CSA tables. For example,

```
10 TO 75 95 TO 105 TA ST W460X106
100 TO 200 TA ST W610X101
```

D4.B.4.3 S, M, HP shapes

In addition to welded wide flanges and regular wide flanges, other I shaped sections like S, M and HP shapes are also available. The designation scheme is identical to that listed in the CSA tables. While specifying the sections, it should be remembered that the portion after the decimal point should be omitted. Thus, M310X17.6 should be specified as M310X17 and S180X22.8 should be specified as S180X22. Examples illustrating specifications of these shapes are provided below.

```
10 TO 20 BY 2 TA ST S510X98
45 TO 55 TA ST M150X6
88 90 96 TA ST HP310X79
```

D4.B.4.4 Channel Sections (C & MC shapes)

C and MC shapes are designated as shown in the following example. As in S, M and HP sections, the portion after the decimal point must be omitted in section designations. Thus, MC250X42.4 should be designated as MC250X42.

```
55 TO 90 TA ST C250X30
30 TO 45 TA ST MC200X33
```

D4.B.4.5 Double Channels

Back-to-back double channels, with or without spacing between them, are specified by preceding the section designation by the letter D. For example, a back-to-back double channel section C200X28 without any spacing in between should be specified as:

```
100 TO 120 TA D C200X28
```

If a spacing of 2.5 length units is used, the specification should be as follows:

```
100 TO 120 TA D C200X28 SP 2.5
```

Note that the specification SP after the section designation is used for providing the spacing. The spacing should always be provided in the current length unit.

D4.B.4.6 Angles

To specify angles, the angle name is preceded by the letter L. Thus, a 200X200 angle with a 25mm thickness is designated as L200X200X25. The following examples illustrate angle specifications.

```
75 TO 95 TA ST L100X100X8
33 34 35 TA ST L200X100X20
```

Note: This specification is for “standard” angles, designated by ST. In this specification, the local z-axis corresponds to the Y’-Y’ axis shown in the section table. Another common practice of specifying angles assumes the local y-axis to correspond to the Y’-Y’ axis. To specify angles in accordance with this convention, use the reverse angle designation, RA. Refer to G.4.2 Local Coordinate System (on page 2088) for details on the local axis systems for standard (ST) and reverse (RA) angles.

Refer to the following example for details.

```
10 TO 15 TA RA L55X35X4
```

D4.B.4.7 Double Angles

To specify double angles, the specification ST should be substituted with LD (for long leg back-to-back) or SD (short leg back-to-back). For equal angles, either SD or LD will serve the purpose. Spacing between angles may be provided by using the word SP followed by the value of spacing (in current length unit) after section designation.

```
25 35 45 TA LD L150X100X16
80 TO 90 TA SD L125X75X6 SP 2.5
```

The second example above describes a double angle section consisting of 125X75X6 angles with a spacing of 2.5 length units.

D4.B.4.8 Tees

Tee sections obtained by cutting W sections may be specified by using the T specification instead of ST before the name of the W shape. For example:

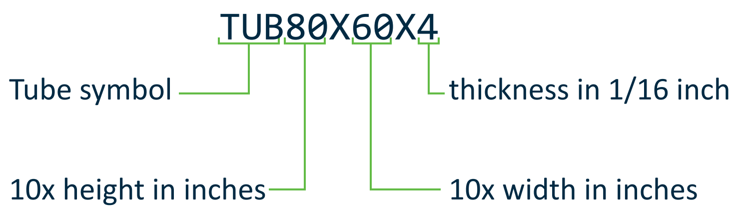
```
100 TO 120 TA T W200X42
```

will describe a T section cut from a W200X42 section.

D4.B.4.9 Rectangular Hollow Sections

These sections may be specified in two possible ways. Those sections listed in the CSA tables may be specified as follows.

```
55 TO 75 TA ST TUB80X60X4
```



In addition, any tube section may be specified by using the DT(for depth), WT(for width), and TH(for thickness) specifications.

For example:

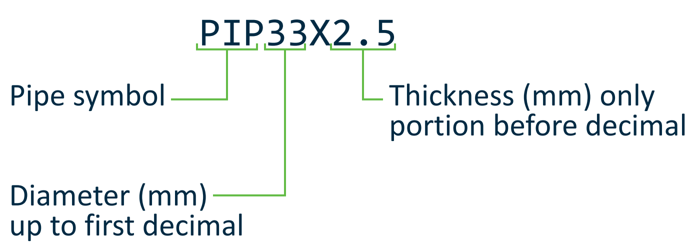
```
100 TO 200 TA ST TUBE DT 8.0 WT 6.0 TH 0.5
```

will describe a tube with a depth of 8 in., width of 6 in. and a wall thickness of 0.5 inches. Note that the values of depth, width and thickness must be provided in current length unit.

D4.B.4.10 Circular Hollow Sections

Sections listed in the CSA tables may be provided as follows:

```
15 TO 25 TA ST PIP33X2.5
```



In addition to sections listed in the CSA tables, circular hollow sections may be specified by using the OD (outside diameter) and ID (inside diameter) specifications. For example:

```
70 TO 90 TA ST PIPE OD 10.0 ID 9.0
```

will describe a pipe with an outside diameter of 10 length units and inside diameter of 9.0 length units. Note that the values of outside and inside diameters must be provided in terms of current length unit.

D4.B.5 Section Classification

The CSA specification allows inelastic deformation of section elements. Thus, local buckling becomes an important criterion. Steel sections are classified as plastic (Class 1), compact (Class 2), noncompact (Class 3), or slender element (Class 4) sections depending upon their local buckling characteristics (See Clause 11.2 and Table 1 of CAN/CSA-S16-01). This classification is a function of the geometric properties of the section. The design procedures are different depending on the section class. STAAD.Pro determines the section classification for the standard shapes and user specified shapes.

Note: The design of Class 4 sections requires STAAD.Pro V8i (SELECTseries 2) build 2007.07 or higher. Otherwise, design is performed for sections that fall into the category of Class 1,2 or 3 sections only.

D4.B.6 Member Resistances

The member resistances are calculated in STAAD.Pro according to the procedures outlined in section 13 of the specification. These depend on several factors such as members unsupported lengths, cross-sectional properties, slenderness factors, unsupported width to thickness ratios and so on. Note that the program automatically takes into consideration appropriate resistance factors to calculate member resistances. Explained here is the procedure adopted in STAAD.Pro for calculating the member resistances.

Note: The design of Class 4 sections requires STAAD.Pro V8i (SELECTseries 2) build 2007.07 or higher.

D4.B.6.1 Nomenclature

where

A	=	Area.
A_e	=	Effective area.
A_f	=	Area of flange.
A_w	=	Area of web.
b_e	=	Effective Flange width.
C_f	=	Compressive force in a member or component under factored load.
C_r	=	Factored compressive resistance.
C_w	=	Warping torsional constant.
C_y	=	Axial compressive load at yield stress.
D	=	Outside diameter of pipe section.
E	=	Elastic modulus of steel.
F_e	=	Elastic critical buckling stress.
F_y	=	Yield strength.
F_{ye}	=	Effective yield stress of section in compression to account for elastic local buckling.
h	=	Clear depth of web.
K	=	Effective length factor.
L	=	Length or span of member.
M_f	=	Bending moment in a member or component under factored load.
M_r	=	Factored moment resistance of a member.
M_y	=	Yield moment resistance.
S	=	Elastic section modulus.
S_e	=	Effective section modulus.
W	=	Web thickness.
λ	=	Non-dimensional slenderness parameter in column formula.
λ_{ye}	=	Effective non-dimensional slenderness parameter in column formula considering effective yield stress.
ϕ	=	Resistance factor

D4.B.6.2 Members Subject to Axial Forces

Axial Tension

The criteria governing the capacity of tension members is based on two limit states. The limit state of yielding in the gross section is intended to prevent excessive elongation of the member. The second limit state involves fracture at the section with the minimum effective net area. The net section area may be specified by the user through the use of the parameter NSF (see Table 3B.1). STAAD calculates the tension capacity of a member based on these two limits states per Cl.13.2 of CAN/CSA-S16-01. Parameters `FYLD`, `FU`, and `NSF` are applicable for these calculations.

Axial Compression

The compressive resistance of columns is determined based on Clause 13.3 of the code. The equations presented in this section of the code assume that the compressive resistance is a function of the compressive strength of the gross section (Gross section Area times the Yield Strength) as well as the slenderness factor (KL/r ratios). The effective length for the calculation of compression resistance may be provided through the use of the parameters `KT`, `KY`, `KZ`, `LT`, `LY`, and `LZ` (see Table 3B.1). Some of the aspects of the axial compression capacity calculations are :

1. For frame members not subjected to any bending, and for truss members, the axial compression capacity in general column flexural buckling is calculated from Cl.13.3.1 using the slenderness ratios for the local Y-Y and Z-Z axis. The parameters KY, LY, KZ and LZ are applicable for this.
2. For single angles, which are frame members not subjected to any bending or truss members, the axial compression capacity in general column flexural buckling and local buckling of thin legs is calculated using the rules of the AISC - LRFD code, 2^{nd} ed., 1994. The reason for this is that the Canadian code doesn't provide any clear guidelines for calculating this value. The parameters KY, LY, KZ, and LZ are applicable for this.
3. The axial compression capacity is also calculated by taking flexural-torsional buckling into account. The rules of Appendix D, page 1-109 of CAN/CSA-S16-01are used for this purpose. Parameters KT and LT may be used to provide the effective length factor and effective length value for flexural-torsional buckling. Flexural-torsional buckling capacity is computed for single channels, single angles, Tees and Double angles.
4. The variable "n" in Cl.13.3.1 is assumed as 2.24 for WWF shapes and 1.34 for all other shapes.
5. While computing the general column flexural buckling capacity of sections with axial compression + bending, the special provisions of 13.8.1(a), 13.8.1(b) and 13.8.1(c) are applied. For example, Lambda = 0 for 13.8.1(a), K=1 for 13.8.1(b), etc.)

For Class 4 members subjected to axial compression, factored compressive resistance should be determined by either of the following equations.

a. $C_r = \phi A_e F_y (1+\lambda^{2n})^{-1/n}$

where

n = 1.34

λ = $\sqrt{(F_y/F_e)}$

F_e = $(\pi^2 E)/(KL/r)^2$

Ae is calculated using reduced element widths meeting the maximum width to thickness ratio specified in Table 1.

Effective width required for the calculation of effective area Ae, for different section shapes are as follows.

- For flanges of I-section, T-section and channel section and legs of angle section

  $b_e = 200t/\sqrt{(F_y)}$
- For stem of T-section

  $b_e = 340t/\sqrt{(F_y)}$
- For flanges of HSS rectangular or Tube sections

  $b_e = 670t/\sqrt{((F_y)}$
- For circular HSS or Pipe section

  $D = 23000t/(F_y$

b. $C_r = \phi A F_{ye} (1+\lambda_{ye}{}^{2n})^{-1/n}$

where

n = 1.34

λ_{ye} = $\sqrt{(F_{ye}/F\_e)}$

F_e = $(\pi^2 E)/(KL/r)^2$

With an effective yield stress, F_{ye}, determined from the maximum width (or diameter)-to-thickness ratio meeting the limit specified in Table 1.

Following are the expressions for effective yield stress for different shaped section.

- For I-section, T-section, channel section and angle section

  $F_{ye} = 40000/(b/t)^2$

- For rectangular HSS section

  $F_{ye}= 448900/(b/t)^2$
- For circular HSS section

  $F_{ye}= 23000/(D/t)$

D4.B.6.3 Members Subject to Bending

The laterally unsupported length of the compression flange for the purpose of computing the factored moment resistance is specified in STAAD with the help of the parameter UNL. If UNL is less than one tenth the member length (member length is the distance between the joints of the member), the member is treated as being continuously laterally supported. In this case, the moment resistance is computed from Clause 13.5 of the code. If UNL is greater than or equal to one tenth the member length, its value is used as the laterally unsupported length. The equations of Clause 13.6 of the code are used to arrive at the moment of resistance of laterally unsupported members. Some of the aspects of the bending capacity calculations are :

1. The weak axis bending capacity of all sections except single angles is calculated as

   For Class 1 & 2 sections, $\varphi \cdot P_y \cdot F_y$

   For Class 3 sections, $\varphi \cdot S_y \cdot F_y$

   where

φ	=	Resistance factor = 0.9
P_y	=	Plastic section modulus about the local Y axis
S_y	=	Elastic section modulus about the local Y axis
F_y	=	Yield stress of steel
2. For single angles, the bending capacities are calculated for the principal axes. The specifications of Section 5, page 6-283 of AISC-LRFD 1994, 2nd ed., are used for this purpose because the Canadian code doesn't provide any clear guidelines for calculating this value.
3. For calculating the bending capacity about the Z-Z axis of singly symmetric shapes such as Tees and Double angles, CAN/CSA-S16-01 stipulates in Clause 13.6(d), page 1-31, that a rational method, such as that given in SSRC's Guide to Stability Design Criteria of Metal Structures, be used. Instead, STAAD uses the rules of Section 2c, page 6-55 of AISC-LRFD 1994, 2nd ed.

Laterally Supported Class 4 members subjected to bending

i. When both the web and compressive flange exceed the limits for Class 3 sections, the member should be considered as failed and an error message will be thrown.
ii. When flanges meet the requirements of Class 3 but web exceeds the limits for Class 3, resisting moment shall be determined by the following equation.

$$M'_r = M_r\left[1 - 0.0005\frac{A_w}{A_f}\left(\frac{h}{w} - \frac{1,900}{\sqrt{M_f/\phi_s}}\right)\right]$$

Where Mr = factored moment resistance as determined by Clause 13.5 or 13.6 but not to exceed ϕMy = factored moment resistance for Class 3 sections = ϕMy

If axial compressive force is present in addition to the moment, modified moment resistance should be as follows.

$$M'_r = M_r\left\{1 - 0.0005\frac{A_w}{A_f}\left[\frac{h}{w} - 1,900\frac{1 - 0.65C_f/(\phi C_y)}{\sqrt{M_f/\phi_s}}\right]\right\}$$

$C_y = A \cdot F_y$

S = Elastic section modulus of steel section.

iii. For sections whose webs meet the requirements of Class 3 and whose flanges exceed the limit of Class 3, the moment resistance shall be calculated as

$$M_r = \phi \cdot S_e \cdot F_y$$

Where:

S_e = effective section modulus determined using effective flange width.

- For Rectangular HSS section, effective flange width

$$b_e = 670 \cdot t/\sqrt{(F_y)}$$

- For I-section, T-section, Channel section, effective flange width and for Angle section, effective length width

$$b_e = 200 \cdot t/\sqrt{(F_y)}$$

But shall not exceed $60 \cdot t$

Laterally Unsupported Class 4 members subjected to bending

As per clause 13.6(b) the moment resistance for class-4 section shall be calculated as follows

i. When $M_u > 0.67M_y$

$$M_r = 1.15\phi M_y\left(1 - \frac{0.28M_y}{M_u}\right)$$

M_r should not exceed $\phi S_e F_y$

ii. When $M_u \leq 0.67M_y$

$$M_r = \phi M_u$$

Where, as per clause 13.6(a),

$$M_u = (\omega_2 \pi)/L \sqrt{(EI_y GJ + (\pi E/L)^2 I_y C_w)}$$

For unbraced length subjected to end moments-

$$\omega_2 = 1.75 + 1.05k + 0.3k^2 \leq 2.5$$

When bending moment at any point within the unbraced length is larger than the larger end moment or when there is no effective lateral support for the compression flange at one of the ends of unsupported length-

$$\omega_2 = 1.0$$

k = Ratio of the smaller factored moment to the larger moment at opposite ends of the unbraced length, positive for double curvature and negative for single curvature.

Se = effective section modulus determined using effective flange width.

- For Rectangular HSS section, effective flange width

$$b_e = 670t/\sqrt{(F_y)}$$

- For I-section, T-section, Channel section, effective flange width and for Angle section, effective length width

$$b_e = 200t/\sqrt{(F_y)}$$

But shall not exceed 60t.

This clause is applicable only for I shaped and Channel shaped section as there is no guide line in the code for other sections.

D4.B.6.4 Members Subject to Combined Forces

Axial compression and bending

The member strength for sections subjected to axial compression and uniaxial or biaxial bending is obtained through the use of interaction equations. In these equations, the additional bending caused by the action of the axial load is accounted for by using amplification factors. Clause 13.8 of the code provides the equations for this purpose. If the summation of the left hand side of these equations exceed 1.0 or the allowable value provided using the `RATIO` parameter (Refer to D4.B.7 Design Parameters (on page 1429)), the member is considered to have failed under the loading condition.

Axial tension and bending

Members subjected to axial tension and bending are also designed using interaction equations. Clause 13.9 of the code is used to perform these checks. The actual `RATIO` is determined as the value of the left hand side of the critical equation.

D4.B.6.5 Shear

The shear resistance of the cross section is determined using the equations of Clause 13.4 of the code. Once this is obtained, the ratio of the shear force acting on the cross section to the shear resistance of the section is calculated. If any of the ratios (for both local Y & Z axes) exceed 1.0 or the allowable value provided using the `RATIO` parameter (see Table 3B.1), the section is considered to have failed under shear. The code also requires that the slenderness ratio of the web be within a certain limit (See Cl.13.4.1.3, page 1-29 of CAN/CSA-S16-01). Checks for safety in shear are performed only if this value is within the allowable limit. Users may by-pass this limitation by specifying a value of 2.0 for the `MAIN` parameter.

D4.B.7 Design Parameters

The design parameters outlined in Table 3B.1 may be used to control the design procedure. These parameters communicate design decisions from the engineer to the program and thus allow the engineer to control the design process to suit an application's specific needs.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements, some or all of these parameter values may be changed to exactly model the physical structure.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 124: Canadian Steel Design CSA-S16-01 Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `CANADIAN 2001`. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).

Parameter Name	Default Value	Description
BEAM	1.0	0.0 = design only for end moments and those at locations specified by SECTION command. 1.0 = Perform design for moments at twelfth points along the beam.
CB	1.0	Greater than 0.0 and less than 2.5 : Value of Omega_2 (Cl.13.6) to be used for calculation. Equal to 0.0 : Calculate Omega_2
CMY	1.0	1.0 = Do not calculate Omega-1 for local Y axis. 2.0 = Calculate Omega-1 for local Y axis. Used in Cl.13.8.4 of code
CMZ	1.0	1.0 = Do not calculate Omega-1 for local Z axis. 2.0 = Calculate Omega-1 for local Z axis. Used in Cl.13.8.4 of code
DFF	None(Mandatory for deflection check)	"Deflection Length"/Maxm. Allowable local deflection. See TR.40 Load Envelope (on page 2663) for deflection checks using serviceability load envelopes.
DJ1	Start Joint of member	Joint No. denoting start point for calculation of "deflection length"
DJ2	End Joint of member	Joint No. denoting end point for calculation of "deflection length"
DMAX	45.0 in.	Maximum allowable depth (Applicable for member selection)
DMIN	0.0 in.	Minimum required depth (Applicable for member selection)
FU	345.0 MPa	Ultimate strength of steel.
FYLD	300.0 MPa	Yield strength of steel.

Parameter Name	Default Value	Description
KT	1.0	K value for flexural torsional buckling.
KY	1.0	K value for general column flexural buckling about the local Y-axis. Used to calculate slenderness ratio.
KZ	1.0	K value for general column flexural buckling about the local Z-axis. Used to calculate slenderness ratio.
LT	Member Length	Length for flexural torsional buckling.
LY	Member Length	Length for general column flexural buckling about the local Y-axis. Used to calculate slenderness ratio.
LZ	Member Length	Length for general column flexural buckling about the local Z-axis. Used to calculate slenderness ratio.
MAIN	0.0	0.0 = Check slenderness ratio against the limits. 1.0= Suppress the slenderness ratio check. 2.0 = Check slenderness ratio only for column buckling, not for web (See Section 3B.6, Shear)
NSF	1.0	Net section factor for tension members.
RATIO	1.0	Permissible ratio of actual load effect to the design strength.
SHEAR	1	Shear stress calculation option. 0) = compute the actual shear stress using VQ/Ib 1) = compute the actual shear stress using V/(Ay or Az)

Parameter Name	Default Value	Description
SSY	0	0 = Sway or Unbraced along local Y axis 1 = Braced along local Y axis This parameter is required to choose the proper value of U_{1y} which is used to determine the cross-sectional strength, overall member strength and lateral torsional buckling strength.
SSZ	0	0 = Sway or Unbraced along local Z axis 1 = Braced along local Z axis This parameter is required to choose the proper value of U_{1z} which is used to determine the cross-sectional strength, overall member strength and lateral torsional buckling strength.
TRACK	0.0	0.0 = Report only minimum design results. 1.0 = Report design strengths also. 2.0 = Provide full details of design.
UNB	Member Length	Unsupported length in bending compression of the bottom flange for calculating moment resistance.
UNT	Member Length	Unsupported length in bending compression of the top flange for calculating moment resistance.

D4.B.8 Code Checking

The purpose of code checking is to check whether the provided section properties of the members are adequate. The adequacy is checked as per the CAN/CSA-S16-01 requirements.

Code checking is done using forces and moments at specified sections of the members. If the BEAM parameter for a member is set to 1, moments are calculated at every twelfth point along the beam. When no sections are specified and the BEAM parameter is set to zero (default), design will be based on member start and end forces only. The code checking output labels the members as PASSed or FAILed. In addition, the critical condition, governing load case, location (distance from the start joint) and magnitudes of the governing forces and moments are also printed. The extent of detail of the output can be controlled by using the TRACK parameter.

Example of commands for CODE CHECKING:

```
UNIT NEWTON METER
PARAMETER
CODE CANADIAN
FYLD 330E6 MEMB 3 4
NSF 0.85 ALL
KY 1.2 MEMB 3 4
UNL 15 MEMB 3 4
RATIO 0.9 ALL
CHECK CODE MEMB 3 4
```

D4.B.9 Member Selection

The member selection process basically involves determination of the least weight member that PASSes the code checking procedure based on the forces and moments of the most recent analysis. The section selected will be of the same type as that specified initially. For example, a member specified initially as a channel will have a channel selected for it. Selection of members whose properties are originally provided from a user table will be limited to sections in the user table. Member selection cannot be performed on TUBES, PIPES or members listed as PRISMATIC.

Example of commands for MEMBER SELECTION:

```
UNIT NEWTON METER
PARAMETER
FYLD 330E6 MEMB 3 4
NSF 0.85 ALL
KY 1.2 MEMB 3 4
UNL 15 MEMB 3 4
RATIO 0.9 ALL
SELECT MEMB 3 4
```

D4.B.10 Tabulated Results of Steel Design

Results of code checking and member selection are presented in a tabular format. The term CRITICAL COND refers to the section of the CAN/CSA-S16-01 specification which governed the design.

If the TRACK parameter is set to 1.0, factored member resistances will be printed. Following is a description of some of the items printed.

CR	Factored compressive resistance
TR	Factored tensile resistance
VR	Factored shear resistance
MRZ	Factored moment resistance (about z-axis)
MRY	Factored moment resistance (about y-axis)

Further details can be obtained by setting TRACK to 2.0.

CR1	CAPACITY (C_r) PER 13.8.2(a)

CR2	CAPACITY (C_r) PER 13.8.2(b)
CRZ	SEE 13.8.2(b) for uniaxial bending (called C_{RX} in that Clause)
CTORFLX	Capacity in accordance with 13.8.2(c)

D4.C. Canadian Codes - Cold Formed Steel Design per S136-94

STAAD.Pro is capable of performing steel design based on the Canadian code S136-94 *Specification for the Design of Cold-Formed Steel Structural Members*, including revisions dated May, 1995. The program allows design of single (non-composite) members in tension, compression, bending, shear, as well as their combinations. For laterally supported members in bending, the Initiation of Yielding method has been used. Cold work of forming strengthening effects have been included as an option.

D4.C.1 Cross-Sectional Properties

You specify the geometry of the cross-section by selecting one of the section shape designations from the Gross Section Property Tables published in the "Cold-Formed Steel Design Manual", AISI, 1996 Edition.

The Tables are currently available for the following shapes:

- Channel with Lips
- Channel without Lips
- Angle with Lips
- Angle without Lips
- Z with Lips
- Z without Lips
- Hat

Shape selection may be done using the member property pages of the graphical user interface (GUI) or by specifying the section designation symbol in the input file.

The properties listed in the tables are gross section properties. STAAD.Pro uses unreduced section properties in the structure analysis stage. Both unreduced and effective section properties are used in the design stage, as applicable.

D4.C.2 Design Procedure

The following two design modes are available:

D4.C.2.1 Code Checking

The program compares the resistance of members with the applied load effects, in accordance with CSA 136. Code checking is carried out for locations specified via the SECTION command or the BEAM parameter. The results are presented in a form of a PASS/FAIL identifier and a RATIO of load effect to resistance for each member checked. You may choose the degree of detail in the output data by setting the TRACK parameter.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

D4.C.2.2 Member Selection

You may request that the program search the cold formed steel shapes database (AISI standard sections) for alternative members that pass the code check and meet the least weight criterion. In addition, a minimum and/or maximum acceptable depth of the member may be specified. The program will then evaluate all database sections of the type initially specified (i.e., channel, angle, etc.) and, if a suitable replacement is found, present design results for that section. If no section satisfying the depth restrictions or lighter than the initial one can be found, the program leaves the member unchanged, regardless of whether it passes the code check or not.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D4.C.2.3 Code Sections Implemented

The program calculates effective section properties in accordance with Clauses 5.6.2.1 through 3 and 5.6.2.6 through 8. Cross-sectional properties and overall slenderness of members are checked for compliance with

- Clause 5.3, Maximum Effective Slenderness Ratio for members in Compression
- Clause 5.4, Maximum Flat Width Ratios for Elements in Compression
- Clause 5.5, Maximum Section Depths.

The program will check member strength in accordance with Clause 6 of the Standard as follows:

- Resistance factors listed in Clauses 6.2 (a), (b), and (e) are used, as applicable.
- Members in tension - Resistance is calculated in accordance with Clauses 6.3.1 and 6.3.2.
- Members in bending and shear

Resistance calculations are based on Clauses:

- 6.4.1 General,
- 6.4.2 and 6.4.2.1 Laterally Supported Members, compressive limit stress based on Initiation of Yielding,
- 6.4.3 Laterally Unsupported Members,
- 6.4.4 Channels and Z-Shaped Members with Unstiffened Flanges - additional limitations,
- 6.4.5 Shear in Webs,
- 6.4.6 Combined Bending and Shear in Webs.
- Members in compression

  Resistance calculations are based on Clauses:

  - 6.6.1.1, 6.6.1.2 (a) and (d), and 6.6.1.3 General,
  - 6.6.2 Sections Not Subject to Torsional-Flexural Buckling,
  - 6.6.3 Singly Symmetric Sections,
  - 6.6.4 Point-Symmetric Sections,
  - 6.6.5 Cylindrical Tubular Sections.
- Members in compression and bending

  Resistance calculations are based on Clause 6.7.1, Singly and Doubly Symmetric Sections. Input for the coefficients of uniform bending must be provided.

D4.C.3 Design Parameters

The following table contains the input parameters for specifying values of design variables and selection of design options.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 125: Canadian Cold Formed Steel Design Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified S136. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
BEAM	1.0	When this parameter is set to 1.0 (default), the adequacy of the member is determined by checking a total of 13 equally spaced locations along the length of the member. If the BEAM value is 0.0, the 13 location check is not conducted, and instead, checking is done only at the locations specified by the SECTION command (See STAAD manual for details). If neither the BEAM parameter nor any SECTION command is specified, STAAD will terminate the run and ask the user to provide one of those 2 commands. This rule is not enforced for TRUSS members.
CMZ	1.0	Coefficient of equivalent uniform bending w_z. See CSA 136, 6.7.2. Used for Combined axial load and bending design. Values range from 0.4 to 1.0.
CMY	0.0	Coefficient of equivalent uniform bending w_y. See CSA 136, 6.7.2. Used for Combined axial load and bending design. Values range from 0.4 to 1.0.
CWY	0	Specifies whether the cold work of forming strengthening effect should be included in resistance computation. See CSA 136, 5.2. 0. effect should not be included 1. effect should be included

Parameter Name	Default Value	Description
DMAX	1000.0	Maximum depth permissible for the section during member selection. This value must be provided in the current units.
DMIN	0.0	Minimum depth required for the section during member selection. This value must be provided in the current units.
FLX	1	Specifies whether torsional-flexural buckling restraint is provided or is not necessary for the member. See CSA 136, 6.6.2 0. Section subject to torsional flexural buckling and restraint not provided 1. restraint provided or unnecessary
FU	450 MPa	Ultimate tensile strength of steel in current units.
FYLD	350 MPa	Yield strength of steel in current units.
KT	1.0	Effective length factor for torsional buckling. It is a fraction and is unit-less. Values can range from 0.01 (for a column completely prevented from torsional buckling) to any user specified large value. It is used to compute the KL/R ratio for twisting for determining the capacity in axial compression.
KY	1.0	Effective length factor for overall column buckling about the local Y-axis. It is a fraction and is unit-less. Values can range from 0.01 (for a column completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the capacity in axial compression.

Parameter Name	Default Value	Description
KZ	1.0	Effective length factor for overall column buckling in the local Z-axis. It is a fraction and is unit-less. Values can range from 0.01 (for a column completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the capacity in axial compression.
LT	Member length	Unbraced length for twisting. It is input in the current units of length. Values can range from 0.01 (for a column completely prevented from torsional buckling) to any user specified large value. It is used to compute the KL/R ratio for twisting for determining the capacity in axial compression.
LY	Member length	Effective length for overall column buckling in the local Y-axis. It is input in the current units of length. Values can range from 0.01 (for a column completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the capacity in axial compression.
LZ	Member length	Effective length for overall column buckling in the local Z-axis. It is input in the current units of length. Values can range from 0.01 (for a column completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the capacity in axial compression.
NSF	1.0	Net section factor for tension members, See CSA 136, 6.3.1.
STIFF	Member length	Spacing in the longitudinal direction of shear stiffeners for stiffened flat webs. It is input in the current units of length. See section CSA 136, 6.4.5

Parameter Name	Default Value	Description
TRACK	0	This parameter is used to control the level of detail in which the design output is reported in the output file. The allowable values are: 0. Prints only the member number, section name, ratio, and PASS/FAIL status. 1. Prints the design summary in addition to that printed by TRACK 1 2. Prints member and material properties in addition to that printed by TRACK 2.
TSA	1	Specifies whether bearing and intermediate transverse stiffeners satisfy the requirements of CSA 136, 6.5. If true, the program uses the more liberal set of interaction equations in 6.4.6. 0. stiffeners do not comply with 6.5 1. stiffeners comply with 6.5

D4.D. Canadian Codes - Timber Design per CAN/CSA-086-01

STAAD.Pro is capable of performing timber design based on the Canadian code CSA 086-01 *Wood Design Standard*.

D4.D.1 General Comments

The design philosophy of this specification is based on the concept of limit state design. Structures are designed and proportioned taking into consideration the limit states at which they would become unfit for their intended use. Two major categories of limit-state are recognized - ultimate and serviceability. The primary considerations in ultimate limit state design are strength and stability, while that in serviceability is deflection. Appropriate load and resistance factors are used so that a uniform reliability is achieved for the entire structure under various loading conditions and at the same time the chances of limits being surpassed are acceptably remote.

In the STAAD.Pro implementation, the code checking portion of the program checks whether code requirements for each selected section are met and identifies the governing criteria.

The following sections describe the salient features of the STAAD implementation of CSA086-01. A detailed description of the design process along with its underlying concepts and assumptions is available in the specification document.

D4.D.2 Analysis Methodology

Analysis is done for the primary and combination loading conditions provided by the user. You are allowed complete flexibility in providing loading specifications and using appropriate load factors to create necessary loading situations.

D4.D.3 Member Property Specifications

A timber section library consisting of Sawn and Glulam timber is available for member property specification.

For specification of member properties, for Sawn timber the timber section library available in STAAD.Pro may be used. The next section describes the syntax of commands used to assign properties from the built-in timber table.

For Glulam timber, member properties can be specified using the YD (depth) and ZD (width) specifications and selecting Combination and Species specifications from the built-in table. The assignment is done with the help of the `PRISMATIC` option (Refer to TR.20.2 Prismatic Property Specification (on page 2263))

D4.D.4 Built-in Timber Section Library

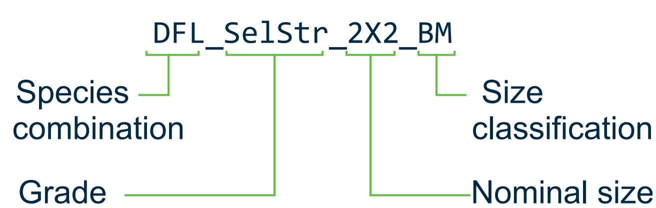
The following information is provided for use when the built-in timber tables are to be referenced for member property specification. These properties are stored in a database file. If called for, the properties are also used for member design.

Following are the description of the different types of species combination available:

D4.D.4.1 Douglas Fir-Larch

The following example illustrates the specification of Douglas Fir-Larch species combination.

```
100 TO 150 TABLE ST DFL_SelStr_2X2_BM
```



D4.D.4.2 Hem-Fir

Designation of Hem-Fir species combination in STAAD is as follows.

```
100 TO 150 TABLE ST Hem-Fir_SelStr_2X10_BM
```

D4.D.4.3 Northern Species

Designation of Northern species combination in STAAD is as follows.

```
100 TO 150 TABLE ST Northern_SelStr_3X12_BM
```

D4.D.4.4 Spruce-Pine-Fir

Designation of Spruce-Pine-Fir species combination in STAAD is as follows.

```
100 TO 150 TABLE ST SPF_SelStr_3X8_BM
```

D4.D.4.5 Glue Laminated timber

Designation of glue-laminated (glu-lam) timber in STAAD.Pro involves defining the material, specifying the dimensions, and associating the material with the member through the `CONSTANTS` command.

D4.D.5 Member Resistance

The member resistances are calculated in STAAD according to the procedures outlined in section 5 (for sawn lumber) and 6 (for Glulam) of CSA086-01.

These depend on several adjustment factors as follows:

KD	Load duration factor (Clause 4.3.2.2-CSA086-01, Table 4.3.2.2)
KH	System factor (Clause 5.4.4 and 6.4.3 and Table 5.4.4 -CSA086-01)
K_T	Treatment factor (Clause 5.4.3 and 6.4.4 -CSA086-01)
KSB	Service condition factor applicable to Bending at extreme fibre (Table 5.4.2 and 6.4.2 -CSA086-01)
KSV	Service condition factor applicable to longitudinal shear (Table 5.4.2 and 6.4.2 CSA086-01)
KSC	Service condition factor applicable to Compression parallel to the grain (Table 5.4.2 and 6.4.2 CSA086-01)
K_SCP	Service condition factor applicable to Compression perpendicular to the grain (Table 5.4.2 and 6.4.2 CSA086-01)
KSE	Service condition factor applicable to modulus of elasticity (Table 5.4.2 and 6.4.2 CSA086-01)
KST	Service condition factor applicable to tension parallel to the grain (Table 5.4.2 and 6.4.2 CSA086-01)
KZB	Size factor applicable to bending (Clause 5.4.5 and Table 5.4.5 -CSA086-01)
KZV	size factor applicable to shear(Clause 5.4.5 and Table 5.4.5 -CSA086-01)
KZT	size factor applicable to tension parallel to grain (Clause 5.4.5 and Table 5.4.5 -CSA086-01)
KZCP	size factor applicable to compression perpendicular to grain (Clause 5.4.5 and Table 5.4.5 -CSA086-01)
K_ZC	size factor applicable to compression parallel to grain (Clause 5.4.5 and Table 5.4.5 -CSA086-01)
CHIX	Curvature factor (Clause 6.5.6.5.2-CSA086-01)
CV	shear load coefficient (Table 6.5.7.4A- CSA086-01)
KN	Notch factor(Clause 5.5.5.4-CSA086-01)

All of these factors must be specified as input according to the classification of timber and stress grade.

Explained here is the procedure adopted in STAAD for calculating the member resistances.

D4.D.5.1 Axial Tension

i. For Sawn timber

The criterion governing the capacity of tension members is based on one limit state. The limit state involves fracture at the section with the minimum effective net area. The net section area may be specified by the user through the use of the parameter NSF (see Table 3B.1). STAAD calculates the tension capacity of a member based on this limit state per Clause 5.5.9 of CSA086-01.

ii. For Glulam timber

The design of glulam tension members differs from sawn timber since CSA 086-01 assigns different specified strength for gross and net section. The specified strength at net section is slightly higher than the strength of the gross section. Therefore, Glulam tension members are designed based on two limit states. The first one is the limit state of yielding in the gross section. The second limit state involves fracture at the section with the minimum effective net area. The net-section area may be specified by the user through the use of the parameter NSF (see Table 3B.1). STAAD calculates the tension capacity of a member based on these two limits states per Clause.6.5.11 of CSA086-01.

D4.D.5.2 Axial Compression

The compressive resistance of columns is determined based on Clause.5.5.6 and Clause.6.5.8.4 of CSA086-01. The equations presented in this section of the code assume that the compressive resistance is a function of the compressive strength of the gross section (Gross section Area times the Yield Strength) as well as the slenderness factor (Kc). The effective length for the calculation of compression resistance may be provided through the use of the parameters KX, KY, KZ, LX, LY and LZ (see Table 3B.1).

D4.D.5.3 Bending

The bending resistance of Sawn members are determined based on Clause 5.5.4 of CSA086-01 and for glulam members are determined based on Clause 6.5.6.5 of CSA086-01. The allowable stress in bending is multiplied by Lateral stability factor, KL to take in account whether lateral support is provided at points of bearing to prevent lateral displacement and rotation

D4.D.5.4 Axial compression and bending

The member strength for sections subjected to axial compression and uni-axial or biaxial bending is obtained through the use of interaction equations. Clause 5.5.10 and 6.5.12 of the code provides the equations for this purpose. If the summation of the left hand side of these equations exceeds 1.0 or the allowable value provided using the RATIO parameter (see Table 3B.1), the member is considered to have FAILed under the loading condition.

D4.D.5.5 Axial tension and bending

The member strength for sections subjected to axial tension and uniaxial or biaxial bending is obtained through the use of interaction equations. Clause 5.5.10 and 6.5.12 of the code provides the equations for this purpose. If the summation of the left hand side of these equations exceeds 1.0 or the allowable value provided using the RATIO parameter (see Table 3B.1), the member is considered to have FAILed under the loading condition.

D4.D.5.6 Shear

The shear resistance of the cross section is determined using the equations of Clause 5.5.5 and 6.5.7.2 of the code. Once this is obtained, the ratio of the shear force acting on the cross section to the shear resistance of the section is calculated. If any of the ratios (for both local Y & Z axes) exceed 1.0 or the allowable value provided using the RATIO parameter (see Table 3B.1), the section is considered to have failed under shear.

D4.D.6 Design Parameters

The design parameters outlined in Table below may be used to control the design procedure. These parameters communicate design decisions from the engineer to the program and thus allows the engineer to control the design process to suit an application's specific needs.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements, some or all of these parameter values may be changed to exactly model the physical structure.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 126: Canadian Timber Design Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `TIMBER CANADIAN`.
CHIX	1.0	Curvature Factor for Compression [Clause 6.5.6.5.2]
CV	1.0	Shear Load Coefficient [Table 6.5.7.4A]
KD	1.0	Load Duration Factor [Clause.4.3.2, Table 4.3.2]
KH	1.0	System Factor [Clause 5.4.4/6.4.3, Table 5.4.4]
KN	1.0	Notch Factor [Clause 5.4.7.2.2]
KSB	1.0	Service Condition Factor for Bending at Extreme Fibre Applicable for bending at extreme fibre [Table 5.4.2 and 6.4.2]
KSC	1.0	Service Condition Factor for Compression, Applicable for compression parallel to grain [Table 5.4.2 and 6.4.2]
KSE	1.0	Service Condition Factor for Modulus of Elasticity, Applicable for modulus of elasticity [Table 5.4.2 and 6.4.2]

Parameter Name	Default Value	Description
KST	1.0	Service Condition Factor for Tension, Applicable for tension parallel to grain [Table 5.4.2 and 6.4.2]
KSV	1.0	Service Condition Factor for Shear, Applicable for longitudinal shear [Table 5.4.2 and 6.4.2]
KX	1.0	K value for flexural torsional buckling
KY	1.0	K value in local Y-axis, usually minor axis
KZ	1.0	K value in local Z-axis, usually major axis
KZB	1.0	Size Factor for Bending, Applicable for bending [Clause.5.4.5 and Table 5.4.5]
KZCP	1.0	Size Factor for Compression, Applicable for compression perpendicular to grain [Clause . 5.4.5 and Table 5.4.5]
KZT	1.0	Size Factor for Tension, Applicable for tension parallel to grain [Clause 5.4.5 and Table 5.4.5]
KZV	1.0	Size Factor for Shear [Clause 5.4.5 and Table 5.4.5]
K_SCP	1.0	Service Condition Factor for Compression, Applicable for compression perpendicular to grain [Clause 5.4.2 and Table 6.4.2]
K_T	1.0	Treatment Factor [Clause 5.4.3/6.4.4]

Parameter Name	Default Value	Description
K_ZC	1.0	Size Factor for Compression, Applicable for compression parallel to grain [Clause 5.4.5 and Table 5.4.5]
LX	Member length	Length for flexural torsional buckling
LY	Member length	Length in local Y axis for slenderness value KL/r
LZ	Member length	Length in local Z axis for slenderness value KL/r
NSF	1.0	Net section factor for tension members
RATIO	1.0	Permissible Ratio of Actual to Allowable Value

D4.D.7 Code Checking

The purpose of code checking is to check whether the provided section properties of the members are adequate. The adequacy is checked as per the CSA086-01 requirements.

Code checking is done using forces and moments at specified sections of the members. The code checking output labels the members as PASSed or FAILed. In addition, the critical condition, governing load case, location (distance from the start joint) and magnitudes of the governing forces and moments are also printed.

Refer to D1.G.6 Member Design Capabilities (on page 1259) for general information on Code Checking. Refer to TR.52.2 Code Checking Specification (on page 2684) for details the specification of the Code Checking command.

D4.D.8 Member Selection

Member selection based CSA086-2001 is *not* available.

D4.D.9 Tabulated Results of Timber Design

Results of code checking and member selection are presented in a tabular format. The term CRITICAL COND refers to the section of the CSA086-01 specification, which governed the design.

Pu	Actual Load in Compression
Tu	Actual Load in Tension
Muy	Ultimate moment in y direction
Muz	Ultimate moment in z direction
V	Ultimate shear force
SLENDERNESS_Y	Actual Slenderness ratio in y direction
SLENDERNESS_Z	Actual Slenderness ratio in z direction
PY	Factored Compressive capacity in y direction
PZ	Factored Compressive capacity in z direction
T	Factored tensile capacity
MY	Factored moment of resistance in y direction
MZ	Factored moment of resistance in z direction
V	Factored shear resistance
SLENDERNESS	Allowable slenderness ratio

D4.E. Canadian Codes - Steel Design per CAN/CSA-S16-09/14/19

STAAD.Pro is capable of performing steel design based on the Canadian codes CAN/CSA-S16-09, CAN/CSA-S16-14, and CAN/CSA-S16-19 *Limit States Design of Steel Structures*.

To use the 2019 edition (default), specify the command:

```
CODE CANADIAN
```

or

```
CODE CANADIAN 2019
```

To use the 2014 edition, specify the command:

```
CODE CANADIAN 2014
```

To use the 2009 edition, specify the command:

```
CODE CANADIAN 2009
```

D4.E.1 General Comments

The design of structural steel members in accordance with the specification CAN/CSA S16-09, S16-14, and S16-19 *Limit States Design of Steel Structures* is can be used in STAAD.Pro This code supersedes the previous editions of the CAN/CSA – S16 code.

The design philosophy embodied in this specification is based on the concept of limit state design. Structures are designed and proportioned taking into consideration the limit states at which they would become unfit for their intended use. Two major categories of limit-states are recognized - ultimate and serviceability. The primary considerations in ultimate limit state design are strength and stability, while that in serviceability is deflection. Appropriate load and resistance factors are used so that a uniform reliability is achieved for all steel structures under various loading conditions and at the same time the probability of limits being surpassed is acceptably low.

In the STAAD.Pro implementation, members are proportioned to resist the design loads without exceeding the limit states of strength, stability and serviceability. Accordingly, the most economic section is selected on the basis of the least weight criteria as augmented by the designer in specification of allowable member depths, desired section type, or other such parameters. The code checking portion of the program checks whether code requirements for each selected section are met and identifies the governing criteria.

The following sections describe the salient features of the STAAD.Pro implementation of CAN/CSA-S16-09, S16-14, and S16-19. A detailed description of the design process along with its underlying concepts and assumptions is available in the specification document.

D4.E.2 Analysis Methodology

The elastic analysis method is used to obtain the forces and moments for design. Analysis is done for the specified primary and combination loading condition. You are allowed complete flexibility in providing loading specifications and using appropriate load factors to create necessary loading situations. Depending upon the analysis requirements, regular stiffness analysis or P-Delta analysis may be specified. Dynamic analysis may also be performed and the results combined with static analysis results.

D4.E.3 Member Property Specifications

For specification of member properties, the steel section library available in STAAD.Pro may be used. The next section describes the syntax of commands used to assign properties from the built-in steel table. Member properties may also be specified using the User Table facility. For more information on these facilities, refer to the STAAD.Pro Technical Reference Manual.

Hot Rolled Profiles

- I Shaped, Wide Flange Sections (including S, M, W, HP, and B Shaped)
- Tee Shaped Sections (including WT and T)
- Channel Shaped Sections (including C and MC shaped)
- Angle Shaped Sections (equal and unequal single angle)
- Tube Shaped Sections (RHS, SHS, Box and user defined tube sections)
- Circular Shaped Sections (including CHS, pipe and user defined circular pipe sections)

The following modified sections are also supported:

- I-section with cover plates

The following composite or compound sections are also supported:

- Double Angle (short leg connected and long leg connected angle sections, with and without spacing)
- Double Channel (back to back and front to front connection, with and without spacing)

Tapered Profiles

- Tapered I
- Tapered Round
- Tapered Tube

Note: Tapered members can be designed using check code method only. Member selection is not supported.

D4.E.4 Built-in Steel Section Library

The following information is provided for use when the built-in steel tables are to be referenced for member property specification. These properties are stored in a database file. If called for, the properties are also used for member design. Since the shear areas are built into these tables, shear deformation is always considered during the analysis of these members.

Almost all Canadian steel sections are available for input. A complete listing of the sections available in the built-in steel section library may be obtained by using the tools of the graphical user interface.

Refer to D4.B.4 Built-in Steel Section Library (on page 1421) for additional details.

D4.E.5 Section Classification

Steel sections are classified as plastic (Class 1), compact (Class 2), noncompact (Class 3), or slender element (Class 4) sections depending upon their local buckling characteristics (See Clause 11 and Tables 1 & 2 of CAN/CSA-S16-09, S16-14, or S16-19). The design procedures are different depending on the section class. STAAD.Pro determines the section classification for the standard shapes and user specified shapes.

D4.E.6 Member Resistances

The member resistances are calculated in STAAD.Pro according to the procedures outlined in section 13 of the specification. These depend on several factors such as members unsupported lengths, cross-sectional properties, slenderness factors, unsupported width to thickness ratios and so on. Note that the program automatically takes into consideration appropriate resistance factors to calculate member resistances. Explained here is the procedure adopted in STAAD.Pro for calculating the member resistances.

$$\phi = 0.9 \text{ and } \phi_u = 0.75$$

Torsion

There are no specific guidelines mentioned in CSA S16 for the torsion design and STAAD does *not* perform torsion check in this case.

Slenderness

The slenderness check is *not* used as a critical member ratio check. If a slenderness check is included and exceed unity (1.0), then it may be reported as the governing criteria. However, if it is less than unity, it will be reported but will not be used as the governing ratio.

D4.E.6.1 Members Subject to Axial Forces

Axial Tension

The criteria governing the capacity of tension members are based on two limit states: resistance due to yielding and resistance due to rupture. The resistance due to rupture depends on effective net section area. You may specify the net section area through the `NSF` design parameter. Additionally, the shear lag factor, U, may be entered using the `SLF` parameter. STAAD.Pro calculates the tension capacity of a member based on these two limits states per Cl.13.2 of CAN/CSA-S16-09. Design parameters `FYLD`, `FU`, `NSF`, and `SLF` (Refer to D4.E.7 Design Parameters (on page 1458)) are applicable for these calculations

i. Yielding, per Cl. 13.2(a)

$$T_r = \phi A_g F_y$$

ii. Rupture, per Cl. 13.2 (b)

$$T_r = \phi_u A_{ne} F_u$$

Note: Pin connection equations in S16-14 and 19 are not checked by the program.

Axial Compression

The compressive resistance of columns is determined based on Clause 13.3 of the code. The equations presented in this section of the code assume that the compressive resistance is a function of the compressive strength of the gross section (Gross section Area times the Yield Strength) as well as the slenderness factor (KL/r ratios). The effective length for the calculation of compression resistance may be provided through the use of the parameters KT, KY, KZ, LT, LY, and LZ (Refer to D4.E.7 Design Parameters (on page 1458)). Some of the aspects of the axial compression capacity calculations are :

I. For doubly symmetric sections meeting the requirement of Table 1, resistance is:

Resistance due to Major axis buckling per Cl. 13.3.1.

Resistance due to Minor axis buckling per Cl. 13.3.1

$$C_r = \phi A F_y \left(1 + \lambda^{2n}\right)^{-1/n}$$

where

n = 1.34 for hot-rolled, fabricated structural sections and hollow structural sections manufactured in accordance with CSA G40.20, Class C (cold-formed non-stress-relieved)

2.24 for doubly symmetric welded three-plate members with flange edges oxy-flame-cut and hollow structural sections manufactured in accordance with CSA G40.20, Class H (hot-formed or cold-formed stress-relieved)

Design parameters NCR and STP are used to evaluate the value of n for a member.

λ = $\sqrt{F_y / F_e}$

F_e = $\dfrac{\pi^2 E}{\left(\frac{kL}{r}\right)^2}$

Note: For CSA S16-19, the value of F_e is used per 13.3.1.1 a) for double-symmetric sections.

II. For any other section not covered under Cl. 13.3.1, the factored compressive resistance, C_r , is computed using the expression given in Cl. 13.3.1 with a value of n = 1.34 and the value of F_e taken as follows:

i. For doubly symmetric sections and axisymmetric sections, the least of F_{ex} , F_{ey} , and F_{ez} .

ii. For singly symmetric sections with the Y axis taken as the axis of symmetry, the lesser of F_{ex} and F_{eyz} where

F_{eyz} = $\dfrac{F_{ey} + F_{ez}}{2\Omega}\left[1 - \sqrt{1 - \dfrac{4F_{ey}F_{ez}\Omega}{(F_{ey} + F_{ez})^2}}\right]$

F_{ex} = $\dfrac{\pi^2 E}{\left(\frac{k_x L_x}{r_x}\right)^2}$

F_{ey} = $\dfrac{\pi^2 E}{\left(\frac{k_y L_y}{r_y}\right)^2}$

F_{ez} = $\left[\dfrac{\pi^2 E C_w}{(K_z L_z)^2} + GJ\right]\dfrac{1}{A\bar{r}_0^2}$

x_0, y_0 = the principal coordinates of the shear center with respect to the centroid of the cross section

$\bar{r}_0^2$ = $x_0^2 + y_0^2 + r_x^2 + r_y^2$

Ω = $\dfrac{r_x^2 + r_y^2}{\bar{r}_0^2}$

iii. For asymmetric sections the smallest root of:

$$(F_e - F_{ex})(F_e - F_{ey})(F_e - F_{ez}) - F_e^2(F_e - F_{ey})\left(\frac{x_0}{\square r_0}\right)^2 - F_e^2(F_e - F_{ex})\left(\frac{y_0}{\square r_0}\right)^2 = 0$$

III. For Class 4 member subjected to axial compression, the factored compressive resistance is:

$$C_r = \phi A_e F_y \left(1 - \lambda^{2n}\right)^{-1/n}$$

A_e is calculated using reduced element widths meeting the maximum width to thickness ratio specified in Table 1.

Effective width required for the calculation of effective area A_e , for different section shapes are as follows.

- For flanges of I-section, T-section and channel section and legs of angle section

$$b_e = 200t / \sqrt{F_y}$$

- For stem of T-section

$$b_e = 340t / \sqrt{F_y}$$

- For flanges of HSS rectangular or Tube sections

$$b_e = 670t / \sqrt{F_y}$$

- For circular HSS or Pipe section

$$D = 23{,}000t/(F_y$$

D4.E.6.2 Members Subject to Bending

The laterally unsupported length of the compression flange for the purpose of computing the factored moment resistance is specified in STAAD.Pro through the UNT and UNB parameters (Refer to D4.E.7 Design Parameters (on page 1458)). The LAT parameter is used to specify if the member is laterally supported against lateral torsional buckling.

I. The factored moment resistance, Mr, developed by a member subjected to uniaxial bending moments about a principal axis where effectively continuous lateral support is provided to the compression flange or where the member has no tendency to buckle laterally, is calculated as:

i. For Class 1 and Class 2 sections (Cl. 13.5(a)):

$$Mr = \phi \cdot Z \cdot F_y = \phi \cdot M_p$$

ii. For Class 3 sections (Cl. 13.5(b)):

$$Mr = \phi \cdot S \cdot F_y = \phi \cdot M_y$$

> **Note:** For S16-19, the exception for single angle profiles is included per Cl. 13.5 D) I.

iii. For Class 4 sections (Cl. 13.5(c)):

$$Mr = \phi \cdot S_e \cdot F_y$$

> **Note:** For S16-19, the exceptions for circular hollow profiles per Cl. 13.5 C) IV and for single angle profiles per Cl. 13.5 d) ii) is included.

where

S_e	=	the effective section modulus determined using an effective flange width, b_e , of $670t / \sqrt{F_y}$ for flanges along two edges parallel to the direction of stress and an effective flange width, b_e of $200t / \sqrt{F_y}$ for

flanges supported along one edge parallel to the direction of stress. For flange supported along one edge, $b_e I_e / t$ shall not exceed 60.

II. For laterally unsupported members, flexural resistance is calculated as follows:

i. For doubly symmetric Class 1 and Class 2 sections (Cl 13.6(a)):

$$M_r = \begin{cases} \phi M_u \text{ when } M_u \leq 0.67 M_p \\ 1.15 \phi M_p \left(1 - \frac{0.28 M_p}{M_u}\right) \leq \phi M_p \text{ when } M_u > 0.67 M_p \end{cases}$$

where

M_u = $\frac{\omega_2 \pi}{L} \sqrt{E I_y G J + \left(\frac{\pi E}{L}\right)^2 I_y C_w}$

ω_2 = $1.75 + 1.05\kappa + 0.3\kappa^2 \leq 2.5$

κ = ratio of smaller factored moment to the larger factored moment at opposite ends of the unbraced length (positive for double curvature and negative for single curvature).

Note: The value for ω_2 can be specified using the CB parameter. Otherwise, it is calculated as indicated here.

Note: For S16-19, Cl. 13.6 H) I pertaining to cantilevers with different bracing conditions is included.

ii. For doubly symmetric Class 3 and Class 4 sections –except closed square and circular sections– and for channels:

$$M_r = \begin{cases} \phi M_u \text{ when } M_u \leq 0.67 M_y \\ 1.15 \phi M_y \left(1 - \frac{0.28 M_y}{M_u}\right) \leq \phi M_p \text{ when } M_u > 0.67 M_y \end{cases}$$

but not greater than ϕM_y for Class 3 sections and the value specified in Cl.13.5(c)(iii) for Class 4 sections.

Note: For S16-19, Cl. 13.6 H) II pertaining to cantilevers with different bracing conditions is included in accordance with Cl. 13.6(b), except for M_u and ω_2, which depend on Cl. 13.6 H) I.

iii. For singly symmetric (monosymmetric) Class 1, Class 2, or Class 3 sections and T-shape sections, lateral torsional buckling strength shall be checked separately for each flange under compression under factored loads at any point along its unbraced length:

- when $M_u > M_{yr}$:

$$M_r = \phi\left[M_p - \left(M_p - M_{yr}\right)\left(\frac{L - L_u}{L_{yr} - L_u}\right)\right] \leq \phi M_p$$

where

M_{yr} = $0.7 S_x F_y$, with S_x taken as the smaller of the two potential values

L_{yr} = length L obtained by setting $M_u = M_{yr}$

L_u = $1.1 r_t \sqrt{E / F_y} = \frac{490 r_t}{\sqrt{F_y}}$

r_t = $\frac{b_c}{\sqrt{12\left(1 + \frac{h_c w}{3 b_c t_c}\right)}}$

h_c = depth of the web in compression

b_c = width of the compression flange

t_c = thickness of the compression flange

- when $M \le M_{yr}$:

$$M_r = \phi M_u$$

where

M_u = the critical elastic moment of the unbraced section =

$$\frac{\omega_3 \pi^2 E I_y}{2L^2}\left[\beta_x + \sqrt{\beta_x^2 + 4\left(\frac{GJL^2}{\pi^2 E I_y} + \frac{C_w}{I_y}\right)}\right]$$

β_x = asymmetry parameter for singly symmetric beam =

$$0.9\left(d - t\right)\left(\frac{2I_{yc}}{I_y} - 1\right)\left[1 - \left(\frac{I_y}{I_x}\right)^2\right]$$

For CSA S16-19, the approximate formula given is only valid for cases where $I_x > 2I_y$ and where $0.1 < I_y/(I_{yc} + I_{yt}) < 0.9$ and it is not valid for T sections.

I_{yc} = moment of inertia of the compression flange about the y-axis

I_{yt} = moment of inertia of the tension flange about the y-axis

when singly symmetric beams are in single curvature,

$\omega_3 = \omega_2$ for beams with two flanges, = 1.0 for T-sections

in all other cases,

$\omega_3 = \omega_2[0.5 + 2(I_{yc}/Iy)^2]$ f, but ≤ 2.0 for T-Sections

Note: For single angles (asymmetric sections) designed per S16-19, Cl. 13.6 G (I) and (II) are used.

D4.E.6.3 Members Subject to Combined Forces

For each of the following interaction equations, the value of the `RATIO` parameter is used in lieu of 1.0 when it is specified (Refer to D4.E.7 Design Parameters (on page 1458)).

Axial compression and bending

The member strength and stability for sections subjected to axial compression and uniaxial or biaxial bending is obtained through the use of interaction equations. In these equations, the additional bending caused by the action of the axial load is accounted for by using amplification factors (Cl. 13.8). ω_{1y} and ω_{1z} are calculated as per Cl. 13.8.5 or as specified in the `CMY` and `CMZ` design parameters, respectively.

I. For Class 1 and Class 2 sections of I-shaped members (Cl. 13.8.2):

$$\frac{C_f}{C_r} + \frac{0.85 U_{1x} M_{fx}}{M_{rx}} + \frac{\beta U_{1y} M_{fy}}{M_{ry}} \le 1.0$$

where

C_f , M_f = the maximum load effects, including stability, as specified in Cl. 8.4.

β = $0.6 + 0.4\lambda_y \le 0.85$

The capacity of the member is investigated for the following:

a. Cross sectional strength with $\beta = 0.6$, where

i. C_r as specified in Cl. 13.3 with $\lambda = 0$

   ii. M_r as specified in Cl. 13.5
   iii. U_{1x} and U_{1y} as specified in Cl. 13.8.4 but not less than 1.0. Design parameters SSY and SSZ are used to evaluate these coefficients.

b. Overall member strength, where

   i. C_r as specified in Cl. 13.3 with $K = 1$, except for uniaxial bending, in which case C_r is based on the axis of bending
   ii. M_r as specified in Cl. 13.5
   iii. U_{1x} and U_{1y} are taken as 1.0 for members in an unbraced frame, and as specified in Cl. 13.8.4 for members in a braced frame. Design parameters SSY and SSZ are used to evaluate these coefficients.

c. Lateral torsional buckling strength, when applicable, where

   i. C_r as specified in Cl. 13.3
   ii. M_{rx} as specified in Cl. 13.6
   iii. M_{ry} as specified in Cl. 13.5
   iv. U_{1x} and U_{1y} are taken as 1.0 for members in an unbraced frame, and as specified in Cl. 13.8.4 for members in a braced frame (where U_{1x} is not less than 1.0). Design parameters SSY and SSZ are used to evaluate these coefficients.

II. For Class 1 and Class 2 square or circular HSS sections per S16-19 only (Cl. 13.8.3):

- For square sections:

$$\frac{C_f}{C_r} + \frac{0.85 U_{1x} M_{fx}}{M_{rx}} + \frac{0.50 U_{1y} M_{fy}}{M_{ry}} \le 1.0$$

- For circular sections:

$$\frac{C_f}{C_r} + \frac{0.85\sqrt{(U_{1x} M_{fx})^2 + (U_{1y} M_{fy})^2}}{M_{rx}} \le 1.0$$

III. For all other cases (Cl13.8.3 per S16-09 / 14 or Cl 13.8.4 of S16-19):

$$\frac{C_f}{C_r} + \frac{U_{1x} M_{fx}}{M_{rx}} + \frac{U_{1y} M_{fy}}{M_{ry}} \le 1.0$$

The capacity of the member is investigated for the following per Cl.13.8.2:

a. Cross sectional strength
b. Overall member strength
c. Lateral torsional buckling strength,

Axial tension and bending

Members subjected to axial tension and bending must satisfy the following equation (Cl. 13.9.1):

$$\frac{T_f}{T_r} + \frac{M_f}{M_r} \le 1.0$$

where

M_r	=	the moment resistance as specified in Cl. 13.5.

Note: For I shapes with equal flanges designed to S16-19, Class 1 and 2 sections are proportioned as per Cl. 13.9.2.

Additionally, the following equations must be satisfied for laterally unsupported members (Cl. 13.9.2 of S16-09 / 14):

$$\frac{M_f}{M_r} - \frac{T_f Z}{M_r A} \le 1.0 \text{ for Class 1 and Class 2 sections}$$

$$\frac{M_f}{M_r} - \frac{T_f S}{M_r A} \le 1.0 \text{ for Class 3 and Class 4 sections}$$

where

M_r	=	the moment resistance as specified in Cl. 13.6.

The following equations must be satisfied for laterally unsupported members designed per S16-19 (Cl. 13.9.3 of S16-19):

$$\frac{M_{fx}}{M_{rx}} + \frac{M_{fy}}{M_{ry}} - \frac{T_f Z_x}{M_{rx} A} \le 1.0 \text{ for Class 1 and Class 2 sections}$$

$$\frac{M_{fx}}{M_{rx}} + \frac{M_{fy}}{M_{ry}} - \frac{T_f S_x}{M_{rx} A} \le 1.0 \text{ for Class 3 and Class 4 sections}$$

where

M_{rx}	=	the moment resistance as specified in Cl. 13.6.1.

where

M_{ry}	=	the moment resistance as specified in Cl. 13.5.

Biaxial Bending

For bending about both axis, the following equation must be satisfied (Cl. 13.8):

$$\frac{M_{fx}}{M_{rx}} + \frac{M_{fy}}{M_{ry}} \le 1.0$$

Shear and Bending

For S16-09 / 14, to resist the combined effects of shear and bending, all of the following equations must be satisfied (Cl. 14.6):

$$0.727\frac{M_f}{M_r} + 0.455\frac{V_f}{V_r} \le 1.0 \qquad \text{(S16-09 / 14)}$$

$$\frac{M_f}{M_r} \le 1.0$$

$$\frac{V_f}{V_r} \le 1.0$$

where

M_r	=	the value determined in accordance with Cl. 13.5 of Cl 13.6 as applicable
V_r	=	the value determined in accordance with Cl. 13.4

For S16-19: for beams with webs with $F_s > 0.60\ F_y$ to resist the combined effects of shear and bending, the shear resistance, V_r, is multiplied by the following reduction factor (Cl. 14.6):

$$\left[2.20 \text{ - } 1.60\frac{M_f}{M_r}\right]$$

The shear resistance is not reduced below $0.60\ \phi A_w F_y$. Also, the shear resistance is not increased due to this calculation.

D4.E.6.4 Members Subject to Shear

Factored shear resistance, V_r , developed by the web of flexural member is calculated as:

$$V_r = \phi A_w F_s$$

where

A_w = shear area

F_s is evaluated as:

I. For unstiffened webs (Cl. 13.4.1.1.(a)):

i. when $\frac{h}{w} \le \frac{1,\ 014}{\sqrt{F_y}}$, $F_s = 0.66F_y$

ii. when $\frac{1,\ 014}{\sqrt{F_y}} < \frac{h}{w} \le \frac{1,\ 435}{\sqrt{F_y}}$, $F_s = \frac{670\sqrt{F_y}}{(h\ /\ w)}$

iii. when $\frac{h}{w} > \frac{1,\ 436}{\sqrt{F_y}}$, $F_s = \frac{961,\ 200}{(h\ /\ w)^2}$

II. For stiffened webs (i.e., when the STIFF parameter is specified) (Cl. 13.4.1.1(b)):

i. when $\frac{h}{w} \le 439\sqrt{\frac{k_v}{F_y}}$, $F_s = 0.66F_y$

ii. when $439\sqrt{\frac{k_v}{F_y}} < \frac{h}{w} \le 502\sqrt{\frac{k_v}{F_y}}$, $F_s = F_{cri}$

iii. when $502\sqrt{\frac{k_v}{F_y}} < \frac{h}{w} \le 621\sqrt{\frac{k_v}{F_y}}$, $F_s = F_{cri} + k_a(0.50F_y - 0.866F_{cri})$

iv. when $621\sqrt{\frac{k_v}{F_y}} < \frac{h}{w}$, $F_s = F_{cre} + k_a(0.50F_y - 0.866F_{cre})$

where

A_e = shear buckling coefficient:

i. when $a/h < 1, k_v = 4 + \frac{5.34}{(a\ /\ h)^2}$

ii. when $a/h \ge 1, k_v = 5.34 + \frac{4}{(a\ /\ h)^2}$

a/h = stiffener aspect ration (i.e., ratio of the distance between stiffeners to web depth)

F_{cri} = $290\frac{\sqrt{F_y k_v}}{(h\ /\ w)}$

k_a = aspect coefficient = $\frac{1}{\sqrt{1 + (a\ /\ h)^2}}$

F_{cre} = $\frac{180,\ 000k_v}{(h\ /\ w)^2}$

For tubular members, the shear resistance, V_r , is calculated as:

$$V_r = 0.66\phi(A_e/2)F_y$$

where

A_e = the cross-sectional area of the tubular member

D4.E.7 Design Parameters

The design parameters outlined in the following table may be used to control the design procedure. These parameters communicate design decisions from the engineer to the program and thus allow the engineer to control the design process to suit an application's specific needs.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements, some or all of these parameter values may be changed to exactly model the physical structure.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 127: Canadian Steel Design CSA-S16-09/14/19 Parameters

Parameter Name	Default Value	Description
CODE	CODE CANADIAN	Used to designate this code (default is the 2019 edition): `CODE CANADIAN (2019)` (for S16-19) `CODE CANADIAN 2014` (for S16-14) `CODE CANADIAN 2009` (for S16-09) `CODE CANADIAN 2001` (D4.B. Canadian Codes - Steel Design per CSA Standard CAN/CSA-S16-01 (on page 1419)) Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
BEAM	1.0	Used to specify locations along member length considered for design: 0.0 = design only for end moments and those at locations specified by a `SECTION` command. 1.0 = Perform design for moments at twelfth points along the beam.

Parameter Name	Default Value	Description
CAN (S16-19 only)	0	This parameter is applicable for doubly symmetric I-shaped cantilever member as per CL 13.6 (h) subjected to transverse load only. 0 = Not a Cantilever member (default) 1 = Unbraced Cantilever Member. Both flanges unbraced. 2 = Cantilever Member braced at tension flange only 3 = Cantilever Member braced at both flanges **Notes:** **1.** Valid for CSA S16 2019 only. This parameter will be used to calculate the factored moment of resistance for a doubly symmetric I-shaped cantilever member. **2.** This parameter can be used with the LHT parameter for CL 13.6 (h) check. **3.** For deflection check, 0 = deflection check based on the principle that maximum deflection occurs within the span between DJ1 and DJ2. Use 1 or 2 or 3 to deflection check based on the principle that maximum deflection is of the cantilever type (see D1.B.1.2 Design Parameters (on page 1134)).
CB	0.0	Value of ω_2 (code Cl 13.6) to be used for calculations. ω_2 is calculated internally if CB is 0.0 or not provided.

Parameter Name	Default Value	Description
CMY	ω_1 calculated as per clause number 13.8.5 (a)	ω_1 in local Y direction for the member. The program calculated value of ω_1 depends on whether the member is subjected to any transverse load or not: • $\omega_1 = 0.6 - 0.4\kappa \geq 0.4$ if the member is not subjected to transverse loads between supports. Refer Clause 13.8.5 (a) • $\omega_1 = 1.0$ if the member is subjected to distributed loads or a series of point loads between supports. Refer Clause 13.8.5 (b) • $\omega_1 = 0.85$ if the member is subjected to a concentrated load or moment between supports. Refer Clause 13.8.5 (c) STAAD.Pro will calculate ω_1 based on the formula specified in 13.8.5 (a) unless you directly specify a value. You may specify any value between 0.4 to 1 for ω_1 .
CMZ	ω_1 calculated as per clause number 13.8.5 (a)	ω_1 in local Z direction for the member. The program calculated value of ω_1 depends on whether the member is subjected to any transverse load or not: • $\omega_1 = 0.6 - 0.4\kappa \geq 0.4$ if the member is not subjected to transverse loads between supports. Refer Clause 13.8.5 (a) • $\omega_1 = 1.0$ if the member is subjected to distributed loads or a series of point loads between supports. Refer Clause 13.8.5 (b) • $\omega_1 = 0.85$ if the member is subjected to a concentrated load or moment between supports. Refer Clause 13.8.5 (c) STAAD.Pro will calculate ω_1 based on the formula specified in 13.8.5 (a) unless you directly specify a value. You may specify any value between 0.4 to 1 for ω_1 .

Parameter Name	Default Value	Description
CPSACING	0.0	Spacing between connectors of built-up members required for slenderness ratio calculation per Cl. 19.1.4.
DFF	None (Mandatory for deflection check)	"Deflection Length"/Maxmimum Allowable local deflection. See TR.40 Load Envelope (on page 2663) for deflection checks using serviceability load envelopes.
DJ1	Start Joint of member	Joint No. denoting start point for calculation of "Deflection Length" (see D1.B.1.2 Design Parameters (on page 1134))
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length" (see D1.B.1.2 Design Parameters (on page 1134))
DMAX	45.0 in.	Maximum allowable depth (Applicable for member selection)
DMIN	0.0 in.	Minimum required depth (Applicable for member selection)
FLX	0	Parameter for specifying the flexural-torsional restraint condition. 0 = Flexural-torsional restraint is not provided 1= Flexural-torsional restraint is provided along the length.
FU	345.0 MPa	Ultimate strength of steel.
FYLD	300.0 MPa	Yield strength of steel.
IMM (S16-19 only)	0	Truss Type as required for CL 13.3.2.2 and CL 13.3.2.3 as per CSA S16-19 0 = Non Truss member 1 = Planner Truss Member 2 = Space Truss Member

Parameter Name	Default Value	Description
KT	1.0	K value for flexural torsional buckling.
KY	1.0	K value for general column flexural buckling about the local Y-axis. Used to calculate slenderness ratio.
KZ	1.0	K value for general column flexural buckling about the local Z-axis. Used to calculate slenderness ratio.
LAT	0	Specify lateral support conditions: 0 = Beam is laterally unsupported. 1 = Beam is laterally supported.
LEG	0	This parameter is meant for plain angles (clause 13.3.3.2). 0 = The angle is connected by the longer leg. 1 = The angle is connected by the shorter leg.
LHT (S16-19 only)	0	Load Height Position as required to check as per CL 13.6.(h) 0 = Load applied at the shear center 1 = Load applied at the tension side of the shear center 2 = Load applied at the compression side of the shear center **Note:** The LHT parameter should be used along with the CAN parameter.
LT	Member Length	Length for flexural torsional buckling.
LY	Member Length	Length for general column flexural buckling about the local Y-axis. Used to calculate slenderness ratio.

Parameter Name	Default Value	Description
LZ	Member Length	Length for general column flexural buckling about the local Z-axis. Used to calculate slenderness ratio.
MAIN	200	Allowable slenderness limit for compression members. A value of 1 suppresses this check. Any value greater than 1 is used as the compression slenderness check value. A value of zero (0) uses the default (i.e., slenderness limit of 200).
NCR	0	This parameter sets the *n* factor to calculate Cr value as per clause number 13.3.1 0 = 1.34 1 = 2.24 **Notes:** **1.** The default value of n is used for all sections. **2.** n = 2.24 for Hollow sections (e.g., HSST, HSSP, Pipe Tube), for doubly symmetric built-up (STP = 2) sections (e.g., W, M, S, HP sections), and for Welded Wide Flange (WWF) sections if NCR is set to 1. WWF sections are designed as built up sections. **3.** n = 1.34 for doubly symmetric hot rolled sections and for single symmetric hot rolled or built-up sections (e.g., Channel, Tee, Angle) regardless of the NCR parameter value.
NSF	1.0	Net section factor for tension members.
PROFILE	-	Used in member selection. Refer to TR.48.1 Parameter Specifications (on page 2676) for details.

Parameter Name	Default Value	Description
RATIO	1.0	Permissible ratio of actual load effect to the design strength.
SLF	1.0	The shear lag factor, U, normally taken from Cl. 12.3.3.2, combined with the `NSF` parameter to determine the rupture strength.
SNUG	1	Specify type of connection for the built-up members (Refer to Cl. 19.1.4): 0 = Welded or pretensioned bolts. 1 = Bolted snug-tight.
SSY	0	0 = Sway or Unbraced along local Y axis 1 = Braced along local Y axis This parameter is required to choose the proper value of U_{1y} which is used to determine the cross-sectional strength, overall member strength and lateral torsional buckling strength. Refer to Axial compression and bending (on page 1454) for details.
SSZ	0	0 = Sway or Unbraced along local Z axis 1 = Braced along local Z axis This parameter is required to choose the proper value of U_{1z} which is used to determine the cross-sectional strength, overall member strength and lateral torsional buckling strength. Refer to Axial compression and bending (on page 1454) for details.
STIFF	Member length of depth of beam, whichever is lesser.	Spacing of traverse stiffeners.
STP	1	1.0 = Rolled section 2.0 = Welded built-up section

Parameter Name	Default Value	Description
TMAIN	300	Allowable slenderness limit for tension members. A value of 1 suppresses this check. Any value greater than 1 is used as the tension slenderness check value. A value of zero (0) uses the default (i.e., slenderness limit of 300).
TRACK	0.0	Design output: 0.0 = Report only minimum design results. 1.0 = Report design strengths also. 2.0 = Provide full details of design.
UNB	Member Length	Unsupported length in bending compression of the bottom flange for calculating moment resistance.
UNT	Member Length	Unsupported length in bending compression of the top flange for calculating moment resistance.

D5. European Codes

D5.A. European Codes - Concrete Design Per DD ENV 1992

Note: This code has been removed from the batch design. To perform design to the current Eurocode 2 design code, please use the D. Advanced Concrete Design (on page 1071).

D5.B. European Codes - Steel Design per Eurocode 3 [DD ENV 1993-1-1:1992]

STAAD.Pro is capable of performing steel design based on the European code EC3 DD ENV 1993-1-1:1992 *Eurocode 3: Design of steel structures Part 1.1 General rules and rules for buildings*.

Note: The DD ENV 1993-1-1:1992 code has now been officially superseded by EN 1993-1-1:2005. Hence releases of STAAD.Pro subsequent to version SS3 (20.07.08.xx) will not support this design code. The SS3 build will perform member design to this code for legacy files but has this code removed from the design codes list in the GUI. Users are advised to use the EN 1993-1-1:2005 version for Eurocode 3 design.

Tip: Design per EC3 DD ENV 1993-1-1:1992 is also available in the Steel Design mode in the Graphical User Interface.

D5.B.1 General Description

1. Selecting the applicable load cases to be considered in the design process.
2. Providing appropriate "Parameter" values if different from the default values.
3. Specify whether to perform code-checking and/or member selection.

These operations can be repeated by the user any number of times depending on the design requirements. The "Parameters" referred to above provide the user with the ability to allocate specific design properties to individual members or member groups considered in the design operation.

D5.B.1.1 Eurocode 3 DD ENV 1993-1-1:1992 (EC3 DD)

The DD ENV version of Eurocode 3, *Design of steel structures, Part 1.1 General rules and rules for buildings* (EC3 DD) provides design rules applicable to structural steel used in buildings and civil engineering works. It is based on the ultimate limit states philosophy that is common to modern standards. The objective of this method of design is to ensure that possibility of failure is reduced to a negligible level. This is achieved through application of safety factors to both the applied loads and the material properties.

The code also provides guidelines on the global methods of analysis to be used for calculating internal member forces and moments. STAAD uses the elastic method of analysis which may be used in all cases. Also there are three types of framing referred to in EC3. These are "Simple", "Continuous", and "Semi-continuous" which reflect the ability of the joints to developing moments under a specific loading condition. In STAAD only "Simple" and "Continuous" joint types can be assumed when carrying out global analysis.

D5.B.1.2 National Application Documents

Various authorities of the CEN member countries have prepared National Application Documents to be used with EC3. These documents provide alternative factors for loads and may also provide supplements to the rules in EC3.

The current version of EC3 DD implemented in STAAD adheres to the factors and rules provided in DD ENV 1993-1-1:1992 and has *not* been modified by any National Application Document.

Note: National Annex documents *are* available for EC3 BS EN 1993-1-1:2005. Refer to D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478)

Axes convention in STAAD.Pro and Eurocode 3

By default, STAAD.Pro defines the major axis of the cross-section as Z-Z and the minor axis as Y-Y. A special case where Z-Z is the minor axis and Y-Y is the major axis is available if the `SET Z UP` command is used and is discussed in TR.5 Set Command Specification (on page 2206). The longitudinal axis of the member is defined as X and joins the start joint of the member to the end with the same positive direction.

Eurocode 3, however, defines the principal cross-section axes in reverse to that of STAAD.Pro, but the longitudinal axis is defined in the same way. Both of these axes definitions follow the orthogonal right hand rule.

Bear this difference in mind when examining the code-check output from STAAD.Pro.

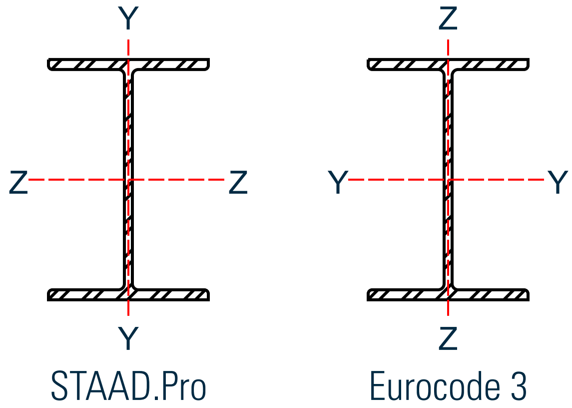

Figure 163: Axis convention in STAAD.Pro and EC3

D5.B.2 Analysis Methodology

Elastic analysis method is used to obtain the forces and moments for design. Analysis is done for the primary and combination loading conditions provided by the user. The user is allowed complete flexibility in providing loading specifications and using appropriate load factors to create necessary loading situations.

D5.B.3 Material Properties and Load Factors

The characteristic yield strength of steel used in EC3 DD design is based on table 3.1 of the code. Design resistances are obtained by dividing the characteristic yield strength by the material partial safety factor Γm. The magnitude of Γm in STAAD.Pro is 1.1 which is applicable to all section types. A separate safety factor parameter named GB1 is used to check the resistance of a member to buckling and also has a default value of 1.1.

Material coefficients for steel in STAAD.Pro take the following default values unless replaced by user's numerical values provided in the input file.

Modulus of Elasticity, E = 205000 N/mm^2
Shear Modulus, G = E/2(1+ ν)
Poisson's Ratio, ν = 0.3
Unit weight, Γ = 76.8 KN/m^3

The magnitude of design loads is dependent on Γ_f, the partial safety factor for the action under consideration. In STAAD.Pro you are allowed total control in providing applicable values for the factors and their use in various load combinations.

D5.B.4 Section Classification

The occurrence of local buckling of the compression elements of a cross-section prevents the development of full section capacity. It is therefore imperative to establish this possibility prior to determining the section capacities. Cross sections are classified in accordance with their geometrical properties and the stress pattern on the compression elements. For each load case considered in the design process, STAAD determines the section class and calculates the capacities accordingly.

The EC3 DD design module in STAAD can design members with all section profiles that are of Class 1 2 or 3 as defined in section 5.3.2 of the code. However, the design of members that have a "Class 4" section profile are limited to WIDE FLANGE, TEE, SINGLE CHANNEL, SINGLE ANGLE, and RECTANGULAR HOLLOW SECTIONS. Also built-up user sections that are class 4 sections are not dealt with in the current version of EC3 design in STAAD.Pro.

Laced and battened members are not considered in the current version of EC3 DD design module in STAAD.Pro.

D5.B.5 Member Design

D5.B.5.1 Design of Beams as per DD ENV 1993-1-1:1992

EC3 DD design in STAAD.Pro considers members that are primarily in bending and/or shear as beams and performs cross section and member capacity checks in accordance with the code. The main requirement for a beam is to have sufficient cross-section resistance to the applied bending moment and shear force. The possibility of lateral-torsional buckling is also taken into consideration when the full length of the member has not been laterally restrained.

The bending capacity is primarily a function of the section type and the material yield strength and is determined according to Cl. 5.4.5 of the code. The shear capacity and the corresponding shear checks are done as per section 5.4.6 of the code.

There are four classes of cross-sections defined in EC3. Class 1 and 2 sections can both attain full capacity with the exception that the class 2 sections cannot sustain sufficient rotation required for plastic analysis of the model. Hence the full plastic section modulus is used in the design calculations. Class 3 sections, due to local buckling, cannot develop plastic moment capacity and the yield stress is limited to the extreme compression fibre of the section. The elastic section modulus is used to determine the moment capacity for class 3 sections. Class 4 sections do suffer from local buckling and explicit allowance must be made for the reduction in section properties before the moment capacity can be determined. Further, because of interaction between shear force and bending moment, the moment resistance of the cross-section may be reduced. This, however, does not occur unless the value of applied shear forces exceeds 50% of the plastic shear capacity of the section. In such cases the web is assumed to resist the applied shear force as well as contributing towards the moment resistance of the cross-section.

As mentioned in the previous section, the design of class 4 sections is limited to WIDE FLANGE, TEE, SINGLE CHANNEL, SINGLE ANGLE, and RECTANGULAR HOLLOW SECTIONS. The effective section properties are worked out as described in Cl. 5.3.5 of the code.

Beams are also checked for lateral-torsional buckling according to section 5.5.2 of the code. The buckling capacity is dependent on the section type as well as the unrestrained length, restraint conditions and type of applied loading. The lateral torsional buckling checks involves the calculation of the “Elastic critical moment”, Mcr, which is calculated in STAAD as per the method given in Annex F of the code.

In the presence of a shear force, beams are also checked for shear as per section 5.4.6 of the code. In cases where the members are subject to combined bending and shear, the combined bending and shear checks are done in STAAD as per clause 5.4.7 of the code.

D5.B.5.2 Design of Axially Loaded Members

The design of members subject to tension loads alone are performed as per Cl 5.4.3 of the code. The tension capacity is calculated based on yield strength, material factor Γm and cross-sectional area of the member with possible reduction due to bolt holes. When bolt holes need to be considered in the capacity calculations the value used for Γm is 1.2 and the yield strength is replaced with the ultimate tensile strength of the material. The tension capacity is then taken as the smaller of the full section capacity and the reduced section capacity as stated above.

The design of members subject to axial compression loads alone are performed as per Cl 5.4.4 of the code. For members with class 1 2 or 3 section profiles, the full section area is considered in calculating the section capacity. However in case of class 4 sections, the “effective cross-section” is considered to calculate the compressive strength. Also any additional moments induced in the section due to the shift of the centroidal axis of the effective section will also be taken into account as per clause 5.4.8.3 of the code. The effective section properties for class 4 sections will be worked out as given in Cl.5.3.5 of the code.

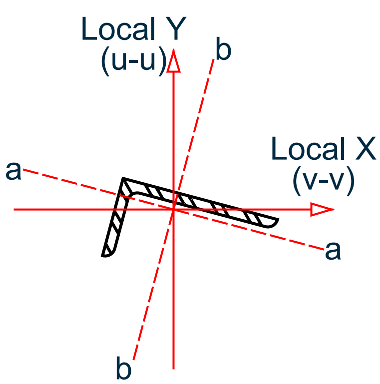
In addition to the cross section checks, buckling resistance will also be checked for such members. This is often the critical case as the buckling strength of the member is influenced by a number of factors including the section type and the unbraced length of the member. The buckling capacity is calculated as per Cl. 5.5 of the code.

DD ENV 1993-1-1:1992 does not specifically deal with single angle, double angles, double channels or Tee sections and does give a method to work out the slenderness of such members. In these cases, the EC3 DD design module of STAAD.Pro uses the methods specified in BS 5950-1:2000 to calculate the slenderness of these members. Cl. 4.7.10 and table 25 of BS 5950-1:2000 are used in the current version of the EC3 DD design module

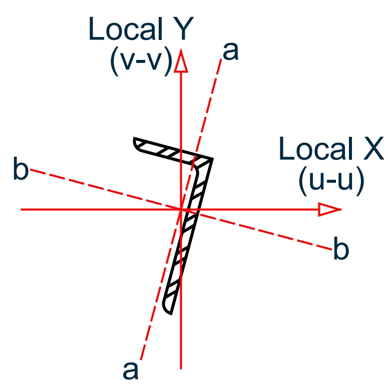
Single Angle Sections

Angle sections are unsymmetric and when using BS 5950:2000 table 25, you must consider four axes: two principal, u-u and v-v and two geometric, a-a and b-b. The effective length for the v-v axis, Lvv, is taken as the `LVV` parameter or $LY \cdot KY$, if not specified. The a-a and b-b axes are determined by which leg of the angle is fixed by the connection and should be specified using the `LEG` parameter, see section 5B.6 for more information on the `LEG` parameter. The effective length in the a-a axis is taken as $LY \cdot KY$ and the effective length in the b-b axis as $LZ \cdot KZ$.

The following diagram shows the axes for angles which have been defined with either an ST or RA specification and is connected by its longer leg (i.e., a-a axis is parallel to the longer leg).



ST angle and USER table angles



RA angle

D5.B.5.3 Design of members with combined axial load and bending

The bending resistance of members could be reduced by the presence of a co-existent axial load. This is then checked against the lateral-torsional buckling resistance of the section. The EC3 DD design module in STAAD takes such a scenario into account and performs the necessary checks as per Cl. 5.4.8 of the code. Class 1 and class 2 sections are checked as per cl. 5.4.8.1 and Class 3 and Class 4 sections are checked as per clauses 5.4.8.2 and 5.4.8.3 respectively. The effective section properties for class 4 sections are worked out as given in Cl. 5.3.5 of the code.

Generally, EC3 requires checking cross-section resistance for local capacity and also checking the overall buckling capacity of the member. In the case of members subject to axial tension and bending, there is provision to take the stabilizing effect of the tension load into consideration. This is achieved by modifying the extreme compression fibre stress and calculating an effective applied moment for the section. The checks are done as per Cl. 5.5.3 of the code. In case of a combined axial compressive load and bending moment, the member will be checked as per the rules in section 5.5.4 of the code.

The presence of large shear force can also reduce the bending resistance of the section under consideration. If the shear load is large enough to cause a reduction in bending resistance, then the reduction due to shear has to be taken into account before calculating the effect of the axial load on the bending resistance of the section. If the member is subject to a combined shear, axial load and bending moment then the section capacity checks will be done as per Cl. 5.4.9 of the code.

As stated in the previous section, DD ENV 1993-1-1:1992 does not specifically deal with single angle, double angles, double channels or Tee sections and does give a method to work out the slenderness of such members. In these cases, the EC3 DD design module of STAAD.Pro uses the methods specified in BS 5950-1:2000 to calculate the slenderness of these members. Cl. 4.7.10 of BS 5950-1:2000 is used in the current version of the EC3 DD design module. Please refer to the note in section 5B.5.2 for St and RA angle specifications.

Please note that laced or battened compression members are not dealt within the current version of EC3 DD design module in STAAD.Pro.

D5.B.6 Design Parameters

Design parameters communicate specific design decisions to the program. They are set to default values to begin with and may be altered to suite the particular structure.

Depending on the model being designed, the user may have to change some or all of the parameter default values. Some parameters are unit dependent and when altered, the new setting must be compatible with the active "unit" specification.

The following table lists all the relevant EC3 parameters together with description and default values.

Table 128: Steel Design Parameters EC3 DD

Parameter Name	Default Value	Description
CODE	Undefined	You must specify EC3 or EUROPE. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).

Parameter Name	Default Value	Description
BEAM	3	Parameter to control the number of sections to checked along the length of a beam: 0. Check sections with end forces only 1. Check at location of maximum Mz along beam 2. Check sections with end forces and forces at location of `BEAM 1.0` check. 3. Check at every 1/13th point along the beam and report the maximum Refer to Note 2 below.
CAN	0	Member will be considered as a cantilever type member for deflection checks. 0 indicates that member will not be treated as a cantilever member 1 indicates that the member will be treated as a cantilever member
CMM	1.0	Indicates type of loading on member. Valid values range from 1 to 6. Refer to Table 7B.3 for more information on its use.
CMN	1.0	Indicates the level of End-Restraint. 1.0 = No fixity 0.5 = Full fixity 0.7 = One end free and other end fixed
DMAX	100.0 cm	Maximum allowable depth for the member.
DMIN	0	Minimum required depth for the member.
DFF	None (Mandatory for deflection check)	Deflection limit

Parameter Name	Default Value	Description
DJ1	Start Joint of member	Joint No. denoting starting point for calculation of "Deflection Length".
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length".
FU		Ultimate tensile strength of steel
GB1	1.1	Partial safety factor used in buckling checks for compression members
GM0	1.1	Corresponds to the Γ_{m0} factor in DD ENV 1993-1-1:1992
GM1	1.1	Corresponds to the Γ_{m1} factor in DD ENV 1993-1-1:1992
GM2	1.1	Corresponds to the Γ_{m2} factor in DD ENV 1993-1-1:1992
KY	1.0	K factor in local y axis.
KZ	1.0	K factor in local z axis.
LEG	0.0	Connection type Refer to Note 1 below.
LVV	Maximum of Lyy and Lzz (Lyy is a term used by BS5950)	Buckling length for angle about its principle axis
LY	Member Length	Compression length in local y axis, Slenderness ratio = (KY)*(LY)/(Ryy)
LZ	Member Length	Compression length in local z axis, Slenderness ratio = (KZ)*(LZ)/(Rzz)

Parameter Name	Default Value	Description
PLG	0	(Polish NA only) Perform additional checks per Cl. 6.3.3 0. Ignore additional PN EN checks 1. Include additional PN EN checks Refer to D5.D.8.7 Clause 6.3.3(5) – Interaction factors kyy, kyz, kzy, and kzz (on page 1555)
PY	Yield Strength	The yield strength default value is set based on the default value of the "SGR" parameter.
NSF	1.0	Net tension factor for tension capacity calculation.
RATIO	1	Permissible ratio of loading to capacity.
SBLT	0.0	Indicates if the section is rolled or built-up. 0.0 = Rolled 1.0 = Built-up
SGR	0.0	Steel grade as per table 3.1 in EC3. 0.0 = Fe 360 1.0 = Fe 430 2.0 = Fe 510
TRACK	0	Controls the level of detail of output. 0 = minimum 1 = intermediate 2 = maximum 4 = perform a deflection check See note 3 below.
UNF	1.0	Unsupported buckling length as a factor of the beam length

Parameter Name	Default Value	Description
UNL	Member Length	Unrestraint length of member used in calculating the lateral-torsional resistance moment of the member.
ZIV	0.8	Specifies a reduction factor for vectoral effects to be used in axial tension checks [Cl 5.5.3(2)]

Notes

1. LEG – (Ref: Table 25 BS5950)

   The slenderness of single and double angle, channel and tee sections are specified in BS 5950 table 25 depending on the connection provided at the end of the member (Refer to D5.B.4 Section Classification (on page 1467)). To define the appropriate connection, a LEG parameter should be assigned to the member.

   The following table indicates the value of the LEG parameter required to match the BS5950 connection definition:

   Table 129: LEG Parameter values

Clause	Bold Configuration	Leg	LEG Parameter
4.7.10.2 Single Angle	(a) - 2 bolts	short leg	1.0
		long leg	3.0
	(b) - 1 bolts	short leg	0.0
		long leg	2.0
4.7.10.3 Double Angles	(a) - 2 bolts	short leg	3.0
		long leg	7.0
	(b) - 1 bolts	short leg	2.0
		long leg	6.0
	(c) - 2 bolts	long leg	1.0
		short leg	5.0
	(d) - 1 bolts	long leg	0.0
		short leg	4.0
4.7.10.4 Channels	(a) - 2 or more rows of bolts		1.0
	(b) - 1 row of bolts		0.0

Clause	Bold Configuration	Leg	LEG Parameter
4.7.10.5 Tee Sections	(a) - 2 or more rows of bolts		1.0
	(b) - 1 row of bolts		0.0

For single angles, the slenderness is calculated for the geometric axes, a-a and b-b as well as the weak v-v axis. The effective lengths of the geometric axes are defined as:

La = KY * KY

Lb = KZ * LZ

The slenderness calculated for the v-v axis is then used to calculate the compression strength pc for the weaker principal axis (z-z for ST angles or y-y for RA specified angles). The maximum slenderness of the a-a and b-b axes is used to calculate the compression strength pc for the stronger principal axis.

Alternatively for single angles where the connection is not known or Table 25 is not appropriate, by setting the LEG parameter to 10, slenderness is calculated for the two principal axes y-y and z-z only. The LVV parameter is not used.

For double angles, the LVV parameter is available to comply with note 5 in table 25. In addition, if using double angles from user tables, (G.6.3 User-Provided Steel Table (on page 2117)) an eleventh value, rvv, should be supplied at the end of the ten existing values corresponding to the radius of gyration of the single angle making up the pair.

2. `BEAM`

   Ensure that this parameter is set to either 1 or 2 while performing code checking for members susceptible to Lateral - Torsional Buckling.

Table 130: Values for the CMM Parameter

CMM Value	Loading and Support Conditions
1	2	3	
CMM Value	Loading and Support Conditions
4	5	6	
3. Checking beam deflection

   With the `TRACK` parameter set to 4, the members included in a `CHECK CODE` command will be checked for the local axis deflection rather than for the stress capacity using the current `LOAD LIST`.

   If both stress capacity and deflection checks are required, then 2 parameter blocks with code checks are required, one with a TRACK 4 command and one with a TRACK 0, 1, or 2, thus:

```
LOAD LIST 1 TO 10
PARAMETER 1
CODE EN 1993
TRACK 2 ALL
CHECK CODE MEMBER 1
***************************
LOAD LIST 100 TO 110
PARAMETER 2
TRACK 4 ALL
DFF 300 MEMB 1
DJ1 1 MEMB 1
DJ2 4 MEMB 1
CODE MEMB 1
```

Note: While both sets of code checks will be reported in the output file, only the last code check results are reported in the GUI.

D5.B.7 Code Checking

The purpose of code checking is to ascertain whether the provided section properties of the members are adequate. The adequacy is checked as per DD ENV 1993-1-1:1992. Code checking is done using the forces and moments at specific sections of the members.

When code checking is selected, the program calculates and prints whether the members have passed or failed the checks; the critical condition ; the value of the ratio of the critical condition (overstressed for value more than 1.0 or any other specified RATIO value); the governing load case, and the location (distance from the start of the member of forces in the member where the critical condition occurs).

Code checking can be done with any type of steel section listed in D3.B.4 Built-In Steel Section Library (on page 1380) or any of the user defined sections as described in G.6.3 User-Provided Steel Table (on page 2117) , with two exceptions; `GENERAL` and `ISECTION`. The EC3 DD design module does not consider these sections or `PRISMATIC` sections in its design process.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

D5.B.8 Member Selection

STAAD.Pro is capable of performing design operations on specified members. Once an analysis has been performed, the program can select the most economical section, i.e., the lightest section, which fulfills the code requirements for the specified member. The section selected will be of the same type section as originally designated for the member being designed. Member selection can also be constrained by the parameters DMAX and DMIN, which limits the maximum and minimum depth of the members.

Member selection can be performed with all the types of steel sections with the same limitations as defined in D5.B.7 Code Checking (on page 1476).

Selection of members, whose properties are originally input from a user created table, will be limited to sections in the user table.

Member selection cannot be performed on members whose section properties are input as prismatic or as the limitations specified in section 5.B.7(A).

D5.B.9 Tabulated Results of Steel Design

For code checking or member selection, the program produces the results in a tabulated fashion. The items in the output table are explained as follows:

MEMBER	refers to the member number for which the design is performed.
TABLE	refers to steel section name, which has been checked against the steel code or has been selected.
RESULTS	prints whether the member has PASSED or FAILED. If the RESULT is FAIL, there will be an asterisk (*) mark on front of the member.
CRITICAL COND	refers to the clause in DD ENV 1993-1-1:1992 code which governs the design.
RATIO	prints the ratio of the actual stresses to allowable stresses for the critical condition. Normally a value of 1.0 or less will mean the member has passed.
LOADING	provides the load case number, which governed the design.
FX, MY, and MZ	provide the axial force, moment in local Y-axis and the moment in local z-axis respectively. Although STAAD does consider all the member forces and moments (except torsion) to perform design, only FX, MY and MZ are printed since they are the ones which are of interest, in most cases.
LOCATION	specifies the actual distance from the start of the member to the section where design forces govern.

Note: For a `TRACK 2` output, the module will also report all the relevant clause checks that have been performed and will also indicate the critical ratio and the load case that caused the critical ratio as well as the corresponding forces that were used for the respective checks. A TRACK 2 output will also include the various design data used for the calculations such as the section modulii, section class, section capacity etc.

D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005]

STAAD.Pro is capable of performing steel design based on the European code EC3 BS EN 1993-1-1:2005 *Eurocode 3: Design of steel structures Part 1.1 General rules and rules for buildings*.

Note: The implementation of EN1993-1-1:2005 includes the amendments as per CEN corrigenda of February 2006 and April 2009.

D5.C.1 General Description

The main steps in performing a design operation are:

1. Selecting the applicable load cases to be considered in the design process.
2. Providing appropriate “Parameter” values if different from the default values.
3. Specify whether to perform code-checking and/or member selection.

These operations can be repeated by the user any number of times depending on the design requirements. The “Parameters” referred to above provide the user with the ability to allocate specific design properties to individual members or member groups considered in the design operation.

D5.C.1.1 Eurocode 3 - EN 1993-1-1:2005 (EN 1993)

The EN 1993 version of Eurocode 3, *Design of steel structures, Part 1.1 General rules and rules for buildings* (EN 1993) provides design rules applicable to structural steel used in buildings and civil engineering works. It is based on the ultimate limit states philosophy that is common to modern standards. The objective of this method of design is to ensure that possibility of failure is reduced to a negligible level. This is achieved through application of safety factors to both the applied loads and the material properties.

The code also provides guidelines on the global methods of analysis to be used for calculating internal member forces and moments. STAAD uses the elastic method of analysis which may be used in all cases. Also there are three types of framing referred to in EC3. These are “Simple”, “Continuous”, and “Semi-continuous” which reflect the ability of the joints to developing moments under a specific loading condition. In STAAD only “Simple” and “Continuous” joint types can be assumed when carrying out global analysis.

D5.C.1.2 National Annex Documents

Various authorities of the CEN member countries have prepared National Annex Documents to be used with EC3. These documents provide alternative factors for loads and may also provide supplements to the rules in EC3.

The current version of EC3 (EN 1993) implemented in STAAD.Pro adheres to the factors and rules provided in EN 1993-1-1:2005. STAAD.Pro includes the following National Annexes:.

a. British National Annex [NA to BS EN 1993-1-1:2005]
b. The Dutch National Annex [NEN-EN 1993-1-1/NB] and
c. Norwegian National Annex [NS-EN 1993-1-1:2005/NA2008]
d. French National Annex [Annexe Nationale a la NF EN 1993-1-1:2005]
e. Finnish National Annex [SFS EN 1993-1-1:2005]
f. Polish National Annex [PN EN 1993-1-1:2005]

g. Singaporean National Annex [SS EN 1993-1-1:2005]
h. Belgian National Annex [NBN EN 1993-1-1 ANB:2018]
i. Malaysian National Annex [MS EN 1993-1-1]
j. German National Annex [DIN EN 1993-1-1:2005]
k. Swedish National Annex [BFS EN 1993-1-1:2005]

The choice of a particular National Annex is based on the value of a new NA parameter that is set when you specify the EN 1993 version of Eurocode 3. Refer to D5.D. European Codes - National Annexes to Eurocode 3 [EN 1993-1-1:2005] (on page 1516) for a description of the NA parameter.

Axes convention in STAAD.Pro and Eurocode 3

By default, STAAD.Pro defines the major axis of the cross-section as Z-Z and the minor axis as Y-Y. A special case where Z-Z is the minor axis and Y-Y is the major axis is available if the `SET Z UP` command is used and is discussed in TR.5 Set Command Specification (on page 2206). The longitudinal axis of the member is defined as X and joins the start joint of the member to the end with the same positive direction.

Eurocode 3, however, defines the principal cross-section axes in reverse to that of STAAD.Pro, but the longitudinal axis is defined in the same way. Both of these axes definitions follow the orthogonal right hand rule.

Bear this difference in mind when examining the code-check output from STAAD.Pro.

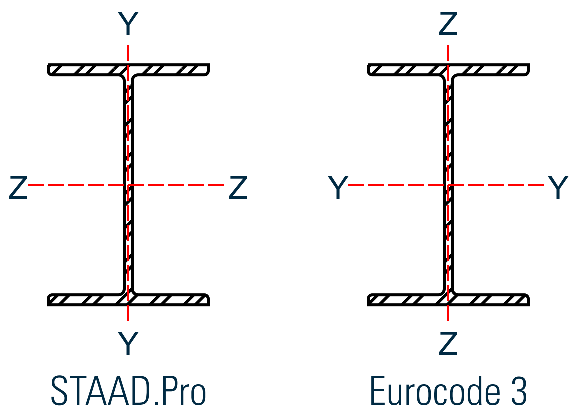

Figure 164: Axis convention in STAAD.Pro and EC3

Refer to D5.C.9 Tabulated Results of Steel Design (on page 1514) for an example of how this appears when Y is up (default).

D5.C.2 Analysis Methodology

Elastic analysis method is used to obtain the forces and moments for design. Analysis is done for the primary and combination loading conditions provided by the user. The user is allowed complete flexibility in providing loading specifications and using appropriate load factors to create necessary loading situations.

D5.C.3 Material Properties and Load Factors

The characteristic yield strength of steel used in EC3 (EN 1993) design is based on table 3.1 of the code. Design resistances are obtained by dividing the characteristic value of a particular resistance by the global partial safety factor for the resistance, γ_m. The magnitude of γ_m is based on Cl. 6.1 of EN 1993-1-1:2005 and can change depending on the selected National Annex.

Material coefficients for steel in STAAD.Pro take the following default values unless replaced by user's numerical values provided in the input file.

Modulus of Elasticity, E = 205,000 N/mm^2
Shear Modulus, G = E/2(1+ ν)
Poisson's Ratio, ν = 0.3
Unit weight, Γ = 76.8 KN/m^3

The magnitude of design loads is dependent on γ_f, the partial safety factor for the action under consideration. You are allowed total control in providing applicable values for the factors and their use in various load combinations.

D5.C.4 Section Classification

The occurrence of local buckling of the compression elements of a cross-section prevents the development of full section capacity. It is therefore imperative to establish this possibility prior to determining the section capacities. Cross sections are classified in accordance with their geometrical properties and the stress pattern on the compression elements. For each load case considered in the design process, the program determines the section class and calculates the capacities accordingly. It is worth noting that the section class reported in the design output corresponds to the most critical loadcase among those being considered for design.

The EC3 (EN 1993) design module in STAAD.Pro can design members with all section profiles that are of Class 1, 2, or 3 as defined in section 5.5 of the code. However, the design of members that have a Class 4 section profile are limited to:

- wide flange (with equal flanges)
- tee
- single channel
- single angle
- rectangular hollow sections
- circular hollow sections

Also built-up user sections that are class 4 sections are not dealt with in the current version of EC3 design in STAAD.Pro, unless they are defined as any of the section types given above.

The design of laced and battened members is not considered in the current version of EC3 (EN 1993) design module in STAAD.Pro. The current version also does not support the design of tapered section profiles or I-Sections with top and/or bottom plates or I sections with unequal flanges.

D5.C.5 Member Design

EN 1993-1-1:2005, together with any specified National Annex, is used for code check or member selection. However, where EN 1993 or the National Annex has *not* specified a method or values for a specific clause or parameter, STAAD.Pro uses Non-Contradictory Complementary Information (NCCI) documents as explained in the following corresponding sections.

The design philosophy embodied in this specification is based on the concept of limit state design. Structures are designed and proportioned taking into consideration the limit states at which they would become unfit for their intended use. Two major categories of limit-state are recognized - ultimate and serviceability. The primary considerations in ultimate limit state design are strength and stability, while that in serviceability is deflection.

The following sections describe the salient features of the design approach. In STAAD.Pro, members are proportioned to resist the design loads without exceeding the limit states of strength, stability, and serviceability. Member selection is done on the basis of selecting the most economic section on the basis of the least weight criteria. It is generally assumed that you (the engineer) will take care of the detailing requirements, such as the provision of stiffeners, and check the local effects like flange buckling, web crippling, etc.

Note: The design of class 4 (slender) sections is limited to:

- wide flange (with equal flanges)
- tee
- single channel
- single angle
- rectangular hollow sections
- circular hollow sections

The effective section properties are evaluated as described in Cl. 6.2.2.5 of the code. Refer to D5.C.4 Section Classification (on page 1480) for additional details.

Tapered member design is limited to I-sections with a tapered web, rectangular hollow sections, and circular sections. The additional design checks for bending required for these members is described in Tapered Members (on page 1484). Tapered member design is limited to EN 1993-1-1 only (i.e., no National Annex checks are considered for these members). Haunch members as described in EN 1993-1-1 are not designed in STAAD.Pro.

You are allowed complete control over the design process through the use of the parameters listed in D5.C.6 Design Parameters (on page 1502). Default values of parameters will yield reasonable results in most circumstances. However, you should control the design and verify results through the use of the design parameters.

- *V. EC3 - Simply supported laterally unrestrained beam* (on page 4068)

D5.C.5.1 Members Subject to Axial Loads

The cross section capacity of tension only members is checked for ultimate limit state as given in Cl. 6.2.3 of the code.

Compression members will be checked for axial capacity of the cross section in addition to lateral buckling/ stability. The cross section capacity will be checked as given in section 6.2.4 of the code.

Lateral stability of a pure compression member will be checked as per the method given in Cl. 6.3 of the code. The compression member stability will be verified as:

$$\frac{N_{Ed}}{N_{b,Rd}} \leq 1.0$$

Where $N_{b,Rd}$ is the design buckling resistance given by:

$$N_{b,Rd} = \frac{\chi A f_y}{\gamma_{M1}} \text{ for Class 1, 2, or 3 cross-sections}$$

$$N_{b,Rd} = \frac{\chi A_{eff} f_y}{\gamma_{M1}} \text{ for Class 4 cross-sections}$$

Where:

χ is the reduction factor as given in section 6.3.12 of the code. The buckling curves used to evaluate the reduction factor are selected from Table 6.2 of the code based on the cross section type and the steel grade.

> **Note:** *Only* the five grades of steel given in table 6.2 will be used when selecting the buckling curve. The steel grade used for this selection is based on the SGR design input parameter (Refer to D5.C.6 Design Parameters (on page 1502)). Even if you have specified a custom yield strength (using the PY parameter), the choice of a buckling curve will be based on the value of SGR parameter.

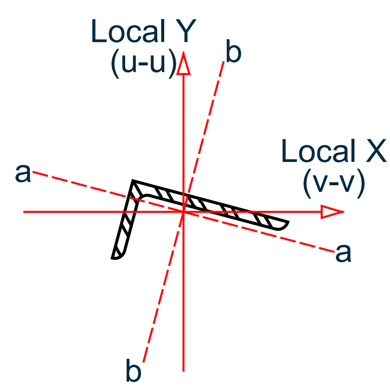
Compression members that are susceptible to torsional or torsional flexural buckling are checked for these modes of failure as well. The non-dimensional slenderness $\bar{\lambda}_T$ for these members is evaluated per Cl. 6.3.1.4 of the EN 1993 code. The maximum slenderness among the flexural buckling slenderness, torsional slenderness, and torsional-flexural slenderness is used to evaluate the reduction factor, χ, for such members. The elastic torsional buckling load, $N_{cr,T}$, and the elastic torsional-flexural buckling load, $N_{cr,TF}$, are evaluated based on the method given in the NCCI “SN001a-EN-EU: Critical axial load for torsional and flexural torsional buckling modes” (unless otherwise specified by a particular National Annex). The effective length for the members can be controlled using the KZ, KY, LZ and LY parameters. If these parameters are specified, the effective length will be calculated as KZ*LZ for length about the Z-Z axis and KY*LY for length about the Y-Y axis. By default, the effective length will be taken as the member length.

EN 1993-1-1:2005 does not specifically deal with single angle, double angles, double channels, or Tee sections and does not provide a method to evaluate the slenderness of such members. In these cases, the EC3 (EN 1993) design module of STAAD.Pro uses the methods specified in BS 5950-1:2000 to calculate the slenderness of these members. Cl. 4.7.10 and Table 25 of BS 5950-1:2000 are used in the current version of the Eurocode 3 design module.

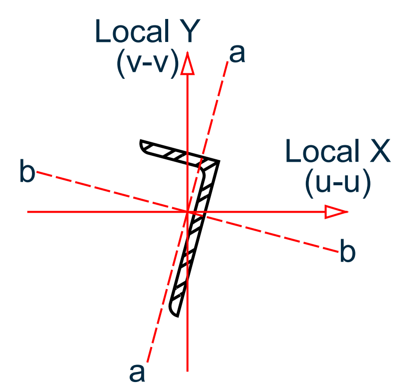
Single Angle Sections

Angle sections are unsymmetric and when using BS 5950:2000 table 25, you must consider four axes: two principal, u-u and v-v and two geometric, a-a and b-b. The effective length for the v-v axis, Lvv, is taken as the LVV parameter or $LY \cdot KY$, if not specified. The a-a and b-b axes are determined by which leg of the angle is fixed by the connection and should be specified using the LEG parameter, see section 5B.6 for more information on the LEG parameter. The effective length in the a-a axis is taken as $LY \cdot KY$ and the effective length in the b-b axis as $LZ \cdot KZ$.

The following diagram shows the axes for angles which have been defined with either an ST or RA specification and is connected by its longer leg (i.e., a-a axis is parallel to the longer leg).



ST angle and USER table angles



RA angle

D5.C.5.2 Members Subject to Bending Moments

The cross section capacity of a member subject to bending is checked as per Cl .6.2.5 of the code. The condition to be satisfied is:

$$\frac{M_{Ed}}{M_{c,Rd}} \leq 1.0$$

Where $M_{c,Rd}$ is the is the design resistance given by:

$$M_{c,Rd} = M_{pl,Rd} = \frac{W_{pl} f_y}{\gamma_{M0}}$$ for class 1 and 2 cross-sections

$$M_{c,Rd} = M_{el,Rd} = \frac{W_{el,min} f_y}{\gamma_{M0}}$$ for class 3 cross-sections

$$M_{c,Rd} = \frac{W_{eff,min} f_y}{\gamma_{M0}}$$ for class 4 cross-sections

Cross sectional bending capacity checks will be done for both major and minor axis bending moments.

Members subject to major axis bending will also be checked for lateral-torsional buckling resistance as per Section 6.3.2 of the code. The design buckling resistance moment $M_{b,Rd}$ will be calculated as:

$$M_{b,Rd} = \chi_{LT} W_y \frac{f_y}{\gamma_{M1}}$$

where

χ_{LT} = the reduction factor for lateral-torsional buckling. This reduction factor is evaluated per Cl. 6.3.2.2 or Cl 6.3.2.3 of the EN 1993 code depending on the section type. For I sections, the program will by default use Cl. 6.3.2.3 to evaluate χ_{LT} and for all other sections the program will resort to Cl 6.3.2.2. However, if a particular National Annex has been specified, the program will check if the National Annex expands on Cl.6.3.2.3 (Table 6.5) to include sections other than I sections. If so, the program will use Cl. 6.3.2.3 for the cross-section(s) included in Cl. 6.2.2.3 (or Table 6.5). For all other cases the program will use Cl. 6.3.2.2.

Note: You have the option to choose the clause to be used to calculate χ_{LT} through the `MTH` design parameter. Setting `MTH` to `0` (default value) will cause the program to choose Cl.6.3.2.3 for I Sections and Cl 6.2.3.2 for all other section types. As mentioned above, if the National Annex expands on Cl. 6.3.2.3 to include sections other than I Sections, the program will use Cl. 6.3.2.3 by default.

When using Cl. 6.3.2.3 to calculate χ_{LT}, the program will consider the correction factor kc (Table 6.6 of EN 1993-1-1:2006) based on the value of the `KC` parameter in the design input. By default the value of `KC` will be taken as 1.0. If you want the program to calculate kc, you must explicitly set the value of the `KC` parameter to zero.

Note: If the National Annex specifies a different method to calculate kc (e.g. the British, Singapore & Polish NAs), the program will use that method by default even if the KC parameter has not been explicitly set to zero. If the NA method does not deal with a specific condition while working out kc, the program will then fall back to table 6.6 of the code, thus ensuring that kc is considered for the particular NA.

The non-dimensional slenderness $\bar{\lambda}_{LT}$ (used to evaluate χ_{LT}) for both the above cases is evaluated as:

$$\bar{\lambda}_{LT} = \sqrt{\frac{W_y f_y}{M_{cr}}}$$

where

M_{cr} = the elastic critical moment for lateral-torsional buckling. EN 1993-1-1 does not however specify a method to evaluate M_{cr}. Hence, the program will make use of the method specified in Annex F of DD ENV 1993-1-1 to evaluate M_{cr} by default.

Note: The method specified in Annex F will be used only when the raw EN 1993-1-1:2005 code is used without any National Annex. If a National Annex has been specified, the calculation of M_{cr} (and $\bar{\lambda}_{LT}$) will be done based on the specific National Annex. (Refer to D5.D. European Codes - National Annexes to Eurocode 3 [EN 1993-1-1:2005] (on page 1516) for specific details). If the National Annex does not specify a particular method or specify a reference document, the program will use the NCCI document SN-003a-EN-EU for doubly symmetric sections and SN030a-EN-EU for mono-symmetric sections that are symmetric about their weak axis. For all other sections types the program will use Annex F of DD ENV 1993-1-1 to calculate M_{cr}. In cases where Annex F does not provide an adequate method to evaluate M_{cr}, such as for Channel sections, the program will resort to the method as per Cl.4.3.6 of BS 5950-1:2000 to calculate the lateral-torsional buckling resistance moment ($M_{b,Rd}$) for the member.

Tapered Members

EN 1993-1-1 provides multiple methods for checking against lateral-torsional buckling in members with tapered I-shaped sections. The method given in Annex BB 3.2 of EN 1993-1-1 is used by STAAD.Pro. This method checks the unbraced length between lateral and torsional restraints against a calculated maximum length to ensure lateral-torsional stability. The tapered member is sub-divided into thirteen (13) analytical sections and bending design checks, including these for lateral-torsional buckling, are performed at each sub-section. While this approach is conservative for elastic analysis, it is necessary for plastic analysis.

The stable length between lateral restraints, L_m, is calculated as follows. This value must be greater than or equal to the design parameter LY.

$$L_m = 0.85 \frac{38 r_{zz}}{\sqrt{\frac{1}{57.4}\left(\frac{N_{\text{Ed}}}{A}\right) + \frac{1}{756 C_1^2}\left(\frac{W_{\text{pl,y}}^2}{A I_T}\right)\left(\frac{f_y}{235}\right)^2}} \quad \text{(Eqn. BB.5)}$$

where

r_{zz}	=	the radius of gyration about the major axis (notation i_z in EN 1993-1-1)
N_{Ed}	=	design value of compression force in the member
A	=	cross-sectional area of the member
$W_{pl,y}$	=	plastic section modulus of the member
I_T	=	torsional constant
f_y	=	yield strength
C_1	=	a factor depending on loading and end conditions; taken $= 1/k_c^2$, where k_c is taken from the KC parameter.

The stable length between torsional restraints, L_s, is calculated as follows. This value must be greater than or equal to the design parameter EFT.

$$L_s = 0.85 \frac{\sqrt{C_n} L_k}{c} \quad \text{(Eqn. BB.12)}$$

where

C_n = modification factor for non-linear moment gradient

$$= \frac{12 \times R_{max}}{\left[R_1 + 3R_2 + 4R_3 + 3R_4 + R_5 + 2(R_S - R_E)\right]} \leq 1.0 \quad \text{(Eqn. BB.14)}$$

R = moment ratio calculated at ends, quarter points, and mid-point of member segment between torsional restraints, calculated as:

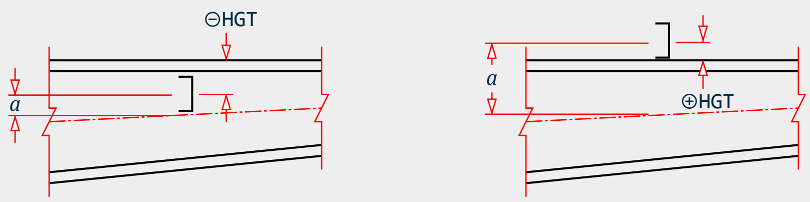
$$= \frac{M_{y,Ed} + aN_{Ed}}{f_y W_{pl,y}} \quad \text{(Eqn. BB.15)}$$

and R_1 is taken from the largest web depth.

$M_{y,Ed}$ = design bending moment about the Y axis

a = the distanced between the centroid of the member and the centroid of the restraining members (e.g., purlins).

> **Note:** This value is controlled in STAAD.Pro using the HGT parameter. To simplify the user input, the HGT parameter is specified in relation to the top of the member.



Purlin Below Top of Steel: HGT Parameter is Negative Value

Purlin Above Top of Steel: HGT Parameter is Positive Value

L_k = stable length between adjacent torsional restraints

$$= \frac{\left(5.4 + \frac{600 f_y}{E}\right)\left(\frac{h}{t_f}\right) r_{zz}}{\sqrt{5.4\left(\frac{f_y}{E}\right)\left(\frac{h}{t_f}\right)^2 - 1}} \quad \text{(Eqn. BB6)}$$

and $\frac{h}{t_f}$ is taken from the shallowest web depth.

E = modulus of elasticity

c = taper factor:

$$= 1 + \frac{3}{\left(h/t_f - 9\right)}\left(\frac{h_{max}}{h_{min}} - 1\right)^{2/3} \quad \text{(Eqn. BB.16)}$$

h = depth of segment

t_f = thickness of the flange

h_{max}, h_{min} = the maximum and minimum depth of the cross-section within the length, L_y (LY), respectively.

> **Note:** There are no provisions for lateral-torsional buckling in tapered hollow sections (i.e., tapered square or circular sections). As this is typically not a governing limit state, STAAD.Pro does not perform any such check.

D5.C.5.3 Members Subject to Shear

The cross section capacity of a member subject to shear is checked as per Cl. 6.2.6 of the code. The condition to be satisfied is:

$$\frac{V_{Ed}}{V_{c,Rd}} \leq 1.0$$

where

$V_{c,Rd}$	=	the is the shear design resistance given by: $V_{c,Rd} = V_{pl,Rd} = \frac{A_v(f_y/\sqrt{3})}{\gamma_{M0}}$
A_v	=	the shear area and is worked out for the various section types as given in Cl. 6.2.6(3) of the code

Shear Buckling

For sections that are susceptible to shear buckling, the program will perform the shear buckling checks as given in Section 5 of EN 1993-1-5. The shear buckling checks will be done *only* for I –Sections and Channel sections. Shear stresses induced from torsional loads are taken into account while performing torsion checks.

Note: Web shear buckling is checked in STAAD.Pro V8i (SELECTseries 3) (release 20.07.08) and later.

The susceptibility of a section to shear buckling will be based on the criteria given in Cl 5.1(2) of EN 1993-1-5 as is as given as follows:

a. For unstiffened webs, if $h_w / t > 72 \times \varepsilon / \eta$, the section must be checked for shear buckling.

The design resistance is calculated as:

$$V_{b,Rd} = V_{bw,Rd} \leq \frac{\eta f_{yw} h_w t}{\sqrt{3}\gamma_{M1}}$$

$$V_{bw,Rd} = \frac{\chi_w f_{yw} h_w t}{\sqrt{3}\gamma_{M1}}$$

where

h_w	=	distance between flanges of an I Section (i.e., depth - 2x flange thickness)
t	=	thickness of the web
ε	=	$\sqrt{(235/f_y)}$, where fy is the yield stress
η	=	1.2 for steel grades up to and including S 460 and = 1.0 for other steel grades
k_τ	=	as defined in sections below
χ_w	=	the web contribution factor obtained from Table 5.1 of the EC3 code and is evaluated per the following table:

Table 131: Evaluate of χ_w

Slenderness Parameter	Rigid End Post	Non-rigid End Post
$\bar{\lambda}_w < 0.83 / \eta$	η	η
$0.83 / \eta \leq \bar{\lambda}_w < 1.08$	$0.83 / \bar{\lambda}_w$	$0.83 / \bar{\lambda}_w$

Slenderness Parameter	Rigid End Post	Non-rigid End Post
$\bar{\lambda}_w \geq 1.08$	$\frac{1.37}{0.7 + \bar{\lambda}_w}$	$0.83 / \bar{\lambda}_w$

$\bar{\lambda}_w$ = $\frac{h_w}{86.4 \times t \times \varepsilon}$

b. For stiffened webs, if $h_w / t > 31 \times E\sqrt{k_\tau / \eta}$, the section must be checked for shear buckling.

The design resistances considers tension field action of the web and flanges acting as struts in a truss model. This is calculated as:

$$V_{b,Rd} = V_{bw,Rd} + V_{bf,Rd} \leq \frac{\eta f_{yw} h_w t}{\sqrt{3}\gamma_{M1}}$$

Where:

where

$V_{bf,Rd}$ = the flange resistance per Cl.5.4 for a flange not completely utilized by bending moment

$V_{bf,Rd}$ = $\frac{h_f t_f^2 f_{yf}}{c\gamma_{M1}}\left[1 - \left(\frac{M_{Ed}}{M_{f,Rd}}\right)^2\right]$

b_f = the width of the flange which provides the least axial resistance, not to be taken greater than $15\varepsilon t_f$ on each side of the web

t_f = the thickness of the flange which provides the least axial resistance

$M_{f,Rd}$ = $M_{f,k}/\gamma_{M0}$, the moment of resistance of the cross section consisting of the effective area of the flanges only. For a typical I Section or PFD, this is evaluated as $b \cdot t_f \cdot h_w$. When an axial load, N_{Ed}, is present, the value of $M_{f,Rd}$ is reduced by multiplying by the following factor:

$$1 - \frac{N_{Ed}}{\left[\frac{(A_{f1} + A_{f2}) f_{yf}}{\gamma_{M0}}\right]}$$

A_{f1} ,A_{f2} = the areas of the top and bottom flanges, respectively

c = $a\left(0.25 + \frac{1.6 b_f t_f^2 f_{yf}}{t h_w^2 f_{yw}}\right)$

a = transverse stiffener spacing. The equation of c is likewise used to solve for a sufficient stiffener spacing in the case of demand from loads exceeding the calculated capacity for a specified stiffener spacing

The following equation must be satisfied for the web shear buckling check to pass:

$$\eta_3 = \frac{V_{Ed}}{V_{b,Rd}} \leq 1.0$$

where

V_{Ed} = the design shear force

Note: The shear forces due to any applied torsion will *not* be accounted for if the TOR parameter has been specifically set to a value of 0 (i.e., ignore torsion option).

If the stiffener spacing has not been provided (using the `STIFF` parameter), then the program assumes that the member end forms a non-rigid post (case c) and proceeds to evaluate the minimum stiffener spacing required.

D5.C.5.4 Members Subject to Torsion

Note: This feature requires STAAD.Pro V8i (SELECTseries 2) build 2007.07 or later.

General

Eurocode 3 (EN 1993-1-1:2005) gives very limited guidance for the analysis and design of torsion members. While both elastic and plastic analyses are permitted generally, the design analysis methods for torsion discussed within EC3 are primarily based on elastic methods. Also, only the first yield design resistance is specifically discussed for torsion members. Furthermore, there is no guidance on section classification nor on how to allow for the effects of local buckling on the design resistance for combined torsional effects. EC3 also does not specifically deal with members subject to combined bending and torsion and loosely states that the yield criteria (Eqn 6.1 in the code) can be used for elastic verification.

The method used by STAAD.Pro is therefore based on the SCI publication “P057: Design of members subject to combined bending and torsion”. Though this publication is based on the British standard BS 5950-1, the principles from this document are applied in the context of Eurocode 3.

Note: At the time this feature has been implemented in STAAD.Pro, SCI are in the process of updating document P057 to be in accordance with Eurocode 3. Hence this method might be subject to modifications subject to the publication of a newer version of P057. The NCCI document “SN007b-EN-EU: Torsion” will also be referenced where appropriate.

Code Basis

Torsion design in EC3 is given in Cl. 6.2.7 of EN 1993-1-1:2005. Therefore, this clause is used primarily for this implementation.

EN 1993-1-1:2005 does not deal with members subject to the combined effects of torsion and lateral torsional buckling. However, EN 1993-1-6 considers such a condition in Appendix A. Therefore, STAAD.pro uses Appendix A of EN 1993-1-6 to check for members subject to combined torsion and LTB.

The following clauses from EC3 are then considered:

- Cl. 6.2.7(1)
- Cl. 6.2.7(9)
- Cl. 6.2.7(5)
- EC-3 -6 App A

Note: STAAD.Pro does, however, use this clause (6.2.7) to report the output for all torsion checks. Also any distortional deformations and any amplification in the torsional or shear stresses due to distortions will be neglected by the program.

- Clause 6.2.7(1)

  States that for members subject to torsion, the design torsional moment T_{Ed} at each cross section should satisfy:

  $$T_{Ed} / R_{Rd} \le 1.0$$

  Where:

  T_{Rd} is the design torsional resistance of the cross section.

This is the primary condition that will need to be satisfied for members subject to torsion. The method for working out the torsional resistance T_{Rd}, for the various cases is dealt in the following sections.

- Cl. 6.2.7(9)

  States that:

  > For combined shear force and torsional moment, the plastic shear resistance accounting for torsional effects should be reduced from $V_{pl,Rd}$ to $V_{pl,T,Rd}$ and the design shear force should satisfy:
  >
  > $V_{Ed} / V_{pl,T,Rd} \leq 1.0$

  The code also gives means to evaluate $V_{pl,T,Rd}$ in equations 6.26 to 6.28. These equations, however, only deal with I/H sections, Channel sections, and structural hollow sections (RHS, SHS, CHS). Therefore, the application of Cl. 6.2.7(9) is only performed for these section profiles.

- Cl 6.2.7(5)

  States that the yield criteria given in Cl. 6.2.1(5) of EN 1993-1-1:2005 may be used for elastic verification. STAAD.Pro evaluates the stresses due to the various actions on the cross section and applies this yield criterion.

The program allows for two types of checks for members subject to torsion for EC3 design:

I. Basic Stress Check: This method is intended to be a simplified stress check for torsional effects. This method will produce the output corresponding to Cl. 6.2.7(5) of EN 1993-1-1.
II. Detailed Checks: This method will perform a full torsional analysis of the member. All four of the clause checks mentioned earlier will be performed.

The details of these checks are as described below.

You have the option to choose the method to be used for a specific member or group of members. This will be facilitated by setting the value of the `TORSION`. The `TORSION` parameter set to zero by default, which results in torsion checks only being performed if the member is subject to torsional moments (i.e., for this default setting, the program will ignore torsion checks if there is no torsional moment in the member). Setting the value of the `TORSION` parameter to three (3) will cause the program to ignore all torsional moments. The detailed output (i.e., `TRACK 2`) will indicate that torsion has been ignored for that particular member. The details of setting the values to one (1) or two (2) and the corresponding checks performed are as described below. Refer to D5.C.6 Design Parameters (on page 1502) for additional details.

Note: If the `TORSION` parameter is set to 1 or 2, the program will perform the appropriate checks even if the member is not subject to torsional moments. In such cases, the program will perform the checks with a value of zero for the torsional moment.

D5.C.5.4.1 Basic stress check
This method is used when the `TORSION` parameter is specified as one (1).

This method is intended to be a simplified stress check for torsional effects per Cl. 6.2.7(5). Any warping stresses that may develop due to the end conditions will be ignored for this option. The program will consider the forces (including torsion) at various sections along the length of the member and for each section, will calculate the resultant stress (Von Mieses) at various points on the cross section. The location and number of points checked for a cross section will depend on the cross section type and will be as described below.

The stress check will be performed using equation 6.1 of EN 1993-1-1:2005 as given below:

$$\left(\frac{\sigma_{x,Ed}}{f_y/\gamma_{M0}}\right)^2 + \left(\frac{\sigma_{z,Ed}}{f_y/\gamma_{M0}}\right)^2 - \left(\frac{\sigma_{x,Ed}}{f_y/\gamma_{M0}}\right)\left(\frac{\sigma_{z,Ed}}{f_y/\gamma_{M0}}\right) + 3\left(\frac{\tau_{Ed}}{f_y/\gamma_{M0}}\right)^2 \leq 1$$

where

$\sigma_{x,Ed}$	=	the longitudinal stress
$\sigma_{z,Ed}$	=	the transverse stress and
τ_{Ed}	=	the resultant shear stress.

Note: Since transverse stresses are very small under normal loading conditions (excluding hydrostatic forces), the term will be negligible and hence is taken as zero.

$$\sigma_{x,Ed} = \sigma_x + \sigma_{bz} + \sigma_{by} = F_x/A_x + M_z/Z_z + M_y/Z_y$$

$$\tau_{Ed} = T/J \cdot t + V_y \cdot Q/(I_z \cdot t) + V_z \cdot Q/(I_y * t)$$

where

T	=	the torsion at the particular section along the length of the member
J	=	the torsion constant
t	=	the thickness of the web/flange
V	=	the shear force
Q	=	the statical moment about the relevant axis
I	=	the second moment of area about the relevant axis

The stress check as per equation 6.1 is performed at various stress points of a cross section as shown in figures below:

Shape	Section Sketch
Doubly symmetric wide flange profile	
Shape	Section Sketch
Pipe profiles $\alpha = \tan^{-1}(M^z/M_y)$	Tube profiles	
Shape	Section Sketch
Channel profiles	
The resultant ratio will be reported under Cl. 6.2.7(5) in the detailed design output.

D5.C.5.4.2 Detailed stress check

This method is used when the `TORSION` parameter is specified as two (2).

This method performs a detailed torsional analysis of a member depending on the torsion loading conditions and the support conditions at the member ends. This method is based on the SCI publication P057 and includes any warping stresses (direct warping stresses and warping shear stresses) depending on the end conditions of the member. This implementation considers seven different cases of loading and end conditions as given in publication P057 – Section 6. The loading/end conditions for a member are specified by the use of the `CMT` design parameter (Refer to D5.C.6 Design Parameters (on page 1502) for parameter values and descriptions).

All the equations used to evaluate the torsional moments and associated stresses are as given in Appendix B of P057. The resultant stresses are evaluated at various sections along the length of the member and the following checks will be performed:

Clause 6.2.7(1) – Torsional resistance of the section.

In general, the torsion at any section T_{Ed} is resolved into two components, viz.

The pure torsional (St. Venant's) moment ($T_{t,Ed}$) and

The warping torsional moment($T_{w,Ed}$)

Therefore,

$$T_{Ed} = T_{t,Ed} + T_{w,Ed} = GJ\varphi' = EH\varphi''' \qquad \text{[Ref SCI pub. P057]}$$

where

φ' and φ'''	=	the first and third derivatives of twist (φ), respectively, and depend on the end conditions and loading. These are evaluated from the equations in Annex B of P057 and are based the specified `CMT` parameter.

Note: Although the equation given the NCCI document SN007b-EN-EU can be used to evaluate T_{wrd}, the NCCI does not give the eqn. to evaluate φ’’’. Therefore, Annex B of P057 is used.

The torsional resistance of the section is also considered as the sum of the pure torsion resistance and the warping torsion resistance. The pure torsion resistance ($T_{t,Rd}$) and the warping torsional resistance ($T_{w,Rd}$) are evaluated as:

For closed sections:

$$T_{t,Rd} = 2 \cdot A_c \cdot t \cdot \tau_{max}$$

where

A_c	=	the area enclosed by the mean perimeter
t	=	the max thickness
τ_{max}	=	the max. allowable shear stress = $(fy/\sqrt{3})/\Gamma m0$

For open sections (I & channel):

$$T_{t,Rd} = \tau_{max} \cdot J / t$$

where

J	=	the torsion const
t	=	the max thickness

$$T_{w,Rd} = (f_y / \Gamma_{m0}) \cdot t \cdot b^2 / 6$$

where

b	=	the width of the section
t	=	the thickness of the flange for I- sections; minimum of flange or web thickness channel sections

The check according to Cl 6.2.7(1) will then be performed to ensure that the following conditions are satisfied:

$$T_{t,Ed} / T_{t,Rd} \leq 1$$

$$T_{w,Ed} / T_{w,Rd} \leq 1$$

$$T_{Ed} / T_{Rd} \leq 1$$

Clause 6.2.7(9) – Plastic shear resistance due to torsion

STAAD.Pro checks for shear resistance of a section based on Cl. 6.2.6 for EC3 and the plastic shear resistance (in the absence of torsion) is evaluated as:

$$V_{pl,Rd} = \frac{A_v\left(f_y/\sqrt{3}\right)}{\gamma_{M0}}$$

where

A_v	=	as pre Cl.6.2.6 (3) for the various sections

When torsion is present, along with the shear force, the design shear resistance will be reduced to $V_{pl,T,Rd}$, where $V_{pl,T,Rd}$ is evaluated as follows:

i. For I or H Sections:

$$V_{pl,T,Rd} = \sqrt{1 - \frac{\tau_{t,Ed}}{1.25\left(f_y/\sqrt{3}\right)/\gamma_{M0}}}V_{pl,Rd}$$

ii. For Channel Sections:

$$V_{pl,T,Rd} = \left[\sqrt{1 - \frac{\tau_{t,Ed}}{1.25(f_y/\sqrt{3})/\gamma_{M0}}} - \frac{\tau_{w,Ed}}{(f_y/\sqrt{3})/\gamma_{M0}}\right] V_{pl,Rd}$$

iii. For Structural Hollow Sections:

$$V_{pl,T,Rd} = \left[1 - \frac{\tau_{t,Ed}}{(f_y/\sqrt{3})/\gamma_{M0}}\right] V_{pl,Rd}$$

where

$\tau_{t,Ed}$	=	the shear stress due to direct (St. Venant's) torsion
$\tau_{w,Ed}$	=	the shear stress due to warping torsion

The various shear stresses due to torsion $\tau_{t,Ed}$ and $\tau_{w,Ed}$ are evaluated as follows:

i. For Closed sections:

The shear stresses due to warping can be ignored as they will be insignificant and hence:

$\tau_{t,Ed} = T_{Ed}/(2 \cdot A_c \cdot t)$ [Ref NCCI Sn007b-EN-EU]

where

T_{Ed}	=	the applied torsion
A_c	=	the area delimited by the mean perimeter
t	=	the thickness of the cross section
$\tau_{w,Ed}$	=	0, since warping is ignored

ii. For Open sections [I, H, Channel] sections:

For I and H sections, the web will not be subject to warping stresses and therefore warping shear can be ignored ($\tau_{w,Ed}$=0).

The stress due to pure torsion is evaluated as:

$\tau_{t,Ed} = G \cdot t \cdot \varphi'$ [Ref SCI pub. P057]

where

G	=	the shear modulus
φ'	=	a function depending on the end condition and loading(T). This will be taken from section 6 and Annex B of P057.

Note: Although the maximum stress is at the thickest section of the profile, the program uses the web thickness for this clause (since the shear capacity is based on the web area) unless the load is parallel to the flanges, in which case the flange thickness is used.

For channel sections that are free to warp at the supports and, thus, are not subject to warping stresses:

The warping shear stress is evaluated as:

$\tau_{w,Ed} = E \cdot S_w \cdot \varphi''' / t$ [Ref SCI pub. P057]

where

E	=	the elastic modulus
S_w	=	the warping statistical moment
φ'	=	a function depending on the end condition and loading(T). This will be taken from section 6 and Annex B of P057.

Clause 6.2.7(5) – Check for elastic verification of yield

Eurocode 3 gives yield criterion as per eqn. 6.1 and STAAD.Pro uses the yield criterion given in EC-3. When a member is subject to combined bending and torsion, some degree of interaction occurs between the two effects. The angle of twist caused by torsion is amplified by the bending moments and will induce additional warping moments and torsional shears. Account must also be taken of the additional minor axis moments produced by the major axis moments acting through the torsional deformations, including the amplifications mentioned earlier.

For members subject to bending and torsion, the stresses are evaluated as follows:

Direct bending stress (major axis): $\sigma_{bz} = M_z \ / \ Z_z$
Direct bending stress (minor axis): $\sigma_{by} = M_y \ / \ Z_y$
Direct stress due to warping: $\sigma w = E \cdot W_{ns} \cdot \varphi''$
Direct stress due to twist (min. axis): $\sigma_{byt} = M_{yt} \ / \ Z_y$
Direct stress due to axial load (if any): $\sigma_c = P / \ A$

where

M_z	=	the major axis moment & My is the minor axis moment
φ''	=	the differential function based on twist (ref P057 Annex B. & Table 6)
W_{ns}	=	the normalized warping function
M_{yt}	=	$\varphi \cdot M_z$ (see Appendix B of P057 to evaluate φ)

Shear stresses due to torsion and/or warping is evaluated as described above for Clause 6.2.7(9).

Check for yield (capacity checks) is then done according to Eqn 6.1 of EN 1993-1-1:2005, as described for the Basic Stress Check (`TORSION` = 1):

$$\left(\frac{\sigma_{x,Ed}}{f_y / \gamma_{M0}}\right)^2 + \left(\frac{\sigma_{z,Ed}}{f_y / \gamma_{M0}}\right)^2 - \left(\frac{\sigma_{x,Ed}}{f_y / \gamma_{M0}}\right)\left(\frac{\sigma_{z,Ed}}{f_y / \gamma_{M0}}\right) + 3\left(\frac{\tau_{Ed}}{f_y / \gamma_{M0}}\right)^2 \le 1$$

Clause EC-3:6 App A – Check for combined Torsion and Lateral Torsional buckling

The interaction check due to the combined effects of bending (including lateral torsional buckling) and torsion will be checked using Annex A of EN 1993-6: 2007. Note that this interaction equation does *not* include the effects of any axial load.

Caution: At present, SCI advises that no significant work has been published for this case and work is still ongoing. So at present is advisable not to allow for torsion in a member with large axial load.

Members subject to combined bending and torsion will be checked to satisfy:

$$\frac{M_{y,ED}}{x_{LT} M_{y,RK} / \gamma_{M1}} + \frac{C_{MZ} M_{z,Ed}}{M_{z,RK} / \gamma_{M1}} + \frac{k_w k_{zw} k_a T_{w,Ed}}{T_{w,Rk} / \gamma_{M1}} \le 1$$

where

C_{mz}	=	the equivalent uniform moment factor for bending about the z-z axis, according to EN 1993-1-1 Table B.3.
k_w	=	$0.7 - \frac{0.2 T_{w,Ed}}{T_{w,Rk} / \gamma_{M1}}$
k_{zw}	=	$1 - \frac{M_{z,Ed}}{M_{z,Rk} / \gamma_{M1}}$
k_a	=	$\frac{1}{1 - M_{y,Ed} / M_{y,cr}}$
$M_{y,Ed}$ and $M_{z,Ed}$	=	the design values of the maximum moment about the y-y and z-z axis, respectively
$M_{y,Rk}$ and $M_{z,Rk}$	=	are the characteristic values of the resistance moment of the cross-section about it y-y and z-z axis, respectively, from EN 1993-1-1, Table 6.7

$M_{y,cr}$	=	the elastic critical lateral-torsional buckling moment about the y-y axis
$T_{w,Ed}$	=	the design value of the warping torsional moment
$T_{w,Rk}$	=	the characteristic value of the warping torsional resistance moment
χ_{LT}	=	the reduction factor for lateral torsional buckling according to 6.3.2 of EN 1993-1-1

Note: For all of the above checks the effective length of the member to be used for torsion can be set by using the `EFT` design parameter.

D5.C.5.5 Members Subject to Combined Forces

Members subject to Bending and Axial Force

When a member is subject to a combined axial load and a bending moment, the program evaluates a reduced moment capacity based on Cl. 6.2.9 of the code. For Class 1, 2, and 3 sections, the program evaluates the reduced moment from the equations given in Cl. 6.2.9.1 of the code. For class 4 sections, the interaction equation given by equation 6.44 are checked.

In the case of members subject to axial load and biaxial bending, the program will consider the interaction equation 6.41 of the code.

Note: By default, the program will use the values of the constants "α" and 'β' as given in the code for the different sections types. However, you can override these values using the `ALPHA` and `BETA` design parameters (Refer to D5.C.6 Design Parameters (on page 1502)).

Note: The program uses the parameter `ELB` (Refer to D5.C.6 Design Parameters (on page 1502)) to override the Cl.6.2.9 checks for combined axial load and bending case. When specfied as `1`, the program uses the more general equation 6.2 of EN 1993-1-1, instead.

Members subject to Bending, Shear, and Axial Force

When a member is subject to a combined axial load, shear force, and a bending moment, the program evaluates the reduced yield strength as given in Cl 6.2.10 (3) of the code. The reduction in the yield strength is done only when the applied shear force exceeds 50% of the design shear resistance $V_{pl,Rd}$. This reduced yield strength is then used to evaluate the reduced moment capacity of the section.

Members subject to Bending and Axial Compression

The bending resistance of members could be reduced by the presence of a co-existent axial load. This is then checked against the lateral-torsional buckling resistance of the section. The EN 1993 design module in STAAD takes such a scenario into account and performs the necessary checks as per Cl. 6.3.3 of the code.

Generally, EC3 requires checking cross-section resistance for local capacity and also checking the overall buckling capacity of the member. In the case of members subject to axial tension and bending, there is provision to take the stabilizing effect of the tension load into consideration. This is achieved by modifying the extreme compression fibre stress and calculating an effective applied moment for the section. The checks are done as per Cl. 6.2.9 of the code. In case of a combined axial compressive load and bending moment, the member is checked per the rules in section 6.3.3 of the code. The program checks to ensure that both the interaction equations 6.61 and 6.62 of the code are satisfied. The interaction factors kzz, kyy, kzy & kyz will be evaluated using Annex B of EN 1993-1-1 by default. Hence for the EN 1993-1-1 code in STAAD.Pro (without National Annexes), uses Annex B. The choice between using Annex A and Annex B will be based on the choice specified by a particular National

Annex, if used. If the National Annex itself gives a choice between Annex A and Annex B, the program uses Annex B to evaluate the interaction factors.

Note: EN 1993-1-1:2005 does not specifically deal with single angle, double angles, double channels or Tee sections and does give a method to evaluate the slenderness of such members. In these cases, the Eurocode 3 (EN 1993-1-1) design module of STAAD.Pro uses the methods specified in BS 5950-1:2000 to calculate the slenderness of these members. Cl. 4.7.10 of BS 5950-1:2000 is used in the current version of the EC3 design module. See D5.C.5.1 Members Subject to Axial Loads (on page 1481) for ST and RA angle specifications.

Note: Laced or battened compression members are *not* dealt within the current version of EC3 (EN 1993) design module in STAAD.Pro.

D5.C.5.6 Design of Slender pipe sections to EN 1993-1-6

The design of Slender CHS sections is performed per EN 1993-1-6:2007 (hereafter, EC3-6). EC3-6 does not specify additional or modified safety factors. Therefore, the program uses the default safety factors from EN 1993-1-1.

Note: You can change these values through the `GM0`, `GM1`, & `GM2` design parameters.

EC3-6 deals with four types of ultimate limits states: plastic limit state, cyclic capacity limit state, buckling limit state, and fatigue. The following are considered by STAAD.Pro:

- LS1 – Plastic limit state: Deals with the condition when the capacity of the structure is exhausted by yielding of the material.
- LS3 – Buckling Limit state: Deals with the condition in which the structure (or shell) develops large displacements normal to the shell surface, caused by loss of stability under compressive and/or shear membrane stresses.

The limit state verification is made based on the “Stress design” method described in EC3-6. The stress design approach takes into account three categories of stresses:

- Primary stresses: Stresses that are generated for the member to be in equilibrium with the direct imposed loads.
- Secondary stresses: Those that are generated for internal compatibility or for compatibility at supports due to imposed loads or displacements (e.g., temperature, settlement etc.)
- Local stresses: Local stresses generated due to cyclic loading (or fatigue).

Only the primary stresses are considered the program. The primary stresses considered are those generated due to axial loads, bending, shear and /or a combination of these conditions.

Note: In the context of slender pipe section design for the Eurocode 3 module, the secondary and local stresses can be neglected since the loads and corresponding stresses dealt with in the design engine are largely direct and shear stresses.

The local axis coordinate system for a CHS is defined as:

	**circumferential**	around the circumference of the circular cross section (θ)
	meridional	along the length of the member (x)
	normal	perpendicular to the tangential plane formed by the circumferential and meridional directions (n)

and the corresponding membrane stresses will follow the convention given below:

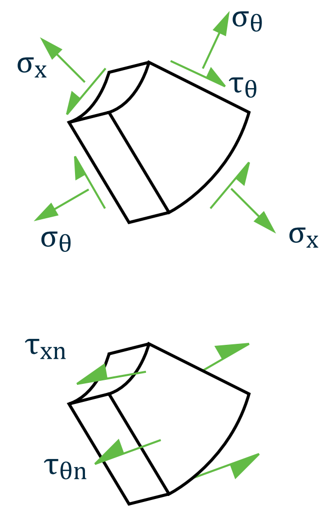

Figure 165: Nomenclature for membrane and transverse stresses in Slender CHS sections

Stress Design

Stress checks are made based on the "Stress design" method as per Section 8.5 of the code. This section deals with the buckling strength of the member (LS3). The principle is to evaluate the membrane stresses due to the applied loads and then compare that to the buckling strength, which is evaluated giving due consideration for local buckling effects.

The membrane stresses are evaluated as given in Annex A of the code. The pipe section is considered as an unstiffened cylindrical shell.

i. Meridional Stresses:

a. Axial load

$$F_x = 2 \cdot \pi \cdot r \cdot P_x$$

$$\sigma_x = -F_x/(2 \cdot \pi \cdot r \cdot t)$$

b. Axial stress from bending

$$M = \pi \cdot r^2 \cdot P_{x,max}$$

$$\sigma_x = \pm M/(\pi^2 \cdot r \cdot t)$$

ii. Shear Stress:

a. Transverse force, V

$$V = \pi \cdot r \cdot P_{\theta,max}$$

$$\tau_{max} = \pm V/(\pi \cdot r \cdot t)$$

b. Shear from torsional moment, M

$$M_t = 2\pi \cdot r^2 \cdot P_\theta$$

$$\tau = M_t/(2\pi^2 \cdot r^2 \cdot t)$$

Where:

r is the radius of the middle surface of the shell wall.
t is the wall thickness of the cylinder

Calculation of Axial Buckling Stress

The buckling strength of A slender pipe section is evaluated using the method given in section 8.5.2 ofEC3-6. The design buckling stresses (buckling resistance) are calculated separately for axial, circumferential, and shear. The circumferential stresses are ignored in STAAD.Pro.

The naming convention and the coordinate axis used will be as given in the following diagram:

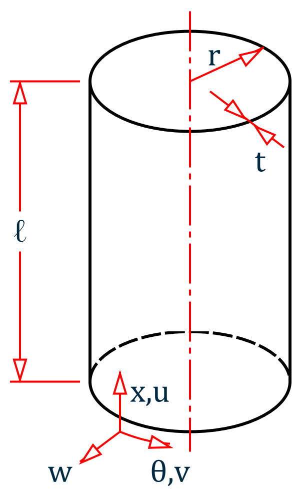

Figure 166: Naming convention and coordinate system used for the buckling stress of a slender CSH section

The axial buckling resistance is given by:

$$\sigma_{x,Rd} = \sigma_{x,Rk}/\gamma_{M1}$$

Note: Γ_{M1} will have the same default value of 1.0 as in EN 1993-1-1.

$\sigma_{x,Rk}$ is the characteristic buckling strength given by:

$$\sigma_{x,Rk} = X_x \cdot f_{yk}$$

Where:

χ_x is the meridional buckling reduction factor. χ_x is evaluated per Section 8.5.2(4) of EC3-6 and is determined as a function of the relative shell slenderness given by:

$$\lambda_x = \sqrt{\frac{f_{yk}}{\sigma_{x,cr}}}$$

Where:

$\sigma_{x,cr}$ is the elastic buckling critical stress.

Once the relative slenderness is evaluated, the reduction factor is calculated as follows:

$\chi = 1$ when $\bar{\lambda} \le \bar{\lambda}_0$

$\chi = 1 - \beta\left(\frac{\bar{\lambda} - \bar{\lambda}_0}{\bar{\lambda}_P - \bar{\lambda}_0}\right)^{\eta}$ when $\bar{\lambda}_0 < \bar{\lambda} < \bar{\lambda}_P$

$\chi = \alpha / \bar{\lambda}^2$ when $\bar{\lambda}_P \le \bar{\lambda}$

where

$\bar{\lambda}_P$ = the plastic limit for slenderness given by:

$$\sqrt{\frac{\alpha}{1 - \beta}}$$

The meridional buckling parameters the factors α and β are evaluated per section D.1.2.2 of EC3-6.

Note: A "Normal" fabrication quality will be assumed when evaluating the fabrication quality parameter as given in table D.2 of the code, unless the fabrication quality is set using the FAB design parameter. Refer to D5.C.6 Design Parameters (on page 1502)

The elastic critical buckling stress, $\sigma_{x,cr}$ and the factors α and β are evaluated per Annex D of EC3-6. The details are as given below:

The CHS section is classified based on the following criteria:

CHS Length Classification	Criteria
Short	$\omega \le 1.7$
Medium	$1.7 < \omega \le 0.5 \cdot r/t$
Long	$\omega > 0.5 \cdot r/t$

Where:

$$\omega = \frac{l}{\sqrt{rt}}$$

The elastic critical buckling critical stress is evaluated as:

$$\sigma_{x,Rcr} = 0.605 \cdot E \cdot C_x \cdot (t/r)$$

Where:

C_x is a factor dependent upon the CHS length classification as described in section D.1.2.1 of EC-3-6.
For a long cylinder, there are two separate methods that can be used to evaluate the C_x factor: Eqns D.9/10 and Eqn D.12. Initially the program evaluates C_x based on the maximum from equations D.9 and D.10. However, for long cylinders that satisfy the conditions in equation D.11, the program will also work out Cx based on equation D.12 and then choose the minimum obtained from D.12 and D.9/10.

Calculation of Shear Buckling Stress

The shear buckling resistance is given by:

$$\tau_{x\theta,Rd} = \tau_{x\theta,Rk}/\gamma_{M1}$$

Note: γ_{M1} will have the same default value of 1.0 as in EN 1993-1-1.

$\tau_{x\theta,Rk}$ is the characteristic buckling shear strength given by:

$$\tau_{x\theta,Rk} = X_\theta \cdot f_{yk}$$

Where:

χ_θ is the shear buckling reduction factor. χ_θ will be worked out as given in section 8.5.2(4) of En 1993-1-6 and is determined as a function of the relative shell slenderness given by:

$$\lambda_\theta = \sqrt{\frac{f_{yk}}{\tau_{x\theta,cr}}}$$

Where:

$\tau_{x\theta,Rk}$ is the elastic buckling critical stress.

The reduction factor, χ_θ, is then evaluated as described for the axial buckling stress, based on the same $\bar{\lambda}_p$, α, and β parameters given in Annex D of EC3-6.

The CHS section is classified based on the following criteria:

CHS Length Classification	**Criteria**
Short	$\omega \le 10$
Medium	$10 < \omega \le 8.7 \cdot r/t$
Long	$\omega > 8.7 \cdot r/t$

Where:

$$\omega = \frac{l}{\sqrt{rt}}$$

The elastic critical buckling critical stress is evaluated as:

$$\tau_{x\theta,Rcr} = 0.75 E C_\tau \sqrt{\frac{1}{\omega}} \left(\frac{t}{r}\right)$$

Where:

C_τ is a factor dependent upon whether the CHS length classification as described in section D.1.4.1 of EC-3-6. A “Normal” fabrication quality will be assumed when working out the fabrication quality parameter as given in table D.6 of the code, unless the fabrication quality is set using the FAB design parameter.

Buckling Strength Verification

The buckling strength verification will be performed so as to satisfy the following conditions:

For axial stresses:

$$\sigma_{x,Ed} \le \sigma_{x,Rd}$$

For shear stresses:

$$\tau_{x\theta,Ed} \leq \tau_{x\theta,Rd}$$

For a combined case of axial and shear stresses acting together, an interaction check will be done according to equation 8.19 of the code as below:

$$\left(\frac{\sigma_{x,Ed}}{\sigma_{x,Rd}}\right)^{k_x} + \left(\frac{\tau_{x\theta,Ed}}{\tau_{x\theta,Rd}}\right)^{k_\tau} \leq 1$$

Where:

k_x and k_τ are the interaction factors as given in section D.1.6 of EN 1993-1-6:

$$k_x = 1.25 + 0.75 \cdot \chi_x$$

$$k_\tau = 1.75 + 0.25 \cdot \chi_\tau$$

D5.C.6 Design Parameters

Design parameters communicate specific design decisions to the program. They are set to default values to begin with and may be altered to suite the particular structure.

Depending on the model being designed, you may have to change some or all of the parameter default values. Some parameters are unit dependent and when altered, the n setting must be compatible with the active “unit” specification.

The follow table lists all the relevant EC3 parameters together with description and default values.

Table 132: Steel Design Parameters EC3 EN

Parameter Name	Default Value	Description
CODE	-	Must be specified as `EN 1993-1-1:2005` to invoke design per Eurocode 3:2005 (EN 1993). Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
ALH	0.5	The ratio of the distance of the point torque (from the start of the member) to the length of the member. The default value of 0.5 represents torque acting at the mid-span of a symmetrically loaded member. Values can range from 0 to 1.
ALPHA	1.0	Used to input a user defined value for the α factor in equation 6.41 for combined bending and axial force checks.

Parameter Name	Default Value	Description
BEAM	3	Parameter to control the number of sections to checked along the length of a beam: 1. Check at location of maximum Mz along beam 2. Check sections with end forces and forces at location of `BEAM 1.0` check. 3. Check at every 1/13th point along the beam and report the maximum
BETA	1.0	Used to input a user defined value for the β factor in equation 6.41 for combined bending and axial force checks.
C1	1.132	Corresponds to the C1 factor to be used to calculate Elastic critical moment M_{cr} as per Clause 6.3.2.2
C2	0.459	Corresponds to the C2 factor to be used to calculate Elastic critical moment M_{cr} as per Clause 6.3.2.2
C3	0	Corresponds to the C3 factor to be used to calculate Elastic critical moment M_{cr} as per Clause 6.3.2.2
CAN	0	Member will be considered as a cantilever type member for deflection checks. 0. indicates that member will not be treated as a cantilever member 1. indicates that the member will be treated as a cantilever member
CMM	1.0	Indicates type of loading and support conditions on member. Used to calculate the C1, C2, and C3 factors to be used in the M_{cr} calculations. Can take a value from 1 to 8. Refer to Note 2 (below) for more information on its use.
CMN	1.0	Indicates the level of End-Restraint. 1.0 = No fixity 0.5 = Full fixity 0.7 = One end free and other end fixed
CMT	1	Used to indicate the loading and support condition for torsion (ref. SCI publication P-057). Can take a value of 1-7. The values correspond to the various cases defined in section 6 and App. B of SCI-P-057. Refer to Note 4 (below) for more information

Parameter Name	Default Value	Description
DFF	360	"Deflection Length" / Max.. allowable local deflection See Note 1d below. See TR.40 Load Envelope (on page 2663) for deflection checks using serviceability load envelopes.
DJ1	Start Jointof member	Joint No. denoting starting point for calculation of "Deflection Length". See Note 1 below.
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length". See Note 1 below.
DMAX	100.0 cm	Maximum allowable depth for the member.
DMIN	0	Minimum required depth for the member.
EFT	Member Length	The distance between the adjacent torsional restraints. Effective length for torsion, lateral-torsional buckling check of tapered members per Annex BB 3.2.2. A value of 0 defaults to the member length.
ELB	0	Used to specify the method for combined axial load + bending checks 0. Uses Cl. 6.2.9 of EN 1993-1-1:2005 1. Uses Cl. 6.2.1(7) - Eqn. 6.2 of EN 1993-1-1:2005
ESTIFF	0	(For use with the Dutch NA only) Method for checking columns forming part of (non)/buttressed framework: 0. Checks per Cl 12.3.1.2.3 of NEN 6770: Section 1 1. Checks per Cl 12.3.1.2.3 of NEN 6770: Section 2 Refer to D5.D.3.8 Clause 6.33 – Uniform members in bending and axial compression (on page 1526) for additional description on this parameter.
FAB	3	Used to specify the fabrication class to be used to check for slender (Class 4) CHS/pipe sections (EN 1993-1-6:2007) 1. Class A – Excellent 2. Class B – High 3. Class C – Normal
FU	0	Ultimate tensile strength of steel.
GM0	1.0	Corresponds to the γ_{m0} factor in EN 1993-1-1:2005
GM1	1.0	Corresponds to the γ_{m1} factor in EN 1993-1-1:2005

Parameter Name	Default Value	Description
GM2	1.25	Corresponds to the γ_{m2} factor in EN 1993-1-1:2005
GST	0	Used to specify the section type to be used for designing a "General Section" from the user table. The member will be considered as the specified type with the user defined properties. The available options and corresponding values are as below: 0. I-Section 1. Single Channel 2. Rectangular Hollow Section 3. Circular Hollow Section 4. Angle Section 5. Tee Section **Note:** This parameter will be ignored if it has been assigned to any section other than a General Section.
HGT	0.0	Distance from the top of the tapered web section to the center of gravity of purlin. • positive values when purlin is above the top flange • negative values when purlin is below the top flange  Purlin Below Top of Steel: HGT Parameter is Negative Value  Purlin Above Top of Steel: HGT Parameter is Positive Value Used for the lateral-torsional buckling calculations for web-tapered members.
KC	1.0	Corresponds to the correction factor as per Table 6.6 of EN 1993-1-1:2005. Program will calculate kc automatically if this parameter is set to `0`. **Note:** For the British, Singapore, & Polish NAs, kc will be calculated as given in the NA by default.
KY	1.0	K factor in local y axis. Used to calculate the effective length for slenderness and buckling calculations.
KZ	1.0	K factor in local z axis. Used to calculate the effective length for slenderness and buckling calculations.

Parameter Name	Default Value	Description
LEG	0	Slenderness values for angles as determined from BS 5950-2000 Table 25. Refer to D3.B.6 Design Parameters (on page 1384)
LVV	Max. value of Lyy	Leg length for Lvv (length about v-v- axis of single angle section), as per Lyy. Used for slenderness calculations.
LY	Member Length	Compression length in local y axis between lateral restraints $$\text{Slenderness ratio} = \texttt{KY}\times\texttt{LY} / \text{Ryy}$$ Distance between lateral restraints used for tapered I sections. Used for the lateral-torsional buckling calculations for web-tapered members. The default is the member's length.
LZ	Member Length	Compression length in local z axis between lateral restraints $$\text{Slenderness ratio} = \texttt{KZ}\times\texttt{LZ} / \text{Rzz}$$
MTH	0	Used to select the clause to be used to calculate the LTB reduction factor, χ_{LT}. The available options and corresponding values are as below: 0. Use default method based on section type (default) 1. Use Cl.6.3.2.2 2. Use Cl.6.3.2.3 By default, the program will use Cl 6.3.2.3 for rolled & built-up I-sections and Cl. 6.3.2.2 for all other sections. If, however, the specified National Annex expands on Cl. 6.3.2.3 to include other section types (e.g., the UK NA), the program will use Cl. 6.3.2.3 by default for that particular section type. Refer to D5.D. European Codes - National Annexes to Eurocode 3 [EN 1993-1-1:2005] (on page 1516) for additional details on NA documents.
MU	0	The ratio of the moment due to the transverse force to the maximum moment M. To be used with `CMM` values of 7 and 8. See Note 2 (below). **Note:** This parameter is only applicable to the French NA & Belgian NA.
NA	0	Choice of National Annex to be used for EC3 design. Refer to D5.D. European Codes - National Annexes to Eurocode 3 [EN 1993-1-1:2005] (on page 1516) for values allowed for this parameter. (Refer to D5.C.1 General Description (on page 1478) for more information)
NSF	1.0	Net tension factor for tension capacity calculation.

Parameter Name	Default Value	Description
PLG	0	To be used to determine whether to include the additional interaction checks as per CL. NA.20(2) and NA.20(3) of the D5.D.8 Polish National Annex to EC3 (on page 1550). **Note:** This parameter is only applicable to the Polish NA.
PY	Yield Strength	The yield strength default value is set based on the default value of the SGR parameter.
RATIO	1	Permissible ratio of loading to capacity.
SBLT	0.0	Indicates if the section is rolled or built-up. 0.0 = Rolled 1.0 = Built-up 2.0 = Cold-formed (uses the appropriate buckling curve from Table 6.2)

Parameter Name	Default Value	Description
SGR	0	Steel grade as in Table 3.1: EN 1993-1-1: 2005: 0.0 - indicates S 235 grade steel - EN10025-2 1.0 - indicates S 275 grade steel 2.0 - indicates S 355 grade steel 3.0 - indicates S 450 grade steel 4.0 - indicates S 275 N/NL grade steel - EN10025-3 5.0 - indicates S 355 N/NL grade steel 6.0 - indicates S 420 N/NL grade steel 7.0 - indicates S 460 N/NL grade steel 8.0 - indicates S 275 M/ML grade steel - EN10025-4 9.0 - indicates S 355 M/ML grade steel 10.0 - indicates S 420 M/ML grade steel 11.0 – indicates S 460 M/ML grade steel 12.0 – indicates S 235 W grade steel - EN10025-5 13.0 – indicates S 355 W grade steel 14.0 – indicates S 460 Q/QL/QL1 grade steel - EN10025-6 15.0 – indicates S 235 H grade steel - EN10210-1 16.0 – indicates S 275 H grade steel 17.0 – indicates S 355 H grade steel 18.0 – indicates S 275 NH/NLH grade steel 19.0 – indicates S 355 NH/NLH grade steel 20.0 – indicates S 420 NH/NLH grade steel 21.0 – indicates S 460 NH/NLH grade steel 22.0 – indicates S 235 H grade steel - EN10219-1 23.0 – indicates S 275 H grade steel 24.0 – indicates S 355 H grade steel 25.0 – indicates S 275 NH/NLH grade steel 26.0 – indicates S 355 NH/NLH grade steel 27.0 – indicates S 460 NH/NLH grade steel 28.0 – indicates S 275 MH/MLH grade steel 29.0 – indicates S 355 MH/MLH grade steel 30.0 – indicates S 420 MH/MLH grade steel 31.0 – indicates S 460 MH/MLH grade steel **Note:** As EN 1993-1-1:2005 does not provide a buckling curve in table 6.2 for grade S 450 steel (in Table 3.1 of EN 1993-1-1:2005), the program will use the same buckling curves as for grade S 460 when calculating the buckling resistance as per clause 6.3.
STIFF	Member Length or depth of beam, whichever is lesser	Distance between transverse stiffener plates, used to prevent web shear buckling. If not specified or if a value of 0 is provided, the program will assume the web is unstiffened.

Parameter Name	Default Value	Description
TOM	0	Total torsion for design used for torsion checks. Can be used to override the total torsional moment to be used for member design.
TORSION	0	Method to be used for a specific member or group of members: 0. Perform basic torsion checks if member is subject to torsion. 1. Perform basic stress check (Ignore warping effects). 2. Perform detailed checks (including warping effects). 3. Ignore all torsion checks **Note:** For options 1 or 2, the program will perform the torsion related checked even if torsional moment is absent and will use a value of zero for the torsional moment.
TRACK	0	Specify level of detail in output. 0. Summary of results only. 1. Summary with member capacities. 2. Detailed results. 4. Deflection check results only.
UNF	1	Unsupported length provided as a fraction of actual member length used for lateral-torsional buckling calculation. **Note:** If both UNF and UNL parameters are specified, the effective length used is UNF×UNL.
UNL	Member Length	Unsupported length for calculating allowable bending stress. Used for the lateral-torsional buckling calculation. Value should be in the current units of length.
ZG	+Section Depth/2	Distance of transverse load from shear center. Used to calculate M_{cr}. **Note:** For Tee sections, ZG will have a default value of (+Flange thickness/2)

Notes

1. CAN, DJ1, and DJ2 – Deflection

a. When performing the deflection check, you can choose between two methods. The first method, defined by a value 0 for the CAN parameter, is based on the local displacement. Refer to TR.44 Printing Section Displacements for Members (on page 2672) for details on local displacement..

If the CAN parameter is set to 1, the check will be based on cantilever style deflection. Let (DX1, DY1, DZ1) represent the nodal displacements (in global axes) at the node defined by DJ1 (or in the absence of DJ1, the start node of the member). Similarly, (DX2, DY2, DZ2) represent the deflection values at DJ2 or the end node of the member.

Compute Delta = SQRT((DX2 - DX1)^2 + (DY2 - DY1)^2 + (DZ2 - DZ1)^2)

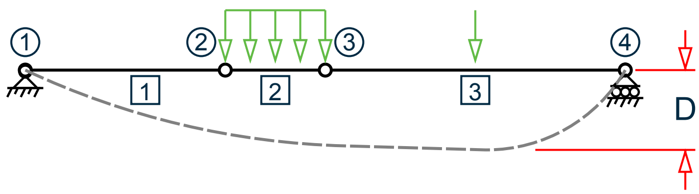
Compute Length = distance between DJ1 & DJ2 or, between start node and end node, as the case may be.

Then, if CAN is specified a value 1, dff = L/Delta

Ratio due to deflection = DFF/dff

b. If `CAN` = 0, deflection length is defined as the length that is used for calculation of local deflections within a member. It may be noted that for most cases the “Deflection Length” will be equal to the length of the member. However, in some situations, the “Deflection Length” may be different. A straight line joining `DJ1` and `DJ2` is used as the reference line from which local deflections are measured.

For example, refer to the figure below where a beam has been modeled using four joints and three members. The “Deflection Length” for all three members will be equal to the total length of the beam in this case. The parameters `DJ1` and `DJ2` should be used to model this situation. Thus, for all three members here, `DJ1` should be `1` and `DJ2` should be `4`.



D = Maximum local deflection for members 1, 2, and 3.

```
PARAMETERS
DFF 300. ALL
DJ1 1 ALL
DJ2 4 ALL
```

c. If `DJ1` and `DJ2` are not used, "Deflection Length" will default to the member length and local deflections will be measured from original member line.

d. If a serviceability load envelope is specified under “LOAD LIST ENV” before a parameter block, the default value of DFF 360 is used for deflection calculations. If DFF 0 is specified for any member, then the deflection check is skipped for that member.

e. The above parameters may be used in conjunction with other available parameters for steel design.

2. The values of `CMM` for various loading and support conditions are as given below:

Table 133: Values for the CMM Parameter

CMM Value	Loading and Support Conditions
1	2	
CMM Value	Loading and Support Conditions
3	4	5	6	7	 varying end moments and uniform loading
8	 varying end moments and central point load

3. Checking beam deflection

   With the `TRACK` parameter set to 4, the members included in a `BEAM CHECK` command will be checked for the local axis deflection rather than for the stress capacity using the current `LOAD LIST`.

   If `LOAD LIST ENV` is used, then serviceability envelope must be present to check for deflections. If only strength load cases are given in `LOAD LIST ENV`, only strength checks will be performed and `TRACK 4` is treated as `TRACK 2`.

   Note: While both sets of code checks will be reported in the output file, only the last code check results are reported in the STAAD.Pro graphical interface.

4. The values of `CMT` for various loading and support conditions are as given below:

Table 134: Loading and Support Conditions represented by CMT Parameter Values

CMT Value	Description	Diagram
1	(Default) : Concentrated Torque at Ends. Ends Torsion fixed and Warping fixed	2	Concentrated Torque along length of member. Ends Torsion fixed and Warping free	3	Concentrated Torque along length of member. Ends Torsion fixed and Warping fixed	4	Uniform Torque in member. Ends Torsion fixed and Warping free	5	Uniform Torque in member. Ends Torsion fixed and Warping fixed	6	Concentrated Torque in cantilever. End Torsion fixed and Warping fixed	

CMT Value	Description	Diagram
7	Uniform Torque in cantilever. End Torsion fixed and Warping fixed	
Note: For CMT = 2 and CMT = 3, you have the option of specifying the distance at which the concentrated torque acts, measured from the start of the member. This can be done by using the ALH design parameter. The ALH parameter indicates the ratio of the distance of the point torque (from the start of the member) to the length of the member. This parameter will have a default value of 0.5 (i.e., the torque acts at the center of the span) and will accept values ranging from 0 to 1.

D5.C.7 Code Checking

The purpose of code checking is to ascertain whether the provided section properties of the members are adequate. The adequacy is checked as per EN 1993-1-1:2005 and a corresponding National Annex (if specified). Code checking is done using the forces and moments at specific sections of the members.

When code checking is selected, the program calculates and prints whether the members have passed or failed the checks; the critical condition; the value of the ratio of the critical condition (overstressed for value more than 1.0 or any other specified RATIO value); the governing load case, and the location (distance from the start of the member of forces in the member where the critical condition occurs).

Code checking can be done with any type of steel section listed in D3.B.4 Built-In Steel Section Library (on page 1380) or any of the user defined sections as described in G.6.3 User-Provided Steel Table (on page 2117) , with the exception of ISECTION. ISECTION has been currently excluded since the option of Tapered section design is currently not supported in the EC3 module. The EC3 (EN 1993) design module does not consider these sections or PRISMATIC sections in its design process.

Note: Checks for slender sections to EN 1993-1-1 are limited to I-SECTIONS, TEE, SINGLE CHANNEL, SINGLE ANGLE and CIRCULAR & RECTANGULAR HOLLOW SECTIONS.

Code checking for GENERAL sections can be also done using the EN1993 module. The program will design GENERAL sections as I sections by default. However, you are given the option to choose a “section type” to be considered while designing the member. Refer to the description of the GST design parameter in D5.C.6 Design Parameters (on page 1502) for details.

D5.C.8 Member Selection

STAAD.Pro is capable of performing design operations on specified members. Once an analysis has been performed, the program can select the most economical section, i.e., the lightest section, which fulfills the code requirements for the specified member. The section selected will be of the same type section as originally designated for the member being designed. Member selection can also be constrained by the parameters DMAX and DMIN, which limits the maximum and minimum depth of the members.

Member selection can be performed with all the types of steel sections with the same limitations as defined in D5.C.7 Code Checking (on page 1513).

Selection of members, whose properties are originally input from a user created table, will be limited to sections in the user table.

Member selection cannot be performed on members whose section properties are input as prismatic or as the limitations specified in D5.C.7 Code Checking (on page 1513).

D5.C.9 Tabulated Results of Steel Design

For code checking or member selection, the program produces the results in a tabulated fashion. The items in the output table are explained as follows:

MEMBER	refers to the member number for which the design is performed.
TABLE	refers to steel section name, which has been checked against the steel code or has been selected.
RESULTS	prints whether the member has PASSED or FAILED. If the RESULT is FAIL, there will be an asterisk (*) mark on front of the member.
CRITICAL COND	refers to the clause in EN 1993-1-1:2005 code which governs the design.
RATIO	prints the ratio of the actual stresses to allowable stresses for the critical condition. Normally a value of 1.0 or less will mean the member has passed.
LOADING	provides the load case number, which governed the design.
FX, MY, and MZ	provide the axial force, moment in local Y-axis and the moment in local z-axis respectively. Although STAAD does consider all the member forces and moments (except torsion) to perform design, only FX, MY and MZ are printed since they are the ones which are of interest, in most cases.
LOCATION	specifies the actual distance from the start of the member to the section where design forces govern.

Note: For a TRACK 2 output, the module will also report all the relevant clause checks that have been performed and will also indicate the critical ratio and the load case that caused the critical ratio as well as the corresponding forces that were used for the respective checks. A TRACK 2 output will also include the various design data used for the calculations such as the section modulii, section class, section capacity etc.

If an NA parameter (other than 0) has been specified and if the particular National Annex requires additional checks outside those specified in EN 1993-1-1:2005 (e.g., The Dutch National Annex), the respective NA clauses and any associated code clauses will be listed along with the critical ratios and the forces that were used for these clause checks.

Documentation notes appear in red.

Note: The results and output follow the axis convention as described in Section 7C.1.3

D5.D. European Codes - National Annexes to Eurocode 3 [EN 1993-1-1:2005]

A number of countries that have signed up to the replace their current steel design standards with the Eurocode, EN 1993-1-1:2005, known commonly as Eurocode 3, have published their National Annex documents. These documents make small changes to the base document and STAAD.Pro has been updated to incorporate some of these National Annex documents.

The parameter NA sets the default material gamma factors and any additional changes outlined in the country specific National Annex such as specific equations or methods. These are described for each National Annex document in the following sections.

The output file printout has been updated to indicate which National Annex (if any) has been used in a code check / select process (For all TRACK settings).

D5.D.1 General Format

The format of the EN 1993-1-1:2005 National Annex is as follows:

```
CODE EN 1993
```

```
NA  f1
```

```
{code  parameters}
```

Refer to D5.C.6 Design Parameters (on page 1502) D5.C.6 Design Parameters (on page 1502)

Where:

`f1` represents the number designation for a specific country's National Annex:

Table 135: Table 5B1.2(B) - Numerical Code for Eurocode National Annex

NA Value	Country
0	None — Uses the base EN 1993-1-1:2005 code, with no national annex changes or additions. The default values specified in En 1993-1-1:2005 will be used for the partial safety factors and various parameter values where applicable (default).
1	United Kingdom (D5.D.5 UK National Annex to EC3 (on page 1528)) — Uses the BS EN 1993-1-1:2005 version of Eurocode 3 along with the UK National Annex.
2	Netherlands (D5.D.3 Dutch National Annex to EC3 (on page 1518)) — Uses the NEN EN 1993-1-1:2005 version of the code. The Dutch National Annex [NEN-EN 1993-1-1/NB] has been added in this module. Please note that the Dutch National requires additional checks as per NEN 6770 and NEN 6771 which will also be performed during design checks with this parameter value
3	Norway (D5.D.4 Norwegian National Annex to EC3 (on page 1527)) — Uses the NS-EN 1993-1-1:2005 version of the code. The Norwegian National Annexe [NS-EN 1993-1-1:2005/Na 2008] has been added to this implementation.
4	France (D5.D.6 French National Annex to EC3 (on page 1537)) — Uses the Annexe Nationale a la NF EN 1993-1-1:2005 version of the code along with the French National Annex..
5	Finland (D5.D.7 Finnish National Annex to EC3 (on page 1543)) - Uses the SFS EN 1993-1-1:2005 version of Eurocode 3 along with the Finnish National Annex.
6	Poland (D5.D.8 Polish National Annex to EC3 (on page 1550)) - Uses the PN EN 1993-1-1:2005 version of Eurocode 3 along with the Polish National Annex.
7	Singapore (D5.D.9 Singaporean National Annex to EC3 (on page 1556)) - Uses the SS EN 1993-1-1:2005 version of Eurocode 3 along with the Singaporean National Annex.

NA Value	Country
8	Belgium (D5.D.10 Belgian National Annex to EC3 (on page 1563)) - Uses the NBN EN 1993-1-1:2005 version of Eurocode 3 along with the Belgian National Annex.
9	Malaysian (D5.D.11 Malaysian National Annex to EC3 (on page 1570)) - Uses the MS EN 1993-1-1:2005 version of Eurocode 3 along with the Malaysian National Annex.
10	German (D5.D.12 German National Annex to EC3 (on page 1575)) - Uses the DIN EN 1993-1-1:2005 version of Eurocode 3 along with the German National Annex.
11	Swedish (D5.D.13 Swedish National Annex to EC3 (on page 1579)) - Uses the BFS EN 1993-1-1:2005 version of Eurocode 3 along with the Swedish National Annex.

D5.D.2 Specifying the design engine to use a national annex

Use the following procedure to include additional check specified by a National Annex:

Batch steel design is performedin the **Analytical Modeling** workflow.

1. On the **Analysis and Design** ribbon tab, select **Steel** in the **Design** gallery.
   The **Steel Design - Whole Structure** dialog box opens.
2. In the **Current Code** drop-down menu, select **EN 1993-1-1:2005**.
3. Click **Define Parameters...**.
   The **Design Parameters** dialog box opens.
4. Select the **NA** parameter in the list box.
5. Select the option corresponding to the National Annex document you want to use .
6. Click **Add**.

   This will insert the following commands into the STAAD input file:

   ```
   CODE EN 1993-1-1:2005
   ```

   ```
   NA n
   ```

Refer to D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) for additional information on steel design per EC3.

A design performed to the new Eurocode 3 National Annex is displayed in the output file (`*.ANL`) with the following header, in addition to the base EC3 output.

D5.D.3 Dutch National Annex to EC3

Adds values from the Dutch National Annex —titled NEN-EN 1993-1-1:2006+C1:2006/NB:2007— for use with Eurocode 3, or EN 1993-1-1:2005. The NA document makes small changes to the base document.

The clauses/sections in EN 1993-1-1:2005 (hereafter referred to as EC-3) that require additional clauses from the Dutch National Annex, NEN-EN 1993-1-1:2006+C1:2006/NB:2007, (hereafter referred to as D-NA) are described in the following sections.

Refer to the [D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005]] (on page 1478) for a description of these clauses. The sections below refer to the corresponding clauses in the D-NA.

Note: Clause 6.3.2.4 deals with a simplified assessment method for beams. STAAD.Pro only uses the more accurate method (6.3.2.2 and 6.3.2.3 in EC-3) and therefore this section is ignored.

The local axis convention in the Dutch codes is: Y – major axis & Z – minor axis (as opposed to the convention followed in STAAD.Pro).

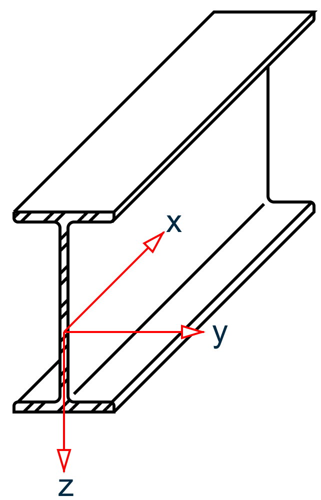

Figure 167: Local axis convention used in the Dutch NA to EC-3

D5.D.3.2 Clause 6.1 – General

The partial safety factors will use the following values:

- Resistance of cross-sections, $\gamma_{M0} = 1.0$
- Resistance of members to instability, $\gamma_{M1} = 1.0$
- Resistance of cross sections to tension, $\gamma_{M2} = 1.25$

The design function in STAAD.Pro sets these values as the default values for the D-NA (`NA 3` is specified).

Note: You can change these values through the `GM0`, `GM1`, & `GM2` design parameters. Refer to [D5.C.6 Design Parameters] (on page 1502)

D5.D.3.3 Clause 6.2.8 – Bending and shear

The D-NA requires the implementation of causes 11.3.1.1 and 11.3.1.3 of NEN 6770.

Clause 11.3.1.1 (NEN 6770): Class 1 and Class 2 I-section profiles

Class 1 and class 2 I section profiles must satisfy the interaction formulae given in tables 10 & 11 of NEN 6770.

Table 10 Provides interaction checks for bending about the major axis (All necessary terms and formulae are described below):

1. If $V_{z;s;d} \leq 0.5 \cdot V_{z;pl;d}$ and $N_{s;d} \leq 0.5 \cdot \alpha_1 \cdot N_{pl;d}$, check equation 11.3.1
2. If $V_{z;s;d} \leq 0.5 \cdot V_{z;pl;d}$ and $N_{s;d} > 0.5 \cdot \alpha_1 \cdot N_{pl;d}$, check equation 11.3.2
3. If $V_{z;s;d} > 0.5 \cdot V_{z;pl;d}$ and $N_{s;d} \leq 0.5 \cdot \alpha_2 \cdot N_{v;u;d}$, check equation 11.3-3
4. If $V_{z;s;d} > 0.5 \cdot V_{z;pl;d}$ and $N_{s;d} > 0.5 \cdot \alpha_2 \cdot N_{v;u;d}$, check equation 11.3-4

where

$V_{z;s;d}$	=	Actual Shear force in the section along Z- axis
$V_{z;pl;d}$	=	Shear capacity of section along Z - axis
		$= A_w \cdot f_{y;d} / \sqrt{3}$
$f_{y;d}$	=	yield stress
A_w	=	$A - 2 (bf - tw - 2r) tf$

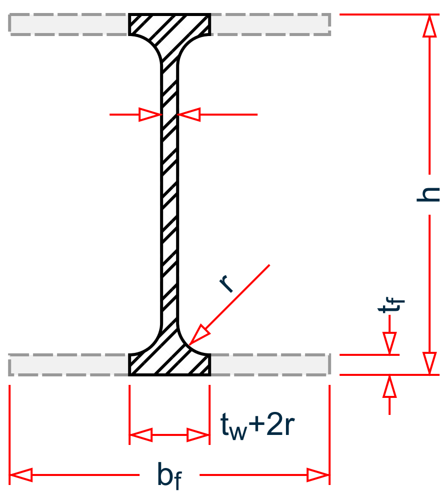

Figure 168: Definition of A_w

$N_{s;d}$	=	Axial force in the section
$N_{pl;d}$	=	Axial capacity of section = $A \cdot f_{y;d}$
$M_{y;s;d}$	=	Bending moment about major axis
$M_{y;pl;d}$	=	Plastic moment capacity of section = $f_{y;d} \cdot W_{y;pl}$
$W_{y;pl}$	=	Plastic section modulus
α_1	=	$min(A\text{-}2bfx\ tf)/A\ ,\ 0.5)$ - used in tables 10 & 11
α_2	=	see eqn 11.3-10- used in tables 10 & 11
$M_{v;y;ud}$	=	see eqn 11.3.12
$N_{;v;u;d}$	=	see eqn 11.3-13

Table 11: Provides interaction formulae for bending about the minor axis

1. If $V_{y;s;d} \leq 0.25 \cdot V_{y;pl;d}$ and $N_{s;d} \leq 1.0 \cdot \alpha_1 \cdot N_{pl;d}$ check equation 11.3-5
2. If $V_{y;s;d} \leq 0.25 \cdot V_{y;pl;d}$ and $N_{s;d} > 1.0 \cdot \alpha_1 \cdot N_{pl;d}$ check equation 11.3-6
3. If$V_{y;s;d} > 0.25 \cdot V_{y;pl;d}$ and $N_{s;d} \leq 1.0 \cdot \alpha_1 \cdot N_{v;u;d}$ check equation 11.3-7
4. If $V_{y;s;d} > 0.25 \cdot V_{y;pl;d}$ and $N_{s;d} > 1.0 \cdot \alpha_1 \cdot N_{v;u;d}$ check equation 11.3-8

where

$V_{y;s;d}$	=	Actual Shear force in the section along Y-axis
$V_{y;pl;d}$	=	Shear capacity of section along Y-axis

$$2bt_f \frac{f_{y;d}}{\sqrt{3}}$$

$M_{v;z;u;d}$	=	$q \cdot M_{z;pld} = q \cdot f_{y;d} \cdot W_{pl;z;d}$
$W_{pl;z;d}$	=	plastic section modulus about minor axis) & q as per eqn 11.3-14
$N_{v;u;d}$	=	$N_{pl;d} - 2 \cdot (1 - q) \cdot b_f \cdot t_f \cdot f_{y;d}$

Clause 11.3.1.3 (NEN 6770) : Class 1 and Class 2 Square and rectangular hollow sections

This clause requires class 1 and class 2 square and rectangular tube profiles to satisfy the interaction equations in Table 13.

1. If $V_{z;s;d} \leq 0.25 \cdot V_{z;pl;d}$ and $N_{s;d} \leq 0.5 \cdot a_3 \cdot N_{pl;d}$ check equation 11.3.22
2. If $V_{z;s;d} \leq 0.25 \cdot V_{z;pl;d}$ and $N_{s;d} > 0.5 \cdot a_3 \cdot N_{pl;d}$ check equation 11.3.23
3. If $V_{z;s;d} > 0.25 \cdot V_{z;pl;d}$ and $N_{s;d} \leq 0.5 \cdot a_4 \cdot N_{v;u;d}$ check equation 11.3-24
4. If $V_{z;s;d} > 0.25 \cdot V_{z;pl;d}$ and $N_{s;d} > 0.5 \cdot a_4 \cdot N_{v;u;d}$ check equation 11.3-25

where

$V_{z;s;d}$	=	Actual Shear force in the section along Z-axis
$V_{z;pl;d}$	=	Shear capacity of section along Z-axis
b	=	breadth of section
h	=	height of section
A	=	area of section
$V_{z;pl;d}$	=	$V_{z;cl;d} = \frac{h}{b+h} A \frac{f_{y;d}}{\sqrt{3}}$
a_3	=	$min\{(A - 2 \cdot b \cdot t)/A \text{ or } 0.5\}$
a_4	=	from equation 11.3.27

=

=

D5.D.3.4 Clause 6.2.10 – Bending shear and axial force

Requires the implementation of clauses 11.3.1.1 to 11.3.1.3 and 11.3.2.1 to 11.3.2.3 of NEN 6770 and clause 11.3 of NEN 6771

Clause 11.3.1.1 (NEN 6770) and Clause 11.3.1.3 (NEN 6770)

Refer to D5.D.3.3 Clause 6.2.8 – Bending and shear (on page 1519)

Clause 11.3.1.2 (NEN 6770): Class 1 and class 2 circular hollow (CHS) profiles

Class 1 and class 2 sections with circular hollow profiles should satisfy the interaction equations given in table 12.

- Check #1 – If Vz;s;d ≤ 0.25 Vz;pl;d check equation 11.3.17
- Check #2 – If Vz;s;d > 0.25 Vz;pl;d check equation 11.3.18.

Refer to D5.D.3.3 Clause 6.2.8 – Bending and shear (on page 1519) of this document for equations to derive Vz;s;d

Vz;pl;d = Shear capacity of CHS sections

$$V_{pl;d} = 2\frac{A}{\pi}\frac{f_{y;d}}{\sqrt{3}}$$

See equations 11.3-19 and 11.3-20 to evaluate Mv;y;u;d and N;v;u;d.

To check for these conditions about the y axis, substitute the index “z” in the above equations with ‘y’ (should be the same of CHS sections).

Clause 11.3.2 (NEN 6770)

Section 11.3.2 in general deals with Biaxial bending with axial force and shear. The general condition to be satisfied in this case is given by equation 11.3-31 of NEN 6770

$$\beta_0\left(\frac{M_{y;s;d}}{M_{N;V;y;u;d}}\right)^{\alpha_1} + \beta_1\left(\frac{M_{z;s;d}}{M_{N;V;z;u;d}}\right)^{\alpha_2} \le 1$$

Clause 11.3.2.1 : Class 1 and class2 I-sections with biaxial bending + shear + axial force

The formula to evaluate M;N;v;y;u;d and M;N;v;z;u;d are to be taken from tables 14 and 15 of NEN 6770 respectively.

Checks for table 14:

1. Check #1 – If Vz;s;d ≤ 0.5 Vz;pl;d and Ns;d ≤ 0.5 x a1 x Npl;d use equation 11.3.32
2. Check #2 – If Vz;s;d ≤ 0.5 Vz;pl;d and Ns;d > 0.5 x a1 x Npl;d use equation 11.3.33
3. Check #3 – If Vz;s;d > 0.5 Vz;pl;d and Ns;d ≤ 0.5 x a2 x Nv;u;d use equation 11.3-34
4. Check #4 – If Vz;s;d > 0.5 Vz;pl;d and Ns;d > 0.5 x a2 x Nv;u;d use equation 11.3-35

Refer to D5.D.3.3 Clause 6.2.8 – Bending and shear (on page 1519) for equations to evaluate Vz;s;d, My;pl;d, Npl;d, Mv;y;ud, N;v;u;d, a1 ,a2 and Vz;pl;d.

Checks for table 15:

1. Check #1 – If Vy;s;d ≤ 0.25 Vy;pl;d and Ns;d ≤ 1.0 x a1 x Npl;d use equation 11.3.36
2. Check #2 – If Vy;s;d ≤ 0.25 Vy;pl;d and Ns;d > 1.0 x a1 x Npl;d use equation 11.3.37
3. Check #3 – If Vy;s;d > 0.25 Vy;pl;d and Ns;d ≤ 1.0 x a1 x Nv;u;d check equation 11.3-38
4. Check #4 – If Vy;s;d > 0.25 Vy;pl;d and Ns;d > 1.0 x a1 x Nv;u;d check equation 11.3-39

Refer to D5.D.3.3 Clause 6.2.8 – Bending and shear (on page 1519) for equations to evaluate Vy;s;d, Mz;pl;d, Npl;d, Mv;z;ud, N;v;u;d, a1 ,a2 and Vy;pl;d.

See table 16 for α1, α1, β0 and β1 use in tables 14 and 15.

Clause 11.3.2.2 : Class 1 and Class 2 Circular hollow tubes

The formula to evaluate M;N;v;y;u;d and M;N;v;z;u;d (to be used in equation 11-3-31, see description of clause 11.3.2 above) are to be taken from table 17 of NEN 6770.

1. Check #1 – If Vz;s;d ≤ 0.25 Vz;pl;d use equation 11.3.44
2. Check #2 – If Vz;s;d > 0.25 Vz;pl;d use equation 11.3.45.

Refer to D5.D.3.3 Clause 6.2.8 – Bending and shear (on page 1519) for equations to evaluate Vz;pl;d, My;pl;d, and Npl;d use in equations 11.3.44 & 11.3.45.

For values to be used for α1, α2, β1 and β2 in this case refer to table 18 of NEN 6770.

Clause 11.3.2.3 : Class 1 and class2 Rectangular and square hollow tubes

The formula to evaluate M;N;v;y;u;d and M;N;v;z;u;d (to be used in equation 11-3-31, see description of clause 11.3.2 above) are to be taken from table 19 of NEN 6770.

1. Check #1 – If Vz;s;d ≤ 0.25 Vz;pl;d and Ns;d ≤ 0.5 x a3 x Npl;d use equation 11.3-48
2. Check #2 – If Vz;s;d ≤ 0.25 Vz;pl;d and Ns;d > 0.5 x a3 x Npl;d use equation 11.3.49
3. Check #3 – If Vz;s;d > 0.25 Vz;pl;d and Ns;d ≤ 0.5 x a4 x Nv;u;d use equation 11.3-50

4. Check #4 – If Vz;s;d > 0.25 Vz;pl;d and Ns;d > 0.5 x a4 x Nv;u;d check equation 11.3-51

Refer to D5.D.3.3 Clause 6.2.8 – Bending and shear (on page 1519) for equations to evaluate Vz;pl;d, My;pl;d, Npl;d, Mv;y;ud, N;v;u;d, a3, a4 and Vz;pl;d to be used in the above equations. For values to be used for α1, α2, β1 and β2 in this case refer to table 20 of NEN 6770.

To check for these conditions about the y axis, substitute the index "z" in the above equations with 'y'.

Clause 11.3 (NEN 6771)

In general, this section deals with Biaxial bending with axial force and shear for class 3 and class 4 sections.

Check for class 3 sections: For class 3 sections use the method in section 11.3 NEN 6770. For class 3 sections the methods and equations discussed above can be used with the "plastic section modulus" being substituted with the 'elastic modulus'.

Check for class 4 sections: Class 4 sections can be treated as class 3 sections if the effective section properties are used as given in clause 10.2.4.2.3 of NEN 6771. Working out the effective section properties for slender sections has already been done in STAAD.Pro.

For I- section profiles and tubular sections, the following cases are checked:

1. If M;y;s;d / MN;y;f;u;d ≤ 1 check equation 11.2-7 (given below)

   $$V_{z;s;d}/V_{z;u;d} \le 1$$

   Where

   $V_{z;s;d}$ is the shear for in the Z direction
   $V_{z;u;d}$ is the shear capacity in the Z direction for ultimate limit state.

   For an I section,

   $$V_{z;u;d} = \frac{2}{3} A_{w;et} \frac{f_{y;d}}{\sqrt{3}}$$

   Where

   Aw,ef = effective web area as given in section 10.2.4.2.3.
   MN;y;f;u;d is the moment capacity about the Y axis for the effective section. = (fy·W,eff)
2. If M;y;s;d / MN;y;f;u;d > 1 and M;y;s;d / M;y;f;u;d ≤1 check equation 11.2-13 (given below):

   $$\frac{M_{y;s;d}}{M_{N;y;f;u;d} + \left(M_{N;y;u;d} - M_{N;y;f;u;d}\right)\left\{1 - \left(\frac{2V_{z;s;d}}{V_{z;u;d}} - 1\right)^2\right\}} \le 1$$

D5.D.3.5 Clause 6.3 – Buckling resistance of members

The D-NA introduces a new clause 6.3.0, which in turns requires the checks as per clauses 12.1.2.2, 12.13.2 and 12.1.4.2 of NEN 6771 to be applied.

Clause 12.1.2.2 (NEN 6771)

This clause in NEN 6771 determines the relative torsional slenderness and is given as:

$$\lambda_{\theta,rel} = \sqrt{\frac{N_{c;u;d}}{F_{E;\theta}}}$$

Where:

$$N_{c;u;d} = A \cdot f_{y;d}$$

A = area of section
$f_{y;d}$ = the yield stress
$F_{E;\theta}$ is the Euler-torsion formula

This value of slenderness is to be used to calculate the modification factors used in section 6.3 of EC-3.

Clause 12.1.3.2 (NEN 6771)

This clause works out the relative torsional-flexural buckling slenderness for compression members. The relative torsional-flexural buckling slenderness is given as:

$$\lambda_{tk,rel} = \sqrt{\frac{N_{c;u;d}}{F_{E;tk}}}$$

Where

$$N_{c;u;d} = A \cdot f_{y;d}$$

A = area of section
$f_{y;d}$ = yield stress
$F_{E;tk}$ is the Euler torsional buckling strength

Clause 12.1.4.2 (NEN 6771)

Buckling lengths of rotationally restrained bars with intermediate spring supports.

Note: STAAD.Pro does not allow for these end conditions, specifically. The effective length factors may be used to accommodate this requirement.

D5.D.3.6 Clause 6.3.1.3 – Slenderness for flexural buckling

The Dutch NA requires the implementation of clause 12.1.1.3 and 12.1.5.3.2 of NEN 6770 and clause 12.1.1.3 of NEN 6771.

Clause 12.1.1.3 (NEN 6770)

This clause gives the equations to evaluate the effective lengths for various support conditions. STAAD.Pro uses the effective length factor “K” which allows the user to set/modify the effective lengths for a member.

Clause 12.1.5.3.2 (NEN 6770)

This clause gives methods to evaluate the buckling length of lattice sections. We do not deal with latticed section in the current version of STAAD.Pro. In any case the buckling length can be adjusted using the “K” factor.

Clause 12.1.1.3 (NEN 6771)

This clause again deals with working out the effective lengths of prismatic and non-prismatic rods. Again, the “K” factor in the current implementation of STAAD.Pro is adequate to cater for adjusting the effective lengths as necessary.

D5.D.3.6 Clause 6.3.1.4 – Slenderness for torsional and torsional-flexural buckling

The D-NA requires the implementation of clauses 12.1.2 and 12.1.3 of NEN 6770

Clause 12.1.2 (NEN 6770): Torsional stability

IPE, HEA, HEB & HEM sections and pipe sections do not need to be checked for torsional instability.

If torsional checks need to be performed, they should be done according to 12.1.2 of NEN 6771.

Clause 12.1.2 (NEN 6771)

This clause gives the condition to check for torsion instability. The condition being:

$$\frac{N_{c;s;d}}{\omega_\theta N_{c;u;d}} \le 1$$

Where:

$N_{c;s;d}$ = the applied axial load
$N_{C;u;d}$ = the axial capacity = A · f_y.

$$\omega_\theta = \frac{\sigma_{\theta;d}}{f_{u;d}}$$

Clause 12.1.3 (NEN 6770): Torsional flexural stability

Doubly symmetric sections need not be checked for torsional flexural instability. However, for I sections that have rigid supports that is not along the axis of the section and any other sections will need to be checked as per clause 12.1.3 of NEN 6771.

Clause 12.1.3 (NEN 6771)

This clause gives the condition to check for torsional flexural instability. The condition being:

$$\frac{N_{c;s;d}}{\omega_{t;k} N_{c;u;d}} \le 1$$

Where:

$N_{c;s;d}$ and $N_{c;u;d}$ as in clause 12.1.2 above.

D5.D.3.7 Clauses 6.3.2.2 and 6.3.2.3 – Lateral torsional buckling curves

Clause 6.3.2.2 – Lateral torsional buckling curves - general

The D-NA states that the values for the imperfection factor, αLT, to be used in equation 6.56 of EC-3 are to be obtained from sTable 6.3 of EC-3. These are the values used by STAAD.Pro.

Clause 6.3.2.3 – Lateral torsional buckling curves for rolled sections or equivalent welded sections

The D-NA states that:

1. The values for the:
   - Imperfection factor αLT0 = 0.4 (used in equation 6.57 of EC-3)
   - B = 0.75 (used in equation 6.57 of EC-3)

   These are the default values used by the program.
2. The buckling curves shall be selected as per Table 6.5.
3. The reduction factor, f, is given by

   $$F = 1 – 0.5(1 - kc)[1 - 2x\ (\lambda LT\ -0.8)^2].$$

   kc is a correction factor for moment distribution determined from Table 6.6. This value can be specified or calculated by the program using the KC parameter. Refer to D5.C.6 Design Parameters (on page 1502)

The current implementation of STAAD.Pro conservatively uses a value of f = 1.0.

D5.D.3.8 Clause 6.33 – Uniform members in bending and axial compression

The D-NA recommends the use of the method in Annex B of EC-3 to determine the values of kyy, kyz, kzy and kzz to be used in 6.3.3 (EC-3) checks. STAAD.Pro uses the method in Annex B.

Clause 12.3.1.2.3 (NEN 6770): Rotation/bending capacity

The Dutch NA also requires additional checks as per clause 12.3.1.2.3 of NEN 6770.

The checks given in this clause deals with additional checks for columns that form part of a buttressed or non-butressed framework. The program uses the `ESTIFF` parameter with two different values to identify the framework type:

Table 136: Framework parameter `ESTIFF` values for the Dutch NA

`ESTIFF` value	Description
0	(default) Column part of a buttressed framework. Selecting this value will internally perform the checks as per section 1 of clause 12.3.1.2.3
1	Column is *not* part of a buttressed framework. Selecting this value will internally perform the checks as per section 2 of clause 12.3.1.2.3

These checks are described below:

1. For columns in buttressed frameworks the buckling length is to be taken based on either

- the system length or
- the distance between adjacent lateral supports

The following conditions should also be satisfied:

If $Nc;s;d / Npl;d < 0.15$, no additional checks are required

If $Nc;s;d / Npl;d \geq 0.15$ and the steel grade is S235 or S 275 then

$$\frac{N_{c;s;d}}{N_{pl;d}} + \frac{\lambda_y}{120} \leq 1$$

Where:

$N_{c;s;d}$ is the axial load in the section
$N_{pl;d}$ = Axial capacity of section = $A \cdot f_{y;d}$
λ_y = Slenderness of the section about the major axis (Y-axis)

If $Nc;s;d / Npl;d \geq 0.15$ and the steel grade is S355 then

$$\frac{N_{c;s;d}}{N_{pl;d}} + \frac{\lambda_y}{100} \leq 1$$

Where:

$N_{c;s;d}$ = the axial load in the section
$N_{pl;d}$ = Axial capacity of section = $A \cdot f_{y;d}$
λ_y = Slenderness of the section about the major axis (Y-axis)

2. For columns that are not part of buttressed frameworks the following additional checks need to be done:

   If $Nc;s;d / Npl;d < 0.15$, no additional checks are required

   If $Nc;s;d / Npl;d \geq 0.15$ and the steel grade is S235 or S 275 then

$$\frac{N_{c;s;d}}{N_{pl;d}} + \frac{\lambda_y}{100} \leq 1$$

   Where:

   $N_{c;s;d}$ = the axial load in the section and
   $N_{pl;d}$ = Axial capacity of section = $A \cdot f_{y;d}$
   λ_y = Slenderness of the section about the major axis (Y-axis)

   If $Nc;s;d / Npl;d \geq 0.15$ and the steel grade is S355 then

$$\frac{N_{c;s;d}}{N_{pl;d}} + \frac{\lambda_y}{80} \leq 1$$

D5.D.4 Norwegian National Annex to EC3

Adds values from the Norwegian National Annex —titled NS-EN 1993-1-1:2005/NA 2008— for use with Eurocode 3, or EN 1993-1-1:2005. The NA document makes small changes to the base document.

The clauses/sections in EN 1993-1-1:2005 (hereafter referred to as EC-3) that require additional clauses from the Norwegian National Annex are:

D5.D.4.1 Clause 6.1(1) – General: Partial Safety Factors for buildings

EN 1993-1-1:2005 specifies the use of the partial safety factors to be used in for design as given in Cl. 6.1 of the code. These factors are γ_{M0}, γ_{M1}, and γ_{M2}. EN 1993 provides default values for these factors. However, any National Annex is allowed to override these default values.

The partial safety factors will use the following values:

- Resistance of cross-sections - γ_{M0} = 1.05
- Resistance of members to instability - γ_{M1} = 1.05
- Resistance of cross sections to tension - γ_{M2} = 1.25

The design function in STAAD.Pro sets these values as the default values for the Norwegian-NA (`NA 3` is specified).

Note: You can change these values through the `GM0`, `GM1`, & `GM2` design parameters. Refer to D5.C.6 Design Parameters (on page 1502)

Note: If any of these parameters are specified as `0`, STAAD.Pro will ignore the user specified value (i.e., 0) and use the default values as given above.

Refer to the basic code (EC3) for a description of these clauses. The sections below refer to the corresponding clauses in the Norwegian -NA.

D5.D.5 UK National Annex to EC3

Adds values from the UK National Annex - titled NA to BS EN 1993-1-1:2005 - for use with Eurocode 3, or EN 1993-1-1:2005. The NA document makes small changes to the base document.

Note: Refer to the D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) for a description of these clauses. The sections below refer to the corresponding clauses in the UK-NA.

The following clauses are not implemented in STAAD.Pro:

Clause 6.3.2.4(1) B – Slenderness for flexural buckling	The UK NA specifies the value of λc0 for I, H channel or box section to be used in equation 6.59 of BS EN 1993-1-1:2005 as 0.4. However, STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the UK National Annex.
Clause 6.3.2.4(2)B – Modification factor "kfl"	The value of the modification factor kfl to be used in equation 6.60 of BS EN 1993-1-1. However, STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the UK National Annex.

The clauses/sections in EN 1993-1-1:2005 that have been dealt with in the UK National Annex (hereafter referred to as the UK-NA) are:

D5.D.5.1 Clause 6.1(1) – General: Partial Safety Factors for buildings

EN 1993-1-1:2005 specifies the use of the partial safety factors to be used in for design as given in Cl. 6.1 of the code. These factors are γ_{M0}, γ_{M1}, and γ_{M2}. EN 1993 provides default values for these factors. However, any National Annex is allowed to override these default values.

The partial safety factors will use the following values for the UK National Annex:

- Resistance of cross-sections, γ_{M0} = 1.0
- Resistance of members to instability, γ_{M1} = 1.0
- Resistance of cross sections to tension, γ_{M2} = 1.1

The design function in STAAD.Pro sets these values as the default values for the UK-NA (`NA 1` is specified).

Note: You can change these values through the `GM0`, `GM1`, & `GM2` design parameters. Refer to D5.C.6 Design Parameters (on page 1502)

Note: If any of these parameters are specified as `0`, STAAD.Pro will ignore the user specified value (i.e., 0) and use the default values as given above.

Caution: The `GB1` parameter that is being used for compression checks in builds preceding this release (STAAD.Pro 2007 build 06) has been removed as this parameter is no longer required in EN 1993-1-1:2005. Hence, any legacy files that use `GB1` parameter will indicate an error message and the user will need to substitute `GB1` with `GM1` in line with EN 1993-1-1:2005.

D5.D.5.2 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks

The UK-NA recommends the use of Table 6.3 and 6.4 of BS EN 1993-1-1:2005 to calculate the imperfection factors for Lateral Torsional Buckling (LTB) checks.

The calculation of the LTB reduction factor χ_{LT}, requires the calculation of the “Elastic Critical Buckling Moment”, Mcr. The UK National Annex does not specify a particular method to calculate M_{cr}. Hence the calculation of M_{cr} has been based on the following NCCI documents:

SN003a-EN-EU – Elastic critical moment for Lateral torsional Buckling:

This document provides a method to calculate “Mcr” specifically for doubly symmetric sections only. Hence only doubly symmetric sections will be considered for this method in the proposed implementation.

The equation to evaluate M_{cr} is given in the NCCI as:

$$M_{cr} = C_1 \frac{\pi^2 E I_s}{(kL)^2} \left[\sqrt{\left(\frac{k}{k_w}\right)^2 \frac{I_w}{I_s} + \frac{(kL)^2 G I_t}{\pi^2 E I_s} + (C_2 z_s)^2} - C_2 z_s \right]$$

C_1 and C_2 are factors that depend on the end conditions and the loading conditions of the member. The NCCI provides values for C_1 and C_2 for the different cases as given in the tables below:

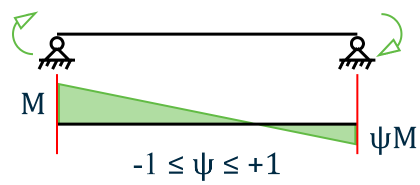

Table 137: Values of C_1 for end moment loading (for k=1)

ψ	C_1
+1,00	1,00
+0,75	1,14
+0,50	1,31
+0,25	1,52
0,00	1,77
-0,25	2,05
-0,50	2,33
-0,75	2,57

Table 138: Values of factors C_1 and C_2, and C_3 for cases with transverse loading (for $k_c = 1$)

Loading and support conditions	Bending moment diagram	C_1	C_2
		1.127	0.454

Loading and support conditions	Bending moment diagram	C_1	C_2
		2.578	1.554
		1.348	0.630
		1.683	1.645

This NCCI considers three separate loading conditions:

- Members with end moments
- Members with transverse loading
- Members with end moments and transverse loading.

The implementation of EC3 in STAAD.Pro accounts for the loading condition and the bending moment diagram through the `CMM` parameter. The first two loading conditions mentioned above and its variants can be dealt with by using the existing values of the `CMM` parameter (i.e., 1 to 6). Hence the appropriate values from this NCCI will be used for "C1" and 'C2' coefficients depending on the value of `CMM` specified. The default value of `CMM` is 1, which considers the member as a pin ended member with UDL along its span. The user will also have the option to specify specific values for C_1 and C_2 using the `C1` and `C2` parameters in the design input mode. Refer to D5.C.6 Design Parameters (on page 1502)

However, for cases with end moments and transverse loading, the NCCI provides graphs to evaluate the C1 and C2 coefficients. It does not however, provide a set of equations for these graphs. However the "end moments and transverse loading" condition cannot be currently specified in the design input. Hence this implementation will introduce two new values for the CMM parameter viz.

`CMM 7`: Member with varying end moments and uniform loading.

`CMM 8`: Member with varying end moments and central point load.

For these two conditions, the UK National Annex (nor the NCCI) does not provide equations to evaluate C1 and C2. Hence in STAAD.Pro the user will have to use the new "C1" & 'C2' parameters to input the required values for C1 & C2 to be used in calculating Mcr. For values of 7 or 8 for the CMM parameter, the program will issue a warning if C1 and C2 have not been specified.

Note: If the NA parameter has not been specified, the program obtains the values of C1 and C2 from Annex F of DD ENV version of 1993-1-1:1992.

SN030a-EN-EU – Mono-symmetrical uniform members under bending and axial compression:

This document provides a method to evaluate the elastic critical moment (Mcr) for uniform mono symmetric sections that are symmetric about the weak axis. Hence for this implementation the elastic critical moment for "Tee-Sections" will be worked out using the method in this NCCI.

Note: Though this method could also be applicable to mono-symmetric built-up sections, STAAD.Pro does not have a means to specify/identify a mono-symmetric built-up section. Hence this implementation will use this method only for Tee-Sections. In any case, the actual LTB capacity will still be worked out as per BS 5950-1 as in the current EC3 implementation.

The equation to evaluate M_{cr} for mono symmetric sections is given as :

$$M_{cr} = C_1 \frac{\pi^2 E I_s}{(k_x L)^2}\left[\sqrt{\left(\frac{k_x}{k_w}\right)^2 \frac{I_w}{I_s} + \frac{(k_x L)^2 G I_T}{\pi^2 E I_x} + (C_2 z_e - C_3 z_1)^2} - \left(C_2 z_e - C_3 z_1\right)\right]$$

The factors C_1, C_2, and C_3 are dependent on the end conditions and loading criteria. This implementation will consider C_1, C_2, and C_3as given in the tables below:

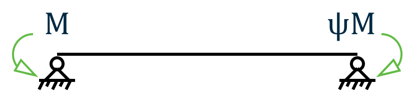

Table 139: Values of C_1 and C_2 for end moment loading (for $k_c = 1$)

Ψ	C_1	C_2
+1.00	1.00	1.00
+0.75	1.14	0.99
+0.50	1.31	0.99
+0.25	1.52	0.98
0.00	1.77	0.94
-0.25	2.05	0.85
-0.50	2.33	0.68
-0.75	2.57	0.38
-1.00	2.55	0.00

Table 140: Values of factors C_1, C_2, and C_3 for cases with transverse loading (for $k_c = 1$)

Loading and support conditions	Bending moment diagram	C_1	C_2	C_3
		1.13	0.45	0.52
		2.57	1.55	0.75

Loading and support conditions	**Bending moment diagram**	**C_1**	**C_2**	**C_3**
		1.35	0.63	1.73
		1.68	1.64	2.64

The CMM parameter (see section (i) above) specified during design input will determine the values of C1, C2 and C3. The default value of CMM is 1, which considers the member as a pin ended member with UDL along its span. This NCCI does not however consider the "end moments and transverse loading" condition. The user however can use the new C1, C2 and C3 parameters to input the required values for C1, C2 and C3 to be used in calculating Mcr. As described in section (i) above, the user must use C1, C2 and C3 parameters along with CMM values of 7 and 8.

Both the NCCI documents mentioned above assume that the member under consideration is free to rotate on plan and that there are no warping restraints for the member (k = kw = 1.0). The current implementation of EC3 in STAAD takes into account of the end conditions using the CMN parameter. A value of K = kw =1 is indicated by a value of CMN = 1.0 in the design input. Hence the above methods will be used only for members which are free to rotate on plan and which have no warping restraints, i.e., CMN = 1.0. For members with partial or end fixities (ie, CMN = 0.5 or CMN = 0.7), the proposed implementation will fall back on to the method and coefficients in DD ENV 1993-1-1:1992 – Annex F.

For all cases that are not dealt with by the National Annex (or the NCCI documents) the proposed implementation will use the method as per the DD ENV 1993-1-1:1992 code.

The term "zg" in the equation to calculate Mcr refers to the distance between the point of application of load on the cross section in relation to the shear center of the cross section. The value of 'zg' is considered positive if the load acts towards the shear center and is negative if it acts away from the shear center. By default, the program will assume that the load acts towards the shear center at a distance equal to (Depth of section/2) from the shear center. The user will be allowed to modify this value by using the new 'ZG' parameter. Specifying a value of ZG = 0 in the design input would indicate that the load acts exactly at the shear center of the section so that the term 'zg' in the equation will have a value of zero.

D5.D.5.3 Clause 6.3.2.3(1) – LTB for rolled sections or equivalent welded section

The UK-NA specifies different values for the $\lambda_{LT,0}$ and β factors to be used in equation 6.57 of BS EN 1993-1-1 for rolled and equivalent welded sections. The current implementation in STAAD.pro does not differentiate between rolled and welded sections and uses the default values in BS EN 1993-1-1 for λLT,0 and β. The values specified in the UK-NA are:

- For rolled sections and hot-rolled & cold formed hollow sections:

  $\lambda_{LT,0} = 0.4$

  $\beta = 0.75$
- For welded sections:

  $\lambda_{LT,0} = 0.2$

$\beta = 1.00$

The current implementation of STAAD.Pro uses the buckling curves based on Table 6.5 of BS EN 1993-1-1:2005. The UK-NA specifies different limits and buckling curves to be used in this clause as given below:

Table 141: Buckling curves to use with BS EN 1993-1-1:2005

Cross Section	Limits	Buckling Curve
Rolled doubly symmetric I and H sections and hot-finished hollow sections	h/b ≤ 2	b
	2.0 < h/b ≤ 3.1	c
	h/b > 3.1	d
Angles (for moments in the major principle plane)		d
All other hot-rolled sections		d
Welded, doubly symmetric sections and cold-formed hollow sections	h/b ≤ 2	c
	2.0 < h/b ≤ 3.1	d

This table again does not specify which buckling curve is to be used in case of welded doubly symmetric sections with h/b ≥ 3.1 and welded non-doubly symmetric sections. Hence for these cases the new implementation will still use the method specified in the base code as per clause 6.3.2.2(2).

D5.D.5.4 Clauses 6.3.2.2 and 6.3.2.3 — Calculation of LTB Reduction factor, χ_{LT} as per UK NA

Clauses 6.3.2.2 and 6.3.2.3 (EN 1993-1-1:2005), both give equations to evaluate the LTB reduction factor χ_{LT} to be used in eqn. 6.55 of BS EN 1993-1-1:2005.

Cl. 6.3.2.2 uses tables 6.3 and 6.4 to choose the buckling curve and the imperfection factors to be used for calculating χ_{LT}. Table 6.4 specifies the choice of buckling curves for "Rolled I Sections", "Welded I Sections" and "Any other sections". Cl 6.3.2.3 on the other hand uses tables 6.5 and 6.3 to choose the buckling curves and imperfection factors. Table 6.5 however only deals with "Rolled I Sections" and "Welded I Sections".

Cl. 6.3.2.2 states "Unless otherwise specified, see 6.3.2.3, for bending members of constant cross section the value of χ_{LT} should be determined from...". Hence in the implementation of EC3 (and the UK Annex) in STAAD.Pro, by default the program will consider clause Cl. 6.3.2.3 to evaluate χ_{LT}. For any case that is not dealt with by Cl. 6.3.2.3, the program will consider Cl. 6.3.2.2 to evaluate χ_{LT}.

Cl. 6.3.2.3 in the UK National Annex states that Table 6.5 in BS EN 1993-1-1:2005 should be replaced with the table given in the NA (See section 4.3 of this document). Hence for all cases dealt with by the table in the UK NA, this implementation will choose the buckling curves from the UK National Annex. For any case that is not dealt with by the table in the UK NA, the program will use the method given in Cl. 6.3.2.2 of BS EN 1993-1-1:2005.

Hence for the following cross sections the program will use the Table in the UK NA for choosing a buckling curve for LTB checks (when the UK NA has been specified):

- Rolled doubly symmetric I & H Sections
- Rolled doubly symmetric hollow sections (SHS, RHS, CHS)
- Angle Sections
- Any other rolled section

- Welded doubly symmetric sections with h/b < 3.1

For the following cross sections, the program will use Cl. 6.3.2.3 of BS EN 1993-1-1:2005 to evaluate χLT

- Welded I & H Sections with h/b ≥ 3.1.

For any other type of cross section that is not dealt with by the National Annex or Cl.6.3.2.3, the program will use Cl. 6.3.2.2 to evaluate χLT .

In any case the Elastic critical moment "Mcr" (used to evaluate the non dimensional slenderness) will be worked out as given in section 4.2 of this document. Since the UK National Annex uses the NCCIs mentioned in the sections above, this implementation will only consider end restraint conditions corresponding to the CMN parameter=1.0 (See section 4.2 above). For all other cases of the CMN parameter values, this implementation will use the method specified in Annex F of DD ENV 1993-1-1:1992.

Note: If a National Annex has not been specified (i.e., NA parameter in the design input = 0), the program will use Cl. 6.3.2.3 only in the case of Rolled or welded I & H Sections. For all other cases, the program will use Cl. 6.3.2.2 of BS EN 1993-1-1:2005. Also, I sections with plates will be treated as built-up sections only if the section has been explicitly specified as a built-up section (i.e., SBLT parameter = 1.0 in design input).

D5.D.5.5 Clause 6.3.2.3(2) – Modification factor, f, for LTB checks

The UK NA specifies the use of eqn. 6.58 of BS EN 1993-1-1:2005 to evaluate the modification factor, f, for the LTB reduction factor χ_{LT}. To evaluate the modification factor BS EN 1993-1-1:2005 uses a correction factor kc given by Table 6.6 in the code.

The UK-NA however, specifies that the correction factor, kc, is to be obtained as below:

$Kc = 1 / \sqrt{C1}$, where C1 is to be obtained from the NCCI documents given in section 4.2 of this document. The NCCI document SN003a-EN-EU specifies the values of C1 to be used in table 3.1 as shown below. This proposed implementation will allow for the reduction factor based on the UK-NA.

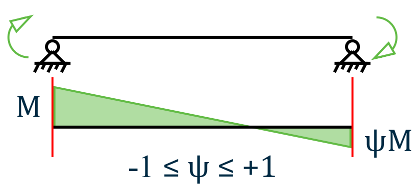

Table 142: Values of C_1 for end moment loading (for k=1)

ψ	C_1
+1,00	1,00
+0,75	1,14
+0,50	1,31
+0,25	1,52
0,00	1,77
-0,25	2,05

ψ	C_1
-0,50	2,33
-0,75	2,57

Table 143: Values of factors C_1 and C_2, and C_3 for cases with transverse loading (for $k_c = 1$)

Loading and support conditions	Bending moment diagram	C_1	C_2
		1.127	0.454
		2.578	1.554
		1.348	0.630
		1.683	1.645

These values are for an end restraint factor of k=1 (i.e., `CMN 1.0`). Hence for all other values of `CMN` (i.e., 0.7 or 0.5) this implementation will use the values of C1 from DD ENV 1993-1-1:1992 Annex F.

The program will use a default value of 1.0 for kc. However the user can also input a custom value of kc by setting the design parameter `KC` to the desired value. The user can also get the program to calculate the value of kc automatically by setting the value of the `KC` parameter in the design input to 0. This will cause the program to evaluate a value of C1 corresponding to the end conditions and the Bending moment of the member and in turn calculate kc as given in the NA. To evaluate C1, the program will use the NCCI documents mentioned in section 4.2 of this document.

D5.D.5.6 Clause 6.3.3(5) – Interaction factors kyy, kyz, kzy, and kzz

The UK-NA recommends that the method in Annex A or Annex B of BS EN 1993-1-1:2005 can be used to calculate the interaction factors for Cl. 6.3.3 checks in the case of doubly symmetric sections. The proposed implementation will hence use equations in Annex B of BS EN 1993-1-1:2005 to calculate these interaction factors for doubly symmetric sections. The current implementation of EC3 BS in STAAD.pro uses the method in Annex B.

However for non-doubly symmetric sections, the UK NA gives the option of using Annex B with some modifications as given in the NA. (Cl. NA-3.2 of the UK NA). The UK NA requires additional checks to be done to check for the maximum allowable values of λ and X to be used in equations 6.61 and 6.62 of BS EN 1993-1-1:2005.

As per the UK NA, for non-doubly symmetric sections, the slenderness about the weak axis (λy in STAAD) and the corresponding reduction factor χy should be taken as the values from the highest values of slenderness (λ) among the flexural buckling slenderness (λy), torsional slenderness (λ_T) and torsional-flexural slenderness (λ_{TF}) as given in Clauses 6.3.1.3 and 6.3.1.4 of BS EN 1993-1-1:2005. Hence for non-doubly symmetric sections the program will calculate the critical non-dimensional slenderness as:

λ_y = the maximum of either λ from Cl. 6.3.1.3 or λ_T from Cl. 6.3.1.4

$$\lambda_T = \sqrt{\frac{A f_y}{N_{cr}}}$$

Where:

N_{cr} = min (N_{CrT}, N_{crTF}).

The UK NA or EC3 does not however specify a method to evaluate NCrT or NcrTF. Hence this implementation will use the method specified in the NCCI document "SN001a-EN-EU: Critical axial load for torsional and flexural torsional buckling modes" to calculate these. See section 4.9 below for details.

Note: The UK National Annex or EC3 does not deal with angle sections in specific and hence this implementation will use the method used in the current EC3 implementation to deal with slenderness of angle sections. In the current implementation this is done as per cl 4.7.10 of BS 5950. This proposed implementation will still use the same method for single and double angle sections to evaluate the slenderness.

Clause NA 3.2 of the UK NA also requires that "Where the section is not an I Section or a hollow section and is a class1 or class 2 section, it will be treated as a class 3 section for the purposes of this clause". Hence for all Class 1 or Class 2 cross sections that are NOT I, H, SHS, RHS or CHS sections, the elastic properties will be used for the purposes of 6.3.3 checks.

D5.D.5.7 Clause 6.3.1.4 - Slenderness for torsional and torsional-flexural buckling

Equations 6.52 and 6.53 of BS EN 1993-1-1:2005 are to be used to calculate the non-dimensional slenderness λ_T, to be used for torsional and torsional-flexural buckling checks. BS EN 1993-1-1:2005 does not provide equations to calculate the elastic critical loads $N_{cr,T,F}$ and $N_{cr,T}$ (refer 6.3.14 of BS EN 1993-1-1:2005).

The NCCI document "SN001a-EN-EU: Critical axial load for torsional and flexural torsional buckling modes" provides methods to calculate the $N_{cr,TF}$ and $N_{cr,T}$ factors and therefore these methods are used to evaluate the elastic critical loads for the UK NA.

The critical axial load for torsional buckling is evaluated as:

where

i_o^2	=	$i_y^2 + i_z^2 + y_o^2 + z_o^2$
i_y and i_z	=	the radius of gyration about the Y-Y (weak axis) and Z-Z (strong axis) respectively

The critical axial load for torsional-flexural buckling is evaluated as:

$$N_{cr,TF} = \frac{i_o^2}{2\left(i_y^2 + i_z^2\right)}\left[N_{cr,y} + N_{cr,T} - \sqrt{(N_{cr,y} + N_{cr,T})^2 - 4N_{cr,y}N_{cr,T}\frac{i_y^2 + i_z^2}{i_o^2}}\right]$$

For details on these equations, refer to the NCCI document SN001a-EN-EU.

D5.D.6 French National Annex to EC3

Adds values from the French National Annex - titled *Annexe Nationale a la NF EN 1993-1-1:2005* - for use with Eurocode 3, or EN 1993-1-1:2005. The NA document makes small changes to the base document.

The following clauses are *not* implemented in STAAD.Pro:

Clause 6.3.2.4(1) B – Slenderness for flexural buckling	STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the French National Annex.
Clause 6.3.2.4(2)B – Modification factor, kfl	STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the French National Annex.

Note: Refer to the D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) for a description of these clauses. The sections below refer to the corresponding clauses in the French-NA.

The clauses/sections in EN 1993-1-1:2005 (hereafter referred to as EC-3) that have been dealt with in the French National Annex (hereafter referred to as FR-NA) and that are relevant to the proposed implementation are:

D5.D.6.1 Clause 3.2.1(1) - Material Properties

The material strengths (i.e., - steel grade strengths) to be used with NF EN 1993-1-1 are given in Table 3.1 of the code. The French National Annex however, specifies a separate table (Table 3.1 NF) for the yield and tensile strengths of steel grades. This new table replaces Table 3.1 in NF EN 1993-1-1:2005. Table 3.1 NF excludes steel grades from standards EN 10210-1 and EN 10219-1 that are given in EC-3.

STAAD.Pro uses the steel grades and values from the table given in the National Annex (i.e., - Table 3.1 NF). Table 3.1 NF is similar to table 3.1 in EC3, apart from the f_u values for S 355 and S355 W grade steel.

Table 144: Material strengths specified for use with the NF-NA

Standard and grade of steel		Nominal thickness, t, of the element (mm)			
		t 40 mm		40 mm < t ≤ 80 mm	
		f_y (N/mm^2)	f_u (N/mm^2)	f_y (N/mm^2)	f_u (N/mm^2)
EN 10025-2	S 235	235	360	215	360
	S 275	275	430	255	410
	S 355	355	490	335	470
	S 450	440	550	410	550

Standard and grade of steel		Nominal thickness, t, of the element (mm)			
		t 40 mm		40 mm < t ≤ 80 mm	
		f_y (N/mm^2)	f_u (N/mm^2)	f_y (N/mm^2)	f_u (N/mm^2)
EN 10025-3	S 275 N/NL	275	390	255	370
	S 355 N/NL	355	490	335	470
	S 420 N/NL	420	520	390	520
	S 460 N/NL	460	540	430	540
EN 10025-4	S 275 M/ML	275	370	255	360
	S 355 M/ML	355	470	335	450
	S 420 M/ML	420	520	390	500
	S 460 M/ML	460	540	430	530
EN 10025-5	S 235 W	235	360	215	340
	S 355 W	355	490	335	490
EN 10025-6	S 460 Q/QL/QL 1	460	570	440	550

If you specify a steel grade that is not given in the Annex Table 3.1 (NF) but is present in Table 3.1 of EN 1993-1-1:2005, the program uses the values from Table 3.1 of EN 1993-1-1:2005. The appropriate yield strength (f_y) used is shown in the design output file.

D5.D.6.2 Clause 6.1(1) – General

EN 1993-1-1:2005 specifies the use of the partial safety factors to be used in for design as given in Cl. 6.1 of the code. These factors are γ_{M0}, γ_{M1}, and γ_{M2}. EN 1993 provides default values for these factors. However, any National Annex is allowed to override these default values.

The partial safety factors will use the following values for the French National Annex:

- Resistance of cross-sections, γ_{M0} = 1.0
- Resistance of members to instability, γ_{M1} = 1.0
- Resistance of cross sections to tension, γ_{M2} = 1.25

The design function in STAAD.Pro sets these values as the default values for the NF-NA (`NA 4` is specified).

Note: You can change these values through the `GM0`, `GM1`, & `GM2` design parameters. Refer to D5.C.6 Design Parameters (on page 1502)

Note: If any of these parameters are specified as `0`, STAAD.Pro will ignore the user specified value (i.e., 0) and use the default values as given above.

> **Caution:** The GB1 parameter that is being used for compression checks in builds preceding this release (STAAD.Pro 2007 build 06) has been removed as this parameter is no longer required in EN 1993-1-1:2005. Hence, any legacy files that use GB1 parameter will indicate an error message and the user will need to substitute GB1 with GM1 in line with EN 1993-1-1:2005.

D5.D.6.3 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks

The French NA recommends the use of Table 6.3 and 6.4 of NF EN 1993-1-1:2005 to calculate the imperfection factors for Lateral Torsional Buckling (LTB) checks.

The calculation of the LTB reduction factor χ_{LT}, requires the calculation of the "Elastic Critical Buckling Moment", M_{cr}. The French NA gives a method to evaluate M_{cr} in its "Annex MCR". This implementation will make use of this method to evaluate Mcr. Annex MCR however deals with the calculation of Mcr for doubly symmetric sections. Hence this implementation will use this method only for doubly symmetric sections. For mono symmetric sections that are symmetric about the minor axis (i.e Tee sections) this implementation will use the method from the NCCI document SN030a-EN-EU as given in the section below. For any other type of section that is not dealt with by the Annex, this implementation will use the method and tables given in Annex F of DD ENV 1993-1-1:1992.

Annex MCR

This document provides a method to calculate M_{cr} specifically for doubly symmetric sections only. Hence only doubly symmetric sections will be considered for this method in this implementation.

The equation to evaluate M_{cr} is given as:

$$M_{cr} = C_1 \frac{\pi^2 E I_s}{(kL)^2}\left[\sqrt{\left(\frac{k}{k_w}\right)^2 \frac{I_w}{I_s} + \frac{(kL)^2 G I_t}{\pi^2 E I_s} + (C_2 z_s)^2} - C_2 z_s\right]$$

C_1 and C_2 are factors that depend on the end conditions and the loading conditions. The NCCI provides values for C_1 and C_2 for the different cases as given in Table1 and Table 2 of the Annex. Table 1 deals with the condition of a simply supported member with end moments and the value of C_1 is determined by the end moment ratio (Refer to the NA for details). Clause 3.2 of the National Annex however gives a formula to evaluate C_1 as:

$$C_1 = \frac{1}{\sqrt{0.325 + 0.423\psi + 0.252\psi^2}}$$

This formula however does not match the values given in Table 1 of the NA. Hence this implementation will use the values of C1 from Table 1 if the end moment ration (ψ) is exactly equal to the values of ψ in the table. For all other cases this implementation will calculate the value of C1 from equation (6) in the Annex.

The value of C2 will be determined from Table 2 of the Annex based on the loading and end conditions (i.e the CMM parameter in STAAD.Pro).

You also have the option to specify specific values for C_1 and C_2 using the C1 and C2 parameters in the design input mode. Refer to D5.C.6 Design Parameters (on page 1502)

The French NA considers three separate loading conditions:

- Members with end moments
- Members with transverse loading
- Members with end moments and transverse loading: use CMM 7 or CMM 8 for this condition.

The load to moment ratio (μ) will then be used in the calculations will then be used to calculate C1 and C2 as given in section 3.5 of Annex MCR (See Annex MCR in the NA for details).

The parameter MU may be specified when using CMM = 7 or 8 to specify the load to moment ratio (µ) to be used in the calculations. For the French National Annex if CMM = 7 or 8 is been specified, you must also either specify a value for MU or values for the C1 and C2 parameters directly.

SN030a-EN-EU – Mono-symmetrical uniform members under bending and axial compression:

This document provides a method to evaluate the elastic critical moment (Mcr) for uniform mono symmetric sections that are symmetric about the weak axis. Hence for this implementation the elastic critical moment for “Tee-Sections” will be worked out using the method in this NCCI.

Note: Though this method could also be applicable to mono-symmetric built-up sections, STAAD.Pro currently does not have a means to specify/identify a mono-symmetric built-up section. Hence this implementation will use this method only for Tee-Sections.

The equation to evaluate M_{cr} for mono symmetric sections is given as:

$$M_{cr} = C_1 \frac{\pi^2 E I_s}{(k_x L)^2}\left[\sqrt{\left(\frac{k_x}{k_w}\right)^2 \frac{I_w}{I_s} + \frac{(k_x L)^2 G I_T}{\pi^2 E I_x} + (C_2 z_e - C_3 z_1)^2} - \left(C_2 z_e - C_3 z_1\right)\right]$$

The factors C_1, C_2, and $C_3$are dependent on the end conditions and loading criteria. This implementation will consider C_1, C_2, and C_3as given in the tables below:

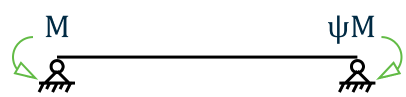

Table 145: Values of C_1 and C_2 for end moment loading (for $k_c = 1$)

Ψ	C_1	C_2
+1.00	1.00	1.00
+0.75	1.14	0.99
+0.50	1.31	0.99
+0.25	1.52	0.98
0.00	1.77	0.94
-0.25	2.05	0.85
-0.50	2.33	0.68
-0.75	2.57	0.37
-1.00	2.55	0.00

Table 146: Values of factors C_1, C_2, and C_3 for cases with transverse loading (for $k_c = 1$)

Loading and support conditions	Bending moment diagram	C_1	C_2	C_3
		1.13	0.45	0.52
		2.57	1.55	0.75
		1.35	0.63	1.73
		1.68	1.64	2.64

The `CMM` parameter specified during design input will determine the values of C1, C2 and C3. The default value of CMM is 0, which considers the member as a pin ended member with UDL along its span. This NCCI does not however consider the "end moments and transverse loading" condition. The user however can use the new "C1", 'C2' and 'C3' parameters to input the required values for C1, C2 and C3 to be used in calculating Mcr.

Note: If "MU" as well as C1, C2 and C3 have been specified, the program will ignore MU and use the user input values of C1, C2 and C3. The current implementation of EC3 in STAAD.Pro obtains these values from Annex F of DD ENV version of 1993-1-1:1992.

Also, the NCCI document and Annex MCR of the FR-NA assume that the member under consideration is free to rotate on plan and that there are no warping restraints for the member(k = kw=1 .i.e., CMN parameter =1.0). Hence the above methods will be used only for members which are free to rotate on plan and which have no warping restraints. For members with partial or end fixities (ie, CMN = 0.5 or CMN = 0.7), this implementation will fall back on to the method and coefficients in DD ENV 1993-1-1:1992.

For all cases that are not dealt with by the National Annex (or the NCCI documents) this implementation will use the method as per the DD ENV 1993-1-1:1992 code.

The term "zg" in the equation to calculate Mcr refers to the distance between the point of application of load on the cross section in relation to the shear center of the cross section. The value of 'zg' is considered positive, if the load acts towards the shear center and is negative if it acts away from the shear center. By default, the program will assume that the load acts towards the shear center at a distance equal to (Depth of section/2) from the shear center. The use will be allowed to modify this value by using the `ZG` parameter. Specifying a value of ZG = 0 in the design input would indicate that the load acts exactly at the shear center of the section so that the term "zg" in the equation will have a value of zero.

Note: There is a separate method specified in the NCCI document "SN006a-EN-EU" to calculate Mcr for cantilever beams. Again this document does not give any specific formulae to evaluate the coefficients. Hence, this has not been implemented in STAAD.Pro.

D5.D.6.4 Clause 6.3.2.3(1) – LTB for rolled sections or equivalent welded section

The FR-NA provides equations to evaluate the $\lambda_{LT,0}$ and α_{LT} factors given in clause 6.3.2.3

For rolled doubly symmetric sections use:

$$\bar{\lambda}_{LT,0} = 0.2 + 0.1\frac{b}{h}$$

$$\alpha_{LT} = 0.4 - 0.2\frac{b}{h}\bar{\lambda}^2_{LT} \geq 0$$

Note: Since EN 1993-1-1:2005 limits the value of $\lambda_{LT,0}$ to 0.4, STAAD.Pro limits $\lambda_{LT,0}$ to a maximum value of 0.4.

For welded doubly symmetric sections use:

$$\bar{\lambda}_{LT,0} = 0.3\frac{b}{h}$$

$$\alpha_{LT} = 0.5 - 0.25\frac{b}{h}\bar{\lambda}^2_{LT} \geq 0$$

For other sections:

$$\lambda_{LT,0} = 0.2$$

$$\alpha_{LT} = 0.76$$

And for all sections, β = 1.0

These equations and factors are then applied to equation 6.57 of NF EN 1993-1-1 to evaluate the Lateral Torsional Buckling reduction factor χ_{LT}.

D5.D.6.5 Clause 6.3.2.3(2) – Modification factor, f, for LTB checks

The French NA specifies that the modification factor is to be obtained as per the default method given in EC-3. Hence this implementation will use the existing functionality to evaluate the correction factor kc to be used in the modification factor f.

The program uses a default value of 1.0 for kc. However the user can also input a custom value of kc by setting the design parameter KC to the desired value. You may instruct the program to calculate the value of kc automatically by setting the value of the KC parameter in the design input to `0`. This will cause the program to evaluate kc from Table 6.6 of NF EN 1993-1-1:2005. This will correspond to the end conditions and the bending moment of the member (i.e., the value of `CMM` parameter specified).

For `CMM = 7`, the program will choose the value of kc to be either 0.90 or 0.91 based on the end moment ratio.

For `CMM = 8`, the program will choose the value of kc to be either 0.77 or 0.82 based on the end moment ratio.

An additional check will also be performed as given below:

$$\chi_{LT,\mathrm{mod}} \leq \frac{1}{\bar{\lambda}^2_{LT}}$$

The French Annex specifies that the modification factor is applicable only to members that are free to rotate on plan (i.e., `CMN 1.0`). Hence for all other values of `CMN`, this implementation will ignore “f” and hence will use $\chi_{LT,mod} = \chi_{LT}$.

D5.D.6.6 Clause 6.3.3(5) – Interaction factors kyy, kyz, kzy, and kzz

The French NA recommends the use of equations in Annex A of NF EN 1993-1-1:2005 to calculate these interaction factors. STAAD.pro uses the method in Annex B for design per EC3 (without National Annex). Therefore, the method in Annex A has been added into the program.

Note: The NA mentions that this method can be extended to singly symmetric I-Sections (symmetric about the minor axis) if the elastic properties are used instead of the plastic properties. However, since STAAD does not have a provision to specify such sections, this case will *not* be considered for this implementation.

The NA also mentions that torsional flexural buckling needs to be taken into account in case of mono symmetric sections. This is taken into account based on the method given in the NCCI document “SN001a-EN-EU: Critical axial load for torsional and flexural torsional buckling modes”. Refer to D5.D.6.7 Clause 6.3.1.4 - Slenderness for torsional and torsional-flexural buckling (on page 1543)

The NA also recommends a lower limit as given below for the term $C_{mi,0}$ in Table A.2 of Annex A:

$$C_{mi,0} \geq 1 - \frac{N_{Ed}}{N_{cr,i}}$$

D5.D.6.7 Clause 6.3.1.4 - Slenderness for torsional and torsional-flexural buckling

Equations 6.52 and 6.53 of NF EN 1993-1-1:2005 are to be used to calculate the non-dimensional slenderness λ_T, to be used for torsional and torsional-flexural buckling checks. NF EN 1993-1-1:2005 does not provide equations to calculate the elastic critical loads $N_{cr,T,F}$ and $N_{cr,T}$ (refer 6.3.14 of NF EN 1993-1-1:2005).

The NCCI document “SN001a-EN-EU: Critical axial load for torsional and flexural torsional buckling modes” provides methods to calculate the $N_{cr,TF}$ and $N_{cr,T}$ factors and therefore these methods are used to evaluate the elastic critical loads for the French NA.

The critical axial load for torsional buckling is evaluated as:

where

i_o^2	=	$i_y^2 + i_z^2 + y_o^2 + z_o^2$
i_y and i_z	=	the radius of gyration about the Y-Y (weak axis) and Z-Z (strong axis) respectively

The critical axial load for torsional-flexural buckling is evaluated as:

$$N_{cr,TF} = \frac{i_o^2}{2\left(i_y^2 + i_z^2\right)}\left[N_{cr,y} + N_{cr,T} - \sqrt{(N_{cr,y} + N_{cr,T})^2 - 4N_{cr,y}N_{cr,T}\frac{i_y^2 + i_z^2}{i_o^2}}\right]$$

For details on these equations, refer to the NCCI document SN001a-EN-EU.

D5.D.7 Finnish National Annex to EC3

Adds values from the Finnish National Annex - titled *National Annex to Standard SFS-EN 1993-1-1* - for use with Eurocode 3, or EN 1993-1-1:2005. The NA document makes small changes to the base document.

The following clauses are *not* implemented in STAAD.Pro:

Clause 6.3.2.4(1) B – Slenderness for flexural buckling	STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the Finnish National Annex.
Clause 6.3.2.4(2)B – Modification factor "kfl"	STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the Finnish National Annex.

Note: Refer to the D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) for a description of these clauses. The sections below refer to the corresponding clauses in the Finnish-NA.

The clauses/sections in EN 1993-1-1:2005 (hereafter referred to as EC-3) that have been dealt with in the Finnish National Annex (hereafter referred to as SFS-NA) and that are relevant to the proposed implementation are:

D5.D.7.1 Clause 3.2.1(1) - Material Properties

The material strengths (i.e., steel grade strengths) to be used with SFS-EN 1993-1-1 are given in Table 3.1 of the code. These steel grade values are specified using the `SGR` parameter (Refer to D5.C.6 Design Parameters (on page 1502)).

The Finnish National Annex states in Cl. 3.1(2) that, apart from the steel grades specified in Table 3.1 of SFS EN 1993-1-1, the following steel grades can also be used:

- Steel grades S315MC, S355MC, S420MC and S460MC according to SFS-EN 10149-2
- Steel grades S260NC, S315NC, S355NC and S420NC according to SFS-EN 10149-3

These grades of steel can be specified by using the `PY` (Yield Strength) and `FU` (Ultimate Strength) parameters in STAAD.Pro. Set these parameters to the respective values as given in SFS-EN 10149-2/3 for the steel grades specified above. The choice of the buckling curve to be used is based on the value of the `SGR` parameter specified. The output will include the appropriate yield strength used for design.

D5.D.7.2 Clause 6.1(1) – General

EN 1993-1-1:2005 specifies the use of the partial safety factors to be used in for design as given in Cl. 6.1 of the code. These factors are γ_{M0}, γ_{M1}, and γ_{M2}. EN 1993 provides default values for these factors. However, any National Annex is allowed to override these default values.

The partial safety factors will use the following values for the Finnish National Annex:

- Resistance of cross-sections, γ_{M0} = 1.0
- Resistance of members to instability, γ_{M1} = 1.0
- Resistance of cross sections to tension, γ_{M2} = 1.25

The design function in STAAD.Pro sets these values as the default values for the SFS-NA (`NA 5` is specified).

Note: You can change these values through the `GM0`, `GM1`, & `GM2` design parameters. Refer to D5.C.6 Design Parameters (on page 1502)

Note: If any of these parameters are specified as `0`, STAAD.Pro will ignore the user specified value (i.e., 0) and use the default values as given above.

Caution: The `GB1` parameter that is being used for compression checks in builds preceding this release (STAAD.Pro 2007 build 06) has been removed as this parameter is no longer required in EN 1993-1-1:2005.

Hence, any legacy files that use `GB1` parameter will indicate an error message and the user will need to substitute `GB1` with `GM1` in line with EN 1993-1-1:2005.

D5.D.7.3 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks

The Finnish NA recommends the use of Table 6.3 and 6.4 of SFS EN 1993-1-1:2005 to calculate the imperfection factors for Lateral Torsional Buckling (LTB) checks.

The calculation of the LTB reduction factor χ_{LT}, requires the calculation of the "Elastic Critical Buckling Moment", M_{cr}. The Finnish National Annex does not specify a particular method to calculate M_{cr}. Hence the calculation of M_{cr} has been based on the following NCCI documents:

SN003a-EN-EU – Elastic critical moment for Lateral torsional Buckling:

This document provides a method to calculate M_{cr} specifically for doubly symmetric sections only. Hence only doubly symmetric sections will be considered for this method. The equation to evaluate M_{cr} is given in the NCCI as:

$$M_{cr} = C_1 \frac{\pi^2 E I_s}{(kL)^2} \left[\sqrt{\left(\frac{k}{k_w}\right)^2 \frac{I_w}{I_s} + \frac{(kL)^2 G I_t}{\pi^2 E I_s} + (C_2 z_s)^2} - C_2 z_s \right]$$

C_1 and C_2 are factors that depend on the end conditions and the loading conditions of the member. The NCCI provides values for C_1 and C_2 for the different cases as given in the tables below:

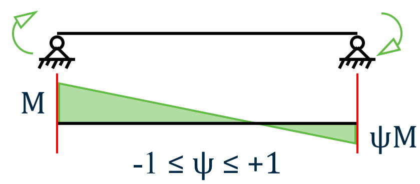

Table 147: Values of C_1 for end moment loading (for k=1)

ψ	C_1
+1,00	1,00
+0,75	1,14
+0,50	1,31
+0,25	1,52
0,00	1,77
-0,25	2,05
-0,50	2,33
-0,75	2,57

This NCCI considers three separate loading conditions:

- Members with end moments
- Members with transverse loading
- Members with end moments and transverse loading.

STAAD.Pro accounts for the loading condition and the bending moment diagram through the `CMM` parameter.

SN030a-EN-EU – Mono-symmetrical uniform members under bending and axial compression:

This document provides a method to evaluate the elastic critical moment (M_{cr}) for uniform mono symmetric sections that are symmetric about the weak axis. Hence, the elastic critical moment for "Tee-Sections" will be worked out using the method in this NCCI.

Note: Though this method could also be applicable to mono-symmetric built-up sections, STAAD.Pro currently does not have a means to specify/identify a mono-symmetric built-up section. Hence this implementation will use this method only for Tee-Sections.

The equation to evaluate M_{cr} for mono symmetric sections is given as :

$$M_{cr} = C_1 \frac{\pi^2 E I_s}{(k_x L)^2} \left[\sqrt{\left(\frac{k_x}{k_w}\right)^2 \frac{I_w}{I_s} + \frac{(k_x L)^2 G I_T}{\pi^2 E I_x} + (C_2 z_e - C_3 z_1)^2} - \left(C_2 z_e - C_3 z_1\right) \right]$$

The factors C_1, C_2, and C_3 are dependent on the end conditions and loading criteria. This implementation will consider C_1, C_2, and C_3 as given in the tables below:

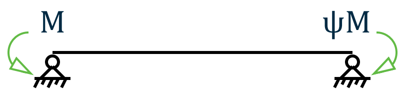

Table 148: Values of C_1 and C_2 for end moment loading (for $k_c = 1$)

Ψ	C_1	C_2
+1.00	1.00	1.00
+0.75	1.14	0.99
+0.50	1.31	0.99
+0.25	1.52	0.98
0.00	1.77	0.94
-0.25	2.05	0.85
-0.50	2.33	0.68
-0.75	2.57	0.37
-1.00	2.55	0.00

Table 149: Values of factors C_1, C_2, and C_3 for cases with transverse loading (for $k_c = 1$)

Loading and support conditions	Bending moment diagram	C_1	C_2	C_3
		1.13	0.45	0.52
		2.57	1.55	0.75
		1.35	0.63	1.73
		1.68	1.64	2.64

The CMM parameter specified during design input will determine the values of C_1, C_2, and C_3. The default value of CMM is 0, which considers the member as a pin ended member with UDL along its span. This NCCI does not however consider the "end moments and transverse loading" condition. You can use the C1, C2, and C3 parameters to input the required values for C_1, C_2, and C_3 to be used in calculating M_{cr}.

Note: If MU as well as C1, C2, and C3 have been specified, the program will ignore MU and use the user input values of C1, C2, and C3. STAAD.Pro obtains these values from Annex F of DD ENV version of 1993-1-1:1992.

Both the NCCI documents mentioned above assume that the member under consideration is free to rotate on plan and that there are no warping restraints for the member ($k = k_w = 1.0$). STAAD.Pro takes into account of the end conditions using the CMN parameter for EC3. A value of $K = k_w = 1$ is indicated by a value of CMN = 1.0 in the design input. Hence the above methods will be used only for members which are free to rotate on plan and which have no warping restraints (i.e., CMN = 1.0). For members with partial or end fixities (i.e., CMN = 0.5 or CMN = 0.7), this implementation will fall back on to the method and coefficients in DD ENV 1993-1-1:1992 – Annex F.

For all cases that are not dealt with by the National Annex (or the NCCI documents) this implementation will use the method as per the DD ENV 1993-1-1:1992 code.

For the term z_j, please refer to Annex E of NBN NA 2018.

The term z_g in the equation to calculate M_{cr} refers to the distance between the point of application of load on the cross section in relation to the shear center of the cross section. The value of z_g is considered positive, if the load acts towards the shear center and is negative if it acts away from the shear center. By default, the program will assume that the load acts towards the shear center at a distance equal to (Depth of section/2) from the shear center. The use will be allowed to modify this value by using the ZG parameter. Specifying a value of ZG = 0 in the design input would indicate that the load acts exactly at the shear center of the section so that the term z_g in the equation will have a value of zero.

Note: The program does not consider the case of cantilevers.

D5.D.7.4 Clause 6.3.2.3(1) – LTB for rolled sections or equivalent welded section

The Finnish-NA provides the values for the terms $\lambda_{LT,0}$ and β factors given in clause 6.3.2.3(1) as follows:

For rolled doubly symmetric sections and hollow sections, use:

$\lambda_{LT,0}$ =0.4 and β = 0.75

For welded doubly symmetric sections and hollow sections use:

$\lambda_{LT,0}$ = 0.2 and β = 1.0

The Finnish NA specifies the following limits for choosing the buckling curves:

Table 150: Selection of lateral torsional buckling curve for cross sections using equation (6.57)

Cross-section (constant cross-section)	Limits	Buckling Curve
Rolled double symmetric I- and H-sections and hot finished hollow sections.	h/b ≤ 2 2 < h/b <3.1	b c
Welded double symmetric I-section and H- sections and cold-formed hollow sections	h/b ≤ 2 2 < h/b < 3.1	c d

The NA says that for all other cases the rules given in Cl 6.3.2.2 should be used. Hence even for rolled or welded doubly symmetric sections with h/b ratio ≥ 3.1, this implementation will resort to checks as per clause 6.3.2.2.

These equations and factors are then applied to equation 6.57 of SFS-EN 1993-1-1 to evaluate the Lateral Torsional Buckling reduction factor χ_{LT}.

D5.D.7.5 Clauses 6.3.2.2 and 6.3.2.3 — Calculation of LTB Reduction factor, χ_{LT} as per Finnish NA

Clauses 6.3.2.2 and 6.3.2.3 (EN 1993-1-1:2005), both give equations to evaluate the LTB reduction factor χ_{LT} to be used in eqn. 6.55 of SFS EN 1993-1-1:2005.

Cl. 6.3.2.2 uses tables 6.3 and 6.4 to choose the buckling curve and the imperfection factors to be used for calculating χ_{LT}. Table 6.4 specifies the choice of buckling curves for "Rolled I Sections", "Welded I Sections" and "Any other sections". Cl 6.3.2.3 on the other hand uses tables 6.5 and 6.3 to choose the buckling curves and imperfection factors. Table 6.5 however only deals with "Rolled I Sections" and "Welded I Sections".

Cl. 6.3.2.2 states "Unless otherwise specified, see 6.3.2.3, for bending members of constant cross section the value of χ_{LT} should be determined from...". Hence in the implementation of EC3 (and the Finnish Annex) in STAAD.Pro: by default the program will consider clause Cl. 6.3.2.3 to evaluate χ_{LT}. For any case that is not dealt with by Cl. 6.3.2.3, the program will consider Cl. 6.3.2.2 to evaluate χ_{LT}.

Cl. 6.3.2.3 in the Finnish National Annex gives equations to evaluate the imperfection factors to be used for various section types (Refer to D5.D.7.3 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB

checks (on page 1545)). Hence for all cases dealt with by the equations in the Finnish NA, this implementation will use Cl 6.3.2.3 to evaluate χ_{LT}.

For any other type of cross section that is not dealt with by the National Annex or Cl.6.3.2.3, the program will use Cl. 6.3.2.2 to evaluate χ_{LT} .

In any case, the elastic critical moment, Mcr, (used to evaluate the non dimensional slenderness) will be evaluated as previously given. Since this implementation uses the NCCIs mentioned in the sections above, only end restraint conditions corresponding to the `CMN` parameter=1.0 (Refer to D5.D.7.3 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks (on page 1545)) will be considered. For all other cases of the `CMN` parameter values, this implementation will use the method specified in Annex F of DD ENV 1993-1-1:1992.

Note: If a National Annex has not been specified (i.e., `NA` parameter in the design input = 0), the program will use Cl. 6.3.2.3 only in the case of Rolled or welded I & H Sections. For all other cases, the program will use Cl. 6.3.2.2 of BS EN 1993-1-1:2005. Also, I sections with plates will be treated as built-up sections only if the section has been explicitly specified as a built-up section (i.e., `SBLT` parameter = 1.0 in design input).

D5.D.7.6 Clause 6.3.2.3(2) – Modification factor, f, for LTB checks

STAAD.Pro uses the value of the modification factor f = 1.0 as given in the Finnish NA.

D5.D.7.7 Clause 6.3.3(5) – Interaction factors kyy, kyz, kzy, and kzz

The Finnish NA recommends the use of equations in Annex A or Annex B of SFS-EN 1993-1-1 to calculate these interaction factors. STAAD.Pro uses the method in Annex B by default. This implementation of the Finnish NA will also use Annex B for Cl.6.3.3 checks.

D5.D.7.8 Clause 6.3.1.4 - Slenderness for torsional and torsional-flexural buckling

Equations 6.52 and 6.53 of SFS EN 1993-1-1:2005 are to be used to calculate the non-dimensional slenderness λ_T, to be used for torsional and torsional-flexural buckling checks. SFS EN 1993-1-1:2005 does not provide equations to calculate the elastic critical loads $N_{cr,T,F}$ and $N_{cr,T}$ (refer 6.3.14 of SFS EN 1993-1-1:2005).

The NCCI document “SN001a-EN-EU: Critical axial load for torsional and flexural torsional buckling modes” provides methods to calculate the $N_{cr,TF}$ and $N_{cr,T}$ factors and therefore these methods are used to evaluate the elastic critical loads for the Finnish NA.

The critical axial load for torsional buckling is evaluated as:

where

i_o^2	=	$i_y^2 + i_z^2 + y_o^2 + z_o^2$
i_y and i_z	=	the radius of gyration about the Y-Y (weak axis) and Z-Z (strong axis) respectively

The critical axial load for torsional-flexural buckling is evaluated as:

$$N_{cr,TF} = \frac{i_o^2}{2\left(i_y^2 + i_z^2\right)}\left[N_{cr,y} + N_{cr,T} - \sqrt{(N_{cr,y} + N_{cr,T})^2 - 4N_{cr,y}N_{cr,T}\frac{i_y^2 + i_z^2}{i_o^2}}\right]$$

For details on these equations, refer to the NCCI document SN001a-EN-EU.

D5.D.8 Polish National Annex to EC3

Adds values from the Polish National Annex - titled *National Annex to Standard NA FOR PN-EN 1993-1-1:2006* - for use with Eurocode 3, or EN 1993-1-1:2005. The NA document makes small changes to the base document.

The following clauses are *not* implemented in STAAD.Pro:

Clause 6.3.2.4(1) B – Slenderness for flexural buckling	STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the Polish National Annex.
Clause 6.3.2.4(2)B – Modification factor "kfl"	STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the Polish National Annex.

Note: Refer to the D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) for a description of these clauses. The sections below refer to the corresponding clauses in the Polish-NA.

The clauses/sections in EN 1993-1-1:2005 (hereafter referred to as EC-3) that have been dealt with in the Polish National Annex, NA for PN-EN 1993-1-1:2006, (hereafter referred to as PN-NA) and that are relevant to the proposed implementation are:

Related Links

- *V. EC3 Polish NA - I Section with UDL* (on page 4178)

D5.D.8.1 Clause 3.2.1(1) - Material Properties

The material strengths (i.e., steel grade strengths) to be used with PN-EN 1993-1-1 are given in Table 3.1 of the code. The Polish National Annex states in Cl. 3.1(2) that the steel grades to be used will be based on Table 3.1 of PN EN 1993-1-1. These steel grade values are specified using the `SGR` parameter (Refer to D5.C.6 Design Parameters (on page 1502)).

D5.D.8.2 Clause 6.1(1) – General

EN 1993-1-1:2005 specifies the use of the partial safety factors to be used in for design as given in Cl. 6.1 of the code. These factors are γ_{M0}, γ_{M1}, and γ_{M2}. EN 1993 provides default values for these factors. However, any National Annex is allowed to override these default values.

The partial safety factors will use the following values for the Polish National Annex:

- Resistance of cross-sections, γ_{M0} = 1.0
- Resistance of members to instability, γ_{M1} = 1.0
- Resistance of cross sections to tension, γ_{M2} = minimum of 1.1 or 0.9 x f_u/f_y

where

f_u	=	the ultimate steel strength
f_y	=	the yield strength of steel

The design function in STAAD.Pro sets these values as the default values for the PN-NA (`NA 6` is specified).

Note: You can change these values through the `GM0`, `GM1`, & `GM2` design parameters. Refer to D5.C.6 Design Parameters (on page 1502)

Note: If any of these parameters are specified as `0`, STAAD.Pro will ignore the user specified value (i.e., 0) and use the default values as given above.

D5.D.8.3 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks

The Polish NA recommends the use of Table 6.3 and 6.4 of PN EN 1993-1-1:2005 to calculate the imperfection factors for Lateral Torsional Buckling (LTB) checks.

The calculation of the LTB reduction factor χ_{LT}, requires the calculation of the “Elastic Critical Buckling Moment”, M_{cr}. The Polish National Annex does not specify a particular method to calculate M_{cr}. Hence the calculation of M_{cr} has been based on the following NCCI documents:

SN003a-EN-EU – Elastic critical moment for Lateral torsional Buckling

This document provides a method to calculate M_{cr} specifically for doubly symmetric sections only. Hence only doubly symmetric sections will be considered for this method. The equation to evaluate M_{cr} is given in the NCCI as:

$$M_{cr} = C_1 \frac{\pi^2 E I_s}{(kL)^2}\left[\sqrt{\left(\frac{k}{k_w}\right)^2 \frac{I_w}{I_s} + \frac{(kL)^2 G I_t}{\pi^2 E I_s} + (C_2 z_s)^2} - C_2 z_s\right]$$

C_1 and C_2 are factors that depend on the end conditions and the loading conditions of the member. The NCCI provides values for C_1 and C_2 for the different cases as given in the tables below:

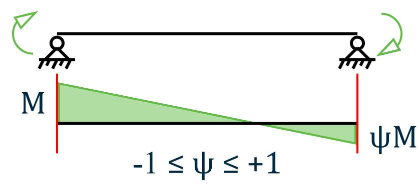

Table 151: Values of C_1 for end moment loading (for k=1)

ψ	C_1
+1,00	1,00
+0,75	1,14
+0,50	1,31
+0,25	1,52
0,00	1,77
-0,25	2,05
-0,50	2,33
-0,75	2,57

This NCCI considers three separate loading conditions:

- Members with end moments
- Members with transverse loading
- Members with end moments and transverse loading.

STAAD.Pro accounts for the loading condition and the bending moment diagram through the `CMM` parameter.

SN030a-EN-EU – Mono-symmetrical uniform members under bending and axial compression

This document provides a method to evaluate the elastic critical moment (M_{cr}) for uniform mono symmetric sections that are symmetric about the weak axis. Hence, the elastic critical moment for “Tee-Sections” will be worked out using the method in this NCCI.

Note: Though this method could also be applicable to mono-symmetric built-up sections, STAAD.Pro currently does not have a means to specify/identify a mono-symmetric built-up section. Hence this implementation will use this method only for Tee-Sections.

The equation to evaluate M_{cr} for mono symmetric sections is given as :

$$M_{cr} = C_1 \frac{\pi^2 E I_s}{(k_x L)^2}\left[\sqrt{\left(\frac{k_x}{k_w}\right)^2 \frac{I_w}{I_s} + \frac{(k_x L)^2 G I_T}{\pi^2 E I_x} + (C_2 z_e - C_3 z_1)^2} - \left(C_2 z_e - C_3 z_1\right)\right]$$

The factors C_1, C_2, and C_3 are dependent on the end conditions and loading criteria. This implementation will consider C_1, C_2, and C_3 as given in the tables below:

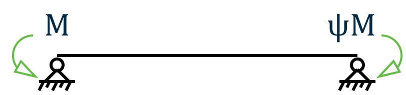

Table 152: Values of C_1 and C_2 for end moment loading (for $k_c = 1$)

Ψ	C_1	C_2
+1.00	1.00	1.00
+0.75	1.14	0.99
+0.50	1.31	0.99
+0.25	1.52	0.98
0.00	1.77	0.94
-0.25	2.05	0.85
-0.50	2.33	0.68
-0.75	2.57	0.38
-1.00	2.55	0.00

Table 153: Values of factors C_1, C_2, and C_3 for cases with transverse loading (for $k_c = 1$)

Loading and support conditions	Bending moment diagram	C_1	C_2	C_3
		1.13	0.45	0.52
		2.57	1.55	0.75
		1.35	0.63	1.73
		1.68	1.64	2.64

The CMM parameter specified during design input will determine the values of C_1, C_2, and C_3. The default value of CMM is 0, which considers the member as a pin ended member with UDL along its span. This NCCI does not however consider the “end moments and transverse loading” condition. You can use the C1, C2, and C3 parameters to input the required values for C_1, C_2, and C_3 to be used in calculating M_{cr}.

Note: If MU as well as C1, C2, and C3 have been specified, the program will ignore MU and use the user input values of C1, C2, and C3. STAAD.Pro obtains these values from Annex F of DD ENV version of 1993-1-1:1992.

Both the NCCI documents mentioned above assume that the member under consideration is free to rotate on plan and that there are no warping restraints for the member (k = kw = 1.0). STAAD.Pro takes into account of the end conditions using the CMN parameter for EC3. A value of K = kw =1 is indicated by a value of CMN = 1.0 in the design input. Hence the above methods will be used only for members which are free to rotate on plan and which have no warping restraints (i.e., CMN = 1.0). Other values of CMN (i.e., CMN = 0.5 or CMN = 0.7) are *not* applicable to the Polish NA.

For all cases that are not dealt with by the National Annex (or the NCCI documents) this implementation will use the method as per the DD ENV 1993-1-1:1992 code.

The term “zg” in the equation to calculate Mcr refers to the distance between the point of application of load on the cross section in relation to the shear center of the cross section. The value of ‘zg’ is considered positive, if the load acts towards the shear center and is negative if it acts away from the shear center. By default, the program will assume that the load acts towards the shear center at a distance equal to (Depth of section/2) from the shear center. The use will be allowed to modify this value by using the ZG parameter. Specifying a value of ZG = 0 in the design input would indicate that the load acts exactly at the shear center of the section so that the term “zg” in the equation will have a value of zero.

Note: There is a separate method specified in the NCCI document "SN006a-EN-EU" to calculate Mcr for cantilever beams. Again this document does not give any specific formulae to evaluate the coefficients. Hence, this has not been implemented in STAAD.Pro.

D5.D.8.4 Clause 6.3.2.3(1) – LTB for rolled sections or equivalent welded section

The Polish-NA provides the values for the terms $\lambda_{LT,0}$ and β factors given in clause 6.3.2.3(1) as follows:

For all sections, use:

$\lambda_{LT,0}$ =0.4 and β = 0.75

The Polish NA specifies the use of uses table 6.5 to work out the buckling curves for use in Cl. 6.3.2.3. Hence table 6.5 in PN-EN 1993-1-1 will be used for this.

These equations and factors are then applied to equation 6.57 of PN-EN 1993-1-1 to evaluate the Lateral Torsional Buckling reduction factor χ_{LT}.

D5.D.8.5 Clauses 6.3.2.2 and 6.3.2.3 — Calculation of LTB Reduction factor, χ_{LT} as per Polish NA

Clauses 6.3.2.2 and 6.3.2.3 (EN 1993-1-1:2005), both give equations to evaluate the LTB reduction factor χ_{LT} to be used in eqn. 6.55 of PN EN 1993-1-1:2005.

Cl. 6.3.2.2 uses tables 6.3 and 6.4 to choose the buckling curve and the imperfection factors to be used for calculating χ_{LT}. Table 6.4 specifies the choice of buckling curves for "Rolled I Sections", "Welded I Sections" and "Any other sections". Cl 6.3.2.3 on the other hand uses tables 6.5 and 6.3 to choose the buckling curves and imperfection factors. Table 6.5 however only deals with "Rolled I Sections" and "Welded I Sections".

Cl. 6.3.2.2 states "Unless otherwise specified, see 6.3.2.3, for bending members of constant cross section the value of χ_{LT} should be determined from...". Hence in the implementation of EC3 (and the Polish Annex) in STAAD.Pro: by default the program will consider clause Cl. 6.3.2.3 to evaluate χ_{LT}. For any case that is not dealt with by Cl. 6.3.2.3, the program will consider Cl. 6.3.2.2 to evaluate χ_{LT}.

Cl. 6.3.2.3 in the Finnish National Annex gives equations to evaluate the imperfection factors to be used for various section types (Refer to D5.D.7.3 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks (on page 1545)). Hence for all cases dealt with by the equations in the Finnish NA, this implementation will use Cl 6.3.2.3 to evaluate χ_{LT}.

For any other type of cross section that is not dealt with by the National Annex or Cl.6.3.2.3, the program will use Cl. 6.3.2.2 to evaluate χ_{LT} .

In any case, the elastic critical moment, M_{cr}, (used to evaluate the non dimensional slenderness) will be evaluated as previously given. Since this implementation uses the NCCIs mentioned in the sections above, only end restraint conditions corresponding to the CMN parameter=1.0 (Refer to D5.D.7.3 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks (on page 1545)) will be considered. For all other cases of the CMN parameter values, this implementation will use the method specified in Annex F of DD ENV 1993-1-1:1992.

Note: If a National Annex has not been specified (i.e., NA parameter in the design input = 0), the program will use Cl. 6.3.2.3 only in the case of Rolled or welded I & H Sections. For all other cases, the program will use Cl. 6.3.2.2 of BS EN 1993-1-1:2005. Also, I sections with plates will be treated as built-up sections only if the section has been explicitly specified as a built-up section (i.e., SBLT parameter = 1.0 in design input).

D5.D.8.6 Clause 6.3.2.3(2) – Modification factor, f, for LTB checks

STAAD.Pro uses the value of the modification factor, *f*, as per eqn 6.58 of PN-EN 1993-1-1. The correction factor, k_c, will be evaluated as:

$$k_c = \sqrt{C_{mLT}}$$

where

C_{mLT}	=	the equivalent uniform moment factor from table B.3 of PN-EN 1993-1-1. C_{mLT} is evaluated based on the end conditions of the member and the shape of the bending moment diagram. However, if the KC parameter is used, then the program will use the specified value.

D5.D.8.7 Clause 6.3.3(5) – Interaction factors kyy, kyz, kzy, and kzz

The Polish NA recommends the equations in Annex B of PN-EN 1993-1-1 to calculate these interaction factors. The current implementation of EC3 BS in STAAD.pro uses the method in Annex B by default. The proposed implementation of the Polish NA will also use Annex B for Cl.6.3.3 checks.

The Polish NA also gives two additional simplified checks. This implementation will provide for these additional checks as well. However as they are intended as optional checks, by default, the program will not perform these checks. However, the user can invoke these checks by using the PLG parameter. Refer to D5.C.6 Design Parameters (on page 1502)

If the value of the PLG parameter is set to 1, the following two checks will be performed as per Cl. NA.20.(2) and NA.20(3) respectively:

- Cl. NA.20.(2): The following condition will be checked

  $$n/\chi \text{ and } + C_{my}\, m_y/\chi_{LT} + C\ mz\ m \text{ with} \leq 1\text{-}\ \Delta_0\ (I = y \text{ or } z)$$

  where

n	=	N_{Ed}/N_{Rd}
m_y	=	$max\ M_{y,Ed}\ (+\ \Delta\ M_{y,\ Ed})/M_{y,\ Rd};\ m_z = max\ M_{,Z\ Ed}\ (+\ \Delta\ M_{,\ Ed})/M_{Z\ Rd,}$
χ and	=	buckling factor
χ_{LT}	=	LTB factor
C_m	=	moment factor from table B 3 of PN EN 1993-1-1
Δ_0	=	correction factor (estimation of maximum reduction) and will be worked out as:

  Δ_0 = 0,1 + 0,2 (w_i – 1), przy czym $w_i = W_{pl,i}/W_{el,i}$, or
  Δ_0 = 0,1 – in case of class 3 and 4 sections.

- Cl. NA.20.(3): This condition will only be checked for circular hollow sections.

  $$n/\chi_i + [(k_{ii}\ m_i)^2 + (C_{mj}\ m_j)^2]\ 1/2 \leq 1\ (i,j = y,z)$$

  where

k	=	the interaction factor from table B.1 of PN-EN 1993-1-1
n, m, and Cmj	=	as previously described

If the PLG parameter has been set to 1, the maximum among the following ratios will be taken as being critical for Cl 6.3.3:

6.3.3: Eqn6.61
6.3.3: Eqn6.62
NA.20(2) and

NA.20(3)

If however `PLG` has been set to `0` (or not specified at all), the program will ignore the last two checks in the list above.

D5.D.8.8 Clause 6.3.1.4 - Slenderness for torsional and torsional-flexural buckling

Equations 6.52 and 6.53 of PN EN 1993-1-1:2005 are to be used to calculate the non-dimensional slenderness λ_T, to be used for torsional and torsional-flexural buckling checks. PN EN 1993-1-1:2005 does not provide equations to calculate the elastic critical loads $N_{cr,TF}$ and $N_{cr,T}$ (refer 6.3.14 of PN EN 1993-1-1:2005).

The NCCI document "SN001a-EN-EU: Critical axial load for torsional and flexural torsional buckling modes" provides methods to calculate the $N_{cr,TF}$ and $N_{cr,T}$ factors and therefore these methods are used to evaluate the elastic critical loads for the Polish NA.

The critical axial load for torsional buckling is evaluated as:

where

i_o^2	=	$i_y^2 + i_z^2 + y_o^2 + z_o^2$
i_y and i_z	=	the radius of gyration about the Y-Y (weak axis) and Z-Z (strong axis) respectively

The critical axial load for torsional-flexural buckling is evaluated as:

$$N_{cr,TF} = \frac{i_o^2}{2\left(i_y^2 + i_z^2\right)}\left[N_{cr,y} + N_{cr,T} - \sqrt{(N_{cr,y} + N_{cr,T})^2 - 4N_{cr,y}N_{cr,T}\frac{i_y^2 + i_z^2}{i_o^2}}\right]$$

For details on these equations, refer to the NCCI document SN001a-EN-EU.

D5.D.9 Singaporean National Annex to EC3

Adds values from the Singaporean National Annex - titled *National Annex to Standard SS-EN 1993-1-1* - for use with Eurocode 3, or EN 1993-1-1:2010. The NA document makes small changes to the base document.

Note: Refer to the D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) for a description of these clauses. The sections below refer to the corresponding clauses in the Singaporean-NA.

The following clauses are not implemented in STAAD.Pro:

Clause 6.3.2.4(1) B – Slenderness for flexural buckling	The SINGAPORE NA specifies the value of λc0 for I, H channel or box section to be used in equation 6.59 of SS EN 1993-1-1:2010 as 0.4. However, STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the Singaporean National Annex.
Clause 6.3.2.4(2)B – Modification factor "kfl"	The value of the modification factor kfl to be used in equation 6.60 of SS EN 1993-1-1. However, STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the Singaporean National Annex.

The clauses/sections in EN 1993-1-1:2010 (hereafter referred to as EC-3) that have been dealt with in the Singaporean National Annex (hereafter referred to as SS-NA) and that are relevant to the proposed implementation are:

Related Links

- *V. EC3 Singapore NA - Channel Section with Conc Load* (on page 4181)

D5.D.9.1 Clause 6.1 – General

The partial safety factors will use the following values:

- Resistance of cross-sections, γ_{M0} = 1.0
- Resistance of members to instability, γ_{M1} = 1.0
- Resistance of cross sections to tension, γ_{M2} = 1.1

The design function in STAAD.Pro sets these values as the default values for the SS-NA (`NA 7` is specified)..

Note: You can change these values through the `GM0`, `GM1`, & `GM2` design parameters. Refer to D5.C.6 Design Parameters (on page 1502)

Note: If any of these parameters have been specified by the user as “0”, STAAD.Pro will ignore the specified value and use the default values as given above.

D5.D.9.2 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks

The Singaporean NA recommends the use of Table 6.3 and 6.4 of NF EN 1993-1-1:2005 to calculate the imperfection factors for Lateral Torsional Buckling (LTB) checks.

The calculation of the LTB reduction factor X_{LT}, requires the calculation of the “Elastic Critical Buckling Moment”, Mcr. The Singaporean National Annex does not specify a particular method to calculate Mcr. Hence the calculation of Mcr has been based on the following NCCI documents:

SN003a-EN-EU – Elastic critical moment for Lateral torsional Buckling

This document provides a method to calculate “Mcr” specifically for doubly symmetric sections only. Hence only doubly symmetric sections will be considered for this method. The equation to evaluate Mcr is given in the NCCI as:

$$M_{cr} = C_1 \frac{\pi^2 EI}{(kL)^2} \left\{ \sqrt{\left(\frac{k}{k_w}\right)^2 \frac{I_w}{I} + \frac{(kL)^2 GI_t}{\pi^2 EI} + (C_2 Z_g)^2} - C_2 Z_g \right\}$$

C1 and C2 are factors that depend on the end conditions and the loading conditions of the member. The NCCI provides values for C1 and C2 for the different cases as given in the tables below:

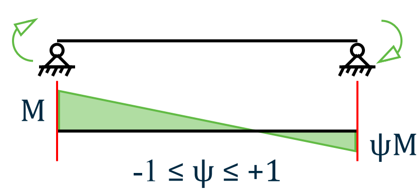

Table 154: Values of C_1 for end moment loading (for k=1)

ψ	C_1
+1,00	1,00
+0,75	1,14
+0,50	1,31
+0,25	1,52
0,00	1,77
-0,25	2,05
-0,50	2,33
-0,75	2,57

This NCCI considers three separate loading conditions:

- Members with end moments
- Members with transverse loading
- Members with end moments and transverse loading.

STAAD.Pro accounts for the loading condition and the bending moment diagram through the `CMM` parameter.

SN030a-EN-EU – Mono-symmetrical uniform members under bending and axial compression:

This document provides a method to evaluate the elastic critical moment (Mcr) for uniform mono symmetric sections that are symmetric about the weak axis. Hence, the elastic critical moment for "Tee-Sections" will be evaluated using the method in this NCCI.

Note: Though this method could also be applicable to mono-symmetric built-up sections, STAAD.Pro currently does not have a means to specify/identify a mono-symmetric built-up section. Hence this implementation will use this method only for Tee-Sections.

The equation to evaluate M_{cr} for mono symmetric sections is given as :

$$M_{cr} = C_1 \frac{\pi^2 E I_z}{(k_x L)^2} \left\{ \sqrt{\left(\frac{k_x}{k_w}\right)^2 \frac{I_w}{I} + \frac{(k_x L)^2 G I_T}{\pi^2 E I_z} + (C_2 z_g - C_3 z_1)^2} - C_2 z_g - C_3 z_1 \right\}$$

The factors C1, C2 and C3 are dependent on the end conditions and loading criteria. This implementation will consider C1, C2 and C3 as given in the tables below:

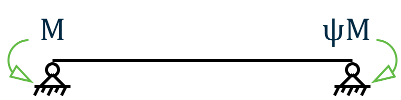

Table 155: Values of C_1 and C_2 for end moment loading (for $k_c = 1$)

Ψ	C_1	C_2
+1.00	1.00	1.00
+0.75	1.14	0.99
+0.50	1.31	0.99
+0.25	1.52	0.98
0.00	1.77	0.94
-0.25	2.05	0.85
-0.50	2.33	0.68
-0.75	2.57	0.37
-1.00	2.55	0.00

Table 156: Values of factors C_1, C_2, and C_3 for cases with transverse loading (for $k_c = 1$)

Loading and support conditions	Bending moment diagram	C_1	C_2	C_3
		1.13	0.45	0.52
		2.57	1.55	0.75
		1.35	0.63	1.73
		1.68	1.64	2.64

The CMM parameter specified during design input will determine the values of C1, C2 and C3. The default value of CMM is 0, which considers the member as a pin ended member with UDL along its span. This NCCI does not however consider the “end moments and transverse loading” condition. The user however can use the new “C1”, ‘C2’ and ‘C3’ parameters to input the required values for C1, C2 and C3 to be used in calculating Mcr.

Note: If "MU" as well as C1, C2 and C3 have been specified, the program will ignore MU and use the user input values of C1, C2 and C3. STAAD.Pro obtains these values from Annex F of DD ENV version of 1993-1-1:1992.

Both the NCCI documents mentioned above assume that the member under consideration is free to rotate on plan and that there are no warping restraints for the member ($k = k_w = 1.0$). STAAD.Pro takes into account of the end conditions using the CMN parameter for EC3. A value of $K = k_w = 1$ is indicated by a value of CMN = 1.0 in the design input. Hence the above methods will be used only for members which are free to rotate on plan and which have no warping restraints (i.e., CMN = 1.0). For members with partial or end fixities (i.e., CMN = 0.5 or CMN = 0.7), this implementation will fall back on to the method and coefficients in DD ENV 1993-1-1:1992 – Annex F.

For all cases that are not dealt with by the National Annex (or the NCCI documents) this implementation will use the method as per the DD ENV 1993-1-1:1992 code.

For the term z_j, please refer to Annex E of NBN NA 2018.

The term z_g in the equation to calculate M_{cr} refers to the distance between the point of application of load on the cross section in relation to the shear center of the cross section. The value of z_g is considered positive, if the load acts towards the shear center and is negative if it acts away from the shear center. By default, the program will assume that the load acts towards the shear center at a distance equal to (Depth of section/2) from the shear center. The use will be allowed to modify this value by using the ZG parameter. Specifying a value of ZG = 0 in the design input would indicate that the load acts exactly at the shear center of the section so that the term z_g in the equation will have a value of zero.

Note: The program does not consider the case of cantilevers.

D5.D.9.3 Clause 6.3.2.3(1) – LTB for rolled sections or equivalent welded section

The Singaporean NA specifies different values for the $\lambda_{LT,0}$ and β factors to be used in equation 6.57 of SS EN 1993-1-1 for rolled and equivalent welded sections. STAAD.Pro does not differentiate between rolled and welded sections and uses the default values in SS EN 1993-1-1 for $\lambda_{LT,0}$ and β. The values specified in the Singapore NA are:

- For rolled sections and hot-rolled & cold formed hollow sections:

  $\lambda_{LT,0} = 0.4$

  $\beta = 0.75$

- For welded sections:

  $\lambda_{LT,0} = 0.2$

  $\beta = 1.00$

STAAD.Pro uses the buckling curves based on Table 6.5 of SS EN 1993-1-1:2005. The Singaporean-NA provides the values for the terms λ_{LT0} and β factors given in clause 6.3.2.3(1) as follows:

Table 157: Buckling curves to use with SS-EN 1993-1-1:2005

Cross Section	Limits	Buckling Curve
Rolled doubly symmetric I and H sections and hot-finished hollow sections	h/b ≤ 2	b
	2.0 < h/b ≤ 3.1	c
	h/b > 3.1	d

Cross Section	Limits	Buckling Curve
Angles (for moments in the major principle plane)		d
All other hot-rolled sections		d
Welded, doubly symmetric sections and cold-formed hollow sections	h/b ≤ 2	c
	2.0 < h/b ≤ 3.1	d

Note: This table does not specify which buckling curve is to be used in case of welded doubly symmetric sections with h/b ≥ 3.1 and welded non-doubly symmetric sections. Hence for these cases the new implementation will still use the method specified in the base code as per clause 6.3.2.2(2).

D5.D.9.4 Clauses 6.3.2.2 and 6.3.2.3 — Calculation of LTB Reduction factor, χ_{LT} as per Singaporean NA

Clauses 6.3.2.2 and 6.3.2.3 (EN 1993-1-1:2005) both give equations to evaluate the LTB reduction factor χ_{LT} to be used in eqn. 6.55 of SS EN 1993-1-1:2005.

Cl. 6.3.2.2 uses tables 6.3 and 6.4 to choose the buckling curve and the imperfection factors to be used for calculating χ_{LT}. Table 6.4 specifies the choice of buckling curves for “Rolled I Sections”, “Welded I Sections” and “Any other sections”. Cl 6.3.2.3 on the other hand uses tables 6.5 and 6.3 to choose the buckling curves and imperfection factors. Table 6.5 however only deals with “Rolled I Sections” and “Welded I Sections”.

Cl. 6.3.2.2 states “Unless otherwise specified, see 6.3.2.3, for bending members of constant cross section the value of χ_{LT} should be determined from...”. Hence in the implementation of EC3 (and the Singaporean Annex) in STAAD.Pro: by default the program will consider clause Cl. 6.3.2.3 to evaluate χ_{LT}. For any case that is not dealt with by Cl. 6.3.2.3, the program will consider Cl. 6.3.2.2 to evaluate χ_{LT}.

Cl. 6.3.2.3 in the Singaporean National Annex states that Table 6.5 in SS EN 1993-1-1:2005 should be replaced with the table given in the NA (See section 4.3 of this document). Hence for all cases dealt with by the table in the Singaporean NA, this implementation will choose the buckling curves from the Singaporean National Annex. For any case that is not dealt with by the table in the Singaporean NA, the program will use the method given in Cl. 6.3.2.2 of SS EN 1993-1-1:2005.

For the following cross sections, the program will use the Table in the Singaporean NA for choosing a buckling curve for LTB checks (when the SS EN has been specified):

- Rolled doubly symmetric I & H Sections
- Rolled doubly symmetric hollow sections (SHS, RHS, CHS)
- Angle Sections
- Any other rolled section
- Welded doubly symmetric sections with h/b < 3.1

For the following cross sections, the program will use Cl. 6.3.2.3 of SS EN 1993-1-1:2005 to evaluate χ_{LT}

- Welded I & H Sections with h/b ≥ 3.1.

For any other type of cross section that is not dealt with by the National Annex or Cl.6.3.2.3, the program will use Cl. 6.3.2.2 to evaluate χ_{LT} .

In any case, the elastic critical moment, M_{cr}, (used to evaluate the non dimensional slenderness) will be evaluated as given above. Since this implementation uses the NCCIs mentioned in the sections above, only end restraint conditions corresponding to the `CMN` parameter=1.0 (See section above) will be considered. For all other cases of the CMN parameter values, this implementation will use the method specified in Annex F of DD ENV 1993-1-1:1992.

Note: If a National Annex has not been specified (i.e., NA parameter in the design input = 0), the program will use Cl. 6.3.2.3 only in the case of Rolled or welded I & H Sections. For all other cases, the program will use Cl. 6.3.2.2 of BS EN 1993-1-1:2005. Also, I sections with plates will be treated as built-up sections only if the section has been explicitly specified as a built-up section (i.e., SBLT parameter = 1.0 in design input).

D5.D.9.5 Clause 6.3.2.3(2) – Modification factor, f, for LTB checks

The Singaporean NA specifies the use of Equation 6.58 of SS EN 1993-1-1:2005 to evaluate the modification factor “f” for the LTB reduction factor χ_{LT}. To evaluate the modification factor SS EN 1993-1-1:2005 uses a correction factor “kc” given by Table 6.6 in the code.

The Singaporean-NA however, specifies that the correction factor “kc” is to be obtained as below:

$$K_c = 1 / \sqrt{C_1}$$

Where:

> C_1 is to be obtained from the NCCI documents as previously described (Refer to D5.D.9.2 Clause 6.3.2.2 – Elastic critical moment and imperfection factors for LTB checks (on page 1557)). The NCCI document SN003a-EN-EU specifies the values of C1 to be used in table 3.1 as shown below. The current implementation does not account for the K_c factor and conservatively uses a reduction factor equal to 1. The program allows for the reduction factor based on the Singaporean-NA.

These values are for an end restraint factor of k = 1 (i.e., design parameter `CMN` = 1.0). Hence for all other values of `CMN` (i.e., 0.7 or 0.5) this implementation will use the values of C_1 from DD ENV 1993-1-1:1992 Annex F.

The program will use a default value of 1.0 for K_c. However, you can also input a custom value of K_c by setting the design parameter `KC` to the desired value. If the `KC` parameter in the design input is set to 0, then the program will automatically calculate its value. This will cause the program to evaluate a value of C_1 corresponding to the end conditions and the Bending moment of the member and in turn calculate K_c as given in the NA. To evaluate C_1, the program will use the NCCI documents as previously described.

D5.D.9.6 Clause 6.3.3(5) – Interaction factors kyy, kyz, kzy, and kzz

The Singaporean NA recommends the methods in either Annex A or Annex B of SS-EN 1993-1-1 to calculate these interaction factors. The current implementation of EC3 BS in STAAD.pro uses the method in Annex B by default. The proposed implementation of the Singaporean NA will also use Annex B for Cl.6.3.3 checks.

However for non-doubly symmetric sections, the Singaporean NA gives the option of using Annex B with some modifications as given in the NA. (Cl. NA-3.2 of the Singaporean NA). The Singaporean NA requires additional checks to be done to check for the maximum allowable values of λ and X to be used in equations 6.61 and 6.62 of SS EN 1993-1-1:2005.

As per the Singaporean NA, for non-doubly symmetric sections, the slenderness about the weak axis (λy in STAAD) and the corresponding reduction factor χy should be taken as the values from the highest values of slenderness (λ) among the flexural buckling slenderness (λy), torsional slenderness (λT) and torsional-flexural slenderness (λTF) as given in Clauses 6.3.1.3 and 6.3.1.4 of SS EN 1993-1-1:2005. Hence for non-doubly symmetric sections the program will calculate the critical non-dimensional slenderness as:

λ_y = the maximum of either λ from Cl 6.3.1.3 or λ_T from Cl 6.3.1.4

Where:

$$\lambda_T = \sqrt{\frac{A \cdot f_y}{N_{cr}}}$$

$N_{cr} = \min(N_{CrT}, N_{crTF})$.

The Singaporean NA or EC3 does not, however, specify a method to evaluate N_{CrT} or N_{crTF}. Therefore, the program uses the method specified in the NCCI document “SN001a-EN-EU: Critical axial load for torsional and flexural torsional buckling modes” to calculate these. Refer to D5.D.9.7 Clause 6.3.1.4 - Slenderness for torsional and torsional-flexural buckling (on page 1563).

Note: The Singaporean National Annex or EC3 does not deal with angle sections in specific and hence this implementation will use the method used in the current EC3 implementation to deal with slenderness of angle sections. In the current implementation this is done as per cl 4.7.10 of BS 5950. This proposed implementation will still use the same method for single and double angle sections to evaluate the slenderness.

Clause NA 3.2 of the Singaporean NA also requires that “Where the section is not an I Section or a hollow section and is a class1 or class 2 section, it will be treated as a class 3 section for the purposes of this clause”. Hence, for all Class 1 or Class 2 cross sections that are *not* I, H, SHS, RHS or CHS sections, the elastic properties will be used for the purposes of 6.3.3 checks.

D5.D.9.7 Clause 6.3.1.4 - Slenderness for torsional and torsional-flexural buckling

Equations 6.52 and 6.53 of SS EN 1993-1-1:2005 are to be used to calculate the non-dimensional slenderness parameter, λ_T, to be used for torsional and torsional-flexural buckling checks. The SS EN 1993-1-1:2005 does not provide equations to calculate the elastic critical loads $N_{cr,T,F}$ and $N_{cr,T}$ (refer 6.3.14 of SS EN 1993-1-1:2005). Therefore, the NCCI document “SN001a-EN-EU: Critical axial load for torsional and flexural torsional buckling modes” provides methods to calculate the $N_{cr,T,F}$ and $N_{cr,T}$ factors and hence will to be included in this implementation of the Singaporean NA.

The program will only consider Channel Sections and Tee- sections while working out the critical torsional and Flexural Torsional buckling loads as per Cl 6.3.1.4.

The critical axial load for torsional buckling is evaluated as:

where

i_o^2	=	$i_y^2 + i_z^2 + y_o^2 + z_o^2$
i_y and i_z	=	the radius of gyration about the Y-Y (weak axis) and Z-Z (strong axis) respectively

The critical axial load for torsional-flexural buckling is evaluated as:

$$N_{cr,TF} = \frac{i_o^2}{2\left(i_y^2 + i_z^2\right)}\left[N_{cr,y} + N_{cr,T} - \sqrt{(N_{cr,y} + N_{cr,T})^2 - 4N_{cr,y}N_{cr,T}\frac{i_y^2 + i_z^2}{i_o^2}}\right]$$

For details on these equations, refer to the NCCI document SN001a-EN-EU.

D5.D.10 Belgian National Annex to EC3

Adds values from the Belgian National Annex—titled *National Annex to Standard NBN-EN 1993-1-1 ANB: 2018*—for use with Eurocode 3, or EN 1993-1-1:2005. The NA document makes small changes to the base document.

The following clauses are *not* implemented in STAAD.Pro:

Clause 6.3.2.4(1) B – Slenderness for flexural buckling	STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the Belgian National Annex.
Clause 6.3.2.4(2)B – Modification factor "kfl"	STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the Belgian National Annex.

Note: Refer to the D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) for a description of these clauses. The sections below refer to the corresponding clauses in the NBN-NA.

The clauses/sections in EN 1993-1-1:2005 (hereafter referred to as EC-3) that have been dealt with in the Belgian National Annex (hereafter referred to as NBN-NA) and that are relevant to the proposed implementation are:

D5.D.10.1 Clause 6.1(1) – General

EN 1993-1-1:2005 specifies the use of the partial safety factors to be used in for design as given in Cl. 6.1 of the code. These factors are γ_{M0}, γ_{M1}, and γ_{M2}. EN 1993 provides default values for these factors. However, any National Annex is allowed to override these default values.

The partial safety factors will use the following values for the Belgian National Annex:

- Resistance of cross-sections, $\gamma_{M0} = 1.0$
- Resistance of members to instability, $\gamma_{M1} = 1.0$
- Resistance of cross sections to tension, $\gamma_{M2} = 1.25$

The design function in STAAD.Pro sets these values as the default values for the NBN-NA (`NA 8` is specified).

Note: You can change these values through the `GM0`, `GM1`, & `GM2` design parameters. Refer to D5.C.6 Design Parameters (on page 1502)

Note: If any of these parameters are specified as `0`, STAAD.Pro will ignore the user-specified value (i.e., 0) and use the default values as given above.

D5.D.10.2 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks

The NBN-NA recommends the use of Table 6.3 and 6.4 of EN 1993-1-1:2005 to calculate the imperfection factors for Lateral Torsional Buckling (LTB) checks.

The calculation of the LTB reduction factor χ_{LT}, requires the calculation of the Elastic Critical Buckling Moment, M_{cr}. The NBN-NA gives a method to calculate M_{cr} in Annex E, which is used by STAAD.Pro. Annex E, however, only deals with the calculation of M_{cr} for doubly symmetric sections and mono symmetric sections that are symmetric about the minor axis (i.e, Tee sections). For any other type of section that is not dealt with by Annex E, STAAD.Pro uses the method and tables given in Annex F of DD ENV 1993-1-1:1992:

Doubly symmetric sections

Annex D of NBN-NA provides equation used to calculate M_{cr} specifically for doubly symmetric sections:

$$M_{cr} = C_1 \frac{\pi^2 EI}{(kL)^2} \left\{ \sqrt{\left(\frac{k}{k_w}\right)^2 \frac{I_w}{I} + \frac{(kL)^2 GI_t}{\pi^2 EI} + (C_2 Z_g)^2} - C_2 Z_g \right\}$$

C_1 & C_2 are factors that depend on the end conditions and the loading conditions. The Annex provides values for C_1 & C_2 for the different cases as given in Table1 and Table 2 of the Annex. Table 1 deals with the condition of a simply supported member with end moments and the value of C_1 is determined by the end moment ratio (Refer to the NA for details). Clause 3.2 of the National Annex however gives a formula to calculate C_1 as:

$$C_1 = 1.77 - 1.04\psi + 0.27\psi^2 \leq 2.60$$

The value of C_2 is determined based on the Table 2 of the Annex, based on the loading and end conditions as specified using the `CMM` parameter.

This NBN-NA considers three separate loading conditions:

- Members with end moments
- Members with transverse loading
- Members with end moments and transverse loading.

STAAD.Pro accounts for the loading condition and the bending moment diagram through the `CMM` parameter.

Mono-symmetric sections with symmetry about their weak axis

Annex D of NBN-NA also provides a method to evaluate the elastic critical moment, M_{cr}, for uniform mono symmetric sections that are symmetric about the weak axis. Hence for this implementation the elastic critical moment for Tee-Sections is evaluated using the method in this Annex.

Note: Though this method could also be applicable to mono-symmetric built-up sections, STAAD.Pro does not have a means to specify/identify a mono-symmetric built-up section. Hence, this implementation will use this method only for Tee-sections.

The equation to evaluate M_{cr} for mono symmetric sections is given as:

$$M_{cr} = C_1 \frac{\pi^2 EI_z}{(k_x L)^2} \left\{ \sqrt{\left(\frac{k_x}{k_w}\right)^2 \frac{I_w}{I} + \frac{(k_x L)^2 GI_T}{\pi^2 EI_z} + (C_2 z_g - C_3 z_j)^2} - C_2 z_g - C_3 z_j \right\}$$

The factors C_1, C_2, and C_3 are dependent on the end conditions and loading criteria. This implementation will consider C_1, C_2 and C_3 as given in the tables below:

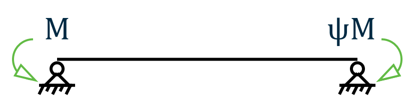

Figure 169: End moments and support conditions

Table 158: Critical moment coefficients for singly symmetric sections with end moments

Bending moment diagram	k_z	Value of coefficients		
		C_1	C_3	
			$\psi_f \leq 0$	$\psi_f > 0$
$\psi = +1$	1.0	1.00	1.000	
	0.5	1.05	1.019	
$\psi = +3/4$	1.0	1.14	1.000	
	0.5	1.19	1.017	
$\psi = +1/2$	1.0	1.31	1.000	
	0.5	1.37	1.000	
$\psi = +1/4$	1.0	1.52	1.000	
	0.5	1.60	1.000	
$\psi = 0$	1.0	1.77	1.000	
	0.5	1.86	1.000	
$\psi = -1/4$	1.0	2.06	1.000	0.850
	0.5	2.15	1.000	0.650
$\psi = -1/2$	1.0	2.35	1.000	$1.3 - 1.2\psi_f$
	0.5	2.42	0.950	$0.77 - \psi_f$
$\psi = -3/4$	1.0	2.60	1.000	$0.55 - \psi_f$
	0.5	2.45	0.850	$0.35 - \psi_f$
$\psi = -1$	1.0	2.60	$-\psi_f$	$-\psi_f$
	0.5	2.45	$0.125 - 0.7\psi_f$	$-0.125 - 0.7\psi_f$

Note: According to Section 3(1): $C_2 z_g = 0$

Table 159: Value of coefficients

Load and support conditions	Bending moment diagram	k_z	Value of coefficients		
			C_1	C_2	C_3
		1.0	1.12	0.45	0.525
		0.5	0.97	0.36	0.478
		1.0	1.35	0.59	0.411
		0.5	1.05	0.48	0.338
		1.0	1.04	0.42	0.562
		0.5	0.95	0.31	0.539

The CMM parameter specified during design input will determine the values of C_1, C_2, and C_3. The default value of CMM is 0, which considers the member as a pin ended member with uniformly distributed load (UDL) along its span. This NCCI does not however consider the "end moments and transverse loading" condition. You can use the parameter MU to describe the moment distribution for cases where the end moments vary (i.e., CMM 7 or CMM 8). Alternatively, you can use the C1, C2, and C3 parameters to input the required values for C_1, C_2, and C_3 to be used in calculating M_{cr}.

Note: If MU as well as C1, C2, and C3 have been specified, the program will ignore MU and use the user input values of C1, C2 and C3. STAAD.Pro obtains these values from Annex F of DD ENV version of 1993-1-1:1992.

Both the NCCI documents mentioned above assume that the member under consideration is free to rotate on plan and that there are no warping restraints for the member ($k = k_w = 1.0$). STAAD.Pro takes into account of the end conditions using the CMN parameter for EC3. A value of $K = k_w = 1$ is indicated by a value of CMN = 1.0 in the design input. Hence the above methods will be used only for members which are free to rotate on plan and which have no warping restraints (i.e., CMN = 1.0). For members with partial or end fixities (i.e., CMN = 0.5 or CMN = 0.7), this implementation will fall back on to the method and coefficients in DD ENV 1993-1-1:1992 – Annex F.

For all cases that are not dealt with by the National Annex (or the NCCI documents) this implementation will use the method as per the DD ENV 1993-1-1:1992 code.

For the term z_j, please refer to Annex E of NBN NA 2018.

The term z_g in the equation to calculate M_{cr} refers to the distance between the point of application of load on the cross section in relation to the shear center of the cross section. The value of z_g is considered positive, if the load acts towards the shear center and is negative if it acts away from the shear center. By default, the program will assume that the load acts towards the shear center at a distance equal to (Depth of section/2) from the shear center. The use will be allowed to modify this value by using the ZG parameter. Specifying a value of ZG = 0 in the design input would indicate that the load acts exactly at the shear center of the section so that the term z_g in the equation will have a value of zero.

Note: The program does not consider the case of cantilevers.

D5.D.10.3 Clause 6.3.2.3(1) – LTB for rolled sections or equivalent welded section

The NBN-NA recommends the use of the values specified in EN 1993-1-1 for the LTB factors λ_{LT0} and β. However it gives two different sets of values for λ_{LT0} and β based on two different conditions as give below:

1. If M_{cr} is determined by considering the properties of the gross cross section and the lateral restraints, the following values are used:

   λ_{LT0} =0.2 and $\beta = 1.0$
2. If M_{cr} is determined by ignoring the lateral restraints, the following values are used:

   λ_{LT0} =0.4 and $\beta = 0.75$

The program evaluates which factors to use based on the CMN parameter. If CMN = 1.0 (default) or = 0.7, then the program assumes the restraints are ignored and the second set of values is used for λ_{LT0} and β. If CMN = 0.5, then the first set of λ_{LT0} and β values is used.

These factors are then applied to equation 6.57 of NBN-EN to evaluate the Lateral Torsional Buckling reduction factor χ_{LT}.

D5.D.10.4 Clauses 6.3.2.2 and 6.3.2.3 — Calculation of LTB Reduction factor, χ_{LT} as per Belgium NA

Clauses 6.3.2.2 and 6.3.2.3 (EN 1993-1-1:2005) both give equations to evaluate the LTB reduction factor χ_{LT} to be used in eqn. 6.55 of NBN-EN 1993-1-1:2018.

Cl. 6.3.2.2 uses tables 6.3 and 6.4 to choose the buckling curve and the imperfection factors to be used for calculating χ_{LT}. Table 6.4 specifies the choice of buckling curves for “Rolled I Sections”, “Welded I Sections” and “Any other sections”. Cl 6.3.2.3 on the other hand uses tables 6.5 and 6.3 to choose the buckling curves and imperfection factors. Table 6.5 however only deals with “Rolled I Sections” and “Welded I Sections”.

Cl. 6.3.2.2 states “Unless otherwise specified, see 6.3.2.3, for bending members of constant cross section the value of χ_{LT} should be determined from...”. Hence in the implementation of EC3 (and the Belgian Annex) in STAAD.Pro: by default the program will consider clause Cl. 6.3.2.3 to evaluate χ_{LT}. For any case that is not dealt with by Cl. 6.3.2.3, the program will consider Cl. 6.3.2.2 to evaluate χ_{LT}.

Cl. 6.3.2.3 in the Belgian National Annex gives equations to evaluate the imperfection factors to be used for various section types. (Refer to D5.D.10.3 Clause 6.3.2.3(1) – LTB for rolled sections or equivalent welded section (on page 1568)). Hence for all cases dealt with by the equations in the NBN-NA, this implementation will use Cl 6.3.2.3 to evaluate χ_{LT}.

For any other type of cross section that is not dealt with by the National Annex or Cl.6.3.2.3, the program will use Cl. 6.3.2.2 to evaluate χ_{LT} .

In any case, the elastic critical moment, Mcr, (used to evaluate the non dimensional slenderness) will be evaluated as given above. Since this implementation uses the NCCIs mentioned in the sections above, only end restraint conditions corresponding to the CMN parameter=1.0 (Refer to D5.D.10.3 Clause 6.3.2.3(1) – LTB for rolled sections or equivalent welded section (on page 1568)) will be considered. For all other cases of the CMN parameter values, this implementation will use the method specified in Annex F of DD ENV 1993-1-1:1992.

You can override the default behavior and specify the clause that is to be used for LTB checks. This can be specified using the `MTH` design parameter (Refer to D5.C.6 Design Parameters (on page 1502)).

> **Note:** If a National Annex has not been specified (i.e., `NA` parameter in the design input = 0), the program will use Cl. 6.3.2.3 only in the case of Rolled or welded I & H Sections. For all other cases, the program will use Cl. 6.3.2.2 of NBN-EN 1993-1-1:2018. Also, I sections with plates will be treated as built-up sections only if the section has been explicitly specified as a built-up section (i.e., `SBLT` parameter = 1.0 in design input).

D5.D.10.5 Clause 6.3.2.3(2) – Modification factor, f, for LTB checks

The Belgian NA specifies that the modification factor is to be obtained as per the default method given in EC-3. Hence the proposed implementation will use the existing functionality to work out the correction factor “kc” to be used in the modification factor f.

The program uses a default value of 1.0 for “kc”. However, you can also input a custom value of “kc” by setting the design parameter `KC` to the desired value. You can also get the program to calculate the value of “kc” automatically by setting the value of the `KC` parameter in the design input to 0. This will cause the program to work out “kc” from table 6.6 of NBN EN 1993-1-1:2018. This will correspond to the end conditions and the bending moment of the member (i.e., the value of `CMM` parameter specified).

- For `CMM` = 7 the program will choose the value of “kc” to be either 0.90 or 0.91 based on the end moment ratio.
- For `CMM` = 8 the program will choose the value of “kc” to be either 0.77 or 0.82 based on the end moment ratio.

An additional check will also be performed as given below:

$$\chi_{LT,\mathrm{mod}} \leq \frac{1}{\lambda_{LT}^{2}}$$

D5.D.10.6 Clause 6.3.3(5) – Interaction factors kyy, kyz, kzy, and kzz

The NBN-NA recommends the equations in Annex A of NBN-EN 1993-1-1 to calculate these interaction factors.

The NA also mentions that torsional flexural buckling needs to be taken into account in case of mono symmetric sections. Torsional flexural buckling will need to be taken into account based on the method given in the NCCI document “SN001a-EN-EU: Critical axial load for torsional and flexural torsional buckling modes”. See section below for details.

The NA also recommends a lower limit as given below for the term $C_{mi,0}$ in table A.2 of Annex A:

$$C_{mi,0} \geq 1 - \frac{N_{Ed}}{N_{cr,i}}$$

D5.D.10.7 Clause 6.3.1.4 - Slenderness for torsional and torsional-flexural buckling

Equations 6.52 and 6.53 of NBN-EN 1993-1-1:2018 are to be used to calculate the non-dimensional slenderness parameter, λ_T, to be used for torsional and torsional-flexural buckling checks. The NBN-EN 1993-1-1:2018 does not provide equations to calculate the elastic critical loads $N_{cr,T,F}$ and $N_{cr,T}$ (refer 6.3.14 of SS EN 1993-1-1:2005). Therefore, the NCCI document “SN001a-EN-EU: Critical axial load for torsional and flexural torsional buckling modes” provides methods to calculate the $N_{cr,T,F}$ and $N_{cr,T}$ factors and hence will to be included in this implementation of the Belgian NA.

The critical axial load for torsional buckling is evaluated as:

where

i_o^2	=	$i_y^2 + i_z^2 + y_o^2 + z_o^2$
i_y and i_z	=	the radius of gyration about the Y-Y (weak axis) and Z-Z (strong axis) respectively

The critical axial load for torsional-flexural buckling is evaluated as:

$$N_{cr,TF} = \frac{i_o^2}{2\left(i_y^2 + i_z^2\right)}\left[N_{cr,y} + N_{cr,T} - \sqrt{(N_{cr,y} + N_{cr,T})^2 - 4N_{cr,y}N_{cr,T}\frac{i_y^2 + i_z^2}{i_o^2}}\right]$$

For details on these equations, refer to the NCCI document SN001a-EN-EU.

The program will only consider channel sections and Tee- sections while working out the critical torsional and Flexural Torsional buckling loads as per Cl 6.3.1.4.

D5.D.11 Malaysian National Annex to EC3

Adds values from the Malaysian National Annex—titled *National Annex to Standard MS-EN 1993-1-1*—for use with Eurocode 3, or EN 1993-1-1:2005. The NA document makes small changes to the base document.

The following clauses are *not* implemented in STAAD.Pro:

Clause 6.3.2.4(1) B – Slenderness for flexural buckling	STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the Malaysian National Annex.
Clause 6.3.2.4(2)B – Modification factor "kfl"	STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the Malaysian National Annex.

Note: Refer to the D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) for a description of these clauses. The sections below refer to the corresponding clauses in the MS-NA.

The clauses/sections in EN 1993-1-1:2005 (hereafter referred to as EC-3) that have been dealt with in the Malaysian National Annex (hereafter referred to as MS-NA) and that are relevant to the proposed implementation are:

D5.D.11.1 Clause 6.1(1) – General: Partial Safety Factors for buildings

EN 1993-1-1:2005 specifies the use of the partial safety factors to be used in for design as given in Cl. 6.1 of the code. These factors are γ_{M0}, γ_{M1}, and γ_{M2}. EN 1993 provides default values for these factors. However, any National Annex is allowed to override these default values.

The partial safety factors will use the following values for the Malaysian National Annex:

- Resistance of cross-sections, γ_{M0} = 1.0
- Resistance of members to instability, γ_{M1} = 1.0
- Resistance of cross sections to tension, γ_{M2} = 1.1

The design function in STAAD.Pro sets these values as the default values for the MS-NA (`NA 9` is specified).

Note: You can change these values through the `GM0`, `GM1`, & `GM2` design parameters. Refer to D5.C.6 Design Parameters (on page 1502)

Note: If any of these parameters are specified as `0`, STAAD.Pro will ignore the user specified value (i.e., 0) and use the default values as given above.

D5.D.11.2 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks

The MS-NA recommends the use of Table 6.3 and 6.4 of MS EN 1993-1-1:2005 to calculate the imperfection factors for Lateral Torsional Buckling (LTB) checks.

The calculation of the LTB reduction factor χ_{LT}, requires the calculation of the Elastic Critical Buckling Moment, M_{cr}. The MS-NA does not specify a particular method to calculate Mcr. Hence the calculation of Mcr has been based on the following NCCI documents:

Doubly symmetric sections

SN003a-EN-EU *NCCI: Elastic critical moment for lateral torsional buckling* provides equation used to calculate M_{cr} specifically for doubly symmetric sections:

$$M_{cr} = C_1 \frac{\pi^2 EI}{(kL)^2}\left\{\sqrt{\left(\frac{k}{k_w}\right)^2 \frac{I_w}{I_S} + \frac{(kL)^2 GI_t}{\pi^2 EI_S} + (C_2 Z_g)^2} - C_2 Z_g\right\}$$

C_1 and C_2 are factors that depend on the end conditions and the loading conditions of the member. The NCCI provides values for C_1 and C_2 for the different cases as given in Table 3.1 and Table 3.2.

The NCCI considers three separate loading conditions:

- Members with end moments
- Members with transverse loading
- Members with end moments and transverse loading.

STAAD.Pro accounts for the loading condition and the bending moment diagram through the `CMM` parameter. The values of C_1 and C_2 may also be directly specified using the `C1` and `C2` parameters, respectively (required for `CMM = 7` or `CMM = 8`).

Mono-symmetric sections with symmetry about their weak axis

Annex D of MS-NA also provides a method to evaluate the elastic critical moment, M_{cr}, for uniform mono symmetric sections that are symmetric about the weak axis. Hence for this implementation the elastic critical moment for Tee-Sections is evaluated using the method in this Annex.

Note: Though this method could also be applicable to mono-symmetric built-up sections, STAAD.Pro currently does not have a means to specify/identify a mono-symmetric built-up section. Hence this implementation will use this method only for Tee-Sections.

The equation to evaluate M_{cr} for mono symmetric sections is given as:

$$M_{cr} = C_1 \frac{\pi^2 EI_z}{(k_x L)^2}\left\{\sqrt{\left(\frac{k_x}{k_w}\right)^2 \frac{I_w}{I} + \frac{(k_x L)^2 GI_T}{\pi^2 EI_z} + (C_2 z_g - C_3 z_1)^2} - C_2 z_g - C_3 z_1\right)\right\}$$

The factors C_1, C_2, and C_3 are dependent on the end conditions and loading criteria. The program considers C_1, C_2, and C_3 as given in the tables 4.1 and 4.2 of the NCCI, based on the `CMM` parameter.

The default value of `CMM = 0`, which considers the member as a pin ended member with uniformly distributed load (UDL) along its span. This NCCI does not however consider the “end moments and transverse loading” condition. You use the `C1`, `C2` and `C3` parameters to input the required values for C_1, C_2, and C_3, respectively, to be used in calculating M_{cr}.

Note: If "MU" as well as C1, C2 and C3 have been specified, the program will ignore MU and use the user input values of C1, C2 and C3. STAAD.Pro obtains these values from Annex F of DD ENV version of 1993-1-1:1992.

Note: When `CMM = 7` or `CMM = 8`, the values for `C1`, `C2` and `C3` parameters must be manually specified.

Both the NCCI documents mentioned above assume that the member under consideration is free to rotate on plan and that there are no warping restraints for the member (k = kw = 1.0). STAAD.Pro takes into account of the end conditions using the `CMN` parameter for EC3. A value of K = kw =1 is indicated by a value of CMN = 1.0 in the design input. Hence the above methods will be used only for members which are free to rotate on plan and which have no warping restraints (i.e., CMN = 1.0). For members with partial or end fixities (i.e., CMN = 0.5 or CMN = 0.7), this implementation will fall back on to the method and coefficients in DD ENV 1993-1-1:1992 – Annex F.

For all cases that are not dealt with by the National Annex (or the NCCI documents) this implementation will use the method as per the DD ENV 1993-1-1:1992 code.

The term z_g in the equation to calculate M_{cr} refers to the distance between the point of application of load on the cross section in relation to the shear center of the cross section. The value of z_g is considered positive, if the load acts towards the shear center and is negative if it acts away from the shear center. By default, the program will assume that the load acts towards the shear center at a distance equal to (Depth of section/2) from the shear center. The use will be allowed to modify this value by using the `ZG` parameter. Specifying a value of ZG = 0 in the design input would indicate that the load acts exactly at the shear center of the section so that the term z_g in the equation will have a value of zero.

Note: The program does not consider the case of cantilevers.

D5.D.11.3 Clause 6.3.2.3(1) – LTB for rolled sections or equivalent welded section

The MS-NA specifies different values for the $\lambda_{LT,0}$ and β factors to be used in equation 6.57 of MS EN 1993-1-1 for rolled and equivalent welded sections. STAAD.Pro does not differentiate between rolled and welded sections and uses the default values in MS EN 1993-1-1 for $\lambda_{LT,0}$ and β. The values specified in the MS-NA are:

1. For rolled sections and hot-rolled & cold formed hollow sections:

   $\lambda_{LT,0}$ = 0.4 and β = 0.75
2. For welded sections:

   $\lambda_{LT,0}$ = 0.2 and β = 1.00

STAAD.Pro uses the buckling curves based on Table 6.5 of MS EN 1993-1-1:2005, based on different limits. This table again does not specify which buckling curve is to be used in case of welded doubly symmetric sections with $h/b \geq 3.1$ and welded non-doubly symmetric sections. Hence for these cases the new implementation will still use the method specified in the base code as per clause 6.3.2.2(2).

D5.D.11.4 Clauses 6.3.2.2 and 6.3.2.3 — Calculation of LTB Reduction factor, χ_{LT} as per Malaysian NA

Clauses 6.3.2.2 and 6.3.2.3 (EN 1993-1-1:2005), both give equations to evaluate the LTB reduction factor χ_{LT} to be used in eqn. 6.55 of MS EN 1993-1-1:2005.

Cl. 6.3.2.2 uses tables 6.3 and 6.4 to choose the buckling curve and the imperfection factors to be used for calculating χ_{LT}. Table 6.4 specifies the choice of buckling curves for "Rolled I Sections", "Welded I Sections" and "Any other sections". Cl 6.3.2.3 on the other hand uses tables 6.5 and 6.3 to choose the buckling curves and imperfection factors. Table 6.5 however only deals with "Rolled I Sections" and "Welded I Sections".

Cl. 6.3.2.2 states "Unless otherwise specified, see 6.3.2.3, for bending members of constant cross section the value of χ_{LT} should be determined from...". Hence in the implementation of EC3 (and the MS NA) in STAAD.Pro, by default the program will consider clause Cl. 6.3.2.3 to evaluate χ_{LT}. For any case that is not dealt with by Cl. 6.3.2.3, the program will consider Cl. 6.3.2.2 to evaluate χ_{LT}.

Cl. 6.3.2.3 in the MS NA states that Table 6.5 in MS EN 1993-1-1:2005 should be replaced with the table given in the NA (Refer to D5.D.11.3 Clause 6.3.2.3(1) – LTB for rolled sections or equivalent welded section (on page 1572)). Hence for all cases dealt with by the table in the MS NA, this implementation will choose the buckling curves from the MS NA. For any case that is not dealt with by the table in the MS NA, the program will use the method given in Cl. 6.3.2.2 of MS EN 1993-1-1:2005.

Hence for the following cross sections the program will use the Table in the MS NA for choosing a buckling curve for LTB checks (when the MS NA has been specified):

- Rolled doubly symmetric I & H Sections
- Rolled doubly symmetric hollow sections (SHS, RHS, CHS)
- Angle Sections
- Any other rolled section
- Welded doubly symmetric sections with h/b < 3.1

For the following cross sections, the program will use Cl. 6.3.2.3 of MS EN 1993-1-1:2005 to evaluate χ_{LT}

- Welded I & H Sections with $h/b \geq 3.1$.

For any other type of cross section that is not dealt with by the National Annex or Cl.6.3.2.3, the program will use Cl. 6.3.2.2 to evaluate χ_{LT} .

In any case the Elastic critical moment "Mcr" (used to evaluate the non dimensional slenderness) will be evaluated as described in D5.D.11.2 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks (on page 1571). Since the MS NA uses the NCCI documents mentioned in the sections above, this implementation will only consider end restraint conditions corresponding to the `CMN` parameter=1.0. For all other cases of the `CMN` parameter values, this implementation will use the method specified in Annex F of DD ENV 1993-1-1:1992.

> **Note:** If a National Annex has not been specified (i.e., NA parameter in the design input = 0), the program will use Cl. 6.3.2.3 only in the case of Rolled or welded I & H Sections. For all other cases, the program will use Cl. 6.3.2.2 of MS EN 1993-1-1:2005. Also, I sections with plates will be treated as built-up sections only if the section has been explicitly specified as a built-up section (i.e., `SBLT` parameter = 1.0 in design input).

D5.D.11.5 Clause 6.3.2.3(2) – Modification factor, f, for LTB checks

The MS NA specifies the use of eqn. 6.58 of MS EN 1993-1-1:2005 to evaluate the modification factor, *f*, for the LTB reduction factor χ_{LT}. To evaluate the modification factor MS EN 1993-1-1:2005 uses a correction factor, kc, given by Table 6.6 in the code.

The program does not calculate the kc factor and conservatively uses a reduction factor equal to 1. The proposed implementation will allow for the reduction factor based on the MS NA.

These values are for an end restraint factor of k = 1 (i.e., `CMN` = 1.0). Hence for all other values of `CMN` (i.e., 0.7 or 0.5), the program uses the values of C1 from DD ENV 1993-1-1:1992 Annex F.

You can also manually specify a value for kc by setting the design parameter, `KC`, to the desired value. The user can also get the program to calculate the value of kc automatically by setting the value of the `KC` parameter in the design input to 0. This will cause the program to evaluate a value of C_1 corresponding to the end conditions and the Bending moment of the member and in turn calculate k_c as given in the NA. To evaluate C_1, the program will use the NCCI documents (Refer to D5.D.11.2 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks (on page 1571)).

Note that for the MS NA, the program will attempt to evaluate k_c by default using the equation in NA,

$$kc = 1/\sqrt{C_1}$$

where C1 will be the value used for the M_{cr} calculations.

If k_c evaluates to be greater than 1.0, the program will then evaluate kc as per Table 6.6 of EN 1993-1-1:2005.

D5.D.11.6 Clause 6.3.3(5) – Interaction factors kyy, kyz, kzy, and kzz

The MS NA recommends that the method in Annex A or Annex B of MS EN 1993-1-1:2005 can be used to calculate the interaction factors for Cl. 6.3.3 checks in the case of doubly symmetric sections. STAAD.Pro uses the equations in Annex B of MS EN 1993-1-1:2005 to calculate these interaction factors for doubly symmetric sections..

However, for non-doubly symmetric sections, the MS NA gives the option of using Annex B with some modifications as given in the NA. (Cl. NA-3.2 of the MS NA). The MS NA requires additional checks to be done to check for the maximum allowable values of λ and X to be used in equations 6.61 and 6.62 of MS EN 1993-1-1:2005.

As per the MS NA, for non-doubly symmetric sections, the slenderness about the weak axis (λ_y in STAAD.Pro) and the corresponding reduction factor χ_y should be taken as the values from the highest values of slenderness (λ) among the flexural buckling slenderness (λ_y), torsional slenderness (λ_T) and torsional-flexural slenderness (λ_{TF}) as given in Clauses 6.3.1.3 and 6.3.1.4 of MS EN 1993-1-1:2005. Hence for non-doubly symmetric sections the program will calculate the critical non-dimensional slenderness as:

$$\lambda_y = \max \begin{cases} \lambda \text{per Cl. 6.3.1.3} \\ \lambda_T \text{per Cl. 6.3.1.4} \end{cases}$$

where

$$\lambda_T = \sqrt{\frac{A \cdot f_y}{N_{cr}}}$$

$$N_{cr} = \min\left(N_{crT}, N_{crTF}\right)$$

The MS NA or EC3 does not, however, specify a method to evaluate N_{crT} or N_{crTF}. Hence, the program uses the method specified in the NCCI document *SN001a-EN-EU: Critical axial load for torsional and flexural torsional buckling modes* to calculate these. Refer to D5.D.11.7 Clause 6.3.1.4 - Slenderness for torsional and torsional-flexural buckling (on page 1575) for details.

Note: The MS NA or EC3 does not deal with angle sections specifically and therefore STAAD.Pro uses the method described in the EC3 implementation to deal with slenderness of angle sections. This is done as per cl 4.7.10 of BS 5950.

Clause NA 3.2 of the MS NA also requires that “Where the section is not an I Section or a hollow section and is a class1 or class 2 section, it will be treated as a class 3 section for the purposes of this clause”. Hence for all Class 1 or Class 2 cross sections that are *not* I, H, SHS, RHS or CHS sections, the elastic properties will be used for the purposes of 6.3.3 checks.

D5.D.11.7 Clause 6.3.1.4 - Slenderness for torsional and torsional-flexural buckling

Equations 6.52 and 6.53 of MS-EN 1993-1-1:2005 are to be used to calculate the non-dimensional slenderness parameter, λ_T, to be used for torsional and torsional-flexural buckling checks. The MS-EN 1993-1-1:2005 does not provide equations to calculate the elastic critical loads $N_{cr,T,F}$ and $N_{cr,T}$ (refer 6.3.14 of SS EN 1993-1-1:2005). Therefore, the NCCI document *SN001a-EN-EU: Critical axial load for torsional and flexural torsional buckling modes* provides methods to calculate the $N_{cr,T,F}$ and $N_{cr,T}$ factors and hence will to be included in this implementation of the MS NA.

The program will only consider Channel Sections and Tee- sections when evaluating the critical torsional and Flexural Torsional buckling loads as per Cl 6.3.1.4.

The critical axial load for torsional buckling is evaluated as:

where

i_o^2	=	$i_y^2 + i_z^2 + y_o^2 + z_o^2$
i_y and i_z	=	the radius of gyration about the Y-Y (weak axis) and Z-Z (strong axis) respectively

The critical axial load for torsional-flexural buckling is evaluated as:

$$N_{cr,TF} = \frac{i_o^2}{2\left(i_y^2 + i_z^2\right)}\left[N_{cr,y} + N_{cr,T} - \sqrt{(N_{cr,y} + N_{cr,T})^2 - 4N_{cr,y}N_{cr,T}\frac{i_y^2 + i_z^2}{i_o^2}}\right]$$

For details on these equations, refer to the NCCI document SN001a-EN-EU.

D5.D.12 German National Annex to EC3

Adds values from the German National Annex—titled DIN EN 1993-1-1:2005—for use with Eurocode 3, or EN 1993-1-1:2005. The NA document makes small changes to the base document.

The clauses/sections in EN 1993-1-1:2005 (hereafter referred to as EC-3) that require additional clauses from the German National Annex (hereafter referred to as DE-NA) are described in the following sections.

Refer to the D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) for a description of these clauses. The sections below refer to the corresponding clauses in the DE-NA.

The following clauses are *not* implemented in STAAD.Pro:

Clause 6.3.2.4(1) B – Slenderness for flexural buckling	STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the German National Annex.
Clause 6.3.2.4(2)B – Modification factor "kfl"	STAAD.Pro does not use this clause for design per EC-3. Therefore, this clause is ignored for the German National Annex.

D5.D.12.1 Clause 6.1(1) – General: Partial Safety Factors for buildings

EN 1993-1-1:2005 specifies the use of the partial safety factors to be used in for design as given in Cl. 6.1 of the code. These factors are Γ_{M0}, Γ_{M1}, and Γ_{M2}. EN 1993 provides default values for these factors. However, any National Annex is allowed to override these default values.

The partial safety factors will use the following values for the German National Annex:

- Resistance of cross-sections, Γ_{M0} = 1.0
- Resistance of members to instability, Γ_{M1} = 1.10

- Resistance of cross sections to tension, Γ_{M2} = 1.25

The design function in STAAD.Pro sets these values as the default values for the DE-NA (`NA 10` is specified).

Note: You can change these values through the `GM0`, `GM1`, & `GM2` design parameters. Refer to D5.C.6 Design Parameters (on page 1502)

Note: If any of these parameters are specified as `0`, STAAD.Pro will ignore the user specified value (i.e., 0) and use the default values as given above.

D5.D.12.2 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks

The DE-NA recommends the use of Table 6.3 and 6.4 of DIN EN 1993-1-1:2005 to calculate the imperfection factors for Lateral Torsional Buckling (LTB) checks.

The calculation of the LTB reduction factor χ_{LT}, requires the calculation of the Elastic Critical Buckling Moment, M_{cr}. The DE-NA does not specify a particular method to calculate Mcr. Hence the calculation of Mcr has been based on the following NCCI documents:

Doubly symmetric sections

SN003a-EN-EU *NCCI: Elastic critical moment for lateral torsional buckling* provides equation used to calculate M_{cr} specifically for doubly symmetric sections:

$$M_{cr} = C_1 \frac{\pi^2 EI}{(kL)^2}\left\{\sqrt{\left(\frac{k}{k_w}\right)^2 \frac{I_w}{I_S} + \frac{(kL)^2 GI_t}{\pi^2 EI_S} + (C_2 Z_g)^2} - C_2 Z_g\right\}$$

C_1 and C_2 are factors that depend on the end conditions and the loading conditions of the member. The NCCI provides values for C_1 and C_2 for the different cases as given in Table 3.1 and Table 3.2.

The NCCI considers three separate loading conditions:

- Members with end moments
- Members with transverse loading
- Members with end moments and transverse loading.

STAAD.Pro accounts for the loading condition and the bending moment diagram through the `CMM` parameter. The values of C_1 and C_2 may also be directly specified using the `C1` and `C2` parameters, respectively (required for `CMM = 7` or `CMM = 8`).

Mono-symmetric sections with symmetry about their weak axis

Annex D of DE-NA also provides a method to evaluate the elastic critical moment, M_{cr}, for uniform mono-symmetric sections that are symmetric about the weak axis. STAAD.Pro uses this method for the evaluating the elastic critical moment for Tee sections.

The equation to evaluate M_{cr} for mono symmetric sections is given as:

$$M_{cr} = C_1 \frac{\pi^2 EI_z}{(k_x L)^2}\left\{\sqrt{\left(\frac{k_x}{k_w}\right)^2 \frac{I_w}{I} + \frac{(k_x L)^2 GI_T}{\pi^2 EI_z} + (C_2 z_g - C_3 z_1)^2} - C_2 z_g - C_3 z_1\right\}$$

The factors C_1, C_2, and C_3 are dependent on the end conditions and loading criteria. The program considers C_1, C_2, and C_3 as given in the tables 4.1 and 4.2 of the NCCI, based on the `CMM` parameter.

The default value of `CMM = 0`, which considers the member as a pin ended member with uniformly distributed load (UDL) along its span. This NCCI does not however consider the “end moments and transverse loading” condition. You use the C1, C2 and C3 parameters to input the required values for C_1, C_2, and C_3, respectively, to be used in calculating M_{cr}.

Note: If "MU" as well as C1, C2 and C3 have been specified, the program will ignore MU and use the user input values of C1, C2 and C3. STAAD.Pro obtains these values from Annex F of DD ENV version of 1993-1-1:1992.

Note: When CMM = 7 or CMM = 8, the values for C1, C2 and C3 parameters must be manually specified.

Both the NCCI documents mentioned above assume that the member under consideration is free to rotate on plan and that there are no warping restraints for the member (k = kw = 1.0). STAAD.Pro takes into account of the end conditions using the CMN parameter for EC3. A value of K = kw =1 is indicated by a value of CMN = 1.0 in the design input. Hence the above methods will be used only for members which are free to rotate on plan and which have no warping restraints (i.e., CMN = 1.0). For members with partial or end fixities (i.e., CMN = 0.5 or CMN = 0.7), this implementation will fall back on to the method and coefficients in DD ENV 1993-1-1:1992 – Annex F.

For all cases that are not dealt with by the National Annex (or the NCCI documents) this implementation will use the method as per the DD ENV 1993-1-1:1992 code.

The term z_g in the equation to calculate M_{cr} refers to the distance between the point of application of load on the cross section in relation to the shear center of the cross section. The value of z_g is considered positive, if the load acts towards the shear center and is negative if it acts away from the shear center. By default, the program will assume that the load acts towards the shear center at a distance equal to (Depth of section/2) from the shear center. The use will be allowed to modify this value by using the ZG parameter. Specifying a value of ZG = 0 in the design input would indicate that the load acts exactly at the shear center of the section so that the term z_g in the equation will have a value of zero.

Note: The program does not consider the case of cantilevers.

D5.D.12.3 Clause 6.3.2.3(1) – LTB for rolled sections or equivalent welded section

The DE-NA specifies that the default values in Table 6.5 for the $\lambda_{LT,0}$ and β factors given in clause 6.3.2.3(1) as follows:

For all sections, use:

$\lambda_{LT,0}$ =0.4 and β = 0.75

D5.D.12.4 Clauses 6.3.2.2 and 6.3.2.3 — Calculation of LTB Reduction factor, χ_{LT} as per German NA

Clauses 6.3.2.2 and 6.3.2.3 (EN 1993-1-1:2005), both give equations to evaluate the LTB reduction factor χ_{LT} to be used in eqn. 6.55 of DIN EN 1993-1-1:2005.

Cl. 6.3.2.2 uses tables 6.3 and 6.4 to choose the buckling curve and the imperfection factors to be used for calculating χ_{LT}. Table 6.4 specifies the choice of buckling curves for "Rolled I Sections", "Welded I Sections" and "Any other sections". Cl 6.3.2.3 on the other hand uses tables 6.5 and 6.3 to choose the buckling curves and imperfection factors. Table 6.5 however only deals with "Rolled I Sections" and "Welded I Sections".

Cl. 6.3.2.2 states "Unless otherwise specified, see 6.3.2.3, for bending members of constant cross section the value of χ_{LT} should be determined from...". Hence in the implementation of EC3 (and the German Annex) in STAAD.Pro: by default the program will consider clause Cl. 6.3.2.3 to evaluate χ_{LT}. For any case that is not dealt with by Cl. 6.3.2.3, the program will consider Cl. 6.3.2.2 to evaluate χ_{LT}.

Note: The MTH design parameter can be used to control the choice of the clause used to calculate χ_{LT}.

In any case, the elastic critical moment, Mcr, (used to evaluate the non dimensional slenderness) will be evaluated as previously given. Since this implementation uses the NCCIs mentioned in the sections above, only end restraint conditions corresponding to the CMN parameter=1.0 (Refer to D5.D.12.2 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks (on page 1576)) will be considered. For all other cases of the CMN parameter values, this implementation will use the method specified in Annex F of DD ENV 1993-1-1:1992.

Note: If a National Annex has not been specified (i.e., NA parameter in the design input = 0), the program will use Cl. 6.3.2.3 only in the case of Rolled or welded I & H Sections. For all other cases, the program will use Cl. 6.3.2.2 of DIN EN 1993-1-1:2005. Also, I sections with plates will be treated as built-up sections only if the section has been explicitly specified as a built-up section (i.e., SBLT parameter = 1.0 in design input).

D5.D.12.5 Clause 6.3.2.3(2) – Modification factor, f, for LTB checks

The DE-NA specifies the use of Equation 6.58 of DIN EN 1993-1-1:2005 to evaluate the modification factor “f” for the LTB reduction factor χ_{LT}. To evaluate the modification factor SS EN 1993-1-1:2005 uses a correction factor “kc” given by Table 6.6 in the code.

The DE-NA however, specifies that the correction factor “kc” is to be obtained as below:

$$K_c = 1/\sqrt{C_1}$$

Where:

C_1 is to be obtained from the NCCI documents as previously described (Refer to D5.D.12.2 Clause 6.3.2.2 – Elastic critical moment and imperfection factors for LTB checks (on page 1576)). The NCCI document SN003a-EN-EU specifies the values of C1 to be used in table 3.1 as shown below. The current implementation does not account for the K_c factor and conservatively uses a reduction factor equal to 1. The program allows for the reduction factor based on the DE-NA.

These values are for an end restraint factor of k = 1 (i.e., design parameter CMN = 1.0). Hence for all other values of CMN (i.e., 0.7 or 0.5) this implementation will use the values of C_1 from DD ENV 1993-1-1:1992 Annex F.

The program will use a default value of 1.0 for K_c. However, you can also input a custom value of K_c by setting the design parameter KC to the desired value. If the KC parameter in the design input is set to 0, then the program will automatically calculate its value. This will cause the program to evaluate a value of C_1 corresponding to the end conditions and the Bending moment of the member and in turn calculate K_c as given in the NA. To evaluate C_1, the program will use the NCCI documents as previously described.

D5.D.12.6 Clause 6.3.3(5) – Interaction factors kyy, kyz, kzy, and kzz

The DE-NA recommends the use of equations in Annex A or Annex B of DIN-EN 1993-1-1 to calculate these interaction factors. STAAD.Pro uses the method in Annex B by default. Thus the program uses Annex B for Cl. 6.3.3 checks.

The DE-NA or EC3 do not deal with angle sections in specific and thus the program uses the method per cl 4.7.10 of BS 5950 for single and double angle sections to evaluate the slenderness.

D5.D.12.7 Clause 6.3.1.4 - Slenderness for torsional and torsional-flexural buckling

Equations 6.52 and 6.53 of DIN EN 1993-1-1:2005 are to be used to calculate the non-dimensional slenderness λ_T, to be used for torsional and torsional-flexural buckling checks. DIN EN 1993-1-1:2005 does not provide equations to calculate the elastic critical loads $N_{cr,T,F}$ and $N_{cr,T}$ (refer 6.3.14 of DIN EN 1993-1-1:2005).

The NCCI document SN001a-EN-EU: *Critical axial load for torsional and flexural torsional buckling modes* provides methods to calculate the $N_{cr,TF}$ and $N_{cr,T}$ factors and therefore these methods are used to evaluate the elastic critical loads for the DE-NA.

The critical axial load for torsional buckling is evaluated as:

where

i_o^2	=	$i_y^2 + i_z^2 + y_o^2 + z_o^2$
i_y and i_z	=	the radius of gyration about the Y-Y (weak axis) and Z-Z (strong axis) respectively

The critical axial load for torsional-flexural buckling is evaluated as:

$$N_{cr,TF} = \frac{i_o^2}{2\left(i_y^2 + i_z^2\right)}\left[N_{cr,y} + N_{cr,T} - \sqrt{(N_{cr,y} + N_{cr,T})^2 - 4N_{cr,y}N_{cr,T}\frac{i_y^2 + i_z^2}{i_o^2}}\right]$$

For details on these equations, refer to the NCCI document SN001a-EN-EU.

D5.D.13 Swedish National Annex to EC3

Adds values from the Swedish National Annex—titled BFS EN 1993-1-1:2005—for use with Eurocode 3, or EN 1993-1-1:2005. The NA document makes small changes to the base document.

The clauses/sections in EN 1993-1-1:2005 (hereafter referred to as EC-3) that require additional clauses from the Swedish National Annex (hereafter referred to as SW-NA) are described in the following sections.

Refer to the D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1478) for a description of these clauses. The sections below refer to the corresponding clauses in the SW-NA.

D5.D.13.1 Clause 3.2.(2) - Steel Grades

The Swedish NA allows the use of custom steel grades as given in Table E-1 of the National Annex. These grades of steel can be specified by using the `PY` (Yield Strength) and `FU` (Ultimate Strength) parameters in STAAD.Pro.

D5.D.13.2 Clause 6.1(1) – General: Partial Safety Factors for Buildings

EN 1993-1-1:2005 specifies the use of the partial safety factors to be used in for design as given in Cl. 6.1 of the code. These factors are Γ_{M0}, Γ_{M1}, and Γ_{M2}. EN 1993 provides default values for these factors. However, any National Annex is allowed to override these default values.

The partial safety factors will use the following values for the Swedish National Annex:

- Resistance of cross-sections, Γ_{M0} = 1.0
- Resistance of members to instability, Γ_{M1} = 1.0
- Resistance of cross sections to tension, Γ_{M2} = $0.9\ x\ f_u/f_y$, but not less than 1.1

Where:

f_u is the ultimate steel strength
f_y is the yield strength of steel

The design function in STAAD.Pro sets these values as the default values for the SW-NA (`NA 10` is specified).

Note: You can change these values through the GM0 and GM1 design parameters. Refer to D5.C.6 Design Parameters (on page 1502) The value of GM2 (Γ_{M2}) is calculated based on the steel grade values specified. Refer to D5.D.13.1 Clause 3.2.(2) - Steel Grades (on page 1579)

Note: If any of these parameters are specified as `0`, STAAD.Pro will ignore the user specified value (i.e., 0) and use the default values as given above.

D5.D.13.3 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks

The SW-NA recommends the use of Table 6.3 and 6.4 of DIN EN 1993-1-1:2005 to calculate the imperfection factors for Lateral Torsional Buckling (LTB) checks.

The calculation of the LTB reduction factor χ_{LT}, requires the calculation of the Elastic Critical Buckling Moment, M_{cr}. The SW-NA does not specify a particular method to calculate Mcr. Hence the calculation of Mcr has been based on the following NCCI documents:

Doubly symmetric sections

SN003a-EN-EU *NCCI: Elastic critical moment for lateral torsional buckling* provides equation used to calculate M_{cr} specifically for doubly symmetric sections:

$$M_{cr} = C_1 \frac{\pi^2 EI}{(kL)^2} \left\{ \sqrt{\left(\frac{k}{k_w}\right)^2 \frac{I_w}{I_S} + \frac{(kL)^2 G I_t}{\pi^2 E I_S} + (C_2 Z_g)^2} - C_2 Z_g \right\}$$

C_1 and C_2 are factors that depend on the end conditions and the loading conditions of the member. The NCCI provides values for C_1 and C_2 for the different cases as given in Table 3.1 and Table 3.2.

The NCCI considers three separate loading conditions:

- Members with end moments
- Members with transverse loading
- Members with end moments and transverse loading.

STAAD.Pro accounts for the loading condition and the bending moment diagram through the `CMM` parameter. The values of C_1 and C_2 may also be directly specified using the `C1` and `C2` parameters, respectively (required for `CMM = 7` or `CMM = 8`).

Mono-symmetric sections with symmetry about their weak axis

Annex D of SW-NA also provides a method to evaluate the elastic critical moment, M_{cr}, for uniform mono-symmetric sections that are symmetric about the weak axis. STAAD.Pro uses this method for the evaluating the elastic critical moment for Tee sections.

The equation to evaluate M_{cr} for mono symmetric sections is given as:

$$M_{cr} = C_1 \frac{\pi^2 E I_z}{(k_x L)^2} \left\{ \sqrt{\left(\frac{k_x}{k_w}\right)^2 \frac{I_w}{I} + \frac{(k_x L)^2 G I_T}{\pi^2 E I_z} + (C_2 z_g - C_3 z_1)^2} - C_2 z_g - C_3 z_1 \right\}$$

The factors C_1, C_2, and C_3 are dependent on the end conditions and loading criteria. The program considers C_1, C_2, and C_3 as given in the tables 4.1 and 4.2 of the NCCI, based on the `CMM` parameter.

The default value of `CMM = 0`, which considers the member as a pin ended member with uniformly distributed load (UDL) along its span. This NCCI does not however consider the “end moments and transverse loading” condition. You use the `C1`, `C2` and `C3` parameters to input the required values for C_1, C_2, and C_3, respectively, to be used in calculating M_{cr}.

Note: If "MU" as well as C1, C2 and C3 have been specified, the program will ignore MU and use the user input values of C1, C2 and C3. STAAD.Pro obtains these values from Annex F of DD ENV version of 1993-1-1:1992.

Note: When `CMM = 7` or `CMM = 8`, the values for `C1`, `C2` and `C3` parameters must be manually specified.

Both the NCCI documents mentioned above assume that the member under consideration is free to rotate on plan and that there are no warping restraints for the member (k = kw = 1.0). STAAD.Pro takes into account of the end conditions using the `CMN` parameter for EC3. A value of K = kw =1 is indicated by a value of CMN = 1.0 in the design input. Hence the above methods will be used only for members which are free to rotate on plan and which have no warping restraints (i.e., CMN = 1.0). For members with partial or end fixities (i.e., CMN = 0.5 or CMN = 0.7), this implementation will fall back on to the method and coefficients in DD ENV 1993-1-1:1992 – Annex F.

For all cases that are not dealt with by the National Annex (or the NCCI documents) this implementation will use the method as per the DD ENV 1993-1-1:1992 code.

The term z_g in the equation to calculate M_{cr} refers to the distance between the point of application of load on the cross section in relation to the shear center of the cross section. The value of z_g is considered positive, if the load acts towards the shear center and is negative if it acts away from the shear center. By default, the program will assume that the load acts towards the shear center at a distance equal to (Depth of section/2) from the shear center. The use will be allowed to modify this value by using the `ZG` parameter. Specifying a value of ZG = 0 in the design input would indicate that the load acts exactly at the shear center of the section so that the term z_g in the equation will have a value of zero.

Note: The program does not consider the case of cantilevers.

D5.D.13.4 Clause 6.3.2.3(1) – LTB for rolled sections or equivalent welded section

The SW-NA specifies that the following values for the $\lambda_{LT,0}$ and β factors:

For all sections, use:

$\lambda_{LT,0}$ =0.4 and β = 0.75

D5.D.13.5 Clauses 6.3.2.2 and 6.3.2.3 — Calculation of LTB Reduction factor, χ_{LT} as per Swedish NA

Clauses 6.3.2.2 and 6.3.2.3 (EN 1993-1-1:2005), both give equations to evaluate the LTB reduction factor χ_{LT} to be used in eqn. 6.55 of BFS EN 1993-1-1:2005.

Cl. 6.3.2.2 uses tables 6.3 and 6.4 to choose the buckling curve and the imperfection factors to be used for calculating χ_{LT}. Table 6.4 specifies the choice of buckling curves for "Rolled I Sections", "Welded I Sections" and "Any other sections". Cl 6.3.2.3 on the other hand uses tables 6.5 and 6.3 to choose the buckling curves and imperfection factors. Table 6.5 however only deals with "Rolled I Sections" and "Welded I Sections".

Cl. 6.3.2.2 states "Unless otherwise specified, see 6.3.2.3, for bending members of constant cross section the value of χ_{LT} should be determined from…". Hence in the implementation of EC3 (and the Swedish Annex) in STAAD.Pro: by default the program will consider clause Cl. 6.3.2.3 to evaluate χ_{LT}. For any case that is not dealt with by Cl. 6.3.2.3, the program will consider Cl. 6.3.2.2 to evaluate χ_{LT}.

Note: The `MTH` design parameter can be used to control the choice of the clause used to calculate χ_{LT}.

In any case, the elastic critical moment, Mcr, (used to evaluate the non dimensional slenderness) will be evaluated as previously given. Since this implementation uses the NCCIs mentioned in the sections above, only end restraint conditions corresponding to the `CMN` parameter=1.0 (Refer to D5.D.13.3 Clause 6.3.2.2 –Elastic critical moment and imperfection factors for LTB checks (on page 1580)) will be considered. For all other cases of the CMN parameter values, this implementation will use the method specified in Annex F of DD ENV 1993-1-1:1992.

Note: If a National Annex has not been specified (i.e., NA parameter in the design input = 0), the program will use Cl. 6.3.2.3 only in the case of Rolled or welded I & H Sections. For all other cases, the program will use Cl. 6.3.2.2 of BFS EN 1993-1-1:2005. Also, I sections with plates will be treated as built-up sections only if the section has been explicitly specified as a built-up section (i.e., SBLT parameter = 1.0 in design input).

D5.D.13.6 Clause 6.3.3(5) – Interaction factors kyy, kyz, kzy, and kzz

The SW-NA recommends the use of equations in Annex A of EN 1993-1-1:2005 to calculate these interaction factors, which are used by STAAD.Pro when the Swedish NA is selected.

The SW-NA or EC3 do not deal with angle sections in specific and thus the program uses the method per cl 4.7.10 of BS 5950 for single and double angle sections to evaluate the slenderness.

D5.D.13.7 Clause 6.3.1.4 - Slenderness for torsional and torsional-flexural buckling

Equations 6.52 and 6.53 of BFS EN 1993-1-1:2005 are to be used to calculate the non-dimensional slenderness λ_T, to be used for torsional and torsional-flexural buckling checks. BFS EN 1993-1-1:2005 does not provide equations to calculate the elastic critical loads $N_{cr,T,F}$ and $N_{cr,T}$ (refer 6.3.14 of BFS EN 1993-1-1:2005).

The NCCI document SN001a-EN-EU: *Critical axial load for torsional and flexural torsional buckling modes* provides methods to calculate the $N_{cr,TF}$ and $N_{cr,T}$ factors and therefore these methods are used to evaluate the elastic critical loads for the SW-NA.

The critical axial load for torsional buckling is evaluated as:

where

i_o^2	=	$i_y^2 + i_z^2 + y_o^2 + z_o^2$
i_y and i_z	=	the radius of gyration about the Y-Y (weak axis) and Z-Z (strong axis) respectively

The critical axial load for torsional-flexural buckling is evaluated as:

$$N_{cr,TF} = \frac{i_o^2}{2\left(i_y^2 + i_z^2\right)}\left[N_{cr,y} + N_{cr,T} - \sqrt{(N_{cr,y} + N_{cr,T})^2 - 4N_{cr,y}N_{cr,T}\frac{i_y^2 + i_z^2}{i_o^2}}\right]$$

For details on these equations, refer to the NCCI document SN001a-EN-EU.

D5.E. European Codes - Timber Design Per EC 5: Part 1-1

STAAD.Pro is capable of performing timber design based on the European code EC5 Part 1-1 *Eurocode 5: Design of timber structures - Part 1.1: General-Common rules and rules for buildings*.

D5.E.1 General Comments

Principles of Limit States Design of Timber Structures are used as specified in the code.

Design per EC5 is limited to the prismatic, rectangular shapes only. There is no Eurocode-specific timber section database or library consisting of pre-defined shapes for analysis or for design. The feature of member selection is thus not applicable to this code.

The design philosophy of this specification is based on the concept of limit state design. Structures are designed and proportioned taking into consideration the limit states at which they would become unfit for their intended use. Two major categories of limit-state are recognized - ultimate and serviceability. The primary considerations in ultimate limit state design are strength and stability, while that in serviceability is deflection. Appropriate load and resistance factors are used so that a uniform reliability is achieved for all timber structures under various loading conditions and at the same time the chances of limits being surpassed are acceptably remote.

In the STAAD.Pro implementation, members are proportioned to resist the design loads without exceeding the limit states of strength, stability and serviceability. Accordingly, the most economic section is selected on the basis of the least weight criteria as augmented by the designer in specification of allowable member depths, desired section type, or other such parameters. The code checking portion of the program checks whether code requirements for each selected section are met and identifies the governing criteria.

The following sections describe the salient features of the STAAD.Pro implementation of EC 5. A detailed description of the design process along with its underlying concepts and assumptions is available in the specification document.

Axes convention in STAAD and EC5

STAAD.Pro defines the major axis of the cross-section as zz and the minor axis as yy. The longitudinal axis of the member is defined as x and joins the start joint of the member to the end with the same positive direction.

EC5, however, defines the principal cross-section axes in reverse to that of STAAD.Pro, but the longitudinal axis is defined in the same way. Both of these axes definitions follow the orthogonal right hand rule.

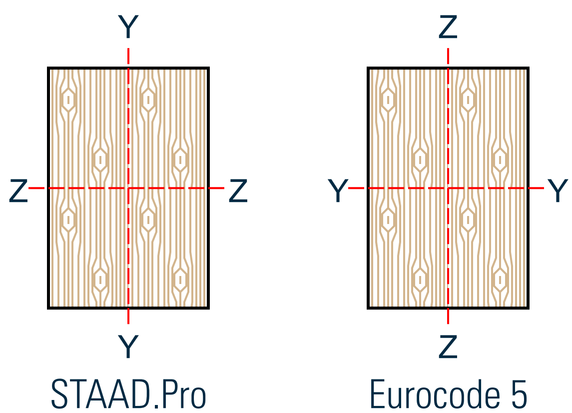

Figure 170: Axis conventions per STAAD and Eurocode 5

Determination of Factors

A. Kmod – Modification factor taking into account of Load-duration (LDC) and Moisture-content (Service Class - SCL). Reference Table 3.1 of EC-5-2004.

For “Solid Timber”, the values are incorporated in the program.

B. γ_m – Partial factor for Material Property values. Reference Table 2.3 of EC-5-2004.

For “Solid Timber”, the value of $\gamma_m = 1.3$ is incorporated in the program.

C. Kh – Size Factor.

For members, subjected to tension, whose maximum c/s dimension is less than the reference width in tension the characteristic strength in tension (ft0k) is to be increased by the factor Kh.

For members, subjected to bending, whose depth is less than reference depth in bending, the characteristic strength in bending (fmk) is to be increased by the factor Kh.

As per clause 3.2(3) of EC 5- 2004, for rectangular solid timber with a characteristic timber density $\rho_k \leq 700$ kg/m^3 the reference depth in bending or the reference width (maximum cross-sectional dimension) is 150 mm.

The value of Kh = Minimum of {(150/h) 0.2 and 1.3} for such solid timber is incorporated in the software. Please refer clause numbers 3.3 and 3.4 for the value of Kh for Glued laminated timber and Laminated veneer lumber respectively.

D. KC90 – Factor taking into account the load configuration, possibility of splitting and degree of compressive deformation.

For members, subjected to compression, perpendicular to the direction of grain alignment, this factor should be taken into account. Default value of 1 is used in STAAD.Pro. You may override the value. Please refer clause 6.1.5 of EC-5-2004 in this regard.

E. Km – Factor considering re-distribution of bending stress in cross section.

For members, subjected to bending, this factor is taken into account for stress checking. For rectangular section the value of Km is 0.7, and this value is incorporated in STAAD.Pro. You may override the value. Please refer clause 6.1.6 of EC-5-2004 in this regard.

F. Kshape – Factor depending on shape of cross section.

For members, subjected to torsional force, design torsional stress should be less than equal design shear strength multiplied by the factor Kshape. This factor is determined by STAAD.Pro internally using the guidelines of clause 6.1.8 of EC-5-2004.

D5.E.2 Analysis Methodology

Table 160: EC5 Nomenclature

Symbol	Description
S_{t0d}	Design tensile stress parallel (at zero degree) to grain alignment.
S_{t90d}	Design tensile stress perpendicular (at 90 degrees) to grain alignment.
S_{c0d}	Design compressive stress parallel to grain alignment.
S_{c90d}	Design compressive stress perpendicular to grain alignment.
S_{mzd}	Design bending stress about zz axis.
S_{myd}	Design bending stress about yy axis.
S_{vd}	Design shear stress.
S_{tor_d}	Design torsional stress.

Symbol	Description
F_{t0d}	Design tensile strength - parallel to the grain alignment.
F_{t90d}	Design tensile strength - perpendicular to the grain alignment.
F_{c0d}	Design compressive strength - parallel to the grain alignment.
F_{c90d}	Design compressive strength - perpendicular to the grain alignment.
F_{mzd}	Design bending strength - about zz-axis.
F_{myd}	Design bending strength - about yy-axis.
F_{vd}	Design shear strength about yy axis.
RATIO	Permissible ratio of stresses as input using the `RATIO` parameter. The default value is 1.
l_z ,$l_{rel,z}$	Slenderness ratios corresponding to bending about zz axis.
l_y,$l_{rel,y}$	Slenderness ratios corresponding to bending about yy axis.
$E_{0,05}$	Fifth percentile value of modulus of elasticity parallel to grain.
$G_{0,05}$	Fifth percentile value of shear modulus parallel to grain.
I_z	Second moment of area about the strong z-axis.
I_y	Second moment of area about the weak y-axis.
I_{tor}	Torsional moment of inertia.
f_{mk}	Characteristic bending strength.
b, h	Width and depth of beam.

Equations for Characteristic Values of Timber Species as per Annex-A of EN 338:2003

The following equations were used to determine the characteristic values:

For a particular Timber Strength Class (TSC), the following characteristic strength values are required to compute the other related characteristic values.

i. Bending Strength – $f_{m,k}$
ii. Mean Modulus of Elasticity in bending – $E_{0, mean}$
iii. Density - ρ_k

Sl No.	Property	Symbol	Wood Type	
			Softwood (C)	Hardwood (D)
1.	Tensile Strength parallel to grain	$f_{t,0,k}$	0.6 * $f_{m,k}$	
2.	Tensile Strength perpendicular to grain	$f_{t,90,k}$	Minimum of {0.6 and (0.0015*r_k)}	
3.	Compressive Strength parallel to grain	$f_{c,0,k}$	5 * $(f_{m,k})^{0.45}$	
4.	Compressive Strength perpendicular to grain	$f_{c,90,k}$	0.007*r_k	0.0015*r_k
5.	Shear Strength	$f_{v,k}$	Minimum of {3.8 and (0.2*$f_{m,k}^{\ 0.8}$)}	
6.	Modulus of Elasticity parallel to grain	$E_{0,05}$	0.67* $E_{0,mean}$	0.84* $E_{0,mean}$
7.	Mean Modulus of Elasticity perpendicular to grain	$E_{90,mean}$	$E_{0,mean}$ /30	$E_{0,mean}$ /15
8.	Mean Shear Modulus	G_{mean}	$E_{0,mean}$ /16	
9.	Shear Modulus	$G_{0,05}$	$E_{0,05}$ /16	

The values of the characteristic strengths computed using the above equations, may differ with the tabulated values in Table-1 of EN 338:2003. However, in all such cases, the values obtained from the provided equations are treated as actual and is used by the program, as the values of Table-1 are based on these equations.

Design values of Characteristic Strength

As per clause 2.4.1, Design values of a strength property shall be calculated as:

$$X_d = K\ mod \cdot (X_k/\gamma_m)$$

Where:

X_d is design value of strength property
X_k characteristic value of strength property
γ_m is partial factor for material properties.

The member resistance in timber structure is calculated in STAAD according to the procedures outlined in EC5. This depends on several factors such as cross sectional properties, different load and material factors, timber strength class, load duration class, service class and so on. The methodology adopted in STAAD for calculating the member resistance is explained here.

Check for Tension stresses

If the direction of applied axial tension is parallel to the direction of timber grain alignment, the following formula should be checked per Equation 6.1 of EC-5 2004:

$$S_{t0d}/F_{t0d} \leq$$

If the direction of applied axial tension is perpendicular to the direction of timber grain alignment, the following formula should be checked:

$$S_{t90d}/F_{t90d} \leq$$

Check for Compression stresses

If the direction of applied axial compression is parallel to the direction of timber grain alignment, the following formula should be checked per Equation 6.2 of EC-5 2004:

$$S_{c0d}/F_{c0d} \leq$$

If the direction of applied axial compression is perpendicular to the direction of timber grain alignment, the following formula should be checked per Equation 6.3 of EC-5 2004:

$$S_{t0d}/(F_{t0d} \cdot Kc90) \leq$$

Check for Bending stresses

If members are under bending stresses, the following conditions should be satisfied per Equations 6.11 and 6.12 of EC-5 2004.

Note: In STAAD z-z axis is the strong axis.

$$(S_{mzd}/F_{mzd}) + Km \cdot (S_{myd}/F_{myd}) \leq$$

$$Km \cdot (S_{mzd}/F_{mzd}) + (S_{myd}/F_{myd}) \leq$$

Check for Shear stresses

Horizontal stresses are calculated and checked against allowable values per Equation 6.13 of EC-5 2004:

$$S_{vd}/F_{vd} \leq$$

Check for Torsional stresses

Members subjected to torsional stress should satisfy Equation 6.14 of EC-5 2004:

$$S_{tor\_d}/(Kshape \cdot F_{tor\_d}) \leq$$

Check for combined Bending and Axial tension

Members subjected to combined action of bending and axial tension stress should satisfy Equations 6.17 and 6.18 of EC-5 2004:

Note: In STAAD z-z axis is the strong axis.

$$(S_{t0d}/F_{t0d}) + (S_{mzd}/F_{mzd}) + Km \cdot (S_{myd}/F_{myd}) \le$$

$$(S_{t0d}/F_{t0d}) + Km \cdot (S_{mzd}/F_{mzd}) + (S_{myd}/F_{myd}) \le$$

Check for combined Bending and axial Compression

If members are subjected to bending and axial compression stress, Equations 6.19 and 6.20 of EC-5 2004 should be satisfied:

Note: In STAAD z-z axis is the strong axis.

$$(S_{c0d}/F_{c0d})^2 + (S_{mzd}/F_{mzd}) + Km \cdot (S_{myd}/F_{myd}) \le$$

$$(S_{c0d}/F_{c0d})^2 + Km \cdot (S_{mzd}/F_{mzd}) + (S_{myd}/F_{myd}) \le$$

Stability check

A. Column Stability check

The relative slenderness ratios should be calculated per Equations 6.21 and 6.22 of EC-5 2004.

Note: In STAAD z-z axis is the strong axis.

$$\lambda_{rel,z} = \lambda_z/\pi \cdot (S_{c0k}/E_{0,05})^{1/2}$$

$$\lambda_{rel,y} = \lambda_y/\pi \cdot (S_{c0k}/E_{0,05})^{1/2}$$

If both $\lambda_{rel,z}$ and $\lambda_{rel,y}$ are less than or equal to 0.3 the following conditions should be satisfied:

$$(S_{c0d}/F_{c0d})^2 + (S_{mzd}/F_{mzd}) + Km \cdot (S_{myd}/F_{myd}) \le$$

$$(S_{c0d}/F_{c0d})^2 + Km \cdot (S_{mzd}/F_{mzd}) + (S_{myd}/F_{myd}) \le$$

In other cases, the conditions in Equations 6.23 and 6.24 of EC-5 2004 should be satisfied.

Note: In STAAD z-z axis is the strong axis.

$$S_{c0d}/(Kcz \cdot F_{c0d}) + (S_{mzd}/F_{mzd}) + Km \cdot (S_{myd}/F_{myd}) \le$$

$$S_{c0d}/(Kcy \cdot F_{c0d}) + Km \cdot (S_{mzd}/F_{mzd}) + (S_{myd}/F_{myd}) \le$$

Where (Equations 6.25 through 6.28 of EC-5 2004):

$$Kcz = 1/\{K_z + [(K_z)^2 - (\lambda_{rel,z})^2]^{1/2}\}$$

$$Kcy = 1/\{K_y + [(K_{zy})^2 - (\lambda_{rel,y})^2]^{1/2}\}$$

$$Kz = 0.5 \cdot [1 + \beta_c \cdot (\lambda_{rel,z} - 0.3) + (\lambda_{rel,z})^2]$$

$$Ky = 0.5 \cdot [1 + \beta_c \cdot (\lambda_{rel,y} - 0.3) + (\lambda_{rel,y})^2]$$

The value of β_c incorporated in the software is the one for solid timber (i.e., 0.2).

B. Beam Stability check

If members are subjected to only a moment about the strong axis z, the stresses should satisfy Equation 6.33 of EC-5 2004:

$$S_{mzd}/(Kcrit \cdot F_{mzd}) \le$$

Where a combination of moment about the strong z-axis and compressive force exists, the stresses should satisfy Equation 6.35 of EC-5 2004 (ref. to Equations 6.32 and 6.34 of the same):

$$[S_{mzd}/(Kcrit \cdot F_{mzd})]^2 + S_{c0d}/(Kcz \cdot F_{c0d}) \leq$$

Where:

$Kcrit = 1.0$ when $\lambda_{rel,m} \leq 0.75$
$Kcrit = 1.56 - 0.75 \lambda_{rel,m}$ when $0.75 < \lambda_{rel,m} \leq 1.4$
$Kcrit = 1/(\lambda_{rel,m})^2$ when $1.4 < \lambda_{rel,m}$
$\lambda_{rel,m} = (f_{mk}/S_{m,crit})^{1/2}$

For hardwood, use Equation 6.30 of EC-5 2004:

$$S_{m,crit} = \pi \cdot (E_{0,05} \cdot I_y \cdot G_{0,05} \cdot I_{tor})^{1/2}/(l_{ef} \cdot W_z)$$

For softwood, use Equation 6.31 of EC-5 2004:

$$S_{m,crit} = 0.78 \cdot b^2 \cdot E_{0,05}/(h \cdot l_{ef})$$

D5.E.3 Design Parameters

Design parameters communicate specific design decisions to the program. They are set to default values to begin with and may be altered to suite the particular structure.

Depending on the model being designed, the user may have to change some or all of the parameter default values. Some parameters are unit dependent and when altered, the new setting must be compatible with the active "unit" specification.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 161: Timber Design EC 5: Part 1-1 Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `TIMBER EC5` Design Code to follow. See section TR.52.1 Timber Design Parameter Specifications (on page 2683) .
ALPHA	0.0	Angle of inclination of load to the grain alignment. (Ref. Cl.6.1.1, Cl. 6.1.2, Cl.6.1.3, Cl.6.1.4) 0.0 = Load parallel to grain 90.0 = Load Perpendicular to grain

Parameter Name	Default Value	Description
DFF	None	"Deflection Length" / Max. Allowable Net Final Local Deflection. In this case, deflection check will be performed, if both the parameters SERV and DFF are present with specific values. For appropriate range of values, please refer Cl.7.2 (Table 7.2)
DJ1		Start node number for a physical member under consideration for Deflection Check.
DJ2		End node number for a physical member under consideration for Deflection Check.
KC90	1.0	Factor taking into account the load configuration, possibility of splitting and degree of compressive deformation. (Ref. Cl.6.1.5-(2)) • Range: 1.0 ≤ KC90 ≤ 4.0 • Other than the default value, user may specify any value within the range, depending on load-position, load-dispersion, contact length at support locations etc.
KLEF	1.0 (Member Length)	Effective Length Factor to check Lateral Torsional Buckling (Ref. Table 6.1). Factor multiplied by the span of the beam and depends on the support conditions and load configurations. The user will put the appropriate value from the Table 6.1. Required only for `MTYP` value of 1 (Beam).
KY	1.0 (Member Length)	Effective Length Factor for Local-y-axis. (Ref. Cl.6.3.2), for the computation of the relative slenderness ratios.

Parameter Name	Default Value	Description
KZ	1.0 (Member Length)	Effective Length Factor for Local-z-axis. (Ref. Cl.6.3.2), for the computation of the relative slenderness ratios.
LDC	1	Load Duration Class (Ref. Cl. 2.3.1.2), required to get the K-MOD value from Table – 3.1. 1.0 = Permanent action 2.0 = Long term action 3.0 = Medium term action 4.0 = Short term action 5.0 = Instantaneous action
MTYP	0	Member Type: Beam/Column. (Ref. Cl.6.3.2, Cl.6.3.3) 0.0 = Not defined; both clauses are checked (Default) 1.0 = Beam Member 2.0 = Column Member This information is required to find which stability check will be performed as per the Cl 6.3 according to the Member Type.
RATIO	1.0	Permissible ratio of actual to allowable value.
SCL	3	Service Class (Ref. Cl.2.3.1.3) 1.0 = Class 1, Moisture content ≤ 12% 2.0 = Class 2, Moisture content ≤ 20% 3.0 = Class 3, Moisture content > 20%

Parameter Name	Default Value	Description
TRACK	0	Degree/Level of Details of design output results. 1.0 = Print the design output at the minimal detail level 2.0 = Print the design output at the intermediate detail level 3.0 = Print the design output that the maximum detail level
TSC	6 (C24)	Timber Strength Class (Ref. Reference EN338 – 2003) • Softwood: 1 = C14, 2 = C16, 3 = C18, 4 = C20, 5 = C22, 6 = C24, 7 = C27, 8 = C30, 9 = C35, 10 = C40, 11 = C45, 12 = C50. • Hardwood: 13 = D30, 14 = D35, 15 = D40, 16 = D50, 17 = D60, 18 = D70. This TSC definition will calculate the corresponding characteristic strength values using the equations as given in BS-EN-338, Annex - A.

D6. French Codes

D6.A. French Codes - Steel Design per CM66-1977 (French)

STAAD.Pro is capable of performing steel design based on the French code CM66, 1977 edition *Centre Technique Industriel de la Construction Metallique* (*Industrial Technical Center of Metal Construction*) publication entitled *Design Rules for Structural Steelwork* .

D6.A.1 General Comments

The design philosophy embodied in this specification is based on the concept of limit state design. Structures are designed and proportioned according to the limit states of which they would become unfit for their intended use. Two major categories of limit-states are recognized: ultimate and serviceability. The primary considerations in ultimate limit state design are strength and stability; that in serviceability is deflection. Appropriate load and resistance factors are used so that uniform reliability is achieved for all steel structures under various loading conditions and at the same time the chances of limits being surpassed are acceptably remote.

In the STAAD.Pro implementation, members are proportioned to resist the design loads without exceeding the limit states of strength, stability and serviceability. Accordingly, the most economic section is selected on the basis of the least weight criteria, as augmented by the designer in specification of allowable member depths, desired section type, or other related parameters. The code checking portion of the program verifies that code requirements for each selected section are met and also identifies the governing criteria.

The next few sections describe the salient features of STAAD.Pro implementation of "Design Rules for Structural Steelwork." A detailed description of the design process, along with its underlying concepts and assumptions, is available in the specification document.

D6.A.2 Basis of Methodology

The *Design Rules for Structural Steelwork* (Revision 80) permits the usage of elastic analysis. Thus, in STAAD.Pro, linear elastic analysis method is used to obtain the forces and moments in the members. However, strength and stability considerations are based on the principles of plastic behavior. Axial compression buckling and lateral torsional buckling are taken into consideration for calculation of axial compression resistance and flexural resistance of members. Slenderness calculations are made and overall geometric stability is checked for all members.

D6.A.3 Member Capacities

The member strengths are calculated in STAAD.Pro according to the procedures outlined in section 4 of this specification. Note that the program automatically considers co-existence of axial force, shear and bending in calculating section capacities.

For axial tension capacity, procedures of section 4.2 are followed. For axial compression capacity, formulas of section 5.3 are used.

Moment capacities about both axes are calculated using the procedures of sections 4.5 and 4.6. Lateral torsional buckling is considered in calculating ultimate twisting moment per section 5.22 of the specification. The parameter `UNL` (see D6.A.5 Design Parameters (on page 1593)) must be used to specify the unsupported length of the compression flange for a laterally unsupported member. Note that this length is also referred to as twisting length.

D6.A.4 Combined Axial Force and Bending

The procedures of sections 4.55 and 5.32 are implemented for interaction of axial forces and bending. Appropriate interaction equations are used and the governing criterion is determined.

D6.A.5 Design Parameters

The design parameters outlined in the following table may be used to control the design procedure. These parameters communicate design decisions from the engineer to the program, thus allowing the engineer to control the design process to suit an application's specific needs.

The default parameter values have been selected as frequently used numbers for conventional design. Depending on the particular design requirements, some or all of these parameter values may be changed to exactly model the physical structure.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 162: French Steel Design Parameters

Parameter Name	Default Value	Description
CODE	FRENCH	Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
BEAM	0.0	0.0 = design only for end moments and those at locations specified by `SECTION` command. 1.0 = calculate moments at tenth points long the beam, and use maximum Mz for design.
C1	1.0	Parameter used in clause 5.21 in the calculation of M(D), the critical twisting moment and as shown in CM 66 Addendum 80, table 5, usual range from 0.71 to 4.10
C2	1.0	Parameter used in clause 5.21 in the calculation of M(D), the critical twisting moment and as shown in CM 66 Addendum 80, table 5, usual range from 0.0 to 1.56
DFF	None (Mandatory for deflection check)	"Deflection Length" divided by the Maximum allowable local deflection
DJ1	Start Jointof member	Joint No. denoting starting point for calculation of "Deflection Length" (See Note 1)
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length" (See Note 1)
DMAX	100.0 cm.	Maximum allowable depth (used in member selection).
DMIN	0.0 cm.	Minimum allowable depth (used in member selection).
FYLD	250.0 MPa	Yield strength of steel.
KY	1.0	K value for axial compression buckling about local Y-axis. Usually, this is the minor axis.

Parameter Name	Default Value	Description
KZ	1.0	K value for axial compression buckling about local Z-axis. Usually, this is the major axis.
LY	Member Length	Length to calculate slenderness ratio about Y-axis for axial compression.
LZ	Member Length	Length to calculate slenderness ratio about Z-axis for axial compression.
NSF	1.0	Net section factor for tension members.
RATIO	1.0	Permissible ratio of actual load effect and design strength.
SAME	0.0	Controls the sections to try during a SELECT process. 0.0 = Try every section of the same type as original (see note a (on page 1596) below) 1.0 = Try only those sections with a similar name as original, e.g., if the original is an HEA 100, then only HEA sections will be selected, even if there are HEM's in the same table.
TRACK	0.0	0.0 = Suppress printing of all design strengths. 1.0 = Print all design strengths.
UNF	1.0	Unsupported length provided as a fraction of actual member length used for lateral-torsional buckling calculation. **Note:** If both UNF and UNL parameters are specified, the effective length used is UNF×UNL.

Parameter Name	Default Value	Description
UNL	Member Length	Unsupported length for calculating allowable bending stress. Used for the lateral-torsional buckling calculation. Value should be in the current units of length.

a. For angles, if the original section is an equal angle, then the selected section will be an equal angle and vice versa for unequal angles.

D6.A.6 Code Checking and Member Selection

Both code checking and member selection options are available in the STAAD.Pro implementation of CM 66 (Revn. 80).

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D6.A.7 Tabulated Results of Steel Design

Results of code checking and member selection are presented in the output file in a tabular format.

Note: `COND CRITIQUE` refers to the section of the CM 66 (Revn. 80) specification which governed the design.

If the `TRACK` parameter is set to 1.0, calculated member capacities will be printed. The following is a detailed description of printed items:

PC	Member Compression Capacity
TR	Member Tension Capacity
MUZ	Member Moment Capacity (about z-axis)
MUY	Member Moment Capacity (about y-axis)
VPZ	Member Shear Capacity (z-axis)
VPY	Member Shear Capacity (y-axis)

STAAD.Pro contains a broad set of facilities for designing structural members as individual components of an analyzed structure. The member design facilities provide the user with the ability to carry out a number of different design operations. These facilities may be used selectively in accordance with the requirements of the design problem. The operations to perform a design are:

- Specify the members and the load cases to be considered in the design.
- Specify whether to perform code checking or member selection.
- Specify design parameter values, if different from the default values.

These operations may be repeated by the user any number of times depending upon the design requirements.

STAAD.Pro supports steel design of wide flange, S, M, HP shapes, angle, double angle, channel, double channel, beams with cover plate, composite beams and code checking of prismatic properties.

Sample Input data for Steel Design:

```

```

D6.A.8 Built-in French Steel Section Library

The following information is provided for use when the built-in steel tables are to be referenced for member property specification. These properties are stored in a database file. If called for, the properties are also used for member design. Since the shear areas are built into these tables, shear deformation is always considered for these members.

An example of the member property specification in an input file is provided at the end of this section.

A complete listing of the sections available in the built-in steel section library may be obtained by using the tools of the graphical user interface.

Following are the descriptions of different types of sections.

D6.A.8.1 IPE Shapes

These shapes are designated in the following way.

```
10 15  TA ST IPE140
20 TO  30 TA ST IPEA120
33 36  TO 46 BY 2 TA ST IPER180
```

D6.A.8.2 HE shapes

HE shapes are specified as follows.

```
3 5  TA ST HEA120A
7 10  TA ST HEM140
13 14  TA ST HEB100
```

D6.A.8.3 IPN Shapes

The designation for the IPN shapes is similar to that for the IPE shapes.

```
25 TO  35 TA ST IPN200
23 56  TA ST IPN380
```

D6.A.8.4 T Shapes

Tee sections are not input by their actual designations, but instead by referring to the I beam shapes from which they are cut. For example,

```
1 5  TA T IPE140
2 8  TA T HEM120
```

D6.A.8.5 U Channels

Shown below is the syntax for assigning 4 different names of channel sections.

```
1 TO  5 TA ST UAP100
6 TO  10 TA ST UPN220
11 TO  15 TA ST UPN240A
16 TO  20 TA ST UAP250A
```

D6.A.8.6 Double U Channels

Back to back double channels, with or without a spacing between them, are available. The letter D in front of the section name will specify a double channel.

```
11 TA  D UAP150
17 TA  D UAP250A SP 0.5
```

In the above set of commands, member 11 is a back-to-back double channel UAP150 with no spacing in between. Member 17 is a double channel UAP250A with a spacing of 0.5 length units between the channels.

D6.A.8.7 Angles

Two types of specification may be used to describe an angle. The standard angle section is specified as follows:

```
16 20  TA ST L30X30X2.7
```

The above section signifies an angle with legs of length 30mm and a leg thickness of 2.7mm. This specification may be used when the local Z axis corresponds to the z-z axis specified in Chapter 2. If the local Y axis corresponds to the z-z axis, type specification "RA" (reverse angle) should be used instead of ST.

```
17 21  TA RA L25X25X4
22 24  TA RA L100X100X6.5
```

Note that if the leg thickness is a round number such as 4.0, only the number 4 appears in the section name, the decimal part is not part of the section name.

D6.A.8.8 Double Angles

Short leg back-to-back or long leg back-to-back double angles can be specified by means of input of the words SD or LD, respectively, in front of the angle size. In case of an equal angle, either SD or LD will serve the purpose.

```
33 35  TA SD L30X20X4 SP 0.6
37 39  TA LD L80X40X6
43 TO  47 TA LD L80X80X6.5 SP 0.75
```

D6.A.8.9 Tubes (Rectangular or Square Hollow Sections)

Section names of tubes, just like angles, consist of the depth, width and wall thickness as shown below.

```
64 78  TA ST TUB50252.7
66 73  TA ST TUB2001008.0
```

Members 64 and 78 are tubes with a depth of 50mm, width of 25mm and a wall thickness of 2.7mm. Members 66 and 73 are tubes with a depth of 200mm, width of 100mm and a wall thickness of 8.0mm. Unlike angles, the ". 0" in the thickness is part of the section name.

Tubes can also be input by their dimensions instead of by their table designations. For example,

```
6 TA  ST TUBE DT 8.0 WT 6.0 TH 0.5
```

is a tube that has a depth of 8 length units, width of 6 length units, and a wall thickness of 0.5 length units. Only code checking, no member selection, will be performed for TUBE sections specified in this way.

D6.A.8.10 Pipes (Circular Hollow Sections)

To designate circular hollow sections, use PIP followed by numerical value of the diameter and thickness of the section in mm omitting the decimal portion of the value provided for the diameter. The following example illustrates the designation.

```
8 TO  28 TA ST PIP422.6
3 64  78 TA ST PIP21912.5
```

Members 8 to 28 are pipes 42.4mm in dia, having a wall thickness of 2.6mm. Members 3, 64 and 78 are pipes 219.1mm in dia, having a wall thickness of 12.5mm.

Circular hollow sections may also be provided by specifying the outside and inside diameters of the section. For example,

```
1 TO  9 TA ST PIPE OD 25.0 ID 20.0
```

specifies a pipe with outside dia. of 25 length units and inside dia. of 20 length units. Only code checking, no member selection will be performed if this type of specification is used.

D7. German Codes

D7.A. German Codes - Steel Design per DIN 18800 Code

STAAD.Pro is capable of performing concrete design based on the German code DIN 18800, Parts 1 & 2: *Stahlbauten - Teil 1: Bemessung und Konstruktion* (*Steel structures - Part 1: Design and construction*) and *Stahlbauten - Teil 2: Stabilitätsfälle - Knicken von Stäben und Stabwerken* (*Steel structures - Part 2: Analysis of safety against buckling of linear members and frames*)

D7.A.1 General

This section presents some general statements regarding the implementation of the DIN code. The design philosophy and procedural logistics are based on the principles of elastic analysis and allowable stress design. Facilities are available for member selection as well as code checking. Two major failure modes are recognized: failure by overstressing and failure by stability considerations. The following sections describe the salient features of the design approach.

Members are proportioned to resist the design loads without exceeding the allowable stresses or capacities and the most economical section is selected on the basis of the least weight criteria. The code checking part of the program also checks the slenderness requirements and the stability criteria. It is recommended that you use the following steps in performing the steel design:

1. Specify the geometry and loads and perform the analysis.
2. Specify the design parameter values if different from the default values.
3. Specify whether to perform code checking or member selection.

D7.A.2 Analysis Methodology

The elastic analysis method is used to obtain the forces and moments for design. Analysis is done for the primary and combination loading conditions you provide. You are allowed complete flexibility in providing loading specifications and in using appropriate load factors to create necessary loading situations. Depending upon the analysis requirements, regular stiffness analysis or P-Delta analysis may be specified. Dynamic analysis may also be performed and the results combined with static analysis results.

D7.A.3 Member Property Specifications

For specification of member properties of standard German steel sections, the steel section library available in STAAD.Pro may be used. The next section describes the syntax of commands used to assign properties from the built-in steel table. Member properties may also be specified using the User Table facility. For more information on these facilities, refer to G.6 Member Properties (on page 2113) .

D7.A.4 Built-in German Steel Section Library

The following information is provided for use when the built-in steel tables are to be referenced for member property specification. These properties are stored in a database file. If called for, these properties are also used for member design. Since the shear areas are built into these tables, shear deformation is always considered for these members during the analysis. An example of member property specification in an input file is provided at the end of this section.

A complete listing of the sections available in the built-in steel section library may be obtained using the tools of the graphical user interface.

Following are the descriptions of different types of sections.

Refer to G.6.2 Built-In Steel Section Libraries (on page 2116) for additional information.

D7.A.4.1 IPE Shapes

These shapes are designated in the following way:

```
20 TO 30 TA ST IPEA120
33 36 TO 46 BY 2 TA ST IPER140
```

D7.A.4.2 HE Shapes

The designation for HE shapes is similar to that for IPE shapes.

```
25 TO 35 TA ST HEB300
23 56 TA ST HEA160
```

D7.A.4.3 I Shapes

I shapes are identified by the depth of the section. The following example illustrates the designation.

```
14 15 TA ST I200
```

(indicates an I-section with 200mm depth)

D7.A.4.4 T Shapes

Tee sections are not input by their actual designations, but instead by referring to the I beam shapes from which they are cut. For example,

```
1 5 TA T HEA220
2 8 TA T IPE120
```

D7.A.4.5 U Channels

The example below provides the command for identifying two channel sections. The former (U70X40) has a depth of 70mm and a flange width of 40mm. The latter (U260) has a depth of 260mm.

```
11 TA D U70X40
27 TA D U260
```

D7.A.4.6 Double Channels

Back-to-back double channels, with or without spacing between them, are available. The letter “D” in front of the section name will specify a double channel, e.g., D U180. The spacing between the double channels is provided following the expression “SP”.

```
11 TA D U180
27 TA D U280 SP 0.5
```

(Indicates 2 channels back-to-back spaced at 0.5 length units)

D7.A.4.7 Angles

Two types of specifications may be used to describe an angle. The standard angle section is specified as follows:

```
16 20 TA ST L20X20X2.5
```

The above section signifies an angle with legs of length 20mm and a leg thickness of 2.5mm. The above specification may be used when the local z-axis corresponds to the Z-Z axis specified in Chapter 2. If the local y-axis corresponds to the Z-Z axis, type specification "RA" (reverse angle) may be used.

```
17 21 TA RA L40X20X5
```

D7.A.4.8 Double Angles

Short leg back-to-back or long leg back-to-back double angles can be specified by using the word SD or LD, respectively, in front of the angle size. In case of an equal angle, either SD or LD will serve the purpose. Spacing between the angles is provided by using the word SP and the spacing value following the section name.

```
14 TO 20 TA SD L40X20X4 SP 0.5
21 TO 27 TA LD L40X20X4 SP 0.5
```

D7.A.4.9 Pipes (Circular Hollow Sections)

To designate circular hollow sections, use `PIP` followed by numerical value of the diameter and thickness of the section in mm omitting the decimal section of the value provided for diameter. The following example will illustrate the designation.

```
8 TO 28 TA ST PIP602.9
* (60.3mm dia, 2.9mm wall thickness)
3 64 67 TA ST PIP40612.5
*(406.4mm dia, 12.5mm wall thickness)
```

Circular hollow sections may also be provided by specifying the outside and inside diameters of the section. For example,

```
1 TO 9 TA ST PIPE OD 25.0 ID 20.0
```

specifies a pipe with outside dia. of 25 and inside dia. of 20 in current length units. Only code checking and no member selection will be performed if this type of specification is used.

D7.A.4.10 Tubes (Rectangular or Square Hollow Sections)

Tube names are input by their dimensions. For example,

```
15 TO 25 TA ST TUB100603.6
```

is the specification for a tube having sides of 100mm x 60mm and the wall thickness of 3.6mm.

Tubes, like pipes can also be input by their dimensions (Height, Width and Thickness) instead of by their table designations.

```
6 TA ST TUBE DT 8.0 WT 6.0 TH 0.5
```

is a tube that has a height of 8, a width of 6, and a wall thickness of 0.5 in current length units. Only code checking and no member selection will be performed for TUBE sections specified this way.

D7.A.5 Member Capacities

The allowable stresses used in the implementation are based on DIN 18800 (Part 1) - Section 7. The procedures of DIN 18800 Part 2 are used for stability analysis. The basic measure of member capacities are the allowable stresses on the member under various conditions of applied loading such as allowable tensile stress, allowable compressive stress etc. These depend on several factors such as cross sectional properties, slenderness factors, unsupported width to thickness ratios and so on. Explained here is the procedure adopted in STAAD for calculating such capacities.

D7.A.5.1 Checks for Axial Tension

In members with axial tension, the tensile load must not exceed the tension capacity of the member. The tension capacity of the member is calculated on the basis of the member area. STAAD calculates the tension capacity of a given member based on a user supplied net section factor (NSF -a default value of 1.0 is present but may be altered by changing the input value, see D7.A.7 Design Parameters (on page 1604)) and proceeds with member selection or code checking.

D7.A.5.2 Checks for Axial Compression

The compression capacity for members in compression is determined according to the procedure of DIN 18800-Part 2. Compressive resistance is a function of the slenderness of the cross-section (Kl/r ratio) and the user may control the slenderness value by modifying parameters such as KY, LY, KZ and LZ.

D7.A.5.3 Checks for Bending and Shear

The bending compressive and tensile capacities are dependent on such factors as length of outstanding legs, thickness of flanges, unsupported length of the compression flange (UNL, defaults to member length) etc. Shear capacities are a function of web depth, web thickness etc. Users may use a value of 1.0 or 2.0 for the TRACK parameter to obtain a listing of the bending and shear capacities.

D7.A.6 Combined Loading

For members experiencing combined loading (axial force, bending, and shear), applicable interaction formulas are checked at different locations of the member for all modeled loading situations. Members subjected to axial force and bending are checked using the criteria of DIN 18800 (Part 1) - Section 6.1.6. In addition, for members with axial loads and bending, the criteria of DIN 18800(Part 2) - Sections 3.4 and 3.5 are used.

D7.A.7 Design Parameters

You are allowed complete control over the design process through the use of parameters described in the following table. These parameters communicate design decisions from the engineer to the program. The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements of the situation, some or all of these parameter values may have to be changed to exactly model the physical structure.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 163: German Steel Design Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as DIN18800. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).

Parameter Name	Default Value	Description
BEAM	0.0	Number of sections to be checked per member: 0. Design only for end sections. 1. Check at location of maximum MZ along member. 2. Check ends plus location of beam 1.0 check. 3. Check at every 1/13th of the member length and report the maximum.
CB	0	Beam coefficient n, defined in Table 9: If Cb = 0, program will use n = 2.5 for rolled sections and 2.0 for welded sections.
CMM	1.0	Moment factor, Zeta, defined in Table 10: 1. fixed ended member with constant moment, Zeta = 1.0 2. pin ended member with UDL, Zeta = 1.12 3. pin ended member with central point load, Zeta = 1.35 4. fixed ended member, Zeta calculated from end moments.
DMAX	1.0 m	Maximum allowable depth during member selection
DMIN	0.0 m	Minimum required depth during member selection
KY	1.0	K value in local y-axis. Usually, this is the minor axis.
KZ	1.0	K value in local z-axis. Usually, this is the major axis.
LY	Member Length	Length in local y-axis to calculate slenderness ratio.
LZ	Member Length	Length in local z-axis to calculate slenderness ratio.
PY	240 N/sq.mm	Strength of steel.

Parameter Name	Default Value	Description
NSF	1.0	Net section factor for tension members.
RATIO	1.0	Permissible ratio of actual to allowable stresses
SAME	0.0	Control of sections to try during a SELECT process: 0. Try every section of the same type as the original. 1. Try only those with a similar name.
SBLT	0	Specify section as either rolled or built-up: 0. Rolled 1. Built-up
SGR	0.0	Grade of steel: 0. St 37-2 1. St 52-3 2. St E 355
TRACK	0.0	Level of detail in output file: 0. Output summary of results 1. Output summary of results plus member capacities 2. Output detailed results
UNF	1.0	Unsupported length provided as a fraction of actual member length used for lateral-torsional buckling calculation. **Note:** If both UNF and UNL parameters are specified, the effective length used is UNF×UNL.
UNL	Member Length	Unsupported length for calculating allowable bending stress. Used for the lateral-torsional buckling calculation. Value should be in the current units of length.

D7.A.9 Code Checking

The purpose of code checking is to check whether the provided section properties of the members are adequate to carry the forces transmitted to it by the loads on the structure. The adequacy is checked per the DIN requirements.

Code checking is done using forces and moments at specified sections of the members. If the `BEAM` parameter for a member is set to 1, moments are calculated at every twelfth point along the beam, and the maximum moment about the major axis is used. When no sections are specified and the `BEAM` parameter is set to zero (default), design will be based on member start and end forces. The code checking output labels the members as PASSed or FAILed. In addition, the critical condition, governing load case, location (distance from start joint) and magnitudes of the governing forces and moments are also printed.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

D7.A.9 Member Selection

The member selection process basically involves determination of the least weight member that PASSes the code checking procedure based on the forces and moments of the most recent analysis. The section selected will be of the same type as that specified initially. For example, a member specified initially as a channel will have a channel selected for it. Selection of members whose properties are originally provided from a user table will be limited to sections in the user table. Member selection cannot be performed on TUBES, PIPES, or members listed as PRISMATIC.

Sample Input data for Steel Design

```

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D8. Indian Codes

D8.A. Indian Codes - Steel Design per IS 800 - 2007

STAAD.Pro is capable of performing steel design based on the Indian code IS 800-2007 *General construction in steel - Code of practice*.

D8.A.1 General Comments

For steel design, STAAD.Pro compares the actual design forces with the capacities as defined by the Indian Standard Code. The IS 800: 2007 Code is used as the basis of this design.

A brief description of some of the major capacities is described herein.

The following commands should be used to initiate design per Limit State Method of this code:

```
PARAMETER n
```

```
CODE IS800 LSD
```

The following commands should be used to initiate design per Working Stress Method of this code:

```
PARAMETER n
```

```
CODE IS800 WSD
```

Where:

> *n* = optional integer (i.e., - 1, 2) which signifies the numerical order of parameter command block (if multiple blocks are specified).

D8.A.2 Design Process

The design process follows the following design checks.

When a design is performed, the output file reports the maximum utilization ratio from all of these checks.

Table 2 of IS800:2007 contains the various limit of “limiting width to thickness ratio” for various section types. This provision is not applicable for solid rod design.

Design for Work Stress Method

The scope of the implementation for WSD method is limited to the following range of sections – from CL 11.1 to 11.5.3 of the IS800:2007 specification.

D8.A.2.1 Slenderness

As per Section 3.8 Table 3, the slenderness ratio (KL/r) of compression members shall not exceed 180, and the slenderness ratio (L/r) of tension members shall not exceed 400.

You can edit the default values through `MAIN` and `TMAIN` parameters, as defined in D8.A.4 Design Parameters (on page 1617).

D8.A.2.2 Section Classification

The IS 800: 2007 specification allows inelastic deformation of section elements. Thus local buckling becomes an important criterion.

Steel sections are classified as Plastic, Compact, Semi-Compact, or Slender element sections depending upon their local buckling characteristics.

This classification is a function of the geometric properties of the section as well as nature of the load applied to the member. The design procedures are different depending on the section class.

STAAD.Pro is capable of determining the section classification for the standard shapes and design the section for the critical load case accordingly. The Section Classification is done as per section 3.7 of IS 800:2007 and Table B2, for Outstanding and Internal Elements of a section.

For the criteria for being included in those classes, refer to section 3.7.2-(a) – (d) of the code.

Slender Sections

STAAD.Pro is capable of designing I-Sections with slender webs for IS 800:2007.

The IS:800-2007 code does not provide any clear guidelines about what method should be adopted for the design of slender section. The “Flange Only” methodology is used where it is assumed that flexure is taken by the flanges alone and the web will resist shear with adequate shear buckling resistance. This method requires that the flanges be non-slender elements (i.e., on the web is a slender element) to qualify for a valid section for design. If any of the flange elements become slender, the design will not be performed and a warning message is displayed in the output.

D8.A.2.3 Tension

Limit State Method

The criteria governing the capacity of Tension members are based on:

- Design Strength due to Yielding in Gross Section
- Design Strength due to Rupture of Critical Section
- Design Strength due to Block Shear (does not apply to solid rods)

STAAD.Pro calculates the tension capacity of a given member based on these three limit states.

The limit state of yielding in the gross section is intended to prevent excessive elongation of the member, and the corresponding check is done as per section 6.2 of the code.

The Design strength, involving rupture at the section with the net effective area, is evaluated as per section 6.3 of the code. Here, the number of bolts in the connection may be specified through the use of the design parameter ALPHA.

The Design strength, involving block shear at an end connection, is evaluated as per section 6.4 of the code.

Note: Block shear is *not* checked by default. This is only checked for members for which parameters AVG, AVN, ATG, and ATN are specified.

The Net Section Area may be specified through the use of the parameter NSF.

Working Stress Method

The criteria governing the allowable stress from tension in members are based on Section 11.2.1 of the code:

- Yielding of Gross Section - to prevent excessive elongation of the member due to material yielding.

- Rupture of Net Section - to prevent rupture of the net effective section area. The number of bolts in the connection may be specified through the use of the design parameter ALPHA. The code parameter, γ_{M1}, is taken as 1.25 per Table 5, Clause 5.4.1 of the code.
- Block Shear — to prevent block shearing at the end connection. The code parameters,, γ_{M0} and γ_{M1}, are taken as 1.10 and 1.25, respectively, per Table 5, Clause 5.4.1 of the code.

> **Note:** Block shear is *not* checked by default. This is only checked for members for which parameters AVG, AVN, ATG, and ATN are specified.

These criteria are dependent on the steel material yield stress parameter, FYLD, and ultimate tensile strength parameter, FU.

D8.A.2.4 Compression

The design capacity of the section against compressive force, the guiding phenomenon is the flexural buckling.

Limit State Method

The buckling strength of the member is affected by residual stress, initial bow and accidental eccentricities of load.

To account for all these factors, the strength of the members subjected to axial compression is defined by buckling class a, b, c or d as per clause 7.1.2.2 and Table 7 of IS 800:2007.

Imperfection factor, obtained from buckling class, and Euler's Buckling Stress ultimately govern compressive force capacity of the section as per clause 7.1.2 of IS 800:2007.

The buckling class of a solid rod section is determined per Table 10 of the specification.

Working Stress Method

The actual compressive stress is given by:

$$f_c = FX/A_e$$

where:

A_e = The effective section area as per Clause 7.3.2 of the code. This is equal to the gross cross sectional area, AX, for any non-slender (plastic, compact, or semi-compact) D8.A.2.2 Section Classification (on page 1609). In the case of slender sections, this is limited to value of Ae as described below.

The permissive compressive stress is calculated by first determining the Buckling Class of the section per Table 10 of the code and α_{YY} & α_{ZZ} based on Table 7.

$$F_{ac} = 0.6 \cdot F_{cd}$$

where:

F_{cd} = the minimum of the values of Fcd calculated for the local Y and Z axis.

$$F_{cd} = (/\gamma_{mo})/\ [\varphi + (\varphi^2 + \lambda^2]$$

λ = the non-dimensional slenderness factor is evaluated for each local Y and Z axis.

$$\lambda = (/F_{cc})^{1/2}$$

$$\varphi = 0.5[\ 1 + a(\lambda - 0.2) + \lambda^2]$$

F_{cc} = the Euler Buckling Stress.

$$F_{cc} = \pi^2 \cdot E/(Kl/r)^2$$

K = the effective length factor for bending about either the local Y or Z axis, as provided in the `KY` and `KZ` parameters, respectively.
r = radius of gyration about the local Y or Z axis for the section.
`FYLD` = The yield strength of steel specified in the `FYLD` parameter.

Slender Sections

For member with slender section under axial compression, design compressive strength should be calculated on area ignoring depth thickness ratio of web in excess of the class 3 (semi-compact) limit.

Refer to clause 7.3.2 and Table 2 of IS 800:2007, (corresponding to "Internal Element of Compression Flange")

$$A_e = A_g - (d/t_w - 42\varepsilon) \cdot t_w^{\ 2}$$

where:

A_e = Effective area of section.
A_g = Gross area of section.
d = Depth of web.
t_w = thickness of web.

Flexural-Torsional Buckling for Single Angles

In the case of single angles (ST and RA), a axial compression load does not pass through the member centroid. In practical applications, the load must pass through one of the legs. The deviation between the load and the centroid can be considerable, and thus the effect of flexural-torsional buckling must be considered.

The parameters of `ANG`, `FXTY`, and `NBL` are used to control these calculations.

The calculations for the flexural-torsional buckling strength of a single angle member in compression are performed per section 7.5.1.2 of the code (either limit state method or working stress method are applicable).

D8.A.2.5 Shear

The design capacities of the section against shear force in major- and minor-axis directions are evaluated as per section 8.4 of the code, taking care of the following phenomena:

- Nominal Plastic Shear Resistance
- Resistance to Shear Buckling

Shear area of the sections are calculated as per sec. 8.4.1.1. The full cross-sectional area is considered as the shear area for a solid rod section.

Nominal plastic shear resistance is calculated as per sec. 8.4.1.

Among shear buckling design methods, Simple post-critical method is adopted as per sec. 8.4.2.2(a).

Working Stress Design

The actual shear stress is determined about the major and minor axes, respectively:

$$\tau_{bY} = F_Y / A_Y$$

$$\tau_{bZ} = F_Z / A_Z$$

The permissible shear stress is determined as:

a. When subjected to pure shear:

$\tau_{ab} = 0.40 \cdot F_y$

b. When subjected to shear buckling:

$\tau_{ab} = 0.70 \cdot V_n \cdot A_v$

where

V_n	=	Nominal Shear Strength as per Clause 8.4.2.2.(a) $= V_{cr} = \tau_b \cdot A_v$
A_v	=	AY or AZ, whichever is appropriate, with reference to Clause 8.4.1.1.

Shear buckling must be checked when $(d/t_w) > 67 \cdot \epsilon_w$ for webs without stiffener or $(d/t_w) > 67 \cdot \epsilon_w \cdot \sqrt{(K_v/5.35)}$ for webs with stiffeners.

where

d	=	Clear Depth of Web between Flanges.
t_w	=	Thickness of Web.
ϵ_w	=	$\sqrt{(250 / F_y)}$
F_y	=	Yield Strength of Web, specified using the FYLD parameter.
K_v	=	Shear Buckling Coefficient: = 5.35, when transverse stiffeners are provided only at supports. $= 4.0 + 5.35 / (c/d)^2$ for $(c/d) < 1.0$ $= 5.35 + 4.0 / (c/d)^2$ for $(c/d) \geq 1.0$
c	=	Spacing of Transverse Stiffeners
μ	=	Poisson's Ratio
τ_b	=	Shear Stress corresponding to Web-buckling: $= F_y / \sqrt{3}$, when, $\lambda_w \leq 0.8$ $= (1 - 0.8 \cdot (\lambda_w - 0.8)) \cdot (F_y / \sqrt{3})$ when, $0.8 < \lambda_w < 1.2$ $= F_y / (\sqrt{3} \cdot \lambda_w^{\ 2})$ when, $\lambda_w \geq 1.2$
$\tau_{cr,e}$	=	The Elastic Critical Shear Stress of the Web

$\tau_{cr,e} = (K_v \cdot \pi^2 \cdot E) / (12 \cdot (1 - \mu^2) \cdot (d/t_w)^2)$

where

λ_w	=	Non-dimensional Web Slenderness Ratio for Shear Buckling Stress.
λ_w	=	$[F_y / (\sqrt{3} \cdot \tau_{cr,e})]^{1/2}$

Slender Sections

Slender sections should be verified against shear buckling resistance if $d/t_w > 67 \cdot \varepsilon$ for web without stiffeners or if it exceeds $67 \cdot \varepsilon \cdot \sqrt{(K_v/5.35)}$ for a web with stiffeners.

Design methods for resistance to shear buckling are described in clause 8.4.2.2 of IS:800-2007 code.

$V_n = V_{cr}$

where

V_{cr}	=	shear force corresponding to web buckling $= A_v \cdot \tau_b$
τ_b	=	shear stress corresponding to web buckling, determined as follows:

i. When $\lambda_w \leq 0.8$

$\tau_b = f_{yw}/\sqrt{3}$

ii. When $0.8 < \lambda_w < 1.2$

$\tau_b = [1 - 0.8(\lambda_w - 0.8)](f_{yw}/\sqrt{3})$

iii. When $\lambda_w \geq 1.2$

$\tau_b = f_{yw}/((\sqrt{3}\, \lambda_w^{\ 2}))$

λ_w = non-dimensional web slenderness ratio or shear buckling stress, given by:

$= [f_{yw}/(\sqrt{3}\, \tau_{cr,e})]^{1/2}$

$\tau_{cr,e}$ = elastic critical shear stress of the web

$= (k_v \cdot \pi^2 \cdot E)/[12 \cdot (1 - \mu^2)(d/t_w)^2]$

μ = Poisson's ratio

K_v = 5.35 when transverse stiffeners are provided only at supports

$= 4.0 + 5.35/(c/d)^2$ for $c/d < 1.0$

$= 5.35 + 4.0/(c/d)^2$ for $c/d \geq 1.0$

c = spacing of transverse stiffeners

d = depth of the web

D8.A.2.6 Bending

The design bending moment capacity of a section is primarily dependent on whether the member is laterally supported or unsupported.

You can control the lateral support condition of the member by the use of LAT parameter. The type of member (i.e., cantilever, simply supported, or general) is specified using the CAN parameter.

If the member is laterally supported, then the design strength is calculated as per the provisions of the section 8.2.1 of IS 800:2007, based on the following factors:

- Whether section with webs susceptible to shear buckling before yielding
- Ratio of shear force to design shear strength
- Section classification

If the member is laterally unsupported, then the design strength is calculated as per the provisions of the section 8.2.2 of IS 800:2007, based on the following factors:

- Lateral Torsional Buckling
- Section Classification

Laterally unsupported sections of a solid rod are considered as laterally supported as mentioned in Cl. 8.2.2(b). The plastic moment of inertia, Z_p, is calculated as $D^3/6$.

Working Stress Design

Actual bending stress values are given by, about major (Z) and minor (Y) axes, respectively:

$f_{bcz} = M_z/Z_{ecz}$

$f_{btz} = M_z/Z_{etz}$

$f_{bcy} = M_y/Z_{ecy}$

$f_{bty} = M_y/Z_{ety}$

The permissible bending stress is given as follows:

a. For laterally supported beams:

$F_{abc} = F_{abt} = 0.66 \cdot F_y$ for Plastic or Compact sections
$F_{abc} = F_{abt} = 0.60 \cdot F_y$ for Semi-compact sections

where

F_y	=	Yield strength of steel, indicated by the FYLD parameter.

b. For laterally unsupported beams:

i. About the major axis:

$f_{abcz} = 0.60 \cdot M_d / Z_{ecz}$

$f_{abtz} = 0.60 \cdot M_d / Z_{etz}$

where

M_d	=	Design Bending Strength as per Clause 8.2.2 $= \beta_b \cdot Z_{pz} \cdot f_{bd}$
f_{bd}	=	$\chi_{LT} \cdot F_y / \gamma_{mo}$
Z_{ez}	=	Elastic Section Modulus of the Section
Z_{pz}	=	Plastic Section Modulus of the Section
α_{LT}	=	0.21 for Rolled Steel Section and 0.49 for Welded Steel Section
β_b	=	1.0 for Plastic and Compact Section or Z_{ez}/Z_{pz} for Semi-Compact Section
λ_{LT}	=	Non-dimensional slenderness ratio
λ_{LT}	=	$(\beta_b \cdot Z_{pz} \cdot F_y / M_{cr})^{1/2} \leq (1.2 \cdot Z_{ez} \cdot F_y / M_{cr})^{1/2}$
ϕ_{LT}	=	$0.5 \cdot (1 + \alpha_{LT} \cdot (\lambda_{LT} - 0.2) + \lambda_{LT}{}^2)$
χ_{LT}	=	The Bending Stress Reduction Factor to account for Lateral Torsional Buckling
χ_{LTZ}	=	$\dfrac{1}{\phi_{LTZ} + \sqrt{\phi_{LTZ}^2 - \lambda_{LTZ}^2}}$
Z_{ecz}	=	Elastic Section Modulus of the section about Major Axis for the compression side
Z_{etz}	=	Elastic Section Modulus of the section about Major Axis for the tension side
M_{cr}	=	$M_{cr} = \sqrt{\dfrac{\pi^2 E I_y}{L_{LT}^2}\left(G I_t + \dfrac{\pi^2 E I_w}{L_{LT}^2}\right)}$
I_y	=	Moment of inertia about the minor axis
L_{LT}	=	Effective length for lateral torsional buckling as determined using either the KX or LX parameters
I_t	=	Torsional constant of the section
I_t	=	Warping constant of the section
G	=	Shear modulus of the material

ii. About the minor axis, the permissible bending stress is calculated as for a laterally supported section.

Slender Sections

For member with slender section subjected to bending, moment is taken by flanges alone. Design bending strength should be calculated with effective elastic modulus disregarding the contribution of web of the section.

$Z_{ez} = 2 \cdot [B_f \cdot t_f{}^3/12 + (B_f \cdot t_f) \cdot (D/2 - t_f/2)^2)] / (0.5 \cdot D)$

$Z_{ey} = 2 \cdot (B_f \cdot t_f{}^3/12) / (0.5 \cdot B_f)$

Where:

where

Z_{ez}	=	Elastic Section modulus about major principal axis
Z_{ey}	=	Elastic Section modulus about minor principal axis
B_f	=	Width of flange
T_f	=	thickness of flange
D	=	Overall depth of section

The Moment Capacity will be $M_d = Z_e \cdot f_y / \gamma_{m0}$ for “Laterally Supported” condition.

The Moment Capacity will be $M_d = Z_e \cdot f_{bd} / \gamma_{m0}$ for “Laterally Un-Supported” condition.

Where, f_{bd} is defined in clause 8.2.2 of IS:800-2007 (described in previous Working Stress Design section).

Note: Slender section can only attain elastic moment capacity and cannot reach to plastic moment capacity.

D8.A.2.7 Combined Interaction Check

Members subjected to various forces – axial, shear, moment, torsion - are checked against combined interaction check.

Limit State Method

This interaction check is done taking care of two aspects:

- Section strength
- Overall member strength

Section strength interaction ratio is calculated as per sec. 9.3.1 of the code.

Overall Member Strength interaction ratio is calculated as per sec. 9.3.2, taking care of the design parameters `PSI`, `CMX`, `CMY`, and `CMZ`.

Working Stress Method

The following interactions are considered:

a. Combined Bending and Shear — No reduction in allowable stresses for the interaction of bending and shear is considered.

b. Combined Axial Compression and Bending — The following formulas are intended to require member stability:

$$f_c/f_{acy} + 0.6 \cdot K_y(C_{my}f_{bcy}/f_{abcy}) + K_{LT}f_{bcz}/f_{abcz} \leq 1.0$$

$$f_c/f_{acz} + 0.6 \cdot K_y(C_{my}f_{bcy}/f_{abcy}) + K_z f_{bcz}/f_{abcz} \leq 1.0$$

$$f_c/(0.6f_y) + f_{bcy}/f_{abcy} + f_{bcz}/f_{abcz} \leq 1.0$$

where

f_c	=	Actual axial compressive stress.
f_{acy}, f_{acz}	=	Allowable compressive stress, governed by buckling, about the local Y and Z axis, respectively.
f_{bcy}, f_{bcz}	=	Actual bending compressive stress about minor and major axes, respectively.
f_{abcy}, f_{abcz}	=	Allowable bending compressive stress about minor and major axes, respectively.

$$K_y = 1 + (\lambda_y - 0.2) \cdot n_y \leq 1 + 0.8 \cdot n_y$$

$$K_z = 1 + (\lambda_z - 0.2) \cdot n_z \leq 1 + 0.8 \cdot n_z$$

$$K_{LT} = 1 - 0.1 \cdot \lambda_{LT} \cdot n_y/(C_{mLT} - 0.25) \geq 0.1 \cdot n_y/(C_{mLT} - 0.25)$$

c. Combined Axial Tension and Bending — The following formulas are intended to require member stability:

$$f_t/f_{at} + f_{bty}/f_{abty} + f_{btz}/f_{abtz} \leq 1.0$$

where

f_t	=	Actual axial tensile stress.
f_{at}	=	Allowable axial tensile stress.
f_{bty}, f_{btz}	=	Actual bending tensile stress about minor and major axes, respectively.
f_{abty}, f_{abtz}	=	Allowable bending tensile stress about minor and major axes, respectively.

Solid Rod Design

The a_1 and a_2 values are not explicitly available for circular rod section in the IS800:2007 specification. However, there is a design note mentioned for Eq6-41 in the EN 1993-1-1:2005 specification regarding this. Thus, these values are taken as 1.0 by the program.

The IS800:2007 does not provide guidance for the M_{ndy} and M_{ndz} calculation for circular solid rod section. The formula mentioned in the CL 9.3.1.2(e) has been followed by the program for solid circular sections.

D8.A.2.8 Minimum Web Thickness

The minimum web thickness is checked against the serviceability requirements in 8.6.1.1 and the compression flange buckling requirement of 8.6.1.2.

If these sections are not satisfied, then a warning message is included in the output, including the clause which did not meet the web thickness requirements.

This check applies to the following sections:

- Sections with a stiffened web (i.e., connected to flanges along both longitudinal edges):
  - wide flange (rolled, UPT, tapered)
  - I section with cover plates
  - double I-section side-by-side
  - channel
  - double channel (back-to-back and front-to-front)
  - tube, HSS rectangle
- Sections with unstiffened web (i.e., connected to flange along only one longitudinal edge):
  - tee
  - single angle
  - double angle
  - star angle

D8.A.3 Member Property Specification

For specification of member properties, the specified steel section available in Steel Section Library of STAAD.Pro may be used.

The following section types may be used for design:

- I-shapes
- channel

- tee
- HSS tube
- HSS pipe
- angle
- double angle (including “star angle” arrangement; see below)
- double channel
- solid rod (from section database or solid prismatic circular sections which use steel material)

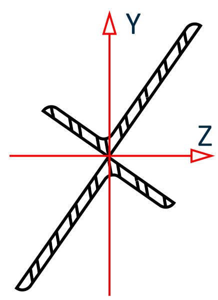
Member properties may also be specified using TR.19 User Steel Table Specification (on page 2241) except for the General and Prismatic member types (other than prismatic circular sections used as steel rods indicated above).

For more information on these facilities, refer to G.6 Member Properties (on page 2113) .

Note: Refer to D8.B.12 Built-in Indian Steel Table (on page 1634) for details on using Indian steel sections per the ISI steel tables.

D8.A.3.1 Star Angle Arrangements

The design of double angles defined as “star angle” sections (i.e., a heel-to-heel alignment using the SA parameter; see section TR.20.1 Assigning Properties from Steel Tables (on page 2257)) per IS 800:2007.



Notes:

- Members using this section must be axial only (i.e., use `TRUSS` specification).
- It is assumed that the star angle arrangement is treated as a welded shape (i.e., two ISA welded at heels). Plated shapes are not accounted for in the program.
- The members are checked for tension and compression limit states for the cross-sectional properties calculated about the principal axes. Other limit states such as bending, shear, and interaction are not considered.

D8.A.4 Design Parameters

The program contains a large number of parameter names which are required to perform design and code checks. These parameter names, with their default values, are listed in the following table.

Table 164: Indian Steel Design IS 800:2007 Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `IS800 LSD` Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
ALPHA	0.8	A factor, based on the end-connection type, controlling the Rupture Strength of the Net Section, as per Section 6.3.3: 0.6) For one or two bolts 0.7) For three bolts 0.8) For four or more bolts 0.9) For threaded rods (per Section 6.3.2)
ANG	0	The location of the angle section through which the axial load passes by. It will only work if the section is single angle. The options are: 0) Centroid. 1) any of the legs. If the value is zero, it means the member is loaded through centroid. In that case Flexural-torsional buckling will not be checked.
ATG	None (Mandatory for Block Shear check)	Minimum Gross Area in Tension from the bolt hole to the toe of the angle, end bolt line, perpendicular to the line of the force.
ATN	None (Mandatory for Block Shear check)	Minimum Net Area in Tension from the bolt hole to the toe of the angle, end bolt line, perpendicular to the line of the force.
AVG	None (Mandatory for Block Shear check)	Minimum Gross Area in shear along bolt line parallel to external force.
AVN	None (Mandatory for Block Shear check)	Minimum Net Area in shear along bolt line parallel to external force.
BEAM	1	0) design at ends and those locations specified by the `SECTION` command. 1) design at ends and at every 1/12th point along member length (default).

Parameter Name	Default Value	Description
CAN	0.0	Beam Type, used for both deflection checks and the limit of bending strength in clause 8.2.1.2: 0) General Member, no limit used in clause 8.2.1.2, member deflection taken as the distance from the displaced end points of the member (DJ1, DJ2) 1) Cantilever Member, Md limited in clause 8.2.1.2, member deflection taken as the cantilever deflection as defined D1.B.1.2 Design Parameters (on page 1134) . 2) Simply Supported Member, Md limited in clause 8.2.1.2. The member deflection is taken as the same as a general member.
CMX	0.9	Equivalent uniform moment factor for Lateral Torsional Buckling(as per Table 18, section 9.3.2.2)
CMY CMZ	0.9	Cm value in local Y & Z axes, as per Section 9.3.2.2.
DFF	None(Mandatory for deflection check)	“Deflection Length” / Maximum allowable local deflection. See TR.40 Load Envelope (on page 2663) for deflection checks using serviceability load envelopes.
DJ1	Start Joint of member	Joint No. denoting starting point for calculation of “Deflection Length”.
DJ2	End Joint of member	Joint No. denoting end point for calculation of “Deflection Length”.
DMAX	1000 in.	Maximum allowable depth.
DMIN	0.0 in.	Minimum allowable depth.
FU	420 MPA	Ultimate Tensile Strength of Steel in current units.
FXTY	0	The fixity of the connection between gusset plate and each end of member. Any value between 0 and 1 is allowed where 1 = Fixed and 0 = Hinged. Default is hinged. A value between 0 and 1 means the level of fixity that is between hinged and fixed. This value will be used to calculate the coefficients k1, k2 and k3 of table 12 by linear interpolation between their specified values for the two extreme (hinged and fixed) conditions.

Parameter Name	Default Value	Description
FYLD	250 MPA	Yield Strength of Steel in current units.
IMM	0	(LSD method only) Member classification for seismic detailing per Section 12 provisions: 0) Beam Member (default) 1) Column Member 2) Bracing (secondary member) See note b below.
KX	1.0	Effective Length Factor for Lateral Torsional Buckling (as per Table-15, Section 8.3.1)
KY	1.0	K value in local Y-axis. Usually, the Minor Axis.
KZ	1.0	K value in local Z-axis. Usually, the Major Axis.
LAT	0	Specifies lateral support of beam, as per Section 8.2.1 and 8.2.2, respectively: 0) Beam is laterally unsupported 1) Beam is laterally supported
LST	0	Defines the number of longitudinal stiffeners used: 0) No longitudinal stiffener 1) Longitudinal stiffener is provided at 0.2D of web from the compression flange 2) Longitudinal stiffeners are provided at 0.2D and 0.5D of the web from the compression flange
LX	Member Length	Effective Length for Lateral Torsional Buckling (as per Table-15, Section 8.3.1)
LY	Member Length	Length to calculate Slenderness Ratio for buckling about local Y axis.
LZ	Member Length	Same as above except in Z-axis (Major).
MAIN	180	Allowable Slenderness Limit for Compression Member (as per Section 3.8) 0 = the default value will be used -1 = the slenderness check will not be performed (any other negative value will be ignored

Parameter Name	Default Value	Description
NBL	1	The number of bolts connecting each end of member with the gusset plate. The options are : 0) one bolt. 1) two or more bolts or weld.
NSF	1.0	Net Section Factor for Tension Member.
PROFILE	None	Used to search for the lightest section for the profile(s) specified for member selection. See TR.48.1 Parameter Specifications (on page 2676) for details.
PSI	1.0	Ratio of the Moments at the ends of the laterally unsupported length of the beam, as per Section 9.3.2.1: 0.8) where Factored Applied Moment and Tension can vary independently 1.0) For any other case
RATIO	1.0	Permissible ratio of the actual to allowable stresses.
SEISMIC	0	(LSD method only) Specifies if the detailing per Section 12 provisions is performed: 0) will *not* perform the detailing for the earthquake load (by default) 1) will perform the detailing for the earthquake load See Note a below.
STP	1	Specifies the section type per Table 2 and Table 10: 1) Hot rolled section 2) Welded section

Parameter Name	Default Value	Description
SSY	0	(LSD method only) Seismic bracing condition along the local Y axis (see note c below): 0- Unbraced along the local Y axis 1- Ordinary Concentrically Braced Frames (OCBF) in the local Y direction (R=4) applicable for X bracing only 2- Special Concentrically Braced Frame (SCBF) in the local Y direction (R=4.5) applicable for column or X bracing only 3- Ordinary Moment Frame (OMF) in the local Y direction (R=4) 4- Special Moment Frame (SMF) in the local Y direction (R=5)
SSZ	0	(LSD method only) Seismic bracing condition along the local Z axis (see note c below): 0- Unbraced along the local Z axis 1- Ordinary Concentrically Braced Frames (OCBF) in the local Z direction (R=4) applicable for X bracing only 2- Special Concentrically Braced Frame (SCBF) in the local Z direction (R=4.5) applicable for column or X bracing only 3- Ordinary Moment Frame (OMF) in the local Z direction (R=4) 4- Special Moment Frame (SMF) in the local Z direction (R=5)
TMAIN	400	Allowable Slenderness Limit for Tension Member (as per Section 3.8) 0 = the default value will be used -1 = the slenderness check will not be performed (any other negative value will be ignored
TRACK	0	Controls the levels of detail to which results are reported. 0) Minimum detail 1) Intermediate detail level 2) Maximum detail
TSP	0	Spacing of transverse stiffeners.

Parameter Name	Default Value	Description
TST	0	Used to control transverse stiffeners in design: 0) No Transverse Stiffener is provided 1) Transverse Stiffener is provided

Notes

a. The program will detail members as per the Section 12 provisions if the design parameter `SEISMIC` is set to 1. It is also recommended that a seismic load using an IS 1893 load definition is in the model. Seismic definitions using other seismic codes are not supported.

b. By default, all the members are considered as main members (i.e., `IMM` = 0). The scope for the seismic detailing depends upon the framing type. The program cannot determine the member or bracing type.

   For example, the detailing guidelines for OCBF framing are applicable for X type of bracing only. Therefore, you must assign the appropriate member type (`IMM` = 2) for the bracing members.

c. The response reduction factor, R, will be determined from the parameters `SSY` and `SSZ`. If this R differs from the that defined in the seismic load list, the program issues a warning.

D8.A.5 Code Checking and Member Selection

Both code checking and member sSelection options are available for the IS 800: 2007 code.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D8.A.5.1 Example 1

Commands for code checking:

```
UNIT NEWTON METER
PARAMETER 1
CODE IS800 LSD
ALPHA 0.7 ALL
CAN 1 MEMB 2
PSI 0.8 MEMB 2
TMAIN 350 MEMB 2
TRACK 2 MEMB 2
CHECK CODE MEMB 2
```

D8.A.5.2 Example 2

Commands for member selection:

```
UNIT NEWTON METER
PARAMETER 1
CODE IS800 LSD
MAIN 160 MEMB 7
KY 0.8 MEMB 7
KZ 0.9 MEMB 7
```

```
FYLD 350 ALL
SELECT ALL
```

D8.A.6 Amendment 1 - January 2012

The various sections of Amendment-1 to the IS:800-2007 Code, dated January 2012, are implemented in STAAD.Pro as applicable.

Please refer the link below for the details of the list and their implementation status in STAAD.Pro.

http://communities.bentley.com/products/structural/structural_analysis___design/w/structural_analysis_and_design__wiki/29602.addendum-1-to-is-800-2007

D8.A.7 Seismic Detailing per Section 12

Seismic detailing of steel members per portions of Section 12 of IS 800-2007 can be performed by STAAD.Pro for LSD design.

The program will check seismic detailing requirements when the D8.A.4 Design Parameters (on page 1617) `SEISMIC` (design detailing for earthquake load) has been specified as 1. It is also recommended that an IS 1893 seismic load definition is included in the model.

Additionally, a set of automatic load combinations is included per IS 800 (in the IS 456 / IS 800 code selection) for IS 800 Clause 12.2.3 which is intended for use with these checks. These are:

1.2×DL + 0.5×LL + 2.5×EL
1.2×DL + 0.5×LL - 2.5×EL
0.9×DL + 2.5×EL
0.9×DL - 2.5×EL

Multiple earthquake load (EL) cases will result in multiples of the different load combinations, as each combination will use only one type of earthquake load in one direction.

Note: To limit the design checks to only the pertinent seismic load combinations per Cl. 12.2.3, a `LOAD LIST` may be used. Otherwise, the checks for Section 12 will be done for all load cases and combinations.

Among the various seismic criteria present in the section 12 of IS800:2007 only compression and tension strength and slenderness are considered as a failure criterion. Detailed output of the seismic checks are provided only for `TRACK 2` output. Other `TRACK` options will only report a seismic provision if it is the critical clause for member checks.

Limitations

Note: This is only available for design using the LFD method. It is not applicable to design using the ASD method.

As the design checks are performed on analytical members (rather than physical members), there are no means by which to ensure provisions of Cl. 12.5.1.2 (i.e., the “strong column, weak beam” design philosophy) are met. That is left to the engineer. Similarly, code checks which require comparison of one member's strength to another are not possible in design checks under STAAD.Pro.

Applicable Code Sections

The following portions of Section 12 have been implemented in STAAD.Pro:

- 12.2.1 - the R values are derived from the specified frame type. If this differs from the R values manually specified in the seismic load definition, a warning is presented in the output. If the assigned R in the local Z and local Y differs, the program will consider the minimum R.
- 12.2.3 - the IS 800 load combinations should be manually added or included from automatically generated load combinations
- 12.3 - the frame type is specified by use of the `SSY` and `SSZ` parameters
- 12.5.1.1
- Ordinary concentrically braced frames
  - 12.7.1.1 - limits the use of OCBFs in seismic zones IV and V, as well as in seismic zone III when the importance factor is greater than one
  - 12.7.1.2 - the bracing type used in the model should be consistent with the `SSY` and `SSZ` parameters specified. Members used as bracing should also be specified using the `IMM` parameter.
  - 12.7.2.1
  - 12.7.2.2
  - 12.7.2.4
  - 12.7.2.6
- Special concentrically braced frames
  - 12.8.1.1
  - 12.8.1.2 - the bracing type used in the model should be consistent with the `SSY` and `SSZ` parameters specified. Members used as bracing should also be specified using the `IMM` parameter.
  - 12.8.2.1
  - 12.8.2.2
  - 12.8.2.3
  - 12.8.2.5
  - 12.8.2.7
  - 12.8.4.1
- 12.10.1.1 - Ordinary moment frames shall not be used in seismic zones IV and V, as well as in seismic zone III when the importance factor is greater than one
- Special moment frames
  - 12.11.1 - checks the material grades assigned (i.e, the `FYLD` and `FU` parameter values assigned) are equal to or higher than grade E250B.
  - 12.11.1.1
  - 12.11.3.1

D8.B. Indian Codes - Steel Design per IS 800 - 1984

STAAD.Pro is capable of performing steel design based on the Indian code IS 800 - 1984 *General construction in steel - Code of practice*.

Note: The IS 800 - 1984 is not appropriate for the design of hollow pipe or tube sections. The design of such members should be done using D8.A. Indian Codes - Steel Design per IS 800 - 2007 (on page 1607).

D8.B.1 Design Operations

STAAD.Pro contains a broad set of facilities for designing structural members as individual components of an analyzed structure. The member design facilities provide the user with the ability to carry out a number of different design operations. These facilities may be used selectively in accordance with the requirements of the design problem. The operations to perform a design are:

- Specify the members and the load cases to be considered in the design.
- Specify whether to perform code checking or member selection.
- Specify design parameter values, if different from the default values.
- Specify whether to perform member selection by optimization.

These operations may be repeated by the user any number of times depending upon the design requirements. The entire ISI steel section table is supported. D8.B.13 Column With Lacings And Battens (on page 1638) describes the specification of steel sections.

D8.B.2 General Comments

This section presents some general statements regarding the implementation of Indian Standard code of practice (IS:800-1984) for structural steel design in STAAD.Pro. The design philosophy and procedural logistics for member selection and code checking are based upon the principles of allowable stress design.

Two major failure modes are recognized:

i. failure by overstressing
ii. failure by stability considerations.

The flowing sections describe the salient features of the allowable stresses being calculated and the stability criteria being used. Members are proportioned to resist the design loads without exceeding the allowable stresses and the most economic section is selected on the basis of least weight criteria. The code checking part of the program checks stability and strength requirements and reports the critical loading condition and the governing code criteria.

It is generally assumed that the engineer will take care of the detailing requirements like provision of stiffeners and check the local effects such as flange buckling and web crippling.

There are no special provisions specifically for double-I sections in IS 800-1984. Therefore, these sections are designed in STAAD.Pro as other general sections using the section property values of the double-I section specified.

D8.B.3 Allowable Stresses

The member design and code checking in STAAD.Pro are based upon the allowable stress design method as per IS:800 (1984). It is a method for proportioning structural members using design loads and forces, allowable stresses, and design limitations for the appropriate material under service conditions.

It is not practical to describe every aspect of IS:800 here. This section, however, will discuss the salient features of the allowable stresses specified by IS:800 as implemented in STAAD.Pro. Appropriate sections of IS:800 will be referenced during the discussion of various types of allowable stresses.

D8.B.3.1 Axial Stress

Tensile Stress

The allowable tensile stress, as calculated in STAAD.Pro as per IS:800 is described below.

The permissible stress in axial tension, σ_{at} in MPa on the net effective area of the sections shall not exceed

$$\sigma_{at} = 0.6\ f_y$$

where

f_y = minimum yield stress of steel in MPa

Compressive Stress

Allowable compressive stress on the gross section of axially loaded compression members shall not exceed $0.6 f_y$ nor the permissible stress s_{ac} calculated based on the following equation (per Clause: 5.1.1):

$$\sigma_{ac} = 0.6\{(f_{cc} \cdot f_y)/[(f_{cc})^n + (f_y)^n]^{1/n}\}$$

where

σ_{ac}	=	Permissible stress in axial compression, in MPa
f_y	=	Yield stress of steel, in MPa
f_{cc}	=	Elastic critical stress in compression = $\pi^2 E/\lambda^2$
E	=	Modulus of elasticity of steel, 2 X 10^5 MPa
λ	=	l/r = Slenderness ratio of the member, ratio of the effective length to appropriate radius of gyration
n	=	A factor assumed as 1.4.

D8.B.3.2 Bending Stress

The allowable bending stress in a member subjected to bending is calculated based on the following formula.

$$\sigma_{bt} \text{ or } \sigma_{bc} = 0.66 f_y \qquad \text{(Clause: 6.2.1)}$$

where

σ_{bt}	=	Bending stress in tension
σ_{bc}	=	Bending stress in compression
f_y	=	Yield stress of steel, in MPa

For an I-beam or channel with equal flanges bent about the axis of maximum strength (z-z axis), the maximum bending compressive stress on the extreme fibre calculated on the effective section shall not exceed the values of maximum permissible bending compressive stress. The maximum permissible bending compressive stress shall be obtained by the following formula: (Clause: 6.2.2)

$$\sigma_{bc} = 0.66\frac{f_{cb} f_y}{\left[(f_{cb})^n + (f_y)^n\right]^{1/n}} \qquad \text{(Clause 6.2.3)}$$

where

f_y	=	Yield stress of steel, in Mpa
n	=	A factor assumed as 1.4.
f_{cb}	=	Elastic critical stress in bending, calculated by the following formula:
		$= k_1\left(X + k_2 Y\right)\frac{c_2}{c_1}$
X	=	$Y\sqrt{1 + \frac{1}{20}\frac{\pi^2}{r_y D}}$ in MPa
Y	=	$\frac{26.5(10)^5}{(1/r_y)^2}$
k_1	=	a coefficient to allow for reduction in thickness or breadth of flanges between points of effective lateral restraint and depends on y, the ratio of the total area of both flanges at the point of least bending moment to the corresponding area at the point of greatest bending moment between such points of restraint.

k_2	=	a coefficient to allow for the inequality of flanges, and depends on w, the ratio of the moment of inertia of the compression flange alone to that of the sum of the moment of the flanges each calculated about its own axis parallel to the y-yaxis of the girder, at the point of maximum bending moment.
l	=	effective length of compression flange
r_y	=	radius of gyration of the section about its axis of minimum strength (y-y axis)
T	=	mean thickness of the compression flange, is equal to the area of horizontal portion of flange divided by width.
D	=	overall depth of beam
c_1 ,c_2	=	respectively the lesser and greater distances from the section neutral axis to the extreme fibres.

D8.B.3.3 Shear Stress

Allowable shear stress calculations are based on Section 6.4 of IS:800.

For shear on the web, the gross section taken into consideration consist of the product of the total depth and the web thickness. For shear parallel to the flanges, the gross section is taken as 2/3 times the total flange area.

D8.B.3.4 Combined Stress

Members subjected to both axial and bending stresses are proportioned accordingly to section 7 of IS:800. All members subject to bending and axial compression are required to satisfy the equation of Section 7.1.1.(a) for intermediate points, and equation of Section 7.1.1.(b) for support points.

For combined axial tension and bending the equation of Section 7.1.2. is required to be satisfied.

Cm coefficients are calculated according to the specifications of Section 7.1.3. information regarding occurrence of sidesway can be provided through the use of parameters `SSY` and `SSZ`. In the absence of any user-provided information, sidesway will be assumed.

D8.B.4 Design Parameters

In the STAAD.Pro implementation of IS:800, you are allowed complete control of the design process through the use of design parameters. Available design parameters to be used in conjunction with IS:800 are listed in the table below along with their default values and applicable restrictions.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 165: Indian Steel Design IS 800:1984 Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `INDIAN` Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).

Parameter Name	Default Value	Description
BEAM	1.0	0.0) design only for end moments and those at locations specified by the SECTION command. 1.0) calculate section forces at twelfth points along the beam, design at each intermediate location and report the critical location where ratio is maximum.
CMY CMZ	0.85 for sidesway and calculated for no sidesway	Cm value in local y & z axes
DFF	None(Mandatory for deflection check)	"Deflection Length" / Maxm. allowable local deflection. See TR.40 Load Envelope (on page 2663) for deflection checks using serviceability load envelopes.
DJ1	Start Joint of member	Joint No. denoting starting point for calculation of "Deflection Length" (See Note 1 (on page 1631))
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length" (See Note 1 (on page 1631))
DMAX	100.0 cm.	Maximum allowable depth.
DMIN	0.0 cm.	Minimum allowable depth.
FYLD	250 MPa (36.25 ksi)	Yield strength of steel.
KY	1.0	K value in local y-axis. Usually, this is minor axis.
KZ	1.0	K value in local z-axis. Usually, this is major axis.
LY	Member Length	Length in local y-axis to calculate slenderness ratio.
LZ	Member Length	Same as above except in local z-axis (major).

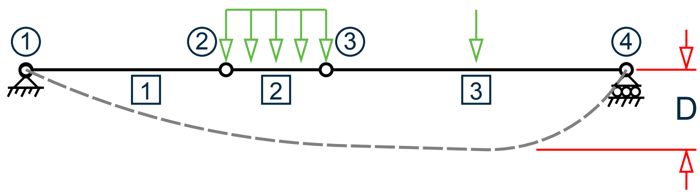
Parameter Name	Default Value	Description
MAIN	180 (Comp. Memb.)	Allowable Kl/r for slenderness calculations for compression members.
NSF	1.0	Net section factor for tension members.
PROFILE	-	Used to search for the lightest section for the profile(s) specified for member selection. See TR.48.1 Parameter Specifications (on page 2676) for details.
RATIO	1.0	Permissible ratio of the actual to allowable stresses.
SSY	0.0	0.0) Sidesway in local y-axis. 1.0) No sidesway
SSZ	0.0	Same as above except in local z-axis.
TMAIN	400 (Tension Memb)	Allowable Kl/r for slenderness calculations for tension members.
TRACK	0.0	0.0) Suppress critical member stresses 1.0) Print all critical member stresses 2.0) Print expanded output. If there is deflection check it will also print the governing load case number for deflection check whenever critical condition for design is not DEFLECTION.
UNF	1.0	Unsupported length provided as a fraction of actual member length used for lateral-torsional buckling calculation. **Note:** If both UNF and UNL parameters are specified, the effective length used is UNF×UNL.

Parameter Name	Default Value	Description
UNL	Member Length	Unsupported length for calculating allowable bending stress. Used for the lateral-torsional buckling calculation. Value should be in the current units of length.

Notes

a. "Deflection Length" is defined as the length that is used for calculation of local deflections within a member. It may be noted that for most cases the "Deflection Length" will be equal to the length of the member. However, in some situations, the "Deflection Length" may be different. A straight line joining `DJ1` and `DJ2` is used as the reference line from which local deflections are measured.

For example, refer to the figure below where a beam has been modeled using four joints and three members. The "Deflection Length" for all three members will be equal to the total length of the beam in this case. The parameters `DJ1` and `DJ2` should be used to model this situation. Thus, for all three members here, `DJ1` should be `1` and `DJ2` should be `4`.



D = Maximum local deflection for members 1, 2, and 3.

```
PARAMETERS
DFF 300. ALL
DJ1 1 ALL
DJ2 4 ALL
```

b. If `DJ1` and `DJ2` are not used, "Deflection Length" will default to the member length and local deflections will be measured from original member line.

c. The above parameters may be used in conjunction with other available parameters for steel design.

D8.B.5 Stability Requirements

Slenderness ratios are calculated for all members and checked against the appropriate maximum values. Section 3.7 of IS:800 summarizes the maximum slenderness ratios for different types of members.

In the STAAD.Pro implementation of IS:800, the appropriate maximum slenderness ratio can be provided for each member. If no maximum slenderness ratio is provided, compression members will be checked against a maximum value of 180 and tension members will be checked against a maximum value of 400.

D8.B.6 Truss Members

A truss member is capable of carrying only axial forces. So in design no time is wasted in calculating bending or shear stresses, thus reducing design time considerably. Therefore, if there is any truss member in an analysis (like bracing or strut, etc.), it is wise to declare it as a truss member rather than as a regular frame member with both ends pinned.

D8.B.7 Deflection Check

This feature allows you to consider deflection as a criteria in the CODE CHECK and MEMBER SELECTION processes.

The deflection check may be controlled using three parameters which are described in D8.B.4 Design Parameters (on page 1628).

Note: Deflection is used in addition to other strength and stability related criteria. The local deflection calculation is based on the latest analysis results.

D8.B.8 Code Checking

The purpose of code checking is to verify whether the specified section is capable of satisfying applicable design code requirements. The code checking is based on the IS:800 (1984) requirements.

Forces and moments at specified sections of the members are utilized for the code checking calculations. Sections may be specified using the BEAM parameter or the SECTION command. If no sections are specified, the code checking is based on forces and moments at the member ends.

The code checking output labels the members as “PASS” or “FAIL”. In addition, the critical condition (applicable IS:800 clause no.), governing load case, location (distance from the start) and magnitudes of the governing forces and moments are also printed out.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

D8.B.9 Member Selection

STAAD.Pro is capable of performing design operations on specified members. Once an analysis has been performed, the program can select the most economical section, that is, the lightest section, which satisfies the applicable code requirements.

The section selected will be of the same type (I-Section, Channel etc.) as originally specified by the user. Member selection may be performed with all types of steel sections listed in D8.B.12 Built-in Indian Steel Table (on page 1634) and user-provided tables. Selection of members whose properties are originally provided from user-specified table is limited to sections in the user-provided table.

Member selection cannot be performed on members whose cross sectional properties are specified as PRISMATIC.

The process of MEMBER SELECTION may be controlled using the parameters listed in D8.B.4 Design Parameters (on page 1628). The parameters DMAX and DMIN may be used to specify member depth constraints for selection. If PROFILE parameter is provided, the search for the lightest section is restricted to that profile. Up to three (3) profiles may be provided for any member with a section being selected from each one.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D8.B.10 Member Selection By Optimization

Steel section selection of the entire structure may be optimized. The optimization method utilizes a state-of-the -art numerical technique which requires automatic multiple analysis.

You may start without a specifically designated section. However, the section profile type (`BEAM`, `COLUMN`, `CHANNEL`, `ANGLE`) must be specified using the `ASSIGN` command (see TR.20.5 Assign Profile Specification (on page 2268)). The optimization is based on member stiffness contributions and corresponding force distributions. An optimum member size is determined through successive analysis/design iterations. This method requires substantial computer time and hence should be used with caution.

Refer to TR.49.2 Member Selection by Optimization (on page 2679) for additional details.

D8.B.11 Tabulated Results of Steel Design

For code checking or member selection, the program produces the result in a tabulated fashion. The items in the output table are explained as follows:

MEMBER	the member number for which the design is performed
TABLE	the INDIAN steel section name which has been checked against the steel code or has been selected.
RESULT	prints whether the member has PASSED or FAILed. If the RESULT is FAIL, there will be an asterisk (*) mark in front of the member number.
CRITICAL COND	the section of the IS:800 code which governs the design.
RATIO	prints the ratio of the actual stresses to allowable stresses for the critical condition. Normally a value of 1.0 or less will mean the member has passed.
LOADING	provides the load case number which governs the design.
FX, MY, and MZ	provide the axial force, moment in local y-axis and moment in local z-axis respectively. Although STAAD does consider all the member forces and moments (except torsion) to perform design, only FX,MY and MZ are printed since they are the ones which are of interest, in most cases.
LOCATION	specifies the actual distance from the start of the member to the section where design forces govern.

Note: If the parameter TRACK is set to `1.0`, the program will block out part of the table and will print allowable bending stresses in compression (FCY & FCZ) and tension (FTY & FTZ), allowable axial stress in compression (FA), and allowable shear stress (FV). When the parameter TRACK is set to 2.0 for all members parameter code values are as shown in the following example.

```

```

D8.B.12 Built-in Indian Steel Table

This is an important feature of the program since the program will read section properties of a steel member directly from the ISI steel tables (as published in ISI-800). These properties are stored in memory corresponding to the section designation (e.g., ISMB250, etc.). If called for, the properties are also used for member design. Since the shear areas are built in to these tables, shear deformation is always considered for these members.

Almost all ISI steel tables are available for input. A complete listing of the sections available in the built-in steel section library may be obtained using the tools of the graphical user interface.

D8.B.12.1 Rolled Steel Beams (ISJB, ISLB, ISMB, and ISHB)

All rolled steel beam sections are available the way they are designated in the ISI handbook (e.g., ISJB225, ISWB400, etc.)

```
20 TO 30 TABLE ST ISLB325
```

Note: In case of two identical beams, the heavier beam is designated with an "A" on the end (e.g., ISHB400 A, etc.).

```
1 TO 5 TABLE ST ISHB400A
```

D8.B.12.2 Rolled Steel Channels (ISJC, ISLC and ISMC)

All these shapes are available as listed in ISI section handbook. Designation of the channels are per the scheme used by ISI.

```
10 TO 20 BY 2 TABLE ST ISMC125
12 TABLE ST ISLC300
```

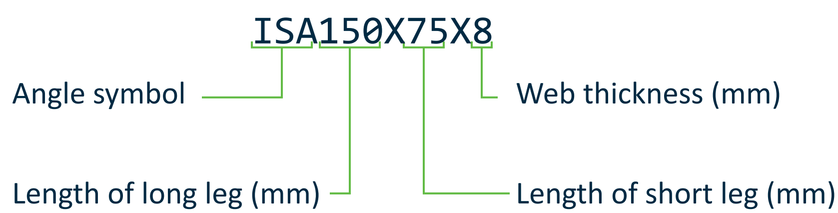
D8.B.12.3 Double Channels

Back to back double channels, with or without spacing between them, are available. The letter D in front of the section name will specify a double channel (e.g., D ISJC125, D ISMC75, etc.).

```
21 22 24 TABLE D ISLC225
```

D8.B.12.4 Rolled Steel Angles

Both rolled steel equal angles and unequal angles are available for use in the STAAD implementation of ISI steel tables. The following example with explanations will be helpful in understanding the input procedure:



At present there is no standard way to define the local y and z axes for an angle section. The standard section has local axis system. The standard angle is specified as:

```
51 52 53 TABLE ST ISA60X60X6
```

This specification has the local z-axis (i.e., the minor axis corresponding to the V-V axis specified in the steel tables. Many engineers are familiar with a convention used by some other programs in which the local y-axis is the minor axis. STAAD.Pro provides for this convention by accepting the command:

```
54 55 56 TABLE RA ISA50X30X6
```

Tip: "RA" denotes reverse angle

D8.B.12.5 Double Angles

Short leg back-to-back or long leg back-to-back double angles can be specified by inputting the word SD or LD, respectively, in front of the angle size. In case of an equal angle either LD or SD will serve the purpose. For example,

```
14 TO 20 TABLE LD ISA50X30X5 SP 1.5
23 27 TABLE SD ISA75X50X6
```

D8.B.12.6 Rolled Tees (ISHT, ISST, ISLT and ISJT)

All the rolled tee sections are available for input as they are specified in the ISI handbook. The following example illustrates the designated method.

```
1 2 5 8 TABLE ST ISNT100
67 68 TABLE ST ISST250
```

D8.B.12.7 Pipes (Circular Hollow Sections)

To designate circular hollow sections from ISI tables, use PIP followed by the numerical value of diameter and thickness of the section in mm omitting the decimal section of the value provided for diameter. The following example will illustrate the designation.

```
10 15 TABLE ST PIP 213.2
```

specifies a 213 mm dia. pipe with 3.2 mm wall thickness

Circular pipe sections can also be specified by providing the outside and inside diameters of the section. For example,

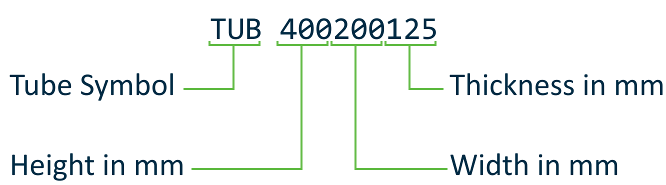
```
1 TO 9 TABLE ST PIPE OD 25.0ID 20.0
```

specifies a pipe with outside dia. of 25 and inside dia. of 20 in current length units

Only code checking and no member selection will be performed if this type of specification is used.

D8.B.12.8 Tubes (Rectangular or Square Hollow Sections)

Designation of tubes from the ISI steel table is illustrated below.



For example,

```
15 TO 25 TABLE ST TUB 160808
```

Tubes, like pipes, can also be input by their dimensions (Height, Width and Thickness) and not by any table designations.

```
6 TABLE ST TUBE DT 8.0 WT 6.0 TH 0.5
```

is a tube that has a height of 8, a width of 6, and a wall thickness of 0.5.

Note: Only code checking and no member selection is performed for TUBE sections specified this way.

D8.B.12.9 Plate And Angle Girders (With Flange Plates)

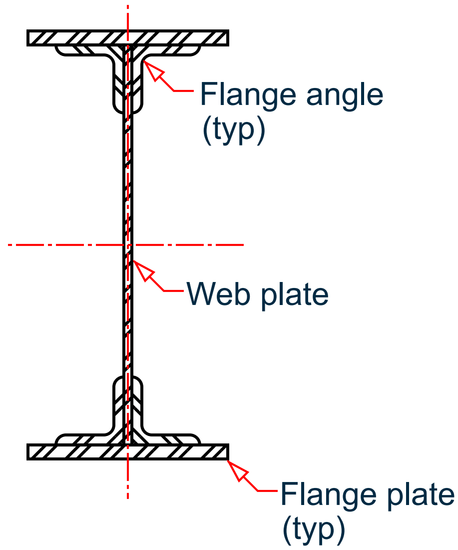


Figure 171: Plate and Angle girder

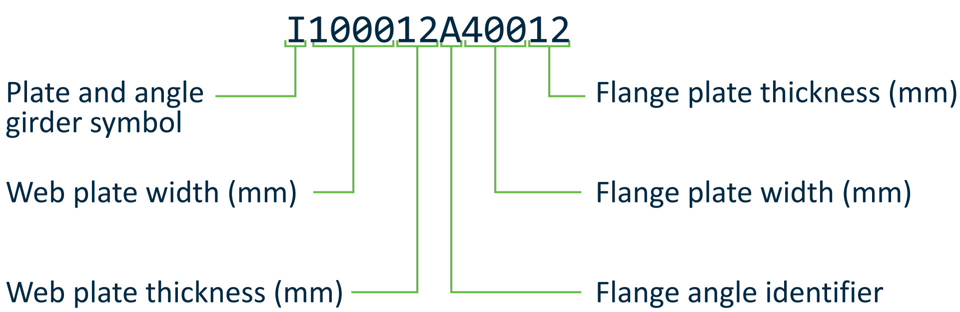
Plate and angle grinders (with flange plates) are available as listed in Table XX of the ISI section handbook. The input of these composite sections are given as indicated in the following diagram. The web height and thickness are the first numeric entries, followed by a letter identifier used to indicate the angle size used, the followed by the flange width and thickness entries.



Flange angle key

Angle Identifier	**Angle Size Used (A × B × t)**
A	150×150×18
B	200×100×15
C	200×150×18
D	200×200×18

D8.B.12.10 Single Joist with Channels and Plates on the Flanges to be Used as Girders

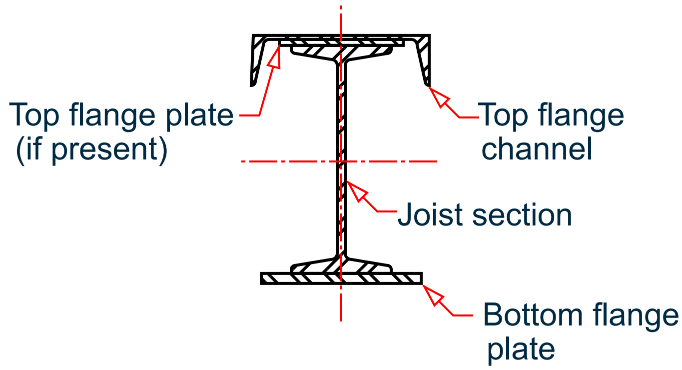


Figure 172: Single Joist with Channel and Plates on the Flanges

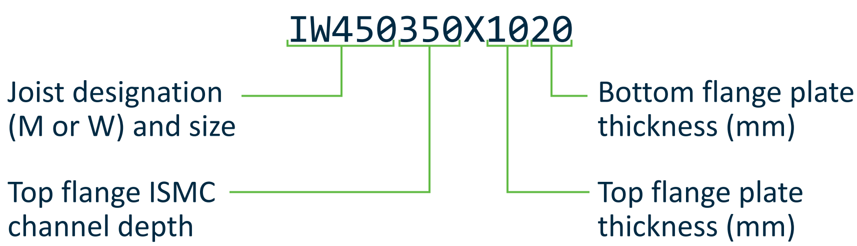
All single joist with channel and plates on the flanges to be used as girders are available as listed in Table XV of the ISI section handbook. The input of these composite sections are given as indicated in the following diagram. The following example with explanations will be helpful in understanding the input procedure.



The plate widths are specific to the combination of joist and channel, so they are not directly specified in the section size. To specify a section *without* a top flange plate (to flange channel only), then a zero may be specified for the top flange thickness value. For example, a `IM600400X016` indicates an ISMB 600 joist with an ISMC 400 top flange channel (no plate) and a 320×16 mm bottom plate.

Note: The table lists two different ISWB600 sections. The heavier ISWB600 has been omitted, since the lighter ISWB600 is more efficient.

D8.B.13 Column With Lacings And Battens

For columns with large loads it is desirable to build rolled sections at a distance and inter-connect them. The joining of element sections is done by two ways:

a. Lacing
b. Batten

Double channel sections (back-to-back and face-to-face) can be joined either by lacing or by batten plates having riveted or welded connection.

The following table gives the parameters that are required for Lacing or batten design. These parameters will have to be provided in unit NEW MMS along with parameters defined in D8.B.4 Design Parameters (on page 1628).

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 166: Parameters used in Indian Lacing or Batten steel member design.

Parameter Name	Default Value	Description
CTYPE	1	Type of joining 1) implies single lacing with riveted connection 2) implies double lacing with riveted connection 3) implies single lacing with welded connection 4) implies double lacing with welded connection 5) implies batten with riveted connection 6) implies batten with welded connection
COG	0.0 mm	Center of gravity of the channel. This parameter is used when member properties are defined through user provided table using GENERAL option.
DBL	20 mm	Nominal diameter of rivet
DCFR	0.0	Used when member properties are defined through user provided table using GENERAL option. 0) double channel back-to-back. 1) double channel face-to-face.
EDIST	32 mm (riveted connection) 25 mm (welded connection)	Edge Distance.
FVB	100 N/mm^2	Allowable shear stress in rivet
FYB	300 N/mm^2	Allowable bearing stress in rivet
SPA	0.0 mm	Spacing between double channels. This parameter is used when member properties are defined through user provided table using GENERAL option.

Parameter Name	Default Value	Description
THETA	50 degree	Angle of inclination of lacing bars. It should lie between 40 degree and 70 degree.
WMIN	6 mm	Minimum thickness of weld
WSTR	108 N/mm^2	Allowable welding stress

D8.C. Indian Codes - Cold Formed Steel Design per IS 801 - 1975

STAAD.Pro is capable of performing steel design based on the Indian code IS 801 1975 *Code of practice for use of cold-formed light gauge steel structural members in general building construction*, reaffirmed in 2010. The program allows design of single (non-composite) members in tension, compression, bending, shear, as well as their combinations. Cold work of forming strengthening effects has been included as an option.

D8.C.1 Cross-Sectional Properties

You specify the geometry of the cross-section by selecting one of the section shape designations from the Gross Section Property Tables from IS:811-1987 (*Specification for cold formed light gauge structural steel sections*).

The AISI Design Manual has been followed to calculate section properties (e.g., Cw) which are not available in the Indian Standard and Manual.

Checks per IS 801 are supported for the following profile shapes:

- Angle with lips
- Angle
- Channel with Lips
- Channel (or eave strut)
- Zee or zee purlin
- Zee with lips
- Hat
- Tube
- Pipe

The properties listed in the tables are gross section properties. STAAD.Pro uses unreduced section properties in the structure analysis stage. Both unreduced and effective section properties are used in the design stage, as applicable.

D8.C.2 Design Procedure

The design procedure according to IS 801 is based on an allowable stress method. In essence, the principle is to determine the maximum allowable design stress for a given section profile. The section properties that are used to calculate the allowable stress are based on the gross section properties or the “effective” section properties, based on the load being applied and the check being considered.

The design procedure varies slightly from profile to profile, based on the characteristics of the elements that form the profile shape. IS 801 classifies the elements (flat plates) that form the section profile into the following element types:

- stiffened element – an element that is supported along two opposite edges either by another element or a stiffening element such as a lip
- unstiffened element – an element that is supported by another element only along one edge
- multiple stiffened element – an element that is supported in between web(s) or stiffened element(s) by intermediate stiffeners that are parallel to the direction of stress

The various checks for a section profile and the design methods adopted depend on the type of the elements that form the profile. The following clauses from IS 801 are implemented and are used as appropriate:

- Cl 5.2.1
  - Cl.5.2.1.1
- Cl.5.2.3
- Cl.5.2.4
- Cl.6.1
  - Cl.6.1.1.1
- Cl.6.2
- Cl.6.3
- Cl.6.4
  - Cl.6.4.1
  - Cl.6.4.2
  - Cl.6.4.3
- Cl.6.6
  - Cl.6.6.1.1
  - Cl.6.6.1.2
  - Cl.6.6.1.3
- Cl.6.7
  - Cl.6.7.1
  - Cl.6.7.2
  - Cl.6.7.3
- Cl.6.8

Note: Deflection checks based on the effective section properties are not performed.

D8.D.2.1 Maximum allowable section segment dimensions

Checks will be done to verify the maximum allowable flat width ratios for the flange segments forming section profile as per Cl.5.2.3 and for the web segments as per Cl.5.2.4. Note that Cl.5.2.3(d) will not be considered as this can vary based on the amount of curling.

D8.D.2.2 Maximum member slenderness

Member slenderness checks will be performed for members subject to compression. The maximum allowable slenderness for a compression member will be limited to 200 as per Cl.6.3.3.

Slenderness for a member about both the z & y local axes will be calculated. If any of these exceeds the limiting value of 200, the program will consider that as a failure criterion. Note that members subject to tension will not have any slenderness checks performed.

D8.D.2.3 Members subject to tension

The following check will be performed for all members in tension:

$$\text{Tensile stress ratio} = F_{actual} / F$$

where

F_{actual}	=	the applied stress on the member. = Applied Tension / A
A	=	the net cross section area of the profile

Note: If the parameter list includes the `NSF` parameter, the net area will be calculated as $A \times NSF$, where A is the gross area of the section. If NSF has not been specified, a default value of 1.0 will be used.

The maximum allowable design stress for members in tension will be calculated as:

$$F = 0.6 \times F_y$$

where

F_y	=	the minimum yield strength of the section.

If the increase in steel strength due to cold work forming is to be considered (ref. `CWY` param), then the design stress will be calculated as:

$$F = 0.6 \times F_{ya}$$

where

F_{ya}	=	the average yield point of the full section and will be calculated as: $Fya = C \times Fyc + (1 - C)\ Fyt.$ (refer to Cl.6.6.1.a for the description of the terms used.)

Note: The FY and FU values are expected to be user inputs. The default value of FY will be taken as 3600 kg/ cm^2(Table 2 of IS:801) and FU will be taken as 4588 kg/cm^2.

D8.D.2.4 Members subject to compression

The following check will be performed for all members in compression:

$$\text{Compression check ratio} = F_{actual} / F_{cap}$$

where

F_{actual}	=	the applied axial stress on the member
F_{cap}	=	the allowable compressive stress for the member

The compression capacity will be calculated as follows:

- For profile shapes with stiffened elements alone and not susceptible to Flexural torsional buckling (Tube):

  The maximum allowable design stress will be calculated as:

  $$F = 0.6 \times Fy$$

  where

F_y	=	the minimum yield strength of the section.

  Note: Allowance will be made for cold forming strength as required.

  Note that if the effect of cold work forming is to be considered, then the enhanced strength Fya will have to be determined based on the value of the factor Q. Hence to determine the factor Q, the program would use the design stress (= $0.6 \times F_y$). This factor Q will then be used to determine the enhanced strength Fya, which will then be used for the design checks.

This design stress, F, will be used to calculate the effective area of the section. The procedure to calculate the effective area involves calculating the effective width of each element that forms the profile. The effective width of each element will be calculated as described below:

- For elements without intermediate stiffeners:

  The effective width of such elements will be calculated as per the equations in Cl.5.2.1.1 (for closed square and rectangular tubes). The value of 'f" used will be the maximum allowable design stress F as in section 3.2.1 above.

  > **Note:** The current implementation does not allow for sections to have multiple stiffened elements as per Cl.5.2.1.2. Hence Cl.5.2.1.2 is *not* be considered for calculating the effective width of elements.

  The maximum allowable compression stress for the member, Fc, will then be determined based on the equations as per Cl.6.6.1.1. Note that the factor Q will be based on the effective area determined using the design stress F as mentioned above.
- For profile shapes with stiffened elements alone (Pipe sections):

  The maximum allowable compressive stress for pipes will be determined as per cl.6.8:

  For sections with D/t < 232000 / Fy, F = 0.6 × Fy

  For section with 232000 / Fy < D/t < 914000 / Fy, F = 46540 / (D/t) + 0.399 Fy

  Section with D/t > 914000 / Fy will not be designed.

  A check will also be done to make sure that the compressive stress < Fa1 as determined by 6.6.1.1. for a value of Q=1.
- For profile shapes with un-stiffened elements alone (Angle sections):

  The maximum allowable design stress Fc will be calculated as per the equations in Cl.6.2 (a), 6.2(b), 6.2(c) or 6.2 (d) as appropriate, based on the plate width-to-thickness ratio of each element.

  This design stress, Fc, will be used to calculate the factor Q when checking for flexural/flexural torsional buckling failure modes. Note that since this section is subject to torsional buckling, the factor Q, to be used to calculate the allowable compressive stress Fa1 as per Cl. 6.6.1.2/3, will be calculated as the ratio between the Fc for the element with the largest w/t ratio to the basic design stress as per Cl.6.1 & 6.2.
- For profile shapes with both stiffened and unstiffened elements and /or susceptible to Flexural torsional buckling (Channel, Zee, Hat, Channels with Lips, Zee with Lips, Angle with lip sections sections):

  These sections are subject to torsional-flexural buckling. The factor Q will be determined as per Cl.6.6.1.1 (3) as:

  $$Q = Qs \times Qa$$

  Qs will be calculated as the ratio between the Fc for the element with the largest w/t ratio to the basic design stress as per Cl.6.1 & 6.2.

  Qa will be calculated for the stiffened elements as per Cl.6.6.1.1 (1) but with Fa taken as the stress used to calculate Qs.

  If Q =1.0, the allowable stress Fa2 will be calculated as per Cl.6.6.1.2. If however the factor Q < 1.0, the allowable stress Fa2 will be calculated as per Cl.6.6.1.2, but with the term Q being replaced with Q.Fy.

D.2.5 Members subject to bending

The following check will be performed for all members in bending:

$$\text{Bending check ratio} = M_{actual} / M_{cap}$$

where

M_{actual}	=	the applied bending stress on the member
M_{cap}	=	the allowable bending stress of the member

This check will be done separately for bending about both the Z & Y axes.

The bending capacity of the section will be based on the maximum allowable bending stress, F_b. The maximum allowable stress in a member subject to bending shall not exceed the following:

1. The maximum allowable stress for the extreme tension fiber as given in Cl.6.1

   $$F_{bt\_allowable} = F = 0.6 \times F_y$$

   where

F_y	=	the minimum yield strength of the section

2. The maximum allowable stress in the extreme compression fiber as given in Cl.6.2

   This will be calculated based on the w/t ratio of the compression element as per Cl.6.2(a), Cl.6.2(b), Cl.6.2(c), or Cl.6.2(d) as applicable. Note that these clauses will be applicable only for unstiffened elements in compression. For stiffened elements F_b will be taken as given in Cl.6.1
3. The maximum allowable lateral buckling stress as given in C.l6.3 (a) or Cl.6.3 (b) as appropriate for the section profile.

   This clause will only be applicable for sections that are subject to bending about their major axis. For sections subject to minor axis bending this check will be ignored.

   The moment of inertia terms, Iyc and the section modulus term Zxc in the equations will be based on the entire section. The value of the moment factor Cb, will be based on the end moments of the analytical member being designed. If the member is subject to axial loads along with the bending moment, the value of Cb will be taken as 1.0
4. The maximum allowable bending stress in the webs of a given section (I, C, Hat, Tube , Z), Fbw shall be calculated as per Cl6.4.2 of the code.

For pipe sections:

The maximum allowable compressive stress for pipes will be determined as per cl.6.8:

- For sections with $D/t < 232000 / F_y$, $F = 0.6 \times F_y$
- For sections with $232000 / F_y < D/t < 914000 / F_y$, $F = 46540 / (D/t) + 0.399 F_y$
- Sections with $D/t > 914000 / F_y$ will not be designed.

D.2.6 Members subject to shear

The applied shear stress will be calculated based on the calculated shear area of the given section profile. The shear area for the various shapes will be taken as follows:

- Angle with Lips
  - For shear along the Y axis: $(D\text{-}t)\times t + 2.0\times(Lip\ Length\text{-}t)\times t$
  - For shear along the X axis: $(B\text{-}t)\times t$
- Angle
  - For shear along the Y axis: $(D\text{-}t)\times t$

- For shear along the X axis: $(B\text{-}t)\times t$
- Channel with Lips
  - For shear along the Y axis: $(D\text{-}2t)\times t + 2.0\times(Lip\ Length\text{-}t)\times t$
  - For shear along the X axis: $2.0\times B\times t$
- Channel or Eave Strut
  - For shear along the Y axis: $(D\text{-}2t)\times t$
  - For shear along the X axis: $2.0\times B\times t$
- Zee or Zee Purlin
  - For shear along the Y axis: $(D\text{-}2t)\times t$
  - For shear along the X axis: $2.0\times B\times t$
- Zee with Lips
  - For shear along the Y axis: $(D\text{-}2t)\times t + 2.0\times(Lip\ Length\text{-}t)\times t$
  - For shear along the X axis: $2.0\times B\times t$
- Hat
  - For shear along the Y axis: $2.0 \times (D\text{-}t)\times t$
  - For shear along the X axis: $B\times t + 2.0\times(Lip\ Length\text{-}t)\times t$
- Tube
  - For shear along the Y axis: $2.0\times(D\text{-}2t)\times t$
  - For shear along the X axis: $2.0\times(B\text{-}2t)\times t$
- Pipe
  - For shear along the Y axis: $0.5 \times 2\times\pi\times r\times t$
  - For shear along the X axis: $0.5 \times 2\times\pi\times r\times t$

For shear checks along the local Y-axis, the maximum allowable shear stress, Fv, in the web of a section (I, C, Hat, Tube, Z) will be calculated as per Cl.6.4.1 based on the h/t ratio of the web element.

The code does not explicitly mention about shear checks along the horizontal (Z-axis). Hence, the program takes the maximum allowable shear stress along Z as $0.4\times Fy$.

D.2.7 Members subject to combined axial, bending, and shear

- Checks for members subject to combined axial compression and bending:

  The combined stress checks will be based on whether the member is susceptible to torsional buckling mode or not. The implementation will consider all loads as being applied through the shear center.

  - Members not susceptible to torsional buckling

    For members that are not susceptible to torsional buckling, both the interaction equations as per Cl.6.7.1 will be checked as below:

    $$fa/ Fa1 + (Cmx \times fbx) / [(1- fa /F'ex)\times Fbx] + (Cmy \times fby) / [(1- fa /F'ey)\times Fby] \le 1.0$$

    $$fa/ Fa0 + fbx/ Fb1x + fby/ Fb1y \le 1.0$$

    where

    fa = P/ A

    with A = the full cross section area

fbx	=	maximum applied bending stress about the x -axis. Note that fb for a section with stiffened compression element will be based on the effective width and the corresponding effective section modulus.
fby	=	maximum applied bending stress about the y -axis. Note that fb for a section with stiffened compression element will be based on the effective width and the corresponding effective section modulus.
Cm	=	a moment factor based on the ratio of the end moments and defined as $0.6- 0.4 \times M1/M2 \geq 0.4$. M1 & M2 are the smaller & larger end moments respectively, about the relevant axis.
Fa1	=	allowable compressive stress as per Cl.6.6.1.1
F'e	=	$12 \times \pi^2 \times E\ /\ [23 \times (KL/r)^2]$ Note that F'e will be calculated for the respective axes.
Fa0	=	is the allowable compressive stress from Cl.6.6.1.1 using L = 0.
Fb1	=	maximum bending stress without any lateral buckling as per Cl.6.1 and Cl.6.2 as appropriate)

- Members susceptible to torsional buckling:

  For members that are susceptible to torsional buckling, both the interaction equations as per Cl.6.7.2 (a) will be checked as below:

  1. Sections that have the factor Q = 1.0:

     The following two checks will be performed for all section profiles:

     $$\frac{f_a}{F_{a1}} + \frac{f_{b1} \times C_m}{F_{b1}\left(1 - f_a / F'_e\right)} \leq 1.0 \text{ and}$$

     $$\frac{f_a}{F_{a0}} + \frac{f_{b1}}{F_{b1}} \leq 1.0$$

     where

fa	=	P/ A with A = the full cross section area
fb1	=	maximum applied bending stress about the relevant axis. Note that fb for a section with stiffened compression element will be based on the effective width and the corresponding effective section modulus.
Cm	=	a moment factor based on the ratio of the end moments and defined as $0.6- 0.4 \times M1/M2 \geq 0.4$. M1 & M2 are the smaller & larger end moments respectively, about the relevant axis. Note that the end moments used will be the ones at the ends of the analytical member being designed.
Fa1	=	allowable compressive stress as per Cl.6.6.1.1
F'e	=	$\frac{12\pi^2 E}{23(KL\ /r)^2}$ Note that F'_e will be calculated for the respective axes.
Fa0	=	the allowable compressive stress from Cl.6.6.1.1 using L = 0.
Fb1	=	maximum bending stress without any lateral buckling as per Cl.6.1 and Cl.6.2 as appropriate)

     Since the loads are being taken as being applied through the shear centre, the checks as per Cl.6.7.2 (b), Cl.6.7.2 (c) & Cl.6.7.2 (d) will not be performed.

  2. Sections that have the factor Q < 1.0:

For members with a Q factor less than 1.0, the interaction checks as per Cl.6.7.2 (a) will be performed, but with the term Fy being replaced with $Q \times Fy$.

- Checks for members subject to combined shear and bending:

  Only web elements of sections will be checked for the effects of combined bending & shear forces. The checks will be done as per Cl.6.4.3. The following check will be performed:

$$\sqrt{\left(\frac{f_{bw}}{F_{bw}}\right)^2 + \left(\frac{f_v}{F_v}\right)^2} \leq 1.0$$

where

fbw	=	the applied bending stress at junction of flange & web
Fbw	=	$36560000 / (h/t)^2 \; kgf/cm^2$
fv	=	the applied shear stress
Fv	=	allowable shear stress as per Cl.6.4.1, but not limited to $0.4 \times Fy$.

D8.C.3 Code Checking and Member Selection

The following two design modes are available:

D8.D.3.1 Code Checking

The program compares the resistance of members with the applied load effects, in accordance with IS:801-1975. Code checking is carried out for locations specified using the `BEAM` parameter. The results are presented in a form of a PASS/FAIL identifier and a `RATIO` of load effect to resistance for each member checked. You may choose the degree of detail in the output data by setting the `TRACK` parameter.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

D8.D.3.2 Member Selection

You may request that the program search the cold formed steel shapes database (standard sections) for an alternative section to pass the code check and meet the least weight criterion. The program will then evaluate all database sections of the type initially specified (i.e., channel, angle, etc.) and, if a suitable replacement is found, presents design results for that section. If no section satisfying the depth restrictions or lighter than the initial one can be found, the program leaves the member unchanged, regardless of whether it passes the code check or not.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D8.C.4 Design Parameters

The following table contains the input parameters for specifying values of design variables and selection of design options.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 167: IS 801: Indian cold formed steel design parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `IS801` Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
BEAM	1.0	When this parameter is set to 0) the 13 location check is not conducted, and instead, checking is done only at the locations specified by the SECTION command (see TR.41 Section Specification (on page 2665) for details) For TRUSS members only start and end locations are designed. 1) the adequacy of the member is determined by checking a total of 13 equally spaced locations along the length of the member.
CB	0	Bending coefficient Cb used for bending checks. By default (value of 0), this is calculated by the program.
CMY	calculated	Coefficient Cm as per Cl. 6.7 for bending about the member Y axis. See IS:801-1975, 6.7. Used for Combined axial load and bending design. Values range from 0.4 to 1.0.
CMZ	calculated	Coefficient Cm as per Cl. 6.7 for bending about the member Z axis. See IS:801-1975, 6.7. Used for Combined axial load and bending design. Values range from 0.4 to 1.0.
CWY	0	Specifies whether the cold work of forming strengthening effect should be included in resistance computation. See IS:801-1975, 6.1.1 0) effect should not be included 1) effect should be included

Parameter Name	Default Value	Description
FLX	0	Specifies whether the member has torsional-flexural buckling restraints that will in turn determine whether the member is susceptible to flexural-torsional bucking mode. See IS:801-1975, 6.6.1 0) No Torsional restraints provided and the section subject to torsional flexural buckling 1) Torsional restraints provided and the section is not subject to torsional flexural buckling
FU	450 MPa (4588.72 kg/cm^2)	Ultimate tensile strength of steel in current units.
FYLD	353.04 MPa (3600.0 kg/cm^2)	Yield strength of steel in current units.
KX	1.0	Effective length factor for torsional buckling. It is a fraction and is unit-less. Values can range from 0.01 (for a column completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for twisting for determining the capacity in axial compression.
KY	1.0	Effective length factor for overall buckling about the local Y-axis. It is a fraction and is unit-less. Values can range from 0.01 (for a column completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the capacity in axial compression.
KZ	1.0	Effective length factor for overall buckling in the local Z-axis. It is a fraction and is unit-less. Values can range from 0.01 (for a member completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the capacity in axial compression.
LX	Member length	Unbraced length for twisting. It is input in the current units of length. Values can range from 0.01 (for a member completely prevented from torsional buckling) to any user specified large value. It is used to compute the KL/R ratio for twisting for determining the capacity in axial compression.

Parameter Name	Default Value	Description
LY	Member length	Effective length for overall buckling in the local Y-axis. It is input in the current units of length. Values can range from 0.01 (for a member completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the capacity in axial compression.
LZ	Member length	Effective length for overall buckling in the local Z-axis. It is input in the current units of length. Values can range from 0.01 (for a member completely prevented from buckling) to any user specified large value. It is used to compute the KL/R ratio for determining the capacity in axial compression.
NSF	1.0	Net section factor for tension members. The net area is calculated as `NSF`×*gross area*.
RATIO	1.0	Permissible ratio of actual to allowable stresses
TRACK	0	This parameter is used to control the level of detail in which the design output is reported in the output file. The allowable values are: 0) Prints only the member number, section name, ratio, and PASS/FAIL status. 1) Prints the design summary including allowable stress in addition to that printed by `TRACK 0`. 2) Prints member, material properties, and stress check table in addition to that printed by `TRACK 1`.
TSA	0	Specifies whether transverse web stiffeners have been provided to check for the requirements of IS: 801-1975, 5.2.4. 0) Web stiffeners not provided 1) Web stiffeners provided
UNL	Member length	Unsupported length (in current units) for calculating the allowable bending stress.

D8.D. Indian Codes - Steel Design per IS 802 - 1995

STAAD.Pro is capable of performing steel design based on the Indian code IS 802 1995 *Use of Structural Steel in Overhead Transmission Line Towers - Code of Practice*.

D8.D.1 General Comments

This section presents some general statements regarding the implementation of Indian Standard code of practice (IS:802-1995 – Part 1) for structural steel design for overhead transmission line towers in STAAD. The design philosophy and procedural logistics for member selection and code checking are based upon the principles of allowable stress design.

Two major failure modes are recognized: failure by overstressing, and failure by stability considerations. The flowing sections describe the salient features of the allowable stresses being calculated and the stability criteria being used. Members are proportioned to resist the design loads without exceeding the allowable stresses and the most economic section is selected on the basis of least weight criteria. The code checking part of the program checks stability and strength requirements and reports the critical loading condition and the governing code criteria.

D8.D.2 Allowable Stresses

The member design and code checking in STAAD.Pro are based upon the allowable stress design method as per IS:802 (1995). It is a method for proportioning structural members using design loads and forces, allowable stresses, and design limitations for the appropriate material under service conditions.

This section discusses the salient features of the allowable stresses specified by IS:802 and implemented in STAAD.Pro.

8D.D.2.1 Axial Stress

Tensile Stress

The allowable tensile stress, as calculated in STAAD.Pro as per IS:802 is described below.

The estimated tensile stresses on the net effective sectional area in various members, multiplied by the appropriate factor of safety shall not exceed minimum guaranteed yield stress of the material.

Thus, the permissible stress in axial tension, σ_{at} in MPa on the net effective area of the sections shall not exceed

$$\sigma_{at} = F_y$$

where

F_y = minimum yield stress of steel in Mpa

Compressive Stress

The estimated compressive stresses in various members multiplied by the appropriate factor of safety shall not exceed the value given by the formulae described below.

I. Condition: when $(b/t) \le [\,(b/t)_{lim} = 210/\sqrt{F_y}]$:

  i. When $KL/r \le C_c$, the allowable compressive stress is (in N/mm^2)

$$F_a = F_y\{1 - 0.5[(KL/r)/C_c]^2\}$$

  ii. When $KL/r > C_c$, the allowable compressive stress is (in N/mm^2)

$$F_a = \pi^2 E/(KL/r)^2$$

II. Condition: when $(b/t)_{lim} < (b/t) \le 378/\sqrt{F_y}$:

The equations in condition 1 shall be used, substituting for F_y the value F_{cr} given by:

$$F_{cr} = F_y[1.677 - 0.677 \cdot (b/t)/(b/t)_{lim}]$$

III. Condition: when $(b/t) > 378/\sqrt{F_y}$

The equations in condition 1 shall be used, substituting for F_y the value F_{cr} given by:

$$F_{cr} = 65{,}550/(b/t)$$

where

F_a = allowable unit stress in compression, Mpa
F_y = minimum guaranteed yield stress of the material, Mpa
K = restraint factor
L = unbraced length of the compression member, cm

R	=	appropriate radius of gyration, cm
E	=	modulus of elasticity, N/mm^2
KL/r	=	largest effective slenderness ratio of any unbraced segment of the member
b	=	distance from edge of the fillet to the extreme fiber, mm
t	=	thickness of flange, mm

Note: The maximum permissible value of b/t for any type of steel shall not exceed 25.

8D.D.3 Stability Requirements

Slenderness ratios are calculated for all members and checked against the appropriate maximum values. The following are the default values used in STAAD.Pro.

8D.D.3.1 Compression Member

Table 168: Slenderness ratio limits of compression members

Type of Member	Slenderness Limit
Leg Members, ground wire peak member and lower members of cross arms in compression	120
Other members carrying computed stress	200
Redundant members and those carrying nominal stresses	250

Slenderness ratios of compression members are determined as follows:

Table 169: Compression slenderness ratio calculation depending on ELA parameter

ELA Value	Type of Member	Calculation of KL/r
1	Leg sections or joint members bolted at connections in both faces	L/r
2	Members with concentric loading at both ends of the unsupported panel with values of L/r up to and including 120	L/r
3	Member with concentric loading at one end and normal eccentricities at the other end of the unsupported panel for value of L/r up to and including 120	30 + 0.75L/r

ELA Value	Type of Member	Calculation of KL/r
4	Members with normal framing eccentricities at both ends of the unsupported panel for values of L/r up to and including 120	60 + 0.5L/r
5	Member unrestrained against rotation at both ends of the unsupported panel for value of L/r from 120 to 200	L/r
6	Members partially restrained against rotation at one end of the unsupported panel for values of L/r over 120 and up to and including 225	28.6 + 0.762L/r
7	Members partially restrained against rotation at both ends of the unsupported panel for values of L/r over 120 and up to and including 250	46.2 + 0.615L/r

If the value for ELA specified for any particular member results in the L/r ratio to fall outside of the specified range, then STAAD.Pro ignores this input and evaluates the slenderness ratio using the KL/r formula.

8D.D.3.2 Tension Members

Slenderness ratio KL/r of a member carrying axial tension only, shall not exceed 400.

8D.D.4 Minimum Thickness Requirement

As per Clause7.1 of IS: 802-1995 minimum thickness of different tower members shall be as follows:

Members	Minimum Thickness (mm)	
	Galvanized	Painted
Leg Members, ground wire peak member and lower members of cross arms in compression	5	6
Other members	4	5

8D.D.5 Code Checking

The purpose of code checking is to verify whether the specified section is capable of satisfying applicable design code requirements. The code checking is based on the IS:802 (1995) requirements. Axial forces at two ends of the members are utilized for the code checking calculations.

Note: Shear and bending forces are *not* considered in design per IS:802 as this code has no provisions for either. If a member design per IS:802 is specified for a member without a TRUSS specification within a model that is not a STAAD TRUSS, then a warning is given in the analysis results file that only axial forces are considered.

The code checking output labels the members as passed or failed. In addition, the critical condition, governing load case, location (distance from the start) and magnitudes of the governing forces are also printed out.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

8D.D.5.1 Design Steps

The following are the steps used by the program in member design:

1. Thickness of the member (maximum of web and flange thicknesses) is checked against minimum allowable thickness, depending upon whether the member is painted or galvanized.
2. If the minimum thickness criterion is fulfilled, the program determines whether the member is under compression or tension for the load case under consideration. Depending upon whether the member is under tension or compression the slenderness ratio of the member is calculated. This calculated ratio is checked against allowable slenderness ratio.
3. If the slenderness criterion is fulfilled check against allowable stress is performed. Allowable axial and tensile stresses are calculated. If the member is under tension and there is no user defined net section factor (NSF), the net section factor is calculated by the program itself (Refer to 8D.D.9 Calculation of Net Section Factor (on page 1660)). Actual axial stress in the member is calculated. The ratio for actual stress to allowable stress, if less than 1.0 or user defined value, the member has passed the check.
4. Number of bolts required for the critical load case is calculated.

8D.D.6 Member Selection

STAAD.Pro is capable of performing design operations on specified members. Once an analysis has been performed, the program can select the most economical section, that is, the lightest section, which satisfies the applicable code requirements. The section selected will be of the same type (either angle or channel) as originally specified by the user. Member selection may be performed with all angle or channel sections and user-provided tables. Selection of members, whose properties are originally provided from user specified table, will be limited to sections in the user provided table.

The process of MEMBER SELECTION may be controlled using the parameters listed in 8D.D.8 Design Parameters (on page 1658). It may be noted that the parameters DMAX and DMIN may be used to specify member depth constraints for selection. If PROFILE parameter is provided, the search for the lightest section is restricted to that profile. Up to three (3) profiles may be provided for any member with a section being selected from each one.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR.49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

8D.D.6.1 Member Selection by Optimization

Steel section selection of the entire structure may be optimized. The optimization method utilizes a state-of-the-art numerical technique which requires automatic multiple analysis. The optimization is based on member stiffness contributions and corresponding force distributions.

An optimum member size is determined through successive analysis/design iterations. This method requires substantial computer time and hence should be used with caution.

Refer to TR.49.2 Member Selection by Optimization (on page 2679) for details.

8D.D.7 Tabulated Results of Steel Design

An example of a `TRACK 2.0` output for a compression member is shown here:

```

8D.D.8 Design Parameters

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 170: Indian Steel Design IS 802 Parameters

Parameter Name	Default Value	Description
CNSF	0.0	This parameter indicates whether user has defined the net section factor or the program will calculate it. 0) Use specified NSF value 1) Net section factor will be calculated.
DANGLE	0.0	This parameter indicates how the pair of angles are connected to each other. This is required to find whether the angle is in single or double shear and the net section factor. 0) Double angle placed back-to-back and connected to each side of a gusset plate 1) Pair of angle placed back-to-back connected by only one leg of each angle to the same side of a gusset plate
DBL	12 mm	Diameter of bolt for calculation of number of bolts and net section factor.
DMAX	100.0 cm.	Maximum allowable depth.
DMIN	0.0 cm.	Minimum allowable depth.
ELA	1.0	This parameter indicates what type of end conditions is to be used. Refer to 8D.D.3 Stability Requirements (on page 1654).
FVB	218 MPA	Allowable shear stress in bolt
FYB	436 MPA	Allowable bearing stress in bolt

Parameter Name	Default Value	Description
FYLD	250 MPA	Yield Strength of steel
GUSSET	5 mm	Thickness of gusset plate. Minimum of the thicknesses of the gusset plate and the leg is used for calculation of the capacity of bolt in bearing
KY	1.0	K value in local y-axis. Usually, this is minor axis.
KZ	1.0	K value in local z-axis. Usually, this is major axis.
LEG	1.0	This parameter is meant for plain angles. 0) The angle is connected by shorter leg 1) The angle is connected by longer leg
LY	Member Length	Unbraced length in local z-axis to calculate slenderness ratio.
LZ	Member Length	Unbraced length in local z-axis to calculate slenderness ratio.

Parameter Name	Default Value	Description
MAIN	1.0	Type of member to find allowable Kl/r for slenderness calculations for members. 1) Leg, Ground wire peak and lower members of cross arms in compression (KL/r = 120) 2) Members carrying computed stress (KL/r = 200) 3) Redundant members and members carrying nominal stresses (KL/r = 250) 4) Tension members (KL/r = 400) 10) Do not perform KL/r check Any value greater than 10.0 indicates user defined allowable KL/r ratio. For this case KY and KZ values are must to find actual KL/r ratio of the member.
NSF	1.0	Net section factor for tension members
NHL	0.0 mm	Deduction for holes. Default value is one bolt width plus 1.5 mm. If the area of holes cut by any straight, diagonal or zigzag line across the member is different from the default value, this parameter is to be defined.
TRACK	0.0	Level of output detail: 0) Suppress critical member stresses 1) Print all critical member stresses 2) Print expanded output. 9) Print design calculations along with expanded output (not available in GUI input).

8D.D.9 Calculation of Net Section Factor

The procedure for calculating the net section factor for an angle section is as follows:

- For a channel section, net section factor is taken to be 1.0.
- For an angle section, it is the ratio of the net effective area, A_{net}, to the gross area, where:

a. Single angle connected by only one leg

$$A_{net} = A_1 + A_2 \times K_1$$

where

A_1	=	net cross-sectional area of the connected leg
A_2	=	gross cross-sectional area of the unconnected leg
K_1	=	$3 \cdot A_1 / (3 \cdot A_1 + A_2)$

The area of a leg of an angle = Thickness of angle × (length of leg – 0.5× thickness of leg)

b. Pair of angles placed back-to-back connected by only one leg of each angle to the same side of a gusset plate

$$A_{net} = A_1 + A_2 \cdot K_1$$

where

A_1	=	net cross-sectional area of the connected leg
A_2	=	gross cross-sectional area of the unconnected leg
K_1	=	$5 \cdot A_1 / (5 \cdot A_1 + A_2)$

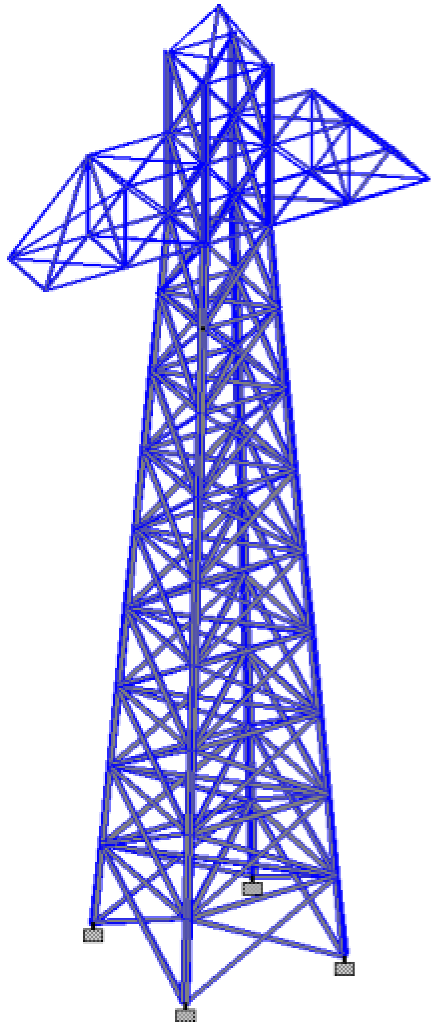
The area of a leg of an angle = Thickness of angle × (length of leg – 0.5× thickness of leg)

c. Double angles placed back-to-back and connected to each side of a gusset plate

A_{net} = gross area minus the deduction for holes

8D.D.10 Example Problem

A transmission line tower is subjected to different loading conditions. Design some members as per IS-802 and show detailed calculation steps for the critical loading condition.



Given

The members are all considered as axial-only members (i.e., truss members).

Note: The model is specified as a `STAAD TRUSS`, which indicates that members have no bending. Refer to G.2 Types of Structures (on page 2085) for details.

End Condition = Members with normal framing eccentricities at both ends of the unsupported panel for values of L/r up to and including 120

Diameter of the bolt = 16 mm

Thickness of the gusset plate = 8 mm

Net Section Factor is to be calculated.

STAAD Input File

Note: This example uses the command `STAAD TRUSS`. If this model had used `STAAD SPACE` (i.e., a space frame rather than a truss model), a warning would be presented since the IS 802 code does not have provisions for non-truss members.

Note: Were you to perform an analysis with the structure type changed to `STAAD SPACE`, then the following warning would be given for each member design:

```
WARNING : THE MEMBER      1 IS NOT A TRUSS MEMBER.
          THIS MEMBER HAS BEEN DESIGNED CONSIDERING AXIAL FORCE ONLY
```

D8.E. Indian Codes - Concrete Design per IS 456

STAAD.Pro is capable of performing concrete design based on the Indian code IS 456 2000 *Code of Practice for Plain and Reinforced Concrete*.

Related Links

- *D8.E. Indian Codes - Concrete Design per IS 456* (on page 1669)

D8.E.1 Section Types for Concrete Design

The following types of cross sections for concrete members can be designed.

- For Beams — Prismatic (Rectangular & Square), T-Beams, and L-shapes
- For Columns — Prismatic (Rectangular, Square, and Circular)

D8.E.2 Member Dimensions

Concrete members which will be designed by the program must have certain section properties input under the `MEMBER PROPERTY` command. The following example shows the required input:

```
UNIT  MM
MEMBER  PROPERTY
1 3  TO 7 9 PRISM YD 450. ZD 250.
11 13  PR YD 350.
14 TO  16 PRIS YD 400. ZD 750. YB 300. ZB 200.
```

In the above input, the first set of members are rectangular (450 mm depth and 250mm width) and the second set of members, with only depth and no width provided, will be assumed to be circular with 350 mm diameter. The third set numbers in the above example represents a T-shape with 750 mm flange width, 200 width, 400 mm overall depth, and 100 mm flange depth (See section 6.20.2).

Note: The program will determine whether the section is rectangular, flanged, or circular and the beam or column design.

D8.E.3 Design Parameters

The program contains a number of parameters which are needed to perform design as per IS:456 2000. Default parameter values have been selected such that they are frequently used numbers for conventional design requirements. These values may be changed to suit the particular design being performed. The following table contains a complete list of the available parameters and their default values. It is necessary to declare length and force units as millimeter and Newton before performing the concrete design.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 171: Indian Concrete Design IS456 2000 Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `INDIAN`. Design code to follow. See TR.53.2 Concrete Design-Parameter Specification (on page 2685).
BRACING	0.0	Column bracing condition: correspond to the terms “Braced”and “Unbraced” described in Notes 1, 2, and 3 of Clause 39.7.1 of IS456:2000. 0) The column is braced about both axes. 1) The column is unbraced about major axis. 2) The column is unbraced about minor axis. 3) The column is unbraced about both axis.
CLB	25 mm	The clear cover for the outermost bottom reinforcement in beams. **Tip:** If you want to specify the clear distance to ties or stirrups, include the full diameter of those in this value. For example, beams with 25 mm clear and 8 mm ties should use `CLB 33`.
CLEAR	30 mm (beams) 40 mm (columns)	The clear distance between to the main member reinforcement. **Tip:** If you want to specify the clear distance to ties or stirrups, include the full diameter of those in this value. For example, columns with 35 mm clear and 8 mm ties should use `CLEAR 43`.

Parameter Name	Default Value	Description
CLT	25 mm	The clear cover for the outermost top reinforcement in beams. **Tip:** If you want to specify the clear distance to ties or stirrups, include the full diameter of those in this value. For example, beams with 25 mm clear and 8 mm ties should use `CLT 33`.
DEPTH	YD	Total depth to be used for design. This value defaults to `YD` as provided under `MEMBER PROPERTIES`.
EFACE	0.0	Face of support location at end of beam. The parameter can also be used to check against shear at any point from the end of the member. **Note:** Both `SFACE` and `EFACE` are input as positive numbers.
ELZ	1.0	Ratio of effective length to actual length of column about major axis. See Note b below.
ELY	1.0	Ratio of effective length to actual length of column about minor axis. See Note b below.

Parameter Name	Default Value	Description
ENSH	0.0	Perform shear check against enhanced shear strength as per Cl. 40.5 of IS456:2000. • ENSH = 1.0 means ordinary shear check to be performed (no enhancement of shear strength at sections close to support) • For ENSH = a positive value(say x), shear strength will be enhanced up to a distance x from the start of the member. This is used only when a span of a beam is subdivided into two or more parts. (Refer note) • For ENSH = a negative value(say –y), shear strength will be enhanced up to a distance y from the end of the member. This is used only when a span of a beam is subdivided into two or more parts.(Refer note) If default value (0.0) is used the program will calculate Length to Overall Depth ratio. If this ratio is greater than 2.5, shear strength will be enhanced at sections (<2d) close to support otherwise ordinary shear check will be performed.
FC	30 N/mm^2	Concrete Yield Stress.
FYMAIN	415 N/mm^2	Yield Stress for main reinforcing steel.
FYSEC	415 N/mm^2	Yield Stress for secondary reinforcing steel.
MINMAIN	10 mm	Minimum main reinforcement bar size.
MAXMAIN	60 mm	Maximum main reinforcement bar size.
MINSEC	8 mm	Minimum secondary reinforcement bar size.

Parameter Name	Default Value	Description
MAXSEC	12 mm	Maximum secondary reinforcement bar size.
METHOD	0	Consider minimum eccentricity one axis at a time: 0) Do not consider 1) Consider as per Cl 25.4 of IS 456:2000
MFACE	0	Design beam for flexure at any point along the length of the beam as specified by SFACE and EFACE parameters. 0) (Off) Do not design at sections 1) (On) Design at specified sections from start and end of the members assigned. **Note:** If SFACE and EFACE sections are *not* previously defined, then the output will present a warning and no flexure design will be performed (i.e., the MFACE parameter is ignored).
RATIO	4.0	Maximum percentage of longitudinal reinforcement in columns.
REINF	0.0	Tied column. A value of 1.0 will mean spiral reinforcement.
RENSH	0.0	Distance of the start or end point of the member from its nearest support. This parameter is used only when a span of a beam is subdivided into two or more parts. (Refer note)

Parameter Name	Default Value	Description
RFACE	4	2) Two faced distribution about major axis. 3) Two faced distribution about minor axis. 4) Longitudinal reinforcement in column is arranged equally along 4 faces.
SFACE	0.0	Face of support location at start of beam. It is used to check against shear at the face of the support in beam design. The parameter can also be used to check against shear at any point from the start of the member.
SPSMAIN	25 mm	Minimum clear distance between main reinforcing bars in beam and column. For column center to center distance between main bars cannot exceed 300 mm.
TORSION	0.0	0) torsion to be considered in beam design. 1) torsion to be neglected in beam design.

Parameter Name	Default Value	Description
TRACK	0	Beam Design: 0) output consists of reinforcement details at START, MIDDLE, and END. 1) critical moments are printed in addition to `TRACK 0.0` output. 2) required steel for intermediate sections defined by `NSECTION` are printed in addition to `TRACK 1.0` output. Column Design: 0) reinforcement details are printed. 1) column interaction analysis results are printed in addition to `TRACK 0.0` output. 2) a schematic interaction diagram and intermediate interaction values are printed in addition to `TRACK 1.0` output.
ULY	1.0	Ratio of unsupported length to actual length of column about minor axis. See Note c below.
ULZ	1.0	Ratio of unsupported length to actual length of column about major axis. See Note c below.
WIDTH	ZD	Width to be used for design. This value defaults to `ZD` as provided under `MEMBER PROPERTIES`.

Notes

a. You may specify reinforcing bar combinations through the `BAR COMBINATION` command. Refer to D8.E.7 Bar Combination (on page 1681) for details.

b. `ELY` and `ELZ` parameters are used to calculate effective length of column to find whether it is a short or long column. Please refer CL 25.1.2 of IS456:2000.

In CL 25.1.2 of IS456:2000, you will find two term, l_{ex} and l_{ey}, which STAAD.Pro calculates as:

- l_{ex} = `ELZ` multiplied by the member length (distance between the two nodes of the member)
- l_{ey} = `ELY` multiplied by the member length (distance between the two nodes of the member)

For the term "D" in CL 25.1.2 of IS456:2000, STAAD.Pro uses the `YD` dimension of the column.

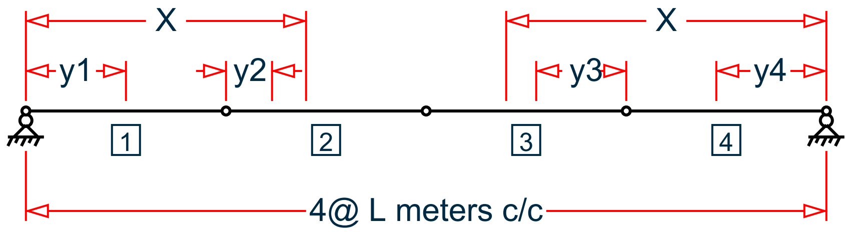
For the term "b" in CL 25.1.2 of IS456:2000, STAAD.Pro uses the `ZD` dimension of the column.

c. `ULY` and `ULZ` parameters are used to calculate unsupported length of column to find minimum eccentricity. Please refer CL 25.4 of IS456:2000.

In CL 25.4 of IS456:2000, you will find an expression "unsupported length of column". This term is calculated as

- `ULZ` multiplied by the member length for the Z axis
- `ULY` multiplied by the member length for the Y axis

d. The value of the `ENSH` parameter (other than 0.0 and 1.0) is used only when the span of a beam is subdivided into two or more parts. When this condition occurs, the `RENSH` parameter is also to be used.



The span of the beam is subdivided four parts, each of length L meter. The shear strength will be enhanced up to X meter from both supports. The input should be the following:

Steps:

a. `ENSH L MEMB 1 =>` Shear strength will be enhanced throughout the length of the member 1, positive sign indicates length measured from start of the member
b. `ENSH (X-L) MEMB 2` => Shear strength will be enhanced up to a length (X-L) of the member 2, length measured from the start of the member
c. `ENSH –L MEMB 4` => Shear strength will be enhanced throughout the length of the member 4, negative sign indicates length measured from end of the member
d. `ENSH –(X-L) MEMB 3` => Shear strength will be enhanced up to a length (X-L) of the member 3, length measured from the end of the member
e. `RENSH L MEMB 2 3` => Nearest support lies at a distance L from both the members 2 and 3.
f. `DESIGN BEAM 1 TO 4=>` This will enhance the shear strength up to length X from both ends of the beam consisting of members 1 to 4 and gives spacing accordingly.

At section = y1 from start of member 1 av = y1

At section = y2 from the start of member 2 av = y2+L

At section = y3 from the end of member 3 av = y3+L

At section = y4 from end of member 4 av = y4

where tc, enhanced = 2dtc/av

At section 0.0, av becomes zero. Thus enhanced shear strength will become infinity. However for any section shear stress cannot exceed tc, max. Hence enhanced shear strength is limited to a maximum value of tc, max.

D8.E.4 Slenderness Effects and Analysis Consideration

Slenderness effects are extremely important in designing compression members. The IS:456 code specifies two options by which the slenderness effect can be accommodated (Clause 39.7). One option is to perform an exact analysis which will take into account the influence of axial loads and variable moment of inertia on member stiffness and fixed end moments, the effect of deflections on moment and forces and the effect of the duration of loads. Another option is to approximately magnify design moments.

STAAD.Pro uses of the first option. To perform this type of analysis, use the command `PDELTA ANALYSIS` instead of `PERFORM ANALYSIS`. The P-Delta analysis will accommodate all requirements of the second- order analysis described by IS:456, except for the effects of the duration of the loads. It is felt that this effect may be safely ignored because experts believe that the effects of the duration of loads are negligible in a normal structural configuration.

Although ignoring load duration effects is somewhat of an approximation, it must be realized that the approximate evaluation of slenderness effects is also an approximate method. In this method, additional moments are calculated based on empirical formula and assumptions on sidesway (Clause 39.7.1 and 39.7.1.1,IS: 456 - 2000). The rules of Clause 39.7.1 have been implemented in STAAD.Pro. They will be checked if the `ELY` and `ELZ` parameters are specified.

Considering all these information, a P-Delta analysis, as performed by STAAD.Pro may be used for the design of concrete members.

Note: To take advantage of this analysis, all the combinations of loading must be provided as primary load cases and <u>not</u> as load combinations. This is due to the fact that load combinations are just algebraic combinations of forces and moments (i.e., analysis results), whereas a primary load case is revised during the P-delta analysis based on the deflections. Loads can be combined prior to analysis using the `REPEAT LOAD` command.

Note: You must specify the appropriate load factors (e.g., 1.5 for dead load, etc.) as STAAD.Pro does not factor the loads automatically.

D8.E.5 Beam Design

Beams are designed for flexure, shear and torsion. If required the effect the axial force may be taken into consideration. For all these forces, all active beam loadings are prescanned to identify the critical load cases at different sections of the beams. The design is performed at 13 evenly spaced points along the length of the beam, including start and end points (i.e., 1/12th points or at ends of 12 equal length segments). All of these sections are scanned to determine the design force envelopes.

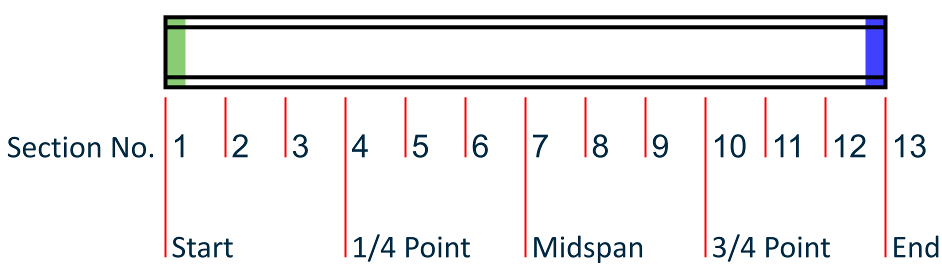


Figure 173: The sections used for design along the length of a member

D8.E.5.1 Design for Flexure

Maximum sagging (creating tensile stress at the bottom face of the beam) and hogging (creating tensile stress at the top face) moments are calculated for all active load cases at each of the above mentioned sections. Each of these sections is designed to resist both of these critical sagging and hogging moments. Where ever the rectangular section is inadequate as singly reinforced section, doubly reinforced section is tried. However, presently the flanged section is designed only as singly reinforced section under sagging moment. It may also be noted all flanged sections are automatically designed as rectangular section under hogging moment as the flange of the beam is ineffective under hogging moment. Flexural design of beams is performed in two passes. In the first pass, effective depths of the sections are determined with the assumption of single layer of assumed reinforcement and reinforcement requirements are calculated. After the preliminary design, reinforcing bars are chosen from the internal database in single or multiple layers. The entire flexure design is performed again in a second pass taking into account of the changed effective depths of sections calculated on the basis of reinforcement provide after the preliminary design. Final provisions of flexural reinforcements are made then. Efforts have been made to meet the guideline for the curtailment of reinforcements as per IS:456-2000 (Clause 26.2.3). Although exact curtailment lengths are not mentioned explicitly in the design output (finally which will be more or less guided by the detailer taking into account of other practical consideration), user has the choice of printing reinforcements provided by STAAD.Pro at 11 equally spaced sections from which the final detail drawing can be prepared.

Once you have specified `SFACE` and `EFACE` parameters to indicate sections, the `MFACE` parameter can be used to design for flexure at any point along the length of the beam, in addition to the equally spaced sections normally used.

D8.E.5.2 Design for Shear

Shear reinforcement is calculated to resist both shear forces and torsional moments. Shear design are performed at 11 equally spaced sections (0.0 to 1.0) for the maximum shear forces amongst the active load cases and the associated torsional moments. Shear capacity calculation at different sections without the shear reinforcement is based on the actual tensile reinforcement provided by the program. Two-legged stirrups are provided to take care of the balance shear forces acting on these sections.

As per Clause 40.5 of IS:456-2000 shear strength of sections (< 2d where d is the effective depth) close to support has been enhanced, subjected to a maximum value of τ_{cmax}.

D8.E.5.3 Beam Design Output

The default design output of the beam contains flexural and shear reinforcement provided at 5 equally spaced (0, .25, .5, .75 and 1.) sections along the length of the beam. User has option to get a more detail output. All beam design outputs are given in IS units. An example of rectangular beam design output with `TRACK 2.0` output is presented below:

```
                  B E A M  N O.      1   D E S I G N  R E S U L T S

D8.E.6 Column Design

Columns are designed for axial forces and biaxial moments at the ends. All active load cases are tested to calculate reinforcement.

The loading which yields maximum reinforcement is called the critical load. Column design is done for square, rectangular, and circular sections. By default, square and rectangular columns and designed with reinforcement distributed on each side equally for the sections under biaxial moments and with reinforcement distributed equally in two faces for sections under uniaxial moment. You may change the default arrangement of the reinforcement with the help of the parameter `RFACE` (see D8.E.3 Design Parameters (on page 1669)). Depending upon the member lengths, section dimensions, and effective length coefficients specified, STAAD.Pro automatically determines the criterion (short or long) of the column design. All major criteria for selecting longitudinal and transverse reinforcement as stipulated by IS:456 have been taken care of in the column design of STAAD.Pro. Default clear spacing between main reinforcing bars is taken to be 25 mm while arrangement of longitudinal bars.

Default column design output (`TRACK 0.0`) contains the reinforcement provided by STAAD.Pro and the capacity of the section. With the option `TRACK 1.0`, the output contains intermediate results such as the design forces, effective length coefficients, additional moments etc. All design output is given in SI units. An example of a `TRACK 2.0` output follows:

```
            C O L U M N   N O.     1  D E S I G N   R E S U L T S

D8.E.7 Bar Combination

Initially the program selects only one bar to calculate the number of bars required and area of steel provided at each section along the length of the beam. You may use the `BAR COMBINATION` command to specify two bar diameters to calculate a combination of each bar to be provided at each section. The syntax for bar combination is given below.

```
START BAR COMBINATION
MD1 <bar diameter>  MEMB  <member list>
MD2 <bar diameter>  MEMB  <member list>
END BAR COMBINATION
```

Note: The bar sizes should be specified in the order of increasing size (i.e., `MD2` bar diameter should be greater than `MD1` bar diameter).

The beam length is divided into three parts, two at its ends and one at span. “Ld” gives the development length to be provided at the two ends of each section.

The typical output for bar combination is shown below:

```
                        OUTPUT FOR BAR COMBINATION

D8.E.8 Element Design

Element design will be performed only for the moments MX and MY at the center of the element. Design will not be performed for SX, SY, SXY, SQX, SQY, or MXY. Also, design is not performed at any other point on the surface of the element.

A typical example of element design output is shown below. The reinforcement required to resist Mx moment is denoted as longitudinal reinforcement and the reinforcement required to resist My moment is denoted as transverse reinforcement (Refer to D8.E.1 Section Types for Concrete Design (on page 1669)). The parameters `FYMAIN`, `FC`, and `CLEAR` listed in D8.E.3 Design Parameters (on page 1669) are relevant to slab design.

Other parameters mentioned in the design parameters table are *not* applicable to slab design.

D8.E.9 Wall Design in accordance with IS 456-2000

Note: Shearwall design has been deprecated in STAAD.Pro CONNECT Edition. The analysis and design engine will allow it but its use is not recommended.

D8.F. Indian Codes - Concrete Design per IS 13920-2016

STAAD.Pro is capable of performing concrete design based on the 2016 edition of the Indian code IS 13920 *Ductile Design and Detailing of Reinforced Concrete Structures Subjected to Seismic Forces - Code of Practice*. Designs per IS 13920-2016 satisfy all provisions of IS 456-2000 and IS 13920-2016 for beams and columns (Refer to D8.E. Indian Codes - Concrete Design per IS 456 (on page 1669)).

The IS:13920 code provides the design and detailing requirements of reinforced concrete (RC) members to resist lateral effects of earthquake shaking. This gives the RC members sufficient strength and ductility to resist severe earthquake shaking without collapse.

RR 21.03.00-3.1 Static Seismic Loads per IBC 2015 / ASCE 7-10

- *RR 21.03.00-3.1 Static Seismic Loads per IBC 2015 / ASCE 7-10* (on page 136)

D8.F.1 Scope

The following reinforced concrete members that can be designed by the latest revision are the following:

a. Reinforced concrete beams (excluding deep beams)
b. Reinforced concrete columns (see note b (on page 1684) for details)

The following types of cross sections for concrete members can be designed:

- For beams:

  prismatic (rectangular and square)
  T-beams (singly reinforced only)
- For columns:

  prismatic: rectangular, square, and circular

Note: IS13920 does not deal with plate design. Plate design is to be performed per IS:456:2000.

Notes

a. The clauses that are already implemented for IS-13920:1993 revision and remains unchanged in revision 2016 are not discussed in these design notes.
b. Clause 7.2 of IS:13920-2016 is checked. Please refer to Relative Strengths of Beams and Columns at a Joint (on page 1686) for additional details.
c. Implementation of Clause 9.0 of IS:13920-2016 for design of beam-column joint for distortional shear is currently excluded.
d. The provisions for the spacing of for special confining reinforcement per Amendment 1 to IS:13920-2016 are not implemented. The design of this reinforcement is designed to the initial IS:13920-2016 edition.
e. STAAD.Pro only designs singly reinforced T beam (flanged) sections.

D8.F.2 Beam Design

Beams are designed for flexure, shear, and torsion. If required the effect of the axial force may be taken into consideration. For all these forces, all active beam loadings are prescanned to identify the critical load cases at different sections of the beams. The total number of sections considered is 13. All of these sections are scanned to determine the design force envelopes.

For design to be performed as per IS:13920 2016 the width of the member shall not be less than 200 mm (Clause 6.1.2). Also the member shall preferably have a width-to depth ratio of more than 0.3 (Clause 6.1.1).

The factored axial stress on the member should not exceed $0.08fck$ (Clause 6.1) for all active load cases. If it exceeds allowable axial stress no design will be performed.

Cl 6.1 of IS:13920-2016 is applicable for beams resisting earthquake induced effects. The program performs a load type check where it determines if the design load contains earthquake or dynamic load or not. If yes, it will perform check against Cl 6.1. Otherwise, the program will ignore the design load for check against this code provision.

D8.F.2.1 Design for Flexure

Design procedure is same as that for IS 456. However while designing following criteria are satisfied as per IS13920 2016:

1. The minimum grade of concrete shall preferably be M20. (Clause 5.2)
2. Steel reinforcements of grade Fe415 or less only shall be used. (Clause 5.3.1)
3. The minimum tension steel ratio on any face, at any section, is given by (Clause 6.2.1b)

$$\rho_{min} = 0.24fck/fy$$

   The maximum steel ratio on any face, at any section, is given by (Clause 6.2.2)

$$\rho_{max} = 0.025$$

4. The longitudinal steel on bottom at a joint face must be at least equal to half the steel at its top at the same section. (Clause 6.2.3)
5. The steel provided at each of the top and bottom face, at any section, shall at least be equal to one-fourth of the maximum negative moment steel provided at the face of either joint. (Clause 6.2.4)
6. Beams shall have at least two 12 mm diameter bars each at the top and bottom faces.

D8.F.2.2 Design for Shear

The shear force to be resisted by vertical hoops is guided by the Clause 6.3.3 of IS 13920:2016 revision. Elastic sagging and hogging moments of resistance of the beam section at ends are considered while calculating shear force. Plastic sagging and hogging moments of resistance can also be considered for shear design if the `PLASTIC` parameter is used (refer to D8.F.4 Design Parameters (on page 1686)).

Shear reinforcement is calculated to resist both shear forces and torsional moments. The procedure is the same as that used for IS 456.

The following criteria are satisfied while performing design for shear as per Cl. 6.3.5 of IS-13920 2016:

- The spacing of vertical hoops over a length of 2d at either end of the beam shall not exceed
  - **a.** d/4
  - **b.** 6 times the diameter of the smallest longitudinal bars
  - **c.** 100 mm

  The spacing calculated from above, if less than that calculated from IS 456 considerations, is provided.
- While calculating shear force reinforcement the provision of Clause 6.3.4c (i.e. neglecting design shear capacity of concrete of RC section) is taken into consideration. The spacing of links is provided in accordance with clause 6.3.5.2 of IS-13920 2016.

Related Links
- *V. IS13920 2016-Singly Reinforced Rectangular Beam* (on page 6163)
- *V. IS13920 2016-Doubly Reinforced Rectangular Beam* (on page 6171)

D8.F.3 Column Design

Columns are designed for axial forces and biaxial moments per IS 456:2000. Columns are also designed for shear forces as per Clause 7.3.4. All major criteria for selecting longitudinal and transverse reinforcement as stipulated by IS:456 are performed by the column design of STAAD.Pro. However following clauses have been satisfied to incorporate provisions of IS 13920 2016:

- The minimum grade of concrete shall preferably be M20. (Clause 5.2)
- Steel reinforcements of grade Fe415 or less only shall be used. (Clause 5.3.1)
- The minimum dimension of column member shall not be less than:
  - **a.** 20 times the diameter of the largest longitudinal reinforcement in the beam passing through or anchoring into the column at the joint, or
  - **b.** 300 mm (Clause 7.1.1)
- The ratio of the shortest cross-sectional dimension to the perpendicular dimension shall preferably be not less than 0.45. (Clause 7.1.2)
- The spacing of hoops shall not exceed half the least lateral dimension of the column, except where special confining reinforcement is provided. (Clause 7.4.2d)
- The minimum diameter of the rectangular hoop is 8 mm when diameter of the longitudinal bar is less than or equal to 32 mm, and 10 mm when diameter of longitudinal bar is more than 32 mm. (Clause 7.4.2a)
- Special confining reinforcement shall be provided over a length l_o from each joint face, towards mid span, and on either side of any section, where flexural yielding may occur. The length l_o shall not be less than:
  - **a.** larger lateral dimension of the member at the section where yielding occurs,
  - **b.** 1/6 of clear span of the member,
  - **c.** 450 mm (Clause 8.1a)
- The spacing of hoops used as special confining reinforcement shall not exceed:
  - **a.** ¼ of minimum member dimension,
  - **b.** 6 times diameter of the smallest longitudinal bars, or

c. 100 mm (Clause 8.1b)

- The area of cross-section of hoops provided are checked against the provisions for minimum area of cross-section of the bar forming rectangular, circular, or spiral hoops, to be used as special confining reinforcement. (Clause 8.1c)

Cl 7.1 of IS:13920-2016 is applicable for columns resisting earthquake induced effects. The program will check whether the design load is gravity load case (as defined by the `GLD` parameter) or earthquake load. If yes, the program will perform this code check. Otherwise, the program will ignore the design load case for check against this code provision.

Note: In previous releases, the design performed checks against this clause for *all* types of design load cases, irrespective of whether they contain earthquake load or not. This logic is now automated to include only earthquake or gravity load case.

Relative Strengths of Beams and Columns at a Joint

Clause 7.2 of IS:13920-2016 checks the relative strength of beams and columns at a joint to evaluate if any column at a joint is acting as a gravity column or is a part of lateral load resisting system. After the concrete design is completed per IS 13920-2016, then this relative strength check is automatically performed at joints in which *all* connecting beams and columns were designed. Thus, no new commands are required for this check to be performed so long as all concrete members at a joint are designed. Per Cl 7.2, the sum of all column moment resistances at a joint shall be greater that 1.4× the sum of all beam moment resistances at the same point.

Note: STAAD.Pro does not have designate columns as gravity load structural elements. Rather, the program considers all columns as lateral load resisting. If this check fails at any joint, the column dimensions, beam dimension, or both should be changed to make the column suitable for the lateral load resisting system.

It is recommend that the design of all concrete beams and columns be performed in one concrete block (a "concrete block" is the information contained in the `START CONCRETE DESIGN … END CONCRETE DESIGN` input section) so this check can be performed. If multiple concrete blocks are defined, all previous relative strength check result will be deleted since multiple design of beams and column designs may change the relative strength of beams and columns at a joint. The strength check performed after the last concrete block will be considered valid and is available as result.

The output file will issue a note regarding the results of this check. A detailed output of the checks can be included in the output using the `TRACK 4` parameter in the concrete design. The detailed output of the joint relative strength checks are also included in the *`filename`*`_13920.txt` file (which is generated regardless of the `TRACK` parameter used or check status).

Note: The program assumes that all beams connected to a column are horiztonal and parallel to global X and Z axes. If beams do not meet this requirement a warning message is issued in the analysis output.

D8.F.4 Design Parameters

The program contains a number of parameters that are needed to perform design as per IS 13920 2016. It accepts all parameters that are needed to perform design as per IS:456. Over and above it has some other parameters that are required only when designed is performed as per IS:13920 2016. Default parameter values have been selected such that they are frequently used numbers for conventional design requirements. These values may be changed to suit the particular design being performed. The following table contains a complete list of the available parameters and their default values. It is necessary to declare length and force units as Millimeter and Newton before performing the concrete design.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 172: Indian Concrete Design IS 13920 2016 Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `IS13920 2016` or `ISH13920` Design code to follow. See TR.53.2 Concrete Design-Parameter Specification (on page 2685).
BRACING	0.0	Beam Design 1.0 = the effect of axial force will be taken into account for beam design. Column Design: Correspond to the terms "Braced" and "Unbraced" described in Notes 1, 2, and 3 of Clause 39.7.1 of IS456:2000. 1.0 = the column is unbraced about major axis. 2.0 = the column is unbraced about minor axis. 3.0 = the column is unbraced about both axis.
DEPTH	YD	Total depth to be used for design. This value defaults to YD (depth of section in Y direction) as provided under `MEMBER PROPERTIES`.

Parameter Name	Default Value	Description
CLB	25 mm	Clear cover to stirrups at bottom for beams. **Note:** If both CLEAR and CLB are defined for beams, CLB is considered in design. Concrete cover to main reinforcement at bottom of beam will be calculated from CLB.
CLEAR	>30 mm 40 mm	Concrete cover to main reinforcement bars for beams Concrete cover to main longitudinal bars for columns **Notes:** 1. This is the clear cover to the outermost main reinforcing bar. It is *not* the clear cover for the stirrups or the tie bars. 2. If the CLB parameter is not defined, then the CLEAR parameter will be used by default.
CLT	25 mm	Clear cover to stirrups at top for beams. **Note:** If both CLEAR and CLT are defined for beams, CLT is considered in design. Concrete cover to main reinforcement at top of beam will be calculated from CLT.

Parameter Name	Default Value	Description
COMBINE	0.0	Default value means there will be no member combination. 1.0 = no printout of sectional force and critical load for combined member in the output. 2.0 = printout of sectional force for combined member in the output. 3.0 = printout of both sectional force and critical load for combined member in the output. *** **Note:** Refer description of COMBINE parameter at the end of the parameter table.
EFACE	0.0	Face of support location at end of beam. The parameter can also be used to check against shear at any point from the end of the member. **Note:** Both `SFACE` and `EFACE` are input as positive numbers. Not valid along with `COMBINE` parameter. *
ELY	1.0	Ratio of effective length to actual length of column about minor axis.
ELZ	1.0	Ratio of effective length to actual length of column about major axis.

Parameter Name	Default Value	Description
ENSH	0.0	Perform shear check against enhanced shear strength as per Cl. 40.5 of IS456:2000. 1.0 = ordinary shear check to be performed (no enhancement of shear strength at sections close to support) a positive value(say x) = shear strength will be enhanced up to a distance x from the start of the member. This is used only when a span of a beam is subdivided into two or more parts. (Refer note after Table 8A.1) a negative value(say –y) = shear strength will be enhanced up to a distance y from the end of the member. This is used only when a span of a beam is subdivided into two or more parts.(Refer note after Table 8A.1) 0.0 = the program will calculate Length to Overall Depth ratio. If this ratio is greater than 2.5, shear strength will be enhanced at sections (<2d) close to support otherwise ordinary shear check will be performed.
EUDL	None	Equivalent u.d.l on span of the beam. This load value must be the unfactored load on span. During design the load value is multiplied by a factor 1.2. If no u.d.l is defined factored shear force due to gravity load on span will be taken as zero. No elastic or plastic moment will be calculated. Shear design will be performed based on analysis result. (Refer note)
FYMAIN	415 N/mm^2	Yield Stress for main reinforcing steel.
FYSEC	415 N/mm^2	Yield Stress for secondary reinforcing steel.

Parameter Name	Default Value	Description
FC	Fcu or 30 N/mm^2	Concrete Yield Stress. The FC value will be taken from Material Definition where Compressive Strength (Fcu) is defined. If the input is not available, the design will consider 30 MPa as default value.
GLD	None	Gravity load number to be considered for calculating equivalent u.d.l on span of the beam, in case no EUDL is mentioned in the input. This load case can be any static load case containing **MEMBER LOAD** on the beam which includes **UNI**, **CON**, **LIN** and **TRAP** member loading. **CMOM** member loading is considered only when it is specified in local direction. **FLOOR LOAD** is also considered. The load can be primary or combination load. For combination load only load numbers included in load combination is considered. The load factors are ignored. Internally the unfactored load is multiplied by a factor 1.2 during design. If both EUDL and GLD parameters are mentioned in the input mentioned EUDL will be considered in design **Note:** No dynamic (Response spectrum, 1893, Time History) and moving load cases are considered. CMOM member loading in global direction is not considered. UMOM member loading is not considered.

Parameter Name	Default Value	Description
HLINK	Spacing of longitudinal bars measured to the outer face	Longer dimension of the rectangular confining hoop measured to its outer face. It shall not exceed 300 mm as per Cl. 7.4.8. If the HLINK value as provided in the input file does not satisfy the clause the value will be internally assumed as the default one. This parameter is valid for rectangular column.
IPLM	0.0	Default value calculates elastic/ plastic hogging and sagging moments of resistance of beam at its ends. 1.0 = calculation of elastic/ plastic hogging and sagging moments of resistance of beam to be ignored at start node of beam. This implies no support exists at start node. -1.0 = calculation of elastic/ plastic hogging and sagging moments of resistance of beam to be considered at start node of beam. . This implies support exists at start node. 2.0 = calculation of elastic/ plastic hogging and sagging moments of resistance of beam to be ignored at end node of beam. This implies no support exists at end node. -2.0 = calculation of elastic/ plastic hogging and sagging moments of resistance of beam to be considered at end node of beam. . This implies support exists at end node. ** **Note:** Not valid along with COMBINE parameter. **

Parameter Name	Default Value	Description
IMB	0.0	Default value calculates elastic/ plastic hogging and sagging moments of resistance of beam at its ends. 1.0 = calculation of elastic/ plastic hogging and sagging moments of resistance of beam to be ignored at both ends of beam. This implies no support exist at either end of the member. -1.0 = calculation of elastic/ plastic hogging and sagging moments of resistance of beam to be considered at both ends of beam. This implies support exist at both ends of the member.** **Note:** Not valid along with `COMBINE` parameter. **
MINMAIN	10 mm	Minimum main reinforcement bar size.
MAXMAIN	60 mm	Maximum main reinforcement bar size.
MINSEC	8 mm	Minimum secondary reinforcement bar size.
MAXSEC	12 mm	Maximum secondary reinforcement bar size.
PLASTIC	0.0	Default value calculates elastic hogging and sagging moments of resistance of beam at its ends. 1.0 = plastic hogging and sagging moments of resistance of beam to be calculated at its ends.
RATIO	4.0	Maximum percentage of longitudinal reinforcement in columns.

Parameter Name	Default Value	Description
REINF	0.0	0.0 = Tied column (default) 1.0 = spiral reinforcement
RENSH	0.0	Distance of the start or end point of the member from its nearest support. This parameter is used only when a span of a beam is subdivided into two or more parts. Refer to Notes (on page 1675) for IS456 Design Parameters.
RFACE	4.0	4.0 = longitudinal reinforcement in column is arranged equally along four faces. 2.0 invokes two faced distribution about major axis. 3.0 invokes two faced distribution about minor axis.
SFACE	0.0	Face of support location at start of beam. It is used to check against shear at the face of the support in beam design. The parameter can also be used to check against shear at any point from the start of the member.* **Note:** Both SFACE and EFACE are input as positive numbers.*
SPSMAIN	25 mm	Minimum clear distance between main reinforcing bars in beam and column. For column center to center distance between main bars cannot exceed 300 mm.
TORISION	0.0	0.0 = torsion to be considered in beam design. 1.0 = torsion to be neglected in beam design.

Parameter Name	Default Value	Description
TRACK	0.0	Beam Design: 0) output consists of reinforcement details at START, MIDDLE and END. 1) critical moments are printed in addition to `TRACK 0` output. 2) required steel for intermediate sections defined by `NSECTION` are printed in addition to `TRACK 1` output. 4) prints the output for joint strength check per Cl. 7.2 of IS 13920-2016 Column Design: 0) reinforcement details are printed. 1) column interaction analysis results are printed in addition to `TRACK 0` output. 2) a schematic interaction diagram and intermediate interaction values are printed in addition to `TRACK 1` output. 4) prints the output for joint strength check per Cl. 7.2 of IS 13920-2016 9) details of section capacity about major and minor axes are printed in addition to `TRACK 1` output
ULY	1.0	Ratio of unsupported length to actual length of column about minor axis.
ULZ	1.0	Ratio of unsupported length to actual length of column about major axis.
WIDTH	ZD	Width to be used for design. This value defaults to ZD as provided under MEMBER PROPERTIES.

Bar combination has been introduced for detailing. Please refer D8.G.6 Bar Combination (on page 1712) for details.

* `EFACE` and `SFACE` command is not valid for member combination.

** `IPLM` and `IMB` commands are not valid for member combination. These commands are ignored for members forming physical member.

*** The purpose of `COMBINE` command is the following:

1. If a beam spanning between two supports is subdivided into many sub-beams this parameter will combine them into one member. It can also be used to combine members to form one continuous beam spanning over more than two supports.
2. When two or more members are combined during design plastic or elastic moments will be calculated at the column supports. At all the intermediate nodes (if any) this calculation will be ignored.

   Note: Please note that the program only recognizes column at right angle to the beam. Inclined column support is ignored.
3. It will calculate sectional forces at 13 sections along the length of the combined member.
4. It will calculate critical loads (similar to that of Design Load Summary) for all active load cases during design. Beams will be combined only when `DESIGN BEAM` command is issued.

The following lines should be satisfied during combination of members:

1. Members to be combined should have same sectional properties if any single span between two column supports of a continuous beam is subdivided into several members.
2. Members to be combined should have same constants (E, Poi ratio, alpha, density, and beta angle)
3. Members to be combined should lie in one straight line.
4. Members to be combined should be continuous.
5. Vertical members (i.e., columns) cannot be combined.
6. Same member cannot be used more than once to form two different combined members.
7. The maximum number of members that can be combined into one member is 299.

Note: Sectional forces and critical load for combined member output will only be available when all the members combined are successfully designed in both flexure and shear.

`ENSH` and `RENSH` parameters will have to be provided (as and when necessary) even if physical member has been formed.

D8.G. Indian Codes - Concrete Design per IS 13920-1993

STAAD.Pro is capable of performing concrete design based on the 1993 edition of the Indian code IS 13920 *Code of Practice for Ductile Detailing of Reinforced Concrete Structures Subjected to Seismic Forces*. Designs per IS 13920-1993 satisfy all provisions of IS 456 - 2000 and IS 13920-1993 for beams and columns (Refer to D8.E. Indian Codes - Concrete Design per IS 456 (on page 1669)).

D8.G.1 Design Operations

Earthquake motion often induces force large enough to cause inelastic deformations in the structure. If the structure is brittle, sudden failure could occur. But if the structure is made to behave ductile, it will be able to sustain the earthquake effects better with some deflection larger than the yield deflection by absorption of energy. Therefore ductility is also required as an essential element for safety from sudden collapse during severe shocks.

D8.G.2 Section Types for Concrete Design

The following types of cross sections for concrete members can be designed.

- For Beams: Prismatic (Rectangular & Square) and T-shape
- For Columns : Prismatic (Rectangular, Square, and Circular)

D8.G.3 Design Parameters

The program contains a number of parameters that are needed to perform design as per IS 13920 1993. It accepts all parameters that are needed to perform design as per IS:456. Over and above it has some other parameters that are required only when designed is performed as per IS:13920 1993. Default parameter values have been selected such that they are frequently used numbers for conventional design requirements. These values may be changed to suit the particular design being performed. The following table contains a complete list of the available parameters and their default values. It is necessary to declare length and force units as Millimeter and Newton before performing the concrete design.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 173: Indian Concrete Design IS 13920 1993 Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `IS13920 1993` Design code to follow. See TR.53.2 Concrete Design-Parameter Specification (on page 2685).

Parameter Name	Default Value	Description
BRACING	0.0	Beam Design 1.0 = the effect of axial force will be taken into account for beam design. Column Design: Correspond to the terms "Braced" and "Unbraced" described in Notes 1, 2, and 3 of Clause 39.7.1 of IS456:2000. 1.0 = the column is unbraced about major axis. 2.0 = the column is unbraced about minor axis. 3.0 = the column is unbraced about both axis.
DEPTH	YD	Total depth to be used for design. This value defaults to YD (depth of section in Y direction) as provided under `MEMBER PROPERTIES`.
CLEAR	25 mm 40 mm	For beam members. For column members **Note:** This is the clear cover to the outermost main reinforcing bar. It is *not* the clear cover for the stirrups or the tie bars.
COMBINE	0.0	Default value means there will be no member combination. 1.0 = no printout of sectional force and critical load for combined member in the output. 2.0 = printout of sectional force for combined member in the output. 3.0 = printout of both sectional force and critical load for combined member in the output. ***

Parameter Name	Default Value	Description
EFACE	0.0	Face of support location at end of beam. The parameter can also be used to check against shear at any point from the end of the member. **Note:** Both SFACE and EFACE are input as positive numbers.*
ELZ	1.0	Ratio of effective length to actual length of column about major axis.
ELY	1.0	Ratio of effective length to actual length of column about minor axis.
ENSH	0.0	Perform shear check against enhanced shear strength as per Cl. 40.5 of IS456:2000. 1.0 = ordinary shear check to be performed (no enhancement of shear strength at sections close to support) a positive value(say x) = shear strength will be enhanced up to a distance x from the start of the member. This is used only when a span of a beam is subdivided into two or more parts. (Refer note after Table 8A.1) a negative value(say –y) = shear strength will be enhanced up to a distance y from the end of the member. This is used only when a span of a beam is subdivided into two or more parts.(Refer note after Table 8A.1) 0.0 = the program will calculate Length to Overall Depth ratio. If this ratio is greater than 2.5, shear strength will be enhanced at sections (<2d) close to support otherwise ordinary shear check will be performed.

Parameter Name	Default Value	Description
EUDL	None	Equivalent u.d.l on span of the beam. This load value must be the unfactored load on span. During design the load value is multiplied by a factor 1.2. If no u.d.l is defined factored shear force due to gravity load on span will be taken as zero. No elastic or plastic moment will be calculated. Shear design will be performed based on analysis result. (Refer note)
FYMAIN	415 N/mm^2	Yield Stress for main reinforcing steel.
FYSEC	415 N/mm^2	Yield Stress for secondary reinforcing steel.
FC	30 N/mm^2	Concrete Yield Stress.

Parameter Name	Default Value	Description
GLD	None	Gravity load number to be considered for calculating equivalent u.d.l on span of the beam, in case no EUDL is mentioned in the input. This load case can be any static load case containing **MEMBER LOAD** on the beam which includes **UNI**, **CON**, **LIN** and **TRAP** member loading. **CMOM** member loading is considered only when it is specified in local direction. **FLOOR LOAD** is also considered. The load can be primary or combination load. For combination load only load numbers included in load combination is considered. The load factors are ignored. Internally the unfactored load is multiplied by a factor 1.2 during design. If both `EUDL` and `GLD` parameters are mentioned in the input mentioned EUDL will be considered in design **Note:** No dynamic (Response spectrum, 1893, Time History) and moving load cases are considered. `CMOM` member loading in global direction is not considered. `UMOM` member loading is not considered.
HLINK	Spacing of longitudinal bars measured to the outer face	Longer dimension of the rectangular confining hoop measured to its outer face. It shall not exceed 300 mm as per Cl. 7.4.8. If the `HLINK` value as provided in the input file does not satisfy the clause the value will be internally assumed as the default one. This parameter is valid for rectangular column.

Parameter Name	Default Value	Description
IPLM	0.0	Default value calculates elastic/ plastic hogging and sagging moments of resistance of beam at its ends. 1.0 = calculation of elastic/ plastic hogging and sagging moments of resistance of beam to be ignored at start node of beam. This implies no support exists at start node. -1.0 = calculation of elastic/ plastic hogging and sagging moments of resistance of beam to be considered at start node of beam. . This implies support exists at start node. 2.0 = calculation of elastic/ plastic hogging and sagging moments of resistance of beam to be ignored at end node of beam. This implies no support exists at end node. -2.0 = calculation of elastic/ plastic hogging and sagging moments of resistance of beam to be considered at end node of beam. . This implies support exists at end node. **
IMB	0.0	Default value calculates elastic/ plastic hogging and sagging moments of resistance of beam at its ends. 1.0 = calculation of elastic/ plastic hogging and sagging moments of resistance of beam to be ignored at both ends of beam. This implies no support exist at either end of the member. -1.0 = calculation of elastic/ plastic hogging and sagging moments of resistance of beam to be considered at both ends of beam. This implies support exist at both ends of the member.**

Parameter Name	Default Value	Description
MINMAIN	10 mm	Minimum main reinforcement bar size.
MAXMAIN	60 mm	Maximum main reinforcement bar size.
MINSEC	8 mm	Minimum secondary reinforcement bar size.
MAXSEC	12 mm	Maximum secondary reinforcement bar size.
PLASTIC	0.0	Default value calculates elastic hogging and sagging moments of resistance of beam at its ends. 1.0 = plastic hogging and sagging moments of resistance of beam to be calculated at its ends.
RATIO	4.0	Maximum percentage of longitudinal reinforcement in columns.
REINF	0.0	0.0 = Tied column (default) 1.0 = spiral reinforcement
RENSH	0.0	Distance of the start or end point of the member from its nearest support. This parameter is used only when a span of a beam is subdivided into two or more parts. Refer to Notes (on page 1675) for IS456 Design Parameters.
RFACE	4.0	4.0 = longitudinal reinforcement in column is arranged equally along four faces. 2.0 invokes two faced distribution about major axis. 3.0 invokes two faced distribution about minor axis.

Parameter Name	Default Value	Description
SFACE	0.0	Face of support location at start of beam. It is used to check against shear at the face of the support in beam design. The parameter can also be used to check against shear at any point from the start of the member.* **Note:** Both SFACE and EFACE are input as positive numbers.*
SPSMAIN	25 mm	Minimum clear distance between main reinforcing bars in beam and column. For column center to center distance between main bars cannot exceed 300 mm.
TORISION	0.0	0.0 = torsion to be considered in beam design. 1.0 = torsion to be neglected in beam design.
TRACK	0.0	Beam Design: 0) output consists of reinforcement details at START, MIDDLE and END. 1) critical moments are printed in addition to TRACK 0 output. 2) required steel for intermediate sections defined by NSECTION are printed in addition to TRACK 1 output. Column Design: 0) reinforcement details are printed. 1) column interaction analysis results are printed in addition to TRACK 0 output. 2) a schematic interaction diagram and intermediate interaction values are printed in addition to TRACK 1 output.

Parameter Name	Default Value	Description
ULY	1.0	Ratio of unsupported length to actual length of column about minor axis.
ULZ	1.0	Ratio of unsupported length to actual length of column about major axis.
WIDTH	ZD	Width to be used for design. This value defaults to ZD as provided under MEMBER PROPERTIES.

Bar combination has been introduced for detailing. Please refer D8.G.6 Bar Combination (on page 1712) for details.

* `EFACE` and `SFACE` command is not valid for member combination.

** `IPLM` and `IMB` commands are not valid for member combination. These commands are ignored for members forming physical member.

*** The purpose of `COMBINE` command is the following:

1. If a beam spanning between two supports is subdivided into many sub-beams this parameter will combine them into one member. It can also be used to combine members to form one continuous beam spanning over more than two supports.
2. When two or more members are combined during design plastic or elastic moments will be calculated at the column supports. At all the intermediate nodes (if any) this calculation will be ignored.

   Note: Please note that the program only recognizes column at right angle to the beam. Inclined column support is ignored.
3. It will calculate sectional forces at 13 sections along the length of the combined member.
4. It will calculate critical loads (similar to that of Design Load Summary) for all active load cases during design. Beams will be combined only when `DESIGN BEAM` command is issued.

The following lines should be satisfied during combination of members:

1. Members to be combined should have same sectional properties if any single span between two column supports of a continuous beam is subdivided into several members.
2. Members to be combined should have same constants (E, Poi ratio, alpha, density, and beta angle)
3. Members to be combined should lie in one straight line.
4. Members to be combined should be continuous.
5. Vertical members (i.e., columns) cannot be combined.
6. Same member cannot be used more than once to form two different combined members.
7. The maximum number of members that can be combined into one member is 299.

Note: Sectional forces and critical load for combined member output will only be available when all the members combined are successfully designed in both flexure and shear.

`ENSH` and `RENSH` parameters will have to be provided (as and when necessary) even if physical member has been formed.

D8.G.4 Beam Design

Beams are designed for flexure, shear and torsion. If required the effect of the axial force may be taken into consideration. For all these forces, all active beam loadings are prescanned to identify the critical load cases at different sections of the beams. The total number of sections considered is 13. All of these sections are scanned to determine the design force envelopes.

For design to be performed as per IS:13920 the width of the member shall not be less than 200 mm(Clause 6.1.3). Also the member shall preferably have a width-to depth ratio of more than 0.3 (Clause 6.1.2).

The factored axial stress on the member should not exceed 0.1fck (Clause 6.1.1) for all active load cases. If it exceeds allowable axial stress no design will be performed.

D8.G.4.1 Design for Flexure

Design procedure is same as that for IS 456. However while designing following criteria are satisfied as per IS-13920:

1. The minimum grade of concrete shall preferably be M20. (Clause 5.2)
2. Steel reinforcements of grade Fe415 or less only shall be used. (Clause 5.3)
3. The minimum tension steel ratio on any face, at any section, is given by (Clause 6.2.1b)

   $$\rho_{min} = 0.24fck/fy$$

   The maximum steel ratio on any face, at any section, is given by (Clause 6.2.2)

   $$\rho_{max} = 0.025$$
4. The positive steel ratio at a joint face must be at least equal to half the negative steel at that face. (Clause 6.2.3)
5. The steel provided at each of the top and bottom face, at any section, shall at least be equal to one-fourth of the maximum negative moment steel provided at the face of either joint. (Clause 6.2.4)

D8.G.4.2 Design for Shear

The shear force to be resisted by vertical hoops is guided by the Clause 6.3.3 of IS 13920:1993 revision. Elastic sagging and hogging moments of resistance of the beam section at ends are considered while calculating shear force. Plastic sagging and hogging moments of resistance can also be considered for shear design if PLASTIC parameter is mentioned in the input file. (Refer Table 8A1.1)

Shear reinforcement is calculated to resist both shear forces and torsional moments. Procedure is same as that of IS 456.

The following criteria are satisfied while performing design for shear as per Cl. 6.3.5 of IS-13920:

The spacing of vertical hoops over a length of 2d at either end of the beam shall not exceed

a. d/4
b. 8 times the diameter of the longitudinal bars

In no case this spacing is less than 100 mm.

The spacing calculated from above, if less than that calculated from IS 456 consideration is provided.

D8.G.4.3 Beam Design Output

The default design output of the beam contains flexural and shear reinforcement provided at 5 equally spaced sections along the length of the beam. User has option to get a more detail output. All beam design outputs are given in IS units. An example of rectangular beam design output with the `TRACK 2.0` is presented below:

```
                  B E A M  N O.      1   D E S I G N  R E S U L T S

D8.G.5 Column Design

Columns are designed for axial forces and biaxial moments per IS 456:2000. Columns are also designed for shear forces as per Clause 7.3.4. All major criteria for selecting longitudinal and transverse reinforcement as stipulated by IS:456 have been taken care of in the column design of STAAD.Pro. However following clauses have been satisfied to incorporate provisions of IS 13920:

- The minimum grade of concrete shall preferably be M20. (Clause 5.2)
- Steel reinforcements of grade Fe415 or less only shall be used. (Clause 5.3)
- The minimum dimension of column member shall not be less than 200 mm. For columns having unsupported length exceeding 4m, the shortest dimension of column shall not be less than 300 mm. (Clause 7.1.2)
- The ratio of the shortest cross-sectional dimension to the perpendicular dimension shall preferably be not less than 0.4. (Clause 7.1.3)
- The spacing of hoops shall not exceed half the least lateral dimension of the column, except where special confining reinforcement is provided. (Clause 7.3.3)
- Special confining reinforcement shall be provided over a length l_0 from each joint face, towards mid span, and on either side of any section, where flexural yielding may occur. The length l_0 shall not be less than a) larger lateral dimension of the member at the section where yielding occurs, b) 1/6 of clear span of the member, and c) 450 mm. (Clause 7.4.1)
- The spacing of hoops used as special confining reinforcement shall not exceed ¼ of minimum member dimension but need not be less than 75 mm nor more than 100 mm. (Clause 7.4.6)
- The area of cross-section of hoops provided are checked against the provisions for minimum area of cross-section of the bar forming rectangular, circular or spiral hoops, to be used as special confining reinforcement. (Clause 7.4.7 and 7.4.8)

D8.G.5.1 Column Design Output

Default column design output (`TRACK 0.0`) contains the reinforcement provided by STAAD.Pro and the capacity of the section. With the option `TRACK 1.0`, the output contains intermediate results such as the design forces, effective length coefficients, additional moments etc. All design output is given in SI units. An example of a column design output (with option `TRACK 1.0`) is given below.

```

D8.G.6 Bar Combination

Initially the program selects only one bar to calculate the number of bars required and area of steel provided at each section along the length of the beam. You may use the `BAR COMBINATION` command to specify two bar diameters to calculate a combination of each bar to be provided at each section. The syntax for bar combination is given below.

```
START BAR COMBINATION
MD1 <bar diameter>  MEMB  <member list>
MD2 <bar diameter>  MEMB  <member list>
END BAR COMBINATION
```

Note: The bar sizes should be specified in the order of increasing size (i.e., `MD2` bar diameter should be greater than `MD1` bar diameter).

The beam length is divided into three parts, two at its ends and one at span. Ld gives the development length to be provided at the two ends of each section.

The typical output for bar combination is shown below:

```
                         OUTPUT FOR BAR COMBINATION

D9. Japanese Codes

D9.A. Japanese Codes - Concrete Design per 1991 AIJ

STAAD.Pro is capable of performing concrete design based on the Japan code AIJ 1991 *Architectural Institute of Japan Standards for Structural Calculation of Steel Reinforced Concrete Structures*. Design for a member involves calculation of the amount of reinforcement required for the member. Calculations are based on the user specified properties and the member forces obtained from the analysis. In addition, the details regarding placement of the reinforcement on the cross section are also reported in the output.

D9.A.1 Section Types for Concrete Design

The following types of cross sections for concrete members can be designed:

- For Beams — Prismatic (Rectangular and Square)
- For Columns — Prismatic (Rectangular, Square, and Circular)

D9.A.2 Member Dimensions

Concrete members which will be designed by the program must have certain section properties input under the `MEMBER PROPERTY` command. These are the D (YD) and b (ZD) dimensions for rectangular or square cross sections and the D (YD) for circular cross sections.

The following is an example the required input:

```
UNIT MM
MEMBER PROPERTY
1 3 TO 7 9 PRISM YD 450. ZD 250.
11 13 PR YD 350.
```

In the above input, the first set of members are rectangular (450 mm depth and 250 mm width) and the second set of members, with only depth and no width provided, will be assumed to be circular with a 350 mm diameter.

Caution: It is absolutely imperative that you do *not* provide the cross section area (AX) as an input.

D9.A.3 Slenderness Effects and Analysis Considerations

Slenderness effects are extremely important in designing compression members. Slenderness effects result in additional forces being exerted on the column over and above those obtained from the elastic analysis. There are two options by which the slenderness effects can be accommodated.

The first option is to compute the secondary moments through an exact analysis. Secondary moments are caused by the interaction of the axial loads and the relative end displacements of a member. The axial loads and joint displacements are first determined from an elastic stiffness analysis and the secondary moments are then evaluated.

The second option is to approximately magnify the moments from the elastic analysis and design the column for the magnified moment. It is assumed that the magnified moment is equivalent to the total moment comprised of the sum of primary and secondary moments.

STAAD provides facilities to design according to both of the above methods. To utilize the first method, the command `PDELTA ANALYSIS` must be used instead of `PERFORM ANALYSIS` in the input file. The user must note that to take advantage of this analysis, all the combinations of loading must be provided as primary load cases and not as load combinations. This is due to the fact that load combinations are just algebraic combinations of forces and moments, whereas a primary load case is revised during the P-delta analysis based on the deflections. Also, note that the proper factored loads (like 1.5 for dead load etc.) should be provided by the user. STAAD does not factor the loads automatically. The second method mentioned above is utilized by providing the magnification factor as a concrete design parameter (See the parameter `MMAG` in D9.A.7 Design Parameters (on page 1716)). The column is designed for the axial load and total of primary and secondary biaxial moments if the first method is used and for the axial load and magnified biaxial moments if the second method is used.

D9.A.4 Beam Design

Beams are designed for flexure, shear, and torsion. The program considers 12 equally spaced divisions of the beam member. However this number can be redefined by `NSECTION` parameter. All these sections are designed for flexure, shear and torsion for all load cases. The results include design results for most critical load case.

Example

```
UNIT  KG CM
START  CONCRETE DESIGN
CODE  JAPAN
FYMAIN  SRR295 ALL
FYSEC  SRR295 ALL
FC  350 ALL
CLEAR  2.5 MEM 2 TO 6
TRACK  1.0 MEMB 2 TO 9
DESIGN  BEAM 2 TO 9
END  CONCRETE DESIGN
```

D9.A.4.1 Design for Flexure

Reinforcement for positive and negative moments are calculated on the basis of section properties provided by the user. Program first try to design the section for g = 0 and pt = balanced reinforcement ratio. If allowable moment is lower than the actual moment program increases g value for same pt and checks the satisfactory conditions. If conditions are not satisfied this procedure continues until g reaches to 1.0 and then pt value is increased keeping g = 1.0. This procedure continues until pt reaches to its maximum value(2 %). But if the allowable moment for pt = maximum value and g = 1.0 is lower than the actual moment the program gives message that the section fails.

This program automatically calculates the Bar size and no. of bars needed to design the section. It arranges the bar in layers as per the requirements and recalculate the effective depth and redesign the sections for this effective depth.

Notes

a. Beams are designed for MZ only. The moment MY is not considered in flexure design
b. MMAG parameter can be used to increase design moment
c. 1.4 cm. is added to the clear cover to take stirrup size into consideration for flexure design.

d. STAAD beam design procedure is based on the local practice and considering the fact that Japan is a high seismic zone area.

D9.A.4.2 Design for Shear

The Design Shear value, Q_D, is evaluated for the beam. The update effective depth is used to then calculate the allowable shear stress. The allowable shear stress of concrete, f_s, is automatically calculated from design load type (permanent or temporary) and given density of concrete. The program then calculates the required bar size, a_w, and spacing of stirrups. The reinforcement ratio for the stirrup, p_w, is calculated for design Bar size and stirrup pitch and all the necessary checking is done.

For seismic loading it is needed to increase shear force ≥ 1.5 times the actual value and this can be done utilizing the Design Shear Modification factor, k (`SMAG` parameter) without changing the Design Moment.

Notes:

a. Stirrups are always assumed to be 2-legged
b. Governing density to determine Light weight or Normal Weight Concrete is 2.3 kg/sq. cm

D9.A.4.3 Design for Torsion

Torsion design for beam is optional. If the `TORSION` parameter value is 1.0, the program will design the assigned beam(s) for torsion. The program first checks whether extra reinforcement is needed for torsion or not. If additional reinforcement is needed, this additional pt is added to flexure pt and additional Pw is added to shear design Pw.

D9.A.5 Column Design

Columns are designed for axial force, MZ moment, MY moment, and shear force. Both the ends of the members are designed for all the load cases and the loading which produces largest amount of reinforcement is called as critical load. If Track 0 or Track 1 is used, design results will be printed for critical load only. But if Track 2 is used, you can get detailed design results of that member. The value of Pt needed for minimum axial force, maximum axial force, maximum MZ, maximum MY among all the load cases for both the ends will be printed. If the `MMAG` parameter is used, the column moments will be multiplied by that value. If the `SMAG` parameter is used, column shear force will be multiplied by that value.

Column design is done for Rectangular, Square and Circular sections. For rectangular and square sections Pt value is calculated separately for MZ and MY, while for circular sections Pg value is calculated for MZ and MY separately.

Column design for biaxial moments is optional. If the `BIAXIAL` parameter value is 1.0, the program will design the column for biaxial moments. Otherwise column design is always uniaxial.

Steps involved:

1. Depending on the axial force zone is determined for Pt = 0.0 .
2. If the column is in "zone A", design is performed by increasing Pt and checking allowable load for that known Pt and known actual eccentricity of the column.
3. If the column is in "zone B" or in "zone C", xn is calculated for given P and Pt and checking is done for allowable moment, if allowable moment is less than the actual moment, program increases Pt and this procedure continues until the column design conditions are satisfied or the column fails as the required Pt is higher than Pt maximum value.
4. If the column is in tension, design is done by considering allowable tensile stress of steel only.
5. If biaxial design is requested program solve the following interaction equation

6. where, a = 1.0+1.66666666 ´ (ratio-0.2), ratio = P/Pcap & 1.0 £ a £ 2.0, Mycap, Mzcap & Pcap represents section capacity
7. If the interaction equation is not satisfied program increases Pt and calculates Pcap, Mycap and Mzcap and solve the interaction equation again and this process continues until the eqn. is satisfied or the column fails as Pt exceeds its maximum limit.
8. If biaxial design is not requested program assumes that interaction equation is satisfied (if uniaxial design is performed successfully).
9. If the interaction equation is satisfied program determines bar size and calculates no. of bars and details output is written.

D9.A.5.1 Example

```
UNIT KGS CMS
START CONCRETE DESIGN
CODE JAPAN
FYMAIN SRR295 ALL
FC 210 ALL
CLEAR 2.5 MEMB 2 TO 6
DESIGN COLUMN 2 TO 6
END CONCRETE DESIGN
```

D9.A.6 Slab and Wall Design

To design a slab or a wall, it must first be modeled using finite elements and analyzed. The command specifications are in accordance with Chapter 2 and Chapter 6 of the Technical Reference Manual.

Elements are designed for the moments Mx and My. These moments are obtained from the element force output (see Chapter 2 of the Technical Reference Manual). The reinforcement required to resist the Mx moment is denoted as longitudinal reinforcement and the reinforcement required to resist the My moment is denoted as transverse reinforcement.

The longitudinal bar is the layer closest to the exterior face of the slab or wall. The following parameters are those applicable to slab and wall design:

1. `FYMAIN` — Yield stress for reinforcing steel - transverse and longitudinal.
2. `FC`— Concrete grade
3. `CLEAR` — Distance from the outer surface of the element to the edge of the bar. This is considered the same on both top and bottom surfaces of the element.
4. `MINMAIN` — Minimum required size of longitudinal/transverse reinforcing bar

The other parameters shown in D9.A.7 Design Parameters (on page 1716) are not applicable to slab or wall design.

D9.A.7 Design Parameters

The program contains a number of parameters which are needed to perform the design. Default parameter values have been selected such that they are frequently used numbers for conventional design requirements. These values may be changed to suit the particular design being performed. Table 10A.1 contains a complete list of the available parameters and their default values. It is necessary to declare length and force units as centimeters and Kilograms before performing the concrete design.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 174: Japanese Concrete Design Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as JAPAN. Design code to follow. See TR.53.2 Concrete Design-Parameter Specification (on page 2685).
BIAXIAL	0.0	Value to define biaxial or uniaxial design type for Column 0. uniaxial design only 1. design for biaxial moments
CLEAR	3.0 cm (beam) 4.0 cm (Column)	Clear cover for Beam or clear side cover for column.
DEPTH	YD	Depth of concrete member. This value defaults to YD as provided under MEMBER PROPERTIES.
EFACE	0.0	Face of support location at end of beam. (Note: Both SFACE & EFACE are input as positive numbers).
FC	210 Kg/cm^2	Compressive Strength of Concrete.
FYMAIN	SR235	Steel grade. Acceptable values for steel grade and their associated yield stress values are shown in the following table. Program automatically calculates yield stress value depending on design load type (permanent or temporary).
FYSEC	SR235	Same as FYMAIN except this is for secondary steel.
LONG	0.0	Value to define design load type 0. Permanent Loading 1. Temporary Loading

Parameter Name	Default Value	Description
MAXMAIN	41.0 cm	Maximum main reinforcement bar size
MAXSEC	41.0 cm	Maximum secondary reinforcement bar size.
MINMAIN	10 mm	Minimum main reinforcement bar size.
MINSEC	10 mm	Minimum secondary reinforcement bar size.
MMAG	1.0	Design moment magnification factor
NSECTION	12	Number of equally-spaced sections to be considered in finding critical moments for beam design.
REINF	0.0	Tied Column. A value of 1.0 will mean spiral.
SFACE	0.0	Face of support location at start of beam.
SMAG	1.0	Design shear magnification factor
TORSION	0.0	Value to request for torsion design for beam 0. torsion design not needed 1. torsion design needed
TRACK	0.0	Beam Design: 0. Critical section design results. 1. Five section design results & design forces. 2. 12 section design results & design forces. Column Design: 1. Detail design results for critical load case only. 2. Design results for minimum P, maximum P, maximum MZ and maximum MY among all load cases for both ends.

Parameter Name	Default Value	Description
WIDTH	ZD	Width of concrete member. This value defaults to ZD as provided under MEMBER PROPERTIES.

Table 175: Table of permissible Steel Grades and associated Yield Stresses for FYMAIN and FYSEC parameters

Steel Grade	Long Term Loading		Short Term Loading	
	Tension & Compression	Shear Reinforcement	Tension & Compression	Shear Reinforcement
SR235 SRR235 SDR235	1600	1600	2400	2400

SD295A SD295B SDR295	2000	2000	3000	3000
SDR345 SD345	2200 (2000)	2000	3500	3500
SD390	2200 (2000)	2000	4000	4000

D9.B. Japanese Codes - Steel Design per 2005 AIJ

STAAD.Pro is capable of performing steel design based on the Japanese code AIJ 2005 *Design Standard for Steel Structures*.

D9.B.1 General

This section presents some general statements regarding the implementation of the "Architectural Institute of Japan" (AIJ) specifications for structural steel design (2005 edition) in STAAD. The design philosophy and procedural logistics are based on the principles of elastic analysis and allowable stress design. Facilities are available for member selection as well as code checking. Two major failure modes are recognized: failure by overstressing and failure by stability considerations. The following sections describe the salient features of the design approach.

Members are proportioned to resist the design loads without exceedance of the allowable stresses or capacities and the most economical section is selected on the basis of the least weight criteria. The code checking part of the program also checks the slenderness requirements and the stability criteria. Users are recommended to adopt the following steps in performing the steel design:

- Specify the geometry and loads and perform the analysis.
- Specify the design parameter values if different from the default values.
- Specify whether to perform code checking or member selection.

The method for calculating allowable bending stress was updated for the AIJ 2005 from the AIJ 2002 code. All other allowable limit states, analysis and design methods, etc., remain unchanged. Refer to the D9.C. Japanese Codes - Steel Design per 2002 AIJ (on page 1728) for additional details.

D9.B.2 Member Capacities

Member design and code checking per AIJ 2005 are based upon the allowable stress design method. It is a method for proportioning structural members using design loads and forces, allowable stresses, and design limitations for the appropriate material under service conditions. The basic measure of member capacities are the allowable stresses on the member under various conditions of applied loading such as allowable tensile stress, allowable compressive stress etc. These depend on several factors such as cross sectional properties, slenderness factors, unsupported width to thickness ratios and so on. Explained here is the procedure adopted in STAAD.Pro for calculating such capacities.

D9.B.2.1 Design Capabilities

All types of available shapes like H-Shape, I-Shape, L-Shapes, CHANNEL, PIPE, TUBE, etc. can be used as member property and STAAD.Pro will automatically adopt the design procedure for that particular shape if Steel Design is requested. STEEL TABLE available within STAAD.Pro or UPTABLE facility can be used for member property.

D9.B.2.2 Methodology

For steel design, STAAD.Pro compares the actual stresses with the allowable stresses as required by AIJ specifications. The design procedure consist of following three steps.

1. Calculation of sectional properties

   The program extracts section properties cross sectional area, A, moment of inertia about Y and Z axes, I_{yy} and I_{zz}, and the St. Venant torsional constant, J, from the built-in steel tables. The program then calculates the elastic section moduli, Z_z and Z_y, torsional section modulus, Z_x, and radii of gyration, i_y and i_z, using the appropriate formulas.
2. Calculation of actual and allowable stresses

   Program calculates actual and allowable stresses by following methods:

   i. Axial Stress:

      Actual tensile stresses,

      $$F_T = \text{force} / (A \times)$$

      where

      NSF = Net Section Factor for tension input as a design parameter

      Actual compressive stress , $F_C = force\ /\ A$

      Allowable tensile stress, f_t

      = FYLD / 1.5 (For Permanent Case)
      = FYLD (For Temporary Case)

      where

FYLD = Yield stress input as a design parameter

Allowable compressive stress, f_c

$$f_c = \begin{cases} \dfrac{\left[1 - 0.4\left(\frac{\lambda}{\Lambda}\right)^2\right]F}{\nu} & when \quad \lambda \le \Lambda \\ \dfrac{0.277F}{\left(\frac{\lambda}{\Lambda}\right)^2} & when \quad \lambda > \Lambda \end{cases}$$

$= f_c \; x \; 1.5$ (for Temporary case)

where

Λ = $\sqrt{\dfrac{\pi^2 E}{0.6F}}$

ν = $\dfrac{3}{2} + \dfrac{2}{3}\left(\dfrac{\lambda}{\Lambda}\right)^2$

λ = maximum slenderness, considering both principal axis

E = Modulus of elasticity of steel (Young's Modulus)

Actual torsional stress, $f_t = torsion \; / \; Z_x$

where

Z_x = J / max(t_f, t_w)

t_f = flange thickness

t_w = web thickness

ii. Bending Stress:

Actual bending stress for My for compression:

$(F_{bcy}) = M_y / Z_{cy}$

Actual bending stress for Mz for compression

$(F_{bcz}) = M_z / Z_{cz}$

Actual bending stress for My for tension

$(F_{bty}) = M_y / Z_{ty}$

Actual bending stress for Mz for tension

$(F_{btz}) = M_z / Z_{tz}$

where

Z_{cy}, Z_{cz} = elastic section modulus for compression due to bending about the y and z axes, respectively

Z_{ty}, Z_{tz} = elastic section modulus for tension due to bending about the y and z axes, respectively

Allowable bending stress for M_y

$(f_{bcy}) = f_t$

Allowable bending stress for M_z

When $\lambda_b \le {}_p\lambda_b$, $f_b = F/\nu$

When ${}_p\lambda_b < \lambda_b \le {}_e\lambda_b$,

$$f_b = \frac{F\left(1 - 0.4\frac{\lambda_b - {}_p\lambda_b}{{}_e\lambda_b - {}_p\lambda_b}\right)}{\nu}$$

When ${}_e\lambda_b < \lambda_b$,

$$f_b = \frac{1}{\lambda_b^2}\frac{F}{2.17}$$

where

λ_b = $\sqrt{M_y / M_e}$

${}_e\lambda_b$ = $1 / \sqrt{0.6}$

ν = $\frac{3}{2} + \frac{2}{3}\left(\frac{\lambda_b}{{}_e\lambda_b}\right)^2$

M_e = $C\sqrt{\frac{\pi^4 EI_y EI_w}{I_b^4} + \frac{\pi^2 EI_y GJ}{I_b^2}}$

${}_p\lambda_b$ = $0.6 + 0.3\left(\frac{M2}{M1}\right)$

or taken as the value of PLB if not 0

C = $1.75 + 1.05\,(M2 / M1) + 0.3\,(M2 / M1)^2 \le 2.3$

M1 = the larger of end moments about the major axis

M2 = the smaller of end moments about the major axi

Note: $M2/M1$ will be +ve for double curvature and -ve for single curvature.

For Temporary case, $f_{bcz} = 1.5\ x\ (f_{bcz}$ for Permanent case)

where

f_t = Allowable bending stress for M_y, f_{bty}

f_{bcz} = Allowable bending stress for M_z, f_{btz}

Note: The parameter CB can be used to specify a value for C directly.

iii. Shear Stress

Actual shear stresses are calculated by the following formula:

$$Q_y = F_y / A_{ww}$$

where

A_{ww} = web shear area = depth times web thickness

$$Q_z = F_z / A_{ff}$$

where

A_{ff} = flange shear area = 2/3 times total flange area

Allowable shear stress:

Permanent Loads: $f_s = (F_y/\sqrt{(3)})/\ 1.5$

Temporary Loads: $f_s = F_y\ /\ \sqrt{(3)}$

where

F_y = yield strength of steel, specified by the FYLD parameter.

3. Checking design requirements:

User provided RATIO value (default 1.0) is used for checking design requirements:

The following conditions are checked to meet the AIJ specifications. For all the conditions calculated value should not be more than the value of RATIO. If for any condition value exceeds RATIO, program gives the message that the section fails.

Conditions:

i. Axial tensile stress ratio = F_T / f_t
ii. Axial compressive stress ratio = F_C / f_c
iii. Combined compression & bending compressive ratio = F_C / f_c+F_{bcz}/f_{bcz}+F_{bcy}/f_{bcy}
iv. Combined compression & bending tensile ratio = $(F_{btz}+F_{bty}-F_C)$ / f_t
v. Combined tension & bending tensile ratio = $(F_T+F_{btz}+F_{bty})$ / f_t
vi. Combined tension & bending compressive ratio = $F_{bcz}/f_{bcz}+F_{bcy}/f_{bcy}- F_T/f_t$
vii. Shear stress ratio in Y = q_y / f_s
viii. Shear stress ratio in Z = q_z / f_s
ix. von Mises stress ratio (if the D9.B.4 Von Mises Stresses Check (on page 1727) were set to be checked) = $f_m/(k \cdot f_t)$

Note: All other member capacities (axial tension, axial compression, and shear) are calculated as for AIJ 2002. Refer to D9.C.5 Member Capacities (on page 1733)

D9.B.3 Design Parameters

You are allowed complete control over the design process through the use of parameters in the following table. These parameters communicate design decisions from the engineer to the program. The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements of the situation, some or all of these parameter values may have to be changed to exactly model the physical structure.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 176: 2005 Japanese Steel Design Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as JAPANESE 2005 to invoke the AIJ 2005. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).

Parameter Name	Default Value	Description
BEAM	1.0	Locations of design: 0.0) design only for end moments or those at locations specified by the `SECTION` command. 1.0) calculate moments at twelfth points along the beam.
CAN	0	Specifies the method used for deflection checks 0) deflection check based on the principle that maximum deflection occurs within the span between DJ1 and DJ2. 1) deflection check based on the principle that maximum deflection is of the cantilever type (see note a (on page 1726))
CB	0	C value from the AIJ code. Refer to D9.B.2 Member Capacities (on page 1720) - Bending Stress for how C is calculated and applied. Use 0.0 to direct the program to calculated Cb. Any other value be used in lieu of the program calculated value.
DFF	None(Mandatory for deflection check)	"Deflection Length" / Maximum allowable local deflection
DJ1	Start Joint of member	Joint No. denoting starting point for calculation of "Deflection Length" (See note b (on page 1726))
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length" (See note b (on page 1726))
DMAX	100 cm	Maximum allowable depth for member.
DMIN	0.0 cm	Minimum allowable depth for member.
FYLD	235 MPA	Yield strength of steel in Megapascal.
KY	1.0	K value in local y-axis. Usually, this is the minor axis.
KZ	1.0	K value in local z-axis. Usually, this is the major axis.
LY	Member Length	Length in local y-axis to calculate slenderness ratio.
LZ	Member Length	Same as above except in z-axis
MAIN	200	Allowable Slenderness Limit for Compression Member 0.0) check for slenderness using default value 1.0) suppress compression slenderness check Any value greater than 1 = Allowable KL/r in compression (up to 250)

Parameter Name	Default Value	Description
MBG	0	Specifies how to calculate the section modulus about the Z-Z axis for H-shape, I-shape, and channel sections when performing major axis bending checks: 0) Consider the flanges and the web 1) Consider only the flanges; the web is ignored for the calculation of the section modulus.
MISES	1	Von Mises check options: 0) Do not perform von Mises check. 1) Standard AIJ calculation. The direct stress σ_x is determined by calculating the stress at each of the corners of the section using signed forces and the appropriate elastic modulus. The magnitude of the maximum stress is used. 2) τ_y excludes torsion stresses. The same as option 1, but in the calculation of the shear stress, the torsional moment is excluded. 3) σ_x based on absolute forces, The direct stress σ_x is calculated using the absolute value of the force at the section divided by the minimum of the elastic section moduli for each axis. 4) σ_x based on absolute forces and τ_y excludes torsion stress. Same as option 3, but excluding the torsional moment when calculating the shear stress. For more details, refer to D9.B.4 Von Mises Stresses Check (on page 1727).
NSF	1.0	Net section factor for tension members.
PLB	0	Plastic critical slenderness ratio. If this is 0 (the default value), it will be calculated according to AIJ 2005 eqn. 5.12 or 5.14. Any other entered value will be used as the value of p-lambda-b.
RATIO	1.0	Permissible ratio of the actual to allowable stresses.
SLF	1	Slender section design option: 0) Slender sections are not designed - an error message will be presented that design of these sections is not supported 1) Slender sections designed with unreduced profile (i.e., full profile) - an error message will be presented that this may be an unconservative design

Parameter Name	Default Value	Description
TMAIN	400	Allowable Slenderness Limit for Tension Member 0.0) check for slenderness using default value 1.0) suppress slenderness check Any value greater than 1 = Allowable KL/r in tension.
TRACK	0.0	Level of output detail: 0) Produce design summary only 1) Produce intermediate detailed output 2) Produce maximum detailed output
UNF	1.0	Unsupported length provided as a fraction of actual member length used for lateral-torsional buckling calculation. **Note:** If both UNF and UNL parameters are specified, the effective length used is UNF×UNL.
UNL	Member Length	Unsupported length for calculating allowable bending stress. Used for the lateral-torsional buckling calculation. Value should be in the current units of length.

D9.B.3.1 Notes

a. When performing the deflection check, you can choose between two methods. The first method, defined by a value 0 for the CAN parameter, is based on the local displacement. Refer to TR.44 Printing Section Displacements for Members (on page 2672) for details on local displacement..

If the CAN parameter is set to 1, the check will be based on cantilever style deflection. Let (DX1, DY1,DZ1) represent the nodal displacements (in global axes) at the node defined by DJ1 (or in the absence of DJ1, the start node of the member). Similarly, (DX2, DY2, DZ2) represent the deflection values at DJ2 or the end node of the member.

Compute Delta = $\sqrt{(DX2 - DX1)^2 + (DY2 - DY1)^2 + (DZ2 - DZ1)^2}$

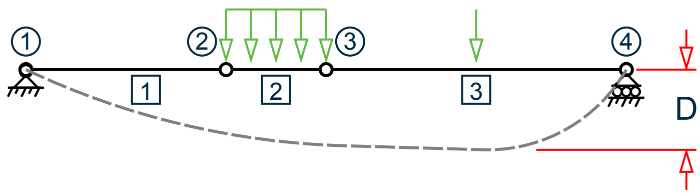
Compute Length = distance between DJ1 and DJ2 or, between start node and end node, as the case may be.

Then, if CAN is specified a value 1, dff = L/Delta

Ratio due to deflection = DFF/dff

b. If CAN = 0, the “Deflection Length” is defined as the length that is used for calculation of local deflections within a member. It may be noted that for most cases the "Deflection Length" will be equal to the length of the member. However, in some situations, the “Deflection Length” may be different. A straight line joining DJ1 and DJ2 is used as the reference line from which local deflections are measured.

For example, refer to the figure below where a beam has been modeled using four joints and three members. The “Deflection Length” for all three members will be equal to the total length of the beam in this case. The parameters DJ1 and DJ2 should be used to model this situation. Thus, for all three members here, DJ1 should be 1 and DJ2 should be 4.



D = Maximum local deflection for members 1, 2, and 3.

```
PARAMETERS
DFF 300. ALL
DJ1 1 ALL
DJ2 4 ALL
```

c. If DJ1 and DJ2 are not used, “Deflection Length” will default to the member length and local deflections will be measured from original member line.

d. The above parameters may be used in conjunction with other available parameters for steel design.

D9.B.4 Von Mises Stresses Check

The von Mises stress equation shown below, which is modified for beam elements based on the corresponding equation in AIJ steel design code (both 2002 and 2005 editions of AIJ), indicates that the left-hand side in the equation should be less than unity. These checks are performed at locations indicated by the BEAM parameter.

Note: As with other design checks, the unity check value can be modified by use of the RATIO parameter.

The von Mises stresses are evaluated and checked per AIJ clause 5.16 as follows:

$$\frac{\sqrt{\sigma_x^2 + 3\tau_{xy}^2}}{k \times f_t} < 1.0$$

where

σ_x = Longitudinal stress in beam element. The following equation is used when the MISES parameter is set to 1 or 2. This is performed multiple times, once in each corner with the appropriate sign of the moment and value of elastic modulus. The largest stress is then used.

$$= \frac{F_x}{A_x} + \frac{M_y}{Z_y} + \frac{M_z}{Z_z}$$

When the MISES parameter is set to 3 or 4, then the longitudinal stress is calculated once using the smalles elastic modulus for each axis as follows.

$$= \left|\frac{F_x}{A_x}\right| + \left|\frac{M_y}{Z_y}\right| + \left|\frac{M_z}{Z_z}\right|$$

F_x = axial force

M_y = bending moment about y-axis

M_z = bending moment about z-axis

A_x = cross-sectional area

Z_y = section modulus about y-axis

Z_z = section modulus about z-axis

τ_{xy} = shear stress in the beam. When the MISES parameter is set to 1 or 3, this includes torsion stresses:

$$= \left| \frac{M_x}{Z_x} \right| + \sqrt{\left| \frac{F_y}{A_y} \right|^2 + \left| \frac{F_z}{A_z} \right|^2}$$

When the `MISES` parameter is set to 2 or 4, the torsion stresses are excluded:

$$= \sqrt{\left| \frac{F_y}{A_y} \right|^2 + \left| \frac{F_z}{A_z} \right|^2}$$

M_x	=	torsional moment.
F_y	=	shear stress in the y direction
F_z	=	shear stress in the z direction
Z_x	=	torsional section modulus
D_x	=	depth of the member
I_x	=	torsional constant
A_y	=	effective shear area in the y direction
A_z	=	effective shear area in the z direction
f_t	=	allowable tensile stress
k	=	loading duration factor as specified by the `TMP` parameter:

1.0 for permanent
1.5 for temporary

In the STRESSES output category, stress value of (numerator of the von Mises stress equation) is output as the value of fm. Along with slenderness ratios, stresses, and deflections, von Mises stress equation is checked. When its left-hand side yields the maximum ratio value, it is printed as RATIO and "VON MISES" is printed as CRITICAL COND.

D9.C. Japanese Codes - Steel Design per 2002 AIJ

STAAD.Pro is capable of performing steel design based on the Japanese code AIJ 2002 *Design Standard for Steel Structures*.

D9.C.1 General

The design philosophy and procedural logistics are based on the principles of elastic analysis and allowable stress design. Facilities are available for member selection as well as code checking. Two major failure modes are recognized: failure by overstressing and failure by stability considerations. The following sections describe the salient features of the design approach.

Members are proportioned to resist the design loads without exceedance of the allowable stresses or capacities and the most economical section is selected on the basis of the least weight criteria. The code checking part of the program also checks the slenderness requirements and the stability criteria. Users are recommended to adopt the following steps in performing the steel design:

- Specify the geometry and loads and perform the analysis.
- Specify the design parameter values if different from the default values.
- Specify whether to perform code checking or member selection.

D9.C.2 Analysis Methodology

Elastic analysis method is used to obtain the forces and moments for design. Analysis is done for the primary and combination loading conditions provided by the user. The user is allowed complete flexibility in providing loading specifications and in using appropriate load factors to create necessary loading situations. Depending upon the analysis requirements, regular stiffness analysis or P-Delta analysis may be specified. Dynamic analysis may also be performed and the results combined with static analysis results.

D9.C.3 Member Property Specifications

For specification of member properties of standard Japanese steel shapes, the steel section library available in STAAD may be used. The next section describes the syntax of commands used to assign properties from the built-in steel table. Members properties may also be specified using the User Table facility. For more information on these facilities, refer to G.6 Member Properties (on page 2113) .

D9.C.4 Built-in Japanese Steel Section Library

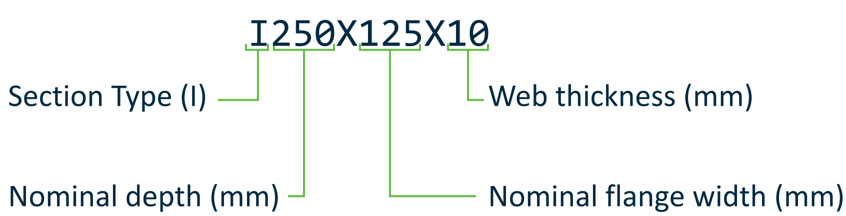
The following information is provided for use when the built-in steel tables are to be referenced for member property specification. These properties are stored in a database file. If called for, these properties are also used for member design. Since the shear areas are built into these tables, shear deformation is always considered for these members during the analysis. An example of member property specification in an input file is provided at the end of this section.

A complete listing of the sections available in the built-in steel section library may be obtained using the tools of the graphical user interface.

Following are the descriptions of different types of sections.

D9.C.4.1 I shapes

I shapes are specified in the following way:

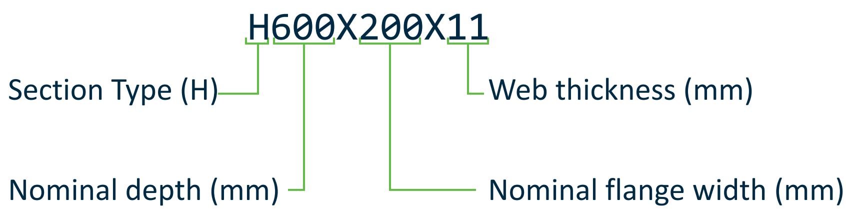


Note: While specifying the web thickness, the portion after the decimal point should be excluded.

```
1 TO 9 TA ST I300X150X11
12 TO 15 TA ST I350X150X9
```

D9.C.4.2 H shapes

H shapes are specified as follows:

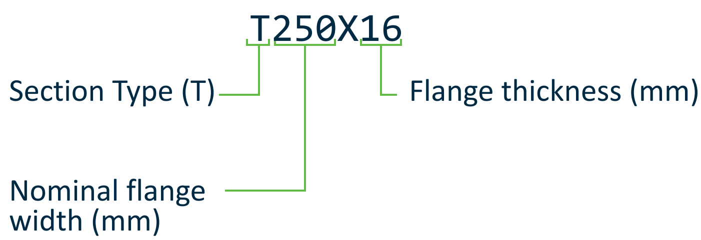


Note: While specifying the web thickness, the portion after the decimal point should be excluded.

```
1 TO 8 TA ST H200X100X4
13 TO 17 TA ST H350X350X12
```

D9.C.4.3 T shapes

T shapes are specified as follows:

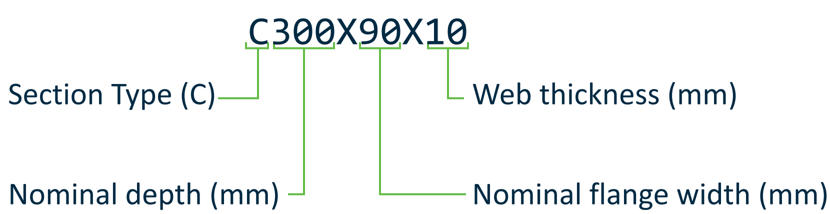


Note: While specifying the web thickness, the portion after the decimal point should be excluded.

```
20 TO 25 TA ST T250X19
```

D9.C.4.4 Channels

Channel sections are specified as follows.



```
25 TO 34 TA ST C125X65X6
46 TO 49 TA ST C200X90X8
```

D9.C.4.5 Double Channels

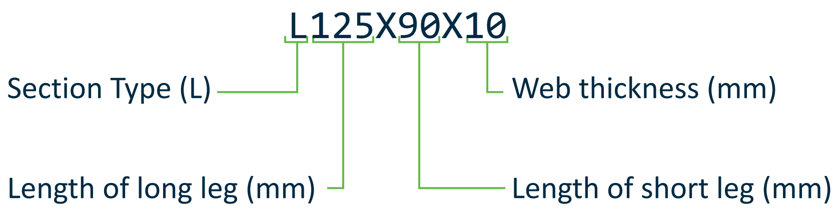
Back to back double channels, with or without a spacing in between them, are available. The letter D in front of the section name is used to specify a double channel. Front-to-front double channels are similarly added by adding FR in front of the section name.

```
17 TO 27 TA D C300X90X10
45 TO 76 TA D C250X90X11 SP 2.0
28 TO 30 TA FR C200X90X8 SP 2.5
```

In the above commands, members 17 to 27 are a back-to-back double channels C300X90X10 with no spacing in between. Members 45 to 76 are a double channels C250X90X11 with a spacing of 2 length units. Members 28 to 30 are front-to-front double channels C200X90X8 with a spacing of 2.5 length units.

D9.C.4.6 Angles

Two types of specification may be used to describe an angle. The standard angle specification is as follows.



The letter L (signifying that the section is an angle) is followed by the length of the legs and then the thickness of the leg, all in millimeters. The word ST signifies that the section is a standard angle meaning that the major principal axis coincides with the local YY axis specified in G.4.2 Local Coordinate System (on page 2088) .

```
1 4 TA ST L150X90X9
```

If the minor principal axis coincides with the local YY axis specified in Chapter 2 of the User's Manual, the word RA (Reverse Angle) should be used instead of ST as shown below.

```

7 TO 23 TA RA L90X75X9
```

D9.C.4.7 Double angles

Short leg back-to-back and long leg back-to-back double angles may be specified by using the words SD or LD in front of the angle size. In the case of an equal angle, either SD or LD will serve the purpose. The spacing between the angles may be specified by using the word SP after the angle size followed by the value of the spacing.

```
8 TO 25 TA SD L100X65X7 SP 2.0
36 TO 45 TA LD L300X90X11 SP 3.0
```

The first example indicates a short legs back-to-back double angle comprised of 100X65X7 angles separated by 2 length units. The latter is a long legs back-to-back double angle comprised of 300X90X11 angles separated by 3 length units.

D9.C.4.8 Tubes

Tube names are input by their dimensions. For example,

```
6 TA ST TUBE DT 8.0 WT 6.0 TH 0.5
```

is a tube that has a height of 8 length units, width of 6 length units and a wall thickness of 0.5 length units. Only code checking, no member selection can be performed on TUBE sections.

D9.C.4.10 Pipes (General Pipe sections)

Circular hollow sections defined by JIS G3444:2005 *Design Standard for Steel Structures - Based on Allowable Stress Concept* as general pipe sections are specified as shown in the following example.

```
1 TO 9 TA ST PIPE PIP267.4x7.0
```

specifies a pipe with outside diameter of 267.0 mm and a thickness of 7.0 mm. Only code checking, no member selection, can be performed on PIPE sections.

D9.C.4.11 Circular Hollow sections

Circular hollow sections defined by JIS G3475:2005 *Design Standard for Steel Structures - Based on Allowable Stress Concept* as Architectural pipe sections are specified as shown in the following example.

```
1 TO 9 TA ST PIPE CHS660.4x16
```

specifies a pipe with outside diameter of 660.4 mm and a thickness of 16.0 mm. Only code checking, no member selection, can be performed on CHS sections.

D9.C.4.12 Rectangular Hollow sections

Rectangular hollow sections defined by JIS G3466:2005 *Design Standard for Steel Structures - Based on Allowable Stress Concept* are specified as shown in the following example.

```
1 TO 9 TA ST PIPE RHS200x100x12
```

specifies a tube with a depth of 200 mm, a width of 100 mm, and a thickness of 12 mm. Only code checking, no member selection, can be performed on RHS sections.

D9.C.4.13 Square Hollow sections

Square hollow sections defined by JIS G3466:2005 *Design Standard for Steel Structures - Based on Allowable Stress Concept* are specified as shown in the following example.

```
1 TO 9 TA ST PIPE SHS200xs00x12
```

specifies a square tube with a width of 200 mm and a thickness of 12 mm. Only code checking, no member selection, can be performed on SHS sections.

D9.C.4.14 Example

The following is a sample input file containing Japanese shapes.

```

D9.C.5 Member Capacities

Member design and code checking per AIJ 2002 are based upon the allowable stress design method. It is a method for proportioning structural members using design loads and forces, allowable stresses, and design limitations for the appropriate material under service conditions. The basic measure of member capacities are the allowable stresses on the member under various conditions of applied loading such as allowable tensile stress, allowable compressive stress etc. These depend on several factors such as cross sectional properties, slenderness factors, unsupported width to thickness ratios and so on. Explained here is the procedure adopted in STAAD for calculating such capacities.

D9.C.5.1 Design Capabilities

All types of available shapes such as H-Shape, I-Shape, L-Shapes, channel, pipe, tube, etc. can be used as member property and STAAD.Pro will automatically adopt the design procedure for that particular shape if Steel Design is requested. The steel tables available within STAAD.Pro or user provided table (UPTABLE) can be used for member properties.

D9.C.5.2 Methodology

For steel design, STAAD.Pro compares the actual stresses with the allowable stresses as required by AIJ specifications. The design procedure consist of following three steps.

1. Calculation of sectional properties

   The program extracts section properties cross sectional area, A, the moment of inertia about Y and Z axes, I_{yy} and I_{zz}, and the St. Venant torsional constant, J, from the built-in steel tables. The program then calculates the elastic section moduli, Z_z and Z_y, torsional section modulus, Z_x, and radii of gyration, i_y and i_z, using the appropriate formulas.

   For I shapes, H shapes, and channel sections, the program calculates the radius of gyration needed for bending using following formula:

   $$i = \sqrt{I_i / A_i}$$

2. Calculation of actual and allowable stresses

   Allowable stresses for structural steel under permanent loading shall be determined on the basis of the values of F given in the following table.

Table 177: Table: Values of F (N/mm²)

	Steel for Construction Structures		Steel for General Structures	Steel for Welded Structures					
Thickness	**SN400** **SNR400** **STKN400**	**SN490** **SNR490** **STKN490**	**SS400** **STK400** **STKR400** **SSC400** **SWH400**	**SS490**	**SS540**	**SM400** **SMA400**	**SM490** **SM490 Y** **SMA490** **STKR490** **STK490**	**SM520**	**SM570**
t≤ 40	235	325	235	275	375	235	325	355	400
40< t ≤ 100	215	295	215	255	-	215	295*	335	400

* F = 325 N/mm² when t > 75mm

Note: In checking members for temporary loading be the combination of stresses described in Chap.3, allowable stresses specified in this chapter may be increases by 50%

Program calculates actual and allowable stresses by following methods:

i. Axial Stress:

Actual tensile stresses,

F_T = force / (A ×)

where

`NSF` = Net Section Factor for tension input as a design parameter

Actual compressive stress , $F_C = force\ /\ A$

Allowable tensile stress, f_t

= `FYLD` / 1.5 (For Permanent Case)
= `FYLD` (For Temporary Case)

where

`FYLD` = Yield stress input as a design parameter

Allowable compressive stress, f_c

$$f_c = \begin{cases} \dfrac{\left[1 - 0.4\left(\dfrac{\lambda}{\Lambda}\right)^2\right]F}{\nu} when \lambda \le \Lambda \\ \dfrac{0.277F}{\left(\dfrac{\lambda}{\Lambda}\right)^2} when \lambda > \Lambda \end{cases}$$

$= f_c \times 1.5$ (for Temporary case)

where

Λ = $\sqrt{\frac{\pi^2 E}{0.6F}}$

ν = $\frac{3}{2} + \frac{2}{3}\left(\frac{\lambda}{\Lambda}\right)^2$

Actual torsional stress, $f_t = torsion\ /\ Z_x$

where

Z_x = J / max(t_f, t_w)

t_f = flange thickness

t_w = web thickness

ii. Bending Stress:

Actual bending stress for My for compression

$(F_{bcy}) = M_y / Z_{cy}$

Actual bending stress for Mz for compression

$(F_{bcz}) = M_z / Z_{cz}$

Actual bending stress for My for tension

$(F_{bty}) = M_y / Z_{ty}$

Actual bending stress for Mz for tension

$(F_{btz}) = M_z / Z_{tz}$

where

Z_{cy}, Z_{cz} = elastic section modulus for compression due to bending about the y and z axes, respectively

Z_{ty}, Z_{tz} = elastic section modulus for tension due to bending about the y and z axes, respectively

Note: The web is ignored in the calculation of Z_z for H-shape, I-shape, and channel sections when the MBG parameter = 1.

Allowable bending stress for M_y

$(f_{bcy}) = f_t$

Allowable bending stress for M_z

$(f_{bcz}) = \{ 1 - .4 \times (lb / i)^2 / (C \lambda^2)\}$ ft max

$= 89{,}000/ (lb \times h / A_f)$

For Temporary case, f_{bcz} = 1.5 x (f_{bcz} for Permanent case)

where

C = $1.75 - 1.05\ (M2\ /\ M1) + 0.3\ (M2\ /\ M1)^2$

Allowable bending stress for M_y, $f_{bty} = f_t$

Allowable bending stress for M_z, $f_{btz} = f_{bcz}$

Note: The parameter CB can be used to specify a value for C directly.

iii. Shear Stress

Actual shear stresses are calculated by the following formula:

$q_y = Q_y / A_{ww}$

where

A_{ww} = web shear area = product of depth and web thickness

$q_z = Q_z / A_{ff}$

where

A_{ff} = flange shear area = 2/3 times total flange area

f_s = Allowable shear stress, $F_s / 1.5$, $F_s = F / \sqrt{(3)}$

3. Checking design requirements:

   User provided RATIO value (default 1.0) is used for checking design requirements

   The following conditions are checked to meet the AIJ specifications. For all the conditions calculated value should not be more than the value of RATIO. If for any condition value exceeds RATIO, the program gives the message that the section fails.

   Conditions:

   i. Axial tensile stress ratio = F_T / f_t
   ii. Axial compressive stress ratio = F_C / f_c
   iii. Combined compression & bending compressive ratio = $F_C / f_c + F_{bcz}/f_{bcz} + F_{bcy}/f_{bcy}$
   iv. Combined compression & bending tensile ratio = $(F_{btz} + F_{bty} - F_C) / f_t$
   v. Combined tension & bending tensile ratio = $(F_T + F_{btz} + F_{bty}) / f_t$
   vi. Combined tension & bending compressive ratio = $F_{bcz}/f_{bcz} + F_{bcy}/f_{bcy} - F_T/f_t$
   vii. Shear stress ratio in Y = q_y / f_s
   viii. Shear stress ratio in Z = q_z / f_s
   ix. von Mises stress ratio (if the D9.C.10 Von Mises Stresses Check (on page 1742) were set to be checked) = $f_m/(k \cdot f_t)$

D9.C.5.4 Allowable stress for Axial Tension

Allowable axial stress in tension is calculated per section 5.1 (1) of the AIJ code. In members with axial tension, the tensile load must not exceed the tension capacity of the member. The tension capacity of the member is calculated on the basis of the member area. STAAD calculates the tension capacity of a given member based on a user supplied net section factor (NSF-a default value of 1.0 is present but may be altered by changing the input value, see Table 8B.1) and proceeds with member selection or code checking.

D9.C.5.5 Allowable stress for Axial Compression

The allowable stress for members in compression is determined according to the procedure of section 5.1 (3). Compressive resistance is a function of the slenderness of the cross-section (Kl/r ratio) and the user may control the slenderness value by modifying parameters such as KY, LY, KZ and LZ. In the absence of user provided values for effective length, the actual member length will be used. The slenderness ratios are checked against the permissible values specified in Chapter 11 of the AIJ code.

D9.C.5.6 Allowable stress for Bending

The permissible bending compressive and tensile stresses are dependent on such factors as length of outstanding legs, thickness of flanges, unsupported length of the compression flange (UNL, defaults to member length) etc. The allowable stresses in bending (compressive and tensile) are calculated as per the criteria of Clause 5.1 (4) of the code.

D9.C.5.7 Allowable stress for Shear

Shear capacities are a function of web depth, web thickness etc. The allowable stresses in shear are computed according to Clause 5.1 (2) of the code.

D9.C.6 Combined Loading

For members experiencing combined loading (axial force, bending and shear), applicable interaction formulas are checked at different locations of the member for all modeled loading situations. Members subjected to axial tension and bending are checked using the criteria of clause 6.2. For members with axial compression and bending, the criteria of clause 6.1 is used.

D9.C.7 Design Parameters

You are allowed complete control over the design process through the use of parameters in the following table. These parameters communicate design decisions from the engineer to the program. The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements of the situation, some or all of these parameter values may have to be changed to exactly model the physical structure.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 178: 2002 Japanese Steel Design Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `JAPANESE 2002` to invoke the AIJ 2002. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
BEAM	1.0	Locations of design: 0.0) design only for end moments or those at locations specified by the `SECTION` command. 1.0) calculate moments at twelfth points along the beam.
CAN	0	Specifies the method used for deflection checks 0) deflection check based on the principle that maximum deflection occurs within the span between DJ1 and DJ2. 1) deflection check based on the principle that maximum deflection is of the cantilever type (see note a (on page 1740))
CB	0	C value from the AIJ code. Refer to D9.C.5 Member Capacities (on page 1733) Bending Stress for how C is calculated and applied. Use 0.0 to direct the program to calculated Cb. Any other value be used in lieu of the program calculated value.

Parameter Name	Default Value	Description
DFF	None(Mandatory for deflection check)	"Deflection Length" / Maximum allowable local deflection
DJ1	Start Joint of member	Joint No. denoting starting point for calculation of "Deflection Length" (See note b (on page 1740))
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length" (See note b (on page 1740))
DMAX	100 cm	Maximum allowable depth for member.
DMIN	0.0 cm	Minimum allowable depth for member.
KY	1.0	K value in local y-axis. Usually, this is the minor axis.
KZ	1.0	K value in local z-axis. Usually, this is the major axis.
LY	Member Length	Length in local y-axis to calculate slenderness ratio.
LZ	Member Length	Same as above except in z-axis
FYLD	235 MPA	Yield strength of steel in Megapascal.
MAIN	200	Allowable Slenderness Limit for Compression Member 0.0) check for slenderness using default value 1.0) suppress compression slenderness check Any value greater than 1 = Allowable KL/r in compression (up to 250)
MBG	0	Specifies how to calculate the section modulus about the Z-Z axis for H-shape, I-shape, and channel sections when performing major axis bending checks: 0) Consider the flanges and the web 1) Consider only the flanges; the web is ignored for the calculation of the section modulus.

Parameter Name	Default Value	Description
MISES	1	Von Mises check options: 0) Do not perform von Mises check. 1) Standard AIJ calculation. The direct stress σ_x is determined by calculating the stress at each of the corners of the section using signed forces and the appropriate elastic modulus. The magnitude of the maximum stress is used. 2) τ_y excludes torsion stresses. The same as option 1, but in the calculation of the shear stress, the torsional moment is excluded. 3) σ_x based on absolute forces, The direct stress σ_x is calculated using the absolute value of the force at the section divided by the minimum of the elastic section moduli for each axis. 4) σ_x based on absolute forces and τ_y excludes torsion stress. Same as option 3, but excluding the torsional moment when calculating the shear stress. For more details, refer to D9.C.10 Von Mises Stresses Check (on page 1742).
NSF	1.0	Net section factor for tension members.
RATIO	1.0	Permissible ratio of the actual to allowable stresses.
SLF	1	Slender section design option: 0) Slender sections are not designed - an error message will be presented that design of these sections is not supported 1) Slender sections designed with unreduced profile (i.e., full profile) - an error message will be presented that this may be an unconservative design
TMAIN	400	Allowable Slenderness Limit for Tension Member 0.0) check for slenderness using default value 1.0) suppress slenderness check Any value greater than 1 = Allowable KL/r in tension.
TRACK	0.0	Level of output detail: 0) Produce design summary only 1) Produce intermediate detailed output 2) Produce maximum detailed output

Parameter Name	Default Value	Description
UNF	1.0	Unsupported length provided as a fraction of actual member length used for lateral-torsional buckling calculation. **Note:** If both UNF and UNL parameters are specified, the effective length used is UNF×UNL.
UNL	Member Length	Unsupported length for calculating allowable bending stress. Used for the lateral-torsional buckling calculation. Value should be in the current units of length.
YNG	0	Method for evaluating Young's modulus, E, for equation 5.8: 0) Use equation 5.8 from *Design Standard for Steel Structures* 1) Use equation SSB-1.10 of JSME

D9.C.7.1 Notes

a. When performing the deflection check, you can choose between two methods. The first method, defined by a value `0` for the `CAN` parameter, is based on the local displacement. Refer to TR.44 Printing Section Displacements for Members (on page 2672) for details on local displacement..

If the `CAN` parameter is set to 1, the check will be based on cantilever style deflection. Let (DX1, DY1,DZ1) represent the nodal displacements (in global axes) at the node defined by `DJ1` (or in the absence of `DJ1`, the start node of the member). Similarly, (DX2, DY2, DZ2) represent the deflection values at `DJ2` or the end node of the member.

Compute Delta = $\sqrt{(DX2 - DX1)^2 + (DY2 - DY1)^2 + (DZ2 - DZ1)^2}$

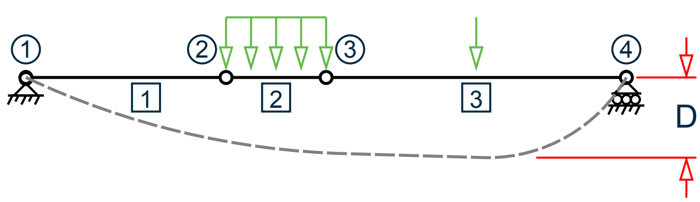
Compute Length = distance between `DJ1` and `DJ2` or, between start node and end node, as the case may be.

Then, if `CAN` is specified a value 1, dff = L/Delta

Ratio due to deflection = `DFF`/dff

b. If `CAN` = 0, the “Deflection Length” is defined as the length that is used for calculation of local deflections within a member. It may be noted that for most cases the “Deflection Length” will be equal to the length of the member. However, in some situations, the “Deflection Length” may be different. A straight line joining `DJ1` and `DJ2` is used as the reference line from which local deflections are measured.

For example, refer to the figure below where a beam has been modeled using four joints and three members. The “Deflection Length” for all three members will be equal to the total length of the beam in this case. The parameters `DJ1` and `DJ2` should be used to model this situation. Thus, for all three members here, `DJ1` should be `1` and `DJ2` should be `4`.



D = Maximum local deflection for members 1, 2, and 3.

```
PARAMETERS
DFF 300. ALL
DJ1 1 ALL
DJ2 4 ALL
```

c. If DJ1 and DJ2 are not used, "Deflection Length" will default to the member length and local deflections will be measured from original member line.
d. The above parameters may be used in conjunction with other available parameters for steel design.

D9.C.8 Code Checking

The purpose of code checking is to check whether the provided section properties of the members are adequate to carry the forces transmitted to it by the loads on the structure. The adequacy is checked per the AIJ requirements.

Code checking is done using forces and moments at specified sections of the members. If the `BEAM` parameter for a member is set to 1, moments are calculated at every twelfth point along the beam, and the maximum moment about the major axis is used. When no sections are specified and the `BEAM` parameter is set to zero (default), design will be based on the forces at the start and end joints of the member. The code checking output labels the members as PASSed or FAILed. In addition, the critical condition, governing load case, location (distance from start joint) and magnitudes of the governing forces and moments are also printed.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

- *V.AIJ 2002 Check for MBG parameter* (on page 4319)

D9.C.9 Member Selection

The member selection process basically involves determination of the least weight member that PASSes the code checking procedure based on the forces and moments obtained from the most recent analysis. The section selected will be of the same type as that specified initially. For example, a member specified initially as a channel will have a channel selected for it. Selection of members whose properties are originally provided from a user table will be limited to sections in the user table.

Note: Member selection cannot be performed on members listed as PRISMATIC or for user-defined sections.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D9.C.10 Von Mises Stresses Check

The von Mises stress equation shown below, which is modified for beam elements based on the corresponding equation in AIJ steel design code (both 2002 and 2005 editions of AIJ), indicates that the left-hand side in the equation should be less than unity. These checks are performed at locations indicated by the `BEAM` parameter.

Note: As with other design checks, the unity check value can be modified by use of the `RATIO` parameter.

The von Mises stresses are evaluated and checked per AIJ clause 5.16 as follows:

$$\frac{\sqrt{\sigma_x^2 + 3\tau_{xy}^2}}{k \times f_t} < 1.0$$

where

σ_x = Longitudinal stress in beam element. The following equation is used when the `MISES` parameter is set to 1 or 2. This is performed multiple times, once in each corner with the appropriate sign of the moment and value of elastic modulus. The largest stress is then used.

$$= \frac{F_x}{A_x} + \frac{M_y}{Z_y} + \frac{M_z}{Z_z}$$

When the `MISES` parameter is set to 3 or 4, then the longitudinal stress is calculated once using the smalles elastic modulus for each axis as follows.

$$= \left| \frac{F_x}{A_x} \right| + \left| \frac{M_y}{Z_y} \right| + \left| \frac{M_z}{Z_z} \right|$$

F_x = axial force

M_y = bending moment about y-axis

M_z = bending moment about z-axis

A_x = cross-sectional area

Z_y = section modulus about y-axis

Z_z = section modulus about z-axis

τ_{xy} = shear stress in the beam. When the `MISES` parameter is set to 1 or 3, this includes torsion stresses:

$$= \left| \frac{M_x}{Z_x} \right| + \sqrt{\left| \frac{F_y}{A_y} \right|^2 + \left| \frac{F_z}{A_z} \right|^2}$$

When the `MISES` parameter is set to 2 or 4, the torsion stresses are excluded:

$$= \sqrt{\left| \frac{F_y}{A_y} \right|^2 + \left| \frac{F_z}{A_z} \right|^2}$$

M_x = torsional moment.

F_y = shear stress in the y direction

F_z = shear stress in the z direction

Z_x = torsional section modulus

D_x = depth of the member

I_x	=	torsional constant
A_y	=	effective shear area in the y direction
A_z	=	effective shear area in the z direction
f_t	=	allowable tensile stress
k	=	loading duration factor as specified by the TMP parameter:

1.0 for permanent

1.5 for temporary

In the STRESSES output category, stress value of (numerator of the von Mises stress equation) is output as the value of fm. Along with slenderness ratios, stresses, and deflections, von Mises stress equation is checked. When its left-hand side yields the maximum ratio value, it is printed as RATIO and "VON MISES" is printed as CRITICAL COND.

D10. Mexican Codes

D10.A. Mexican Codes - Concrete Design per MEX NTC 1987

STAAD.Pro is capable of performing concrete design based on the Mexican code NTC 1987 *Normas Técnicas Complementarias para Diseño y construcción de Estructuras de Concreto* (*Complementary Technical Norms for Design and Construction of Concrete Structures*).

Design of members per NTC 1987 requires the *STAAD Latin American Design Codes* SELECT Code Pack.

D10.A.1 Design Operations

STAAD.Pro has the capabilities for performing concrete design. It will calculate the reinforcement needed for the specified concrete section. All the concrete design calculations are based on the current: Complementary Technical Standards for the Design and Construction of Concrete Structures – Nov. 1987. (Normas Técnicas Complementarias para Diseño y construcción de Estructuras de Concreto) of the Mexican Construction Code for the Federal District –Aug. 1993 (Reglamento de Construcciones para el Distrito Federal).

D10.A.2 Section Types for Concrete Design

The following types of cross sections can be defined for concrete design.

- Columns — Prismatic (Rectangular, Square, and Circular)
- Beams — Prismatic (Rectangular & Square), Trapezoidal, and T-shapes
- Walls — Finite element with a specified thickness

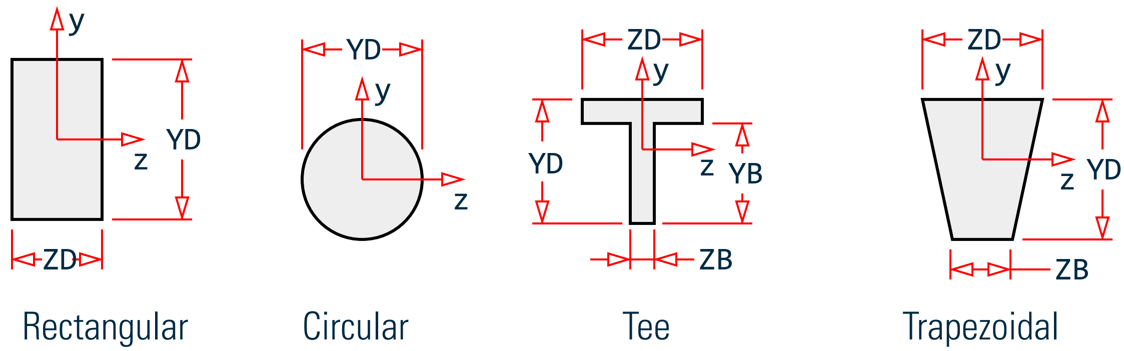

Figure 175: Concrete shape nomenclature for beams and columns

D10.A.3 Member Dimensions

Concrete members which will be designed by the program must have certain section properties input under the `MEMBER PROPERTY` command. The following example shows the required input:

```
UNIT CM
MEMBER PROPERTY
13 TO 79 PRISM YD 40. ZD 20. IZ 53333 IY 13333
11 13 PR YD 20.
14 TO 16 PRIS YD 24. ZD 48. YB 18. ZB 12.
17 TO 19 PR YD 24. ZD  18. ZB 12.
```

In the above input, the first set of members are rectangular (40 cm depth and 20 cm width) and the second set of members, with only depth and no width provided, will be assumed to be circular with 20 cm diameter. Note that no area (AX) is provided for these members. For concrete design, this property must not be provided. If shear areas and moments of inertias are not provided, the program calculates these values from YD and ZD. Notice that in the above example the IZ and IY values provided are actually 50% of the values calculated using YD and ZD. This is a conventional practice which takes into consideration revised section parameters due to cracking of section.

Note that the third and the fourth set of members in the above example represent a T-shape and a TRAPEZOIDAL shape respectively. Depending on the properties (YD, ZD, YB, ZB, etc.) provided, the program will determine whether the section is rectangular, trapezoidal or T-shaped and the BEAM design will be done accordingly.

D10.A.4 Design Parameters

The program contains a number of parameters which are needed to perform design by the Mexican code. Default parameter values have been selected such that they are frequently used numbers for conventional design requirements. These values may be changed to suit the particular design being performed. Table 3.1 is a complete list of the available parameters and their default values.

The manual describes the commands required to provide these parameters in the input file. For example, the values of `SFACE` and `EFACE` (parameters that are used in shear design), the distances of the face of supports from the end nodes of a beam, are assigned values of zero by default but may be changed depending on the actual situation. Similarly, beams and columns are designed for moments directly obtained from the analyses without any magnification. The factors `MMY` and `MMZ` may be used for magnification of column moments. For beams, the user may generate load cases which contain loads magnified by the appropriate load factors.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 179: Mexican Concrete Design Parameters

Parameter Name	Default Value	Parameters
CODE	-	Must be specified as MEXICAN. Design code to follow. See TR.53.2 Concrete Design-Parameter Specification (on page 2685).
BTP	2	Bar type to use: 0. IMPERIAL (No 3 to 18) 1. METRIC (4.2 to 60mm) 2. MEXICAN (No 2 to 18)
CCL	1	Concrete class according to 1.4.1d) to define Modulus of Elasticity 1. Class 1 Concrete 2. Class 2 Concrete
CFB	FALSE	Cold formed Bar classification to define development multipliers according to table 3.1 NTC • FALSE - Not cold formed bar • TRUE - Cold formed bar
CLB	3 cm	Clear cover for bottom reinforcement
CLS	3 cm	Clear cover for side reinforcement
CLT	3 cm	Clear cover for top reinforcement
DAG	2 cm	Maximum diameter of aggregate, in current units.
DCP	TRUE	Beam Loads and reactions in direct compression Cl-2.1.5.a.I 2nd paragraph • FALSE - Loads applied indirectly • TRUE - Direct compression

Parameter Name	Default Value	Parameters
DEPTH	YD	Depth of concrete member, in current units. This value defaults to YD as provided under MEMBER PROPERTIES.
DIM	TRUE	• FALSE: Not precautions taken - Section reduction to section 1.5 NTC Concrete • TRUE: Precautions are taken to assure dimensions
DSD	TRUE	Ductile frames in accordance with Section 5 of the code. Some design conditions are considered (not including, for the time being, geometric or confinement ones) • FALSE - Non-Ductile frames • TRUE - Ductile Frames
EFACE	0	Face to support location of end of beam. If specified, for shear force at start is computed at a distance of EFACE+d from the start joint of the member. Positive number.
EXP	FALSE	Exposition to soil or weather to define cover and min Steel reinforcement • FALSE - Not exposed to soil or weather • TRUE - Exposed to soil or weather
FC	200 Kg/cm^2	Compressive Strength of Concrete
FYMAIN	4,200 Kg/cm^2	Yield Stress for main reinforcing steel
FYSEC	4,200 Kg/cm^2	Yield Stress for secondary (stirrup) reinforcing steel
LSS	0	Part of the longitudinal steel considered to reduce shear. 0 (zero) is conservative. Value between 1 and 0.

Parameter Name	Default Value	Parameters
LTC	FALSE	Light Concrete to define development multipliers according to table 3.1 NTC • FALSE - Regular concrete • TRUE - Lightweight concrete
MAXMAIN	12	Maximum main reinforcement bar size (Number 2 -18)
MINMAIN	2.5	Minimum main reinforcement bar size (Number 2 -18)
MINSEC	2.5	Minimum secondary reinforcement bar size (Number 2 -18)
MMY	1.0	Moment magnification factor for columns, about My.
MMZ	1.0	Moment magnification factor for columns, about Mz.
MOE	198,000 Kg/cm^2	Concrete modulus of elasticiy.
NSECTION	12	Number of equally-spaced sections to be considered in finding critical moments for beam design
PHI	90 degrees	Stirrups angle with the axis of the element
PSS	TRUE	Slab beared perimeter. To calculate min steel required according to 2.1.2
REINF	0	Tied Column. A value of 1 will mean spiral.
SFACE	0	Face to support location of start of beam. If specified, for shear force at start is computed at a distance of SFACE+d from the start joint of the member. Positive number
TEQ	FALSE	Beam needed for torsional equilibrium Cl.2.1.6a) 2nd paragraph • FALSE - No • TRUE - Yes

Parameter Name	Default Value	Parameters
TRACK	0	Beam Design 0. Critical Moment will not be printed out with beam design report. 1. Will mean a print out. 2. Will print out required steel areas for all intermediate sections specified by `NSECTION`. Column Design 0. Will print out detailed design results. 1. Will mean a print out column interation analysis results in addition to TRACK 0 output. 2. will print out a schematic interaction diagram and intermediate interaction values in addition to all of the above.
WIDTH	ZD	Width of concrete member, in current units. This value defaults to `ZD` as provided under `MEMBER PROPERTIES`

* These values must be provided in the current unit system being used.

Note: When using metric bars for design, provide values for these parameters in actual ‘mm‘ units instead of the bar number. The following metric bar sizes are available: 4.2mm, 6 mm, 8 mm, 10 mm, 12 mm, 16 mm, 20 mm, 25 mm, 32 mm, 40 mm, 50 mm and 60 mm.

D10.A.5 Beam Design

Beams are designed for flexure, shear and torsion. For all these forces, all active beam loadings are prescanned to locate the possible critical sections. The total number of sections considered is 12 (twelve) unless this number is redefined with an `NSECTION` parameter. All of these equally spaced sections are scanned to determine moment and shear envelopes.

D10.A.5.1 Design for Flexure

Reinforcement for positive and negative moments are calculated on the basis of the section properties provided by the user. If the section dimensions are inadequate to carry the applied load, that is if the required reinforcement is greater than the maximum allowable for the cross section, the program reports that beam fails in maximum reinforcement. Rectangular sections are also designed with compression reinforcement.

Effective depth is chosen as Total depth - (Clear cover + diameter of stirrup + half the dia. of main reinforcement), and a trial value is obtained by adopting proper bar sizes for the stirrups and main reinforcements. The relevant clauses in Sections 1.5, 1.6, 2.1.1-2-5, 3.10 and 5.2.2 of NTC Concrete are utilized to obtain the actual amount of steel required as well as the maximum allowable and minimum required steel. These values are reported as ROW, ROWMX and ROWMN in the output and can be printed using the parameter TRACK 1.0 (see D10.A.4 Design Parameters (on page 1744)). In addition, the maximum, minimum and actual bar spacing are also printed.

It is important to note that beams are designed for flexural moment MZ only. The moment MY is not considered in the flexural design.

D10.A.5.2 Design for Shear

Shear reinforcement is calculated to resist both shear forces and torsional moments. Shear forces are calculated at a distance (d+SFACE) and (d+EFACE) away from the end nodes of the beam. SFACE and EFACE have default values of zero unless provided under parameters (see D10.A.4 Design Parameters (on page 1744)). Note that the value of the effective depth "d" used for this purpose is the update value and accounts for the actual c.g. of the main reinforcement calculated under flexural design. Clauses 2.1.5-6 and 5.2.4 of NTC Concrete are used to calculate the reinforcement for shear forces and torsional moments. Based on the total stirrup reinforcement required, the size of bars, the spacing, the number of bars and the distance over which they are provided are calculated. Stirrups due to geometric conditions are assumed to be 2-legged, due to design conditions could be 2 or 4-legged.

D10.A.5.3 Design for Anchorage

In the output for flexural design, the anchorage details are also provided. At any particular level, the START and END coordinates of the layout of the main reinforcement is described along with the information whether anchorage in the form of a hook or continuation is required or not at these START and END points. Note that the coordinates of these START and END points are obtained after taking into account the anchorage requirements. Anchorage length is calculated on the basis of the Clauses described in Section 3.1 of NTC concrete. In case the program selects 2 different diameters for the main or compression reinforcement, only the anchorage for the largest diameter is analyzed.

D10.A.5.4 Output

Level	Serial number of bar level which may contain one or more bar group
Height	Height of bar level from the bottom of the beam
Bar Info	Reinforcement bar information specifying number of bars and bar size
From	Distance from the start of the beam to the start of the reinforcement bar
To	Distance from the start of the beam to the end of the reinforcement bar
Anchor (STA/ END)	States whether anchorage, either hook or continuation, is needed at the start (STA) or at the end (END).
Row	Actually required flexural reinforcement (As/bd) where b = width of cross section (ZD for a rectangular or square section) and d = effective depth of cross section (YD minus the distance from extreme tension fiber to the centroid of main reinforcement).
ROWMN	Minimum required flexural reinforcement (Amin/bd)
ROWMX	Maximum required flexural reinforcement (Amax/bd)
Spacing	Distance between centers of adjacent bars of main reinforcement
Vu	Factored shear force at section

Vc	Nominal shear strength provided by concrete
Vs	Nominal shear strength provided by shear reinforcement
Tu	Factored torsional moment at section
Tc	Nominal torsional moment strength provided by concrete
Ts	Nominal torsional moment strength provided by torsion reinforcement

D10.A.5.5 Example Output for Beam Design

```

D10.A.6 Column Design

Columns design in STAAD.Pro per the Mexican code is performed for axial force and uniaxial as well as biaxial moments. All active loadings are checked to compute reinforcement. The loading which produces the largest amount of reinforcement is called the critical load. Column design is done for square, rectangular and circular sections. For rectangular and circular sections, reinforcement is always assumed to be equally distributed on all faces. This means that the total number of bars for these sections will always be a multiple of four (4). If the MMAGx & -MMAGy parameters are specified, the column moments are multiplied by the corresponding MMAG value to arrive at the ultimate moments on the column. Minimum eccentricity conditions to be satisfied according to section 2.1.3.a are checked.

Method used: Bresler Load Contour Method

Known Values: Pu, Muy, Muz, B, D, Clear cover, Fc, Fy

Ultimate Strain for concrete : 0.003

Steps involved:

1. Assume some reinforcement. Minimum reinforcement (1% for ductile design or according to section 4.2.2) is a good amount to start with.

2. Find an approximate arrangement of bars for the assumed reinforcement.
3. Calculate PNMAX = Po, where Po is the maximum axial load capacity of the section. Ensure that the actual nominal load on the column does not exceed PNMAX. If PNMAX is less than the axial force Pu/FR, (FR is the strength reduction factor) increase the reinforcement and repeat steps 2 and 3. If the reinforcement exceeds 6% (or 4% for ductile design), the column cannot be designed with its current dimensions.
4. For the assumed reinforcement, bar arrangement and axial load, find the uniaxial moment capacities of the column for the Y and the Z axes, independently. These values are referred to as MYCAP and MZCAP respectively.
5. Solve the Interaction Bresler equation:

   $$(M_{ny}/M_{ycap})^{\alpha} + (M_{nz}/M_{zcap})^{\alpha}$$

   Where α = 1.24. If the column is subjected to uniaxial moment: α = 1
6. If the Interaction equation is satisfied, find an arrangement with available bar sizes, find the uniaxial capacities and solve the interaction equation again. If the equation is satisfied now, the reinforcement details are written to the output file.
7. If the interaction equation is not satisfied, the assumed reinforcement is increased (ensuring that it is under 6% or 4% respectively) and steps 2 to 6 are repeated.

By the moment to check shear and torsion for columns the sections have to be checked as beams and the most strict of both shear and torsion reinforcement adopted.

D10.A.7 Column Interaction

The column interaction values may be obtained by using the design parameter TRACK 1.0 or TRACK 2.0 for the column member. If a value of 2.0 is used for the TRACK parameter, 12 different Pn-Mn pairs, each representing a different point on the Pn-Mn curve are printed. Each of these points represents one of the several Pn-Mn combinations that this column is capable of carrying about the given axis, for the actual reinforcement that the column has been designed for. In the case of circular columns, the values are for any of the radial axes. The values printed for the TRACK 1.0 output are:

- P0 = Maximum allowable pure axial load on the column (moment zero).
- Pnmax = Maximum allowable axial load on the column.
- P_bal = Axial load capacity of balanced strain condition.
- M_bal = Uniaxial moment capacity of balanced strain condition.
- E_bal = M_bal / P_bal = Eccentricity of balanced strain condition.
- M0 = Moment capacity at zero axial load.
- P_tens = Maximum permissible tensile load on the column.
- Des. Pn = Pu/FR where FR is the Strength Reduction Factor and Pu is the axial load for the critical load case.
- Des.Mnx = Mux*MMAGx/FR where FR is the Strength Reduction Factor and Mu is the bending moment for the appropriate axis for the critical load case.
- Mu = $\sqrt{}(Mux.Mmagx)^2 + (Muy.Mmagy)^2$
- e/h = (Mn/Pn)/h where h is the length of the column

D10.A.8 Column Design Output

The next table illustrates different levels of the column design output.

The output is generated without any TRACK specification (or `TRACK 0`):

```
   ====================================================================

        COLUMN  NO.     1  DESIGN PER MEX NTC-87 - AXIAL + BENDING

   FY - 411.9  FC -  19.6 MPa     SQRE SIZE   30.0 x  30.0 (mm) TIED

           AREA OF STEEL REQUIRED =1422.857

   BAR CONFIGURATION       REINF PCT.   LOAD   LOCATION   PHI
   ----------------------------------------------------------

    12 - NUMBER  4           1.693        1      END     0.700
   (PROVIDE EQUAL NUMBER OF BARS ON EACH FACE)
```

`TRACK 1` generates the following additional output:

```
       COLUMN INTERACTION: MOMENT ABOUT Z -AXIS (KN-MET)

    --------------------------------------------------------
       P0          Pn max        P-bal.       M-bal.      e-bal.(mm)
       1807.71      1807.71       472.28        89.02      18.8
       M0          P-tens.       Des.Pn      'Des.Mn     e/h
         66.71      -627.70       106.12        35.18    0.074
    -----------------------------------------------------------------------

       COLUMN INTERACTION: MOMENT ABOUT Y -AXIS (KN-MET)

    --------------------------------------------------------
       P0          Pn max        P-bal.       M-bal.      e-bal.(mm)
       1807.71      1807.71       472.28        89.02      18.8
       M0          P-tens.       Des.Pn      'Des.Mn     e/h
         66.71      -627.70       106.12        44.63    0.093
    -----------------------------------------------------------------------
```

`TRACK 2` generates the interaction diagram output in addition to all the above:

```
                            Pn          Mn          Pn          Mn       (@
Z )
            |                1668.66       12.60       834.33       76.51

D10.A.9 Slab Design

Slabs are designed per Mexican NTC specifications. To design a slab, it must be modeled using finite elements.

Element design will be performed only for the moments MX and MY at the center of the element. Design will not be performed for FX, FY, FXY, MXY. Also, design is not performed at any other point on the surface of the element. Shear is checked with Q.

A typical example of element design output is shown below. The reinforcement required to resist Mx moment is denoted as longitudinal reinforcement and the reinforcement required to resist My moment is denoted as transverse reinforcement. The parameters FYMAIN, FC, CLB, CLS, CLT, DIM, and EXP listed in D10.A.4 Design Parameters (on page 1744) are relevant to slab design. Other parameters mentioned are not used in slab design.

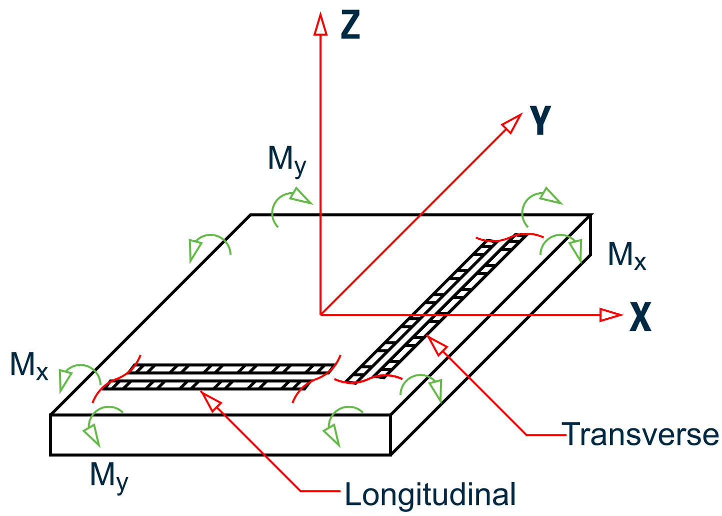

Figure 176: Element moments: Longitudinal (L) and Transverse (T)

D10.B. Mexican Codes - Steel Design per NTC 1987

STAAD.Pro is capable of performing steel design based on the Mexican code NTC 1987 *(Normas Técnicas Complementarias para Diseño y construcción de Estructuras Metálicas)* (*Complementary Technical Standards for the Design and Construction of Steel Structures – Dec. 1987*) or the *Reglamento de Construcciones para el Distrito Federal* (*Mexican Construction Code for the Federal District* –Aug. 1993).

Design of members per NTC 1987 requires the *STAAD Latin American Design Codes* SELECT Code Pack.

D10.B.1 General

The design philosophy considered is that of the Load Cases and Resistance Method or Limit States Design usually known as Load and Resistance Factor Design (LRFD).

Structures are designed and proportioned taking into consideration the limit states at which they would become unfit for their intended use. Two major categories of limit-state are recognized--ultimate and serviceability. The primary considerations in ultimate limit state design are strength and stability, while that in serviceability is deflection. Appropriate load and resistance factors are used so that a uniform reliability is achieved for all steel structures under various loading conditions and at the same time the chances of limits being surpassed are acceptably remote.

In the STAAD.Pro implementation of the Mexican Standards for steel structures, members are proportioned to resist the design loads without exceeding the limit states of strength, and stability. It allows to check deformation to verify serviceability.

Accordingly, the most economic section is selected on the basis of the least weight criteria as augmented by the designer in specification of allowable member depths, desired section type, or other such parameters. The code checking portion of the program checks that main code requirements for each selected section are met and identifies the governing criteria.

The following sections describe the salient features of the Mexican specifications as implemented in STAAD.Pro steel design. A brief description of the fundamental concepts is presented here.

D10.B.2 Limit States Design Fundamentals

The primary objective of the Limit States Design Specification is to provide a uniform reliability for all steel structures under various loading conditions.

The Limit States Design Method uses separate factors for each load and resistance. Because the different factors reflect the degree of uncertainty of different loads and combinations of loads and of the accuracy of predicted strength, a more uniform reliability is possible.

The method may be summarized by the inequality

$$Y_i\ Q_i \leq R_n\ FR$$

On the left side of the inequality, the required strength is the summation of the various load effects, Q_i, multiplied by their respective load factors, Y_i. The design strength, on the right side, is the nominal strength or resistance, R_n, multiplied by a resistance factor, FR.

In the STAAD implementation of the Mexican Standards, it is assumed that the user will use appropriate load factors and create the load combinations necessary for analysis. The design portion of the program will take into consideration the load effects (forces and moments) obtained from analysis. In calculation of resistances of various elements (beams, columns etc.), resistance (nominal strength) and applicable resistance factor will be automatically considered.

D10.B.3 Member End Forces and Moments

Member end forces and moments in the member result from loads applied to the structure. These forces are in the local member coordinate system. the following figures show the member end actions with their directions. Refer to G.18 Member End Forces (on page 2187) .

D10.B.4 Section Classification

The Limit States Design specification allows inelastic deformation of section elements. Thus local buckling becomes an important criterion. Steel sections are classified as compact (type 2), noncompact (type 3), or slender element (type 4), sections depending upon their local buckling characteristics, besides sections type 1 are able for plastic design. This classification is a function of the geometric properties of the section. The design procedures are different depending on the section class. STAAD is capable of determining the section classification for the standard shapes and design accordingly.

D10.B.5 Member in Axial Tension

The criteria governing the capacity of tension members is based on two limit states. The limit state of yielding in the gross section is intended to prevent excessive elongation of the member. The second limit state involves fracture at the section with the minimum effective net area. The net section area may be specified by the user through the use of the parameter `NSF` (D10.B.11 Design Parameters (on page 1761)), that always refers to the gross section. STAAD calculates the tension capacity of a given member based on these two limit states and proceeds with member selection or code check accordingly.

In addition to the tension resistance criterion, the user defines if tension members are required to satisfy slenderness limitations which are a function of the nature of use of the member (main load resisting component, bracing member, etc.). In both the member selection and code checking process, STAAD immediately does a slenderness check on appropriate members before continuing with other procedures for determining the adequacy of a given member.

D10.B.6 Axial Compression

The column strength equations take into account inelastic deformation and other recent research in column behavior. Two equations governing column strength are available, one for inelastic buckling and the other for elastic or Euler buckling. Both equations include the effects of residual stresses and initial out-of-straightness. Compression strength for a particular member is calculated by STAAD.Pro according to the procedure outlined in Section 3.2 of the NTC. For slender elements, the procedure described in Section 2.3.6.NTC is also used.

The procedures of Section 3.2 of the Commentaries, design helps and examples of the Complementary Technical Standards for the Design and Construction of Steel Structures (de los Comentarios, ayudas de diseño y ejemplos de las Normas Técnicas Complementarias para el Diseño y Construcción de Estructuras Metálicas, DDF (Comentarios - Julio 1993) were implemented for the determination of design strength for these limit states.

Effective length for calculation of compression resistance may be provided through the use of the parameters KY, KZ and/or LY, LZ. If not provided, the entire member length will be taken into consideration.

In addition to the compression resistance criterion, compression members are required to satisfy slenderness limitations which are a function of the nature of use of the member (main load resisting component, bracing member, etc.). In both the member selection and code checking process, STAAD.Pro immediately does a slenderness check on appropriate members before continuing with other procedures for determining the adequacy of a given member.

D10.B.7 Flexural Design Strength

In the Limit States Design Method, the flexural design strength of a member is determined mainly by the limit state of lateral torsional buckling. Inelastic bending is allowed and the basic measure of flexural capacity is the plastic moment capacity of the section.

The flexural resistance is a function of plastic moment capacity, actual laterally unbraced length, limiting laterally unbraced length, buckling moment and the bending coefficient. The limiting laterally unbraced length Lu and flexural resistance Mr are functions of the section geometry and are calculated as per the procedure of Section 3.3.2 of the NTC.

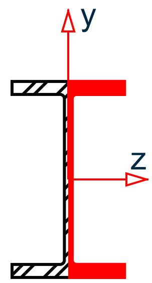
The purpose of bending coefficient Cb is to account for the influence of the moment gradient on lateral-torsional buckling. This coefficient can be specified by the user through the use of parameter `CB` or CBy (D10.B.11 Design Parameters (on page 1761)) or may be calculated by the program (according to the American LRFD specification) if CB is specified as 0.0. In the absence of the parameter `CB`, a default value of 1.0 will be used.

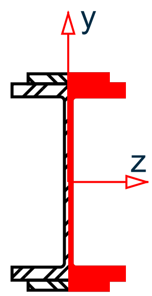
To specify laterally unsupported length, either or both of the parameters `UNL` and `UNF` (see D10.B.11 Design Parameters (on page 1761)) can be used.

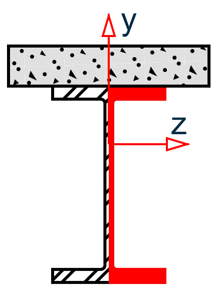
It is taken into account the reduction of flexural resistance due to slender web according to section 4.5.8 of the NTC

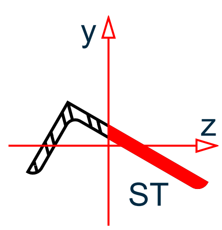
For the sections where the web and flange are slender the American LRDF specification was used.

Stress Zones Due to Bending









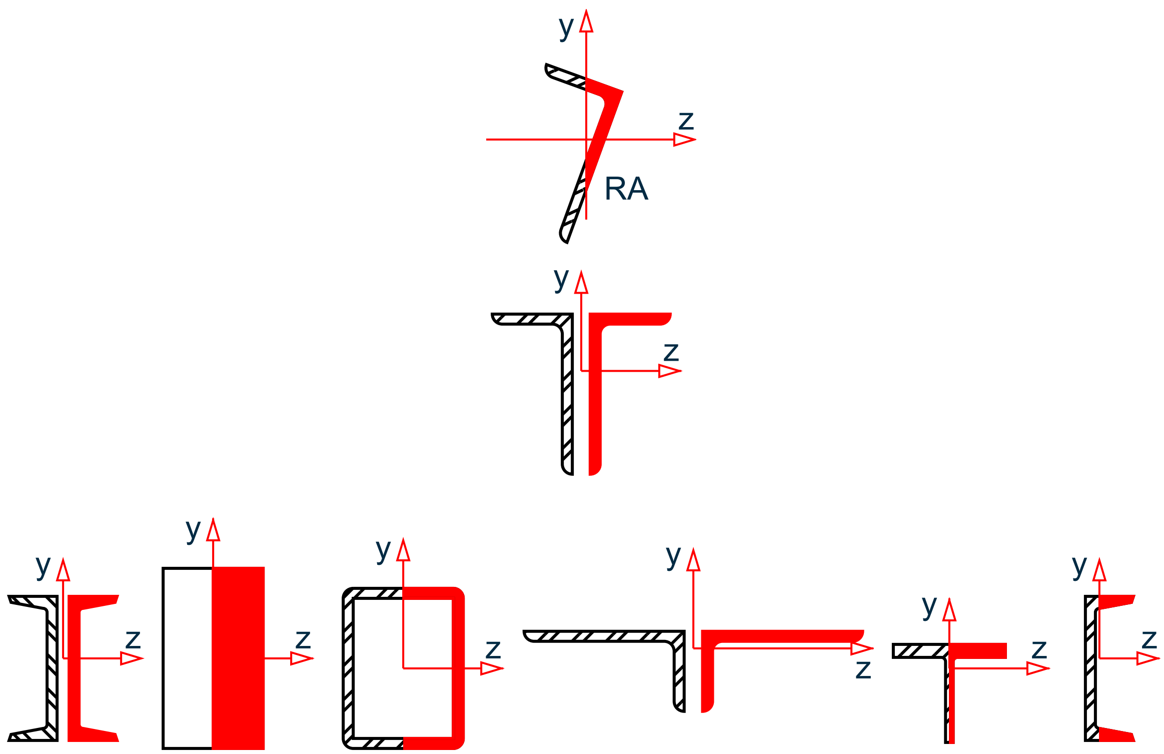


Figure 177: Stress zones due to bending about the Y axis (MY) for various section types

> **Note:** Local X axis goes into the page; Global Y is vertically upwards; Shaded area indicates zone under compression; Non-shaded area indicates zone under tension

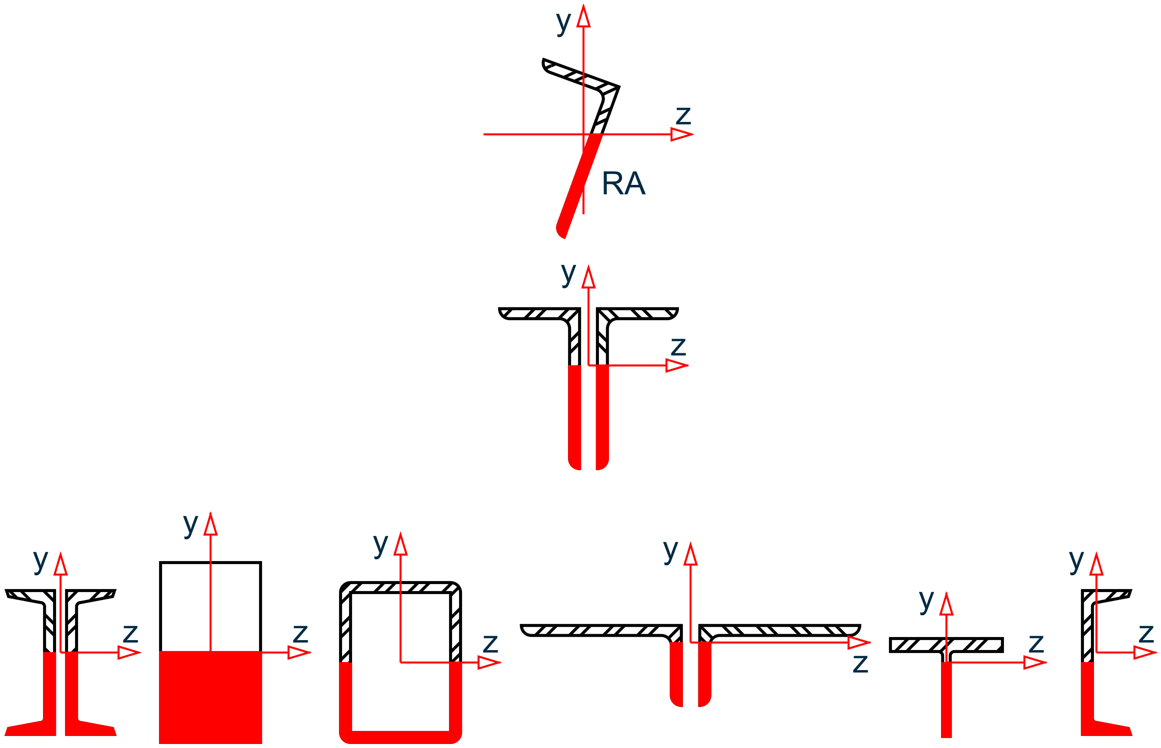

Figure 178: Stress zones due to bending about the Z axis (MZ) for various section types

Note: Local X axis goes into the page; Global Y is vertically upwards; Shaded area indicates zone under compression; Non-shaded area indicates zone under tension.

D10.B.8 Design for Shear

The procedure of Sect. 3.3.3 of the NTC is used in STAAD to design for shear forces in members. Besides combined bending and shear is checked according to section 3.3.4 of the NTC, considering also the limits for stiffeners of the web according to sections 4.5.6/7 of the NTC. Shear in wide flanges and channel sections is resisted by the area of the web/s..

D10.B.9 Combined Compression Axial Force and Bending

The interaction of flexure and axial forces in singly and doubly symmetric shapes is governed by formulas of the Section 3.4 of the NTC. These interaction formulas cover the general case of biaxial bending combined with axial force. They are also valid for uniaxial bending and axial force.

It is considered that the frames are part of structures that have shear walls or rigid elements so that the lateral displacements of a floor could be disregarded. The program has included formulas to include structures with lateral displacements in the future considering for B2 the columns individually and not the complete floor analysis.

It is taken into account if the elements have transverse loads and if the ends are angularly restrained.

D10.B.10 Combined Tension Axial Force and Bending

Based on Section 3.5 4 of the NTC.

D10.B.11 Design Parameters

Design per Mexican Standards is requested by using the CODE. Other applicable parameters are summarized in Table 13B.1 below. These parameters communicate design decisions from the engineer to the program and thus allow the engineer to control the design process to suit an application's specific needs.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements, some or all of these parameter values may be changed to exactly model the physical structure.

The parameters DMAX and DMIN may only be used for member selection only.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 180: Design Parameters According to Mexican NTC Standards - Steel

Parameter Name	Default Value	Description
CODE	-	Must be specified as MEXICAN. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
BEAM	0	0: Design at ends and those locations specified by SECTION command. 1: Design at ends and at every y cada 1/12th point along member length
CB	1	Coefficient C defined per section 3.3.2.2. If Cb is set to 0.0 it will be calculated by the program according to LRFD USA (CbMex=1/CbUSA). Any other value will be directly used in the design.
CMB	1	Cfactor for combined forces when there are transverse loads in the members. Section 3.4.3.3.ii of NTC CMB 1.0 = Members ends are restricted angularly. CMB 0.85 = Members ends are not restricted angularly.

Parameter Name	Default Value	Description
DFF	None(Mandatory for deflection check, TRACK 4.0)	"Deflection Length" / Maxm. allowable local deflection See Note 1 below.
DJ1	Start Jointof member	Joint No. denoting starting point for calculation of "Deflection Length ." See Note 1 below.
DJ2	End Joint of member	Joint No. denoting end point for calculation of "Deflection Length." See Note 1 below.
DMAX	114 cm	Maximum allowable depth
DMIN	0.0 cm	Minimum allowable depth
DSD	T	Perform the ductile seismic design in accordance with Section 11 (True or False). Main design conditions are considered (not including, at the moment, geometric ones)
FU	4,230 Kg/cm^2	Ultimate tensile strength of steel
FYLD	2,530 kg/cm^2	Minimum Yield strength of steel
IMM	0	Main or secondary member for the purpose of checking slenderness 0. Main member 1. Secondary and wind trusses
INO	0	Curve Definition according to NTC. 3.2.2.1a, defined for I shapes or tubes 0. n=1.4, laminated I shapes, tubes or built up with 3 or 4 welded plates obtained from wider plates cuts with oxygen. 1. n=1, I shapes, tubes or built up with 3 or 4 welded plates

Parameter Name	Default Value	Description
IRR	0	Variable defined for the whole structure indicating if it is regular or irregular according to section 3.4 of the NTC. Columns that are part of regular structures Columns that are part of irregular structures
KX	1.0	Effective length factor for flexural-torsional buckling
KY	1.0	Effective length factor for local Y axis- Usually minor axis
KZ	1.0	Effective length factor for local Z axis- Usually major axis
LDR	T	Defines if the structure has elements to bear the wind load (shear walls, wind trusses, or bracing rigid elements) that restrict lateral displacements and allow to disregard slenderness effects. (True or False)
LX	Member length	Length for determining flexural-torsional buckling
LY	Member length	Length to calculate slenderness ratio for buckling about local Y axis.
LZ	Member length	Length to calculate slenderness ratio for buckling about local Z axis.
NSF	1	Net section factor for tension members
RATIO	1.0	Permissible ratio of actual load effect and design strength
STIFF	Longer of Member length or depth	Spacing of stiffeners for beams for shear design

Parameter Name	Default Value	Description
TRACK	0	Controls the level of detail in output 0. = Suppress all design strengths 1. = Print all design strengths 2. = Print expanded design output
UNB	Member length	Unsupported length (L) of the bottom* flange for calculating flexural strength . Will be used only if compression is in the bottom flange. See Note 2 below.
UNT	Member length	Unsupported length (L) of the top* flange for calculating flexural strength . Will be used only if compression is in the top flange. See Note 2 below.

D10.B.11.1 Notes

1. For deflection check, parameters `DFF`, `DJ1`, and `DJ2` from D3.B.6 Design Parameters (on page 1384) may be used. All requirements remain the same.
2. Top and Bottom represent the positive and negative side of the local Y axis (local Z axis if `SET Z UP` is used).

D10.B.12 Code Checking and Member Selection

Both code checking and member selection options are available in STAAD Mexican Standards implementation.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D10.B.13 Tabulated Results of Steel Design

Results of code checking and member selection are presented in a tabular format.

CRITICAL COND refers to the section of the Mexican NTC which governed the design.

If the TRACK is set to 1.0, member design strengths will be printed out.

D11. New Zealand Codes

D11.A. New Zealand Codes - Steel Design per NZS 3404-1997

STAAD.Pro is capable of performing steel design based on the New Zealand code NZS 3404-1997 *New Zealand Standard for Steel Structures*, Parts 1 & 2, including Amendments 1 & 2.

D11.A.1 Member Property Specifications

For specification of member properties, either the steel section library available in STAAD.Pro or the User Table facility may be used.

The following shapes are supported for design per NC3404-1997:

I Section (rolled and welded)
Tee cut from rolled I-section
Single Channel
Single Angle
Pipe / CHS
Tube / RHS / SHS
Tapered I

Note: Using any shape not listed will result in an error message in the output and the section will *not* be designed.

D11.A.2 Material Properties

Any material with modulus of elasticity between 137,895 MPa (20,000 ksi) – 344738 MPa (50,000 ksi). You can design members with either built-in material constants or user-defined materials.

Note: If any material with modulus of elasticity value out of that range is assigned to member, it will be designed but an additional warning message will be produced.

Refer to TR.26.1 Define Material (on page 2303) for further information on the Define Material feature.

Refer to TR.26.2 Specifying Constants for Members and Elements (on page 2305) for further information on the Built-in Material Constants feature.

Yield stress, f_y , and ultimate stress, f_u , are calculated based on steel grade table. The design parameters `FYLD`, `FU`, and `SGR` are used to directl specify these values.

D11.A.3 Section Classification

The slenderness limit for each element is calculated using table 5.2 and 6.2.4 for elements under uniform compressive stress and varying compressive stress (bending stress).

The `IST` design parameter related to section classification calculations.

D11.A.4 Member Resistance

The member resistance is calculated in STAAD according to the procedures outlined in NZS 3404-1997. Calculated design capacities are compared to corresponding axial, bending moment, and shear forces determined from the STAAD.Pro analysis. These are used to report the fail or pass status for the members designed.

Slenderness

The slenderness check is *not* used as a critical member ratio check. If a slenderness check is included and exceed unity (1.0), then it may be reported as the governing criteria. However, if it is less than unity, it will be reported but will not be used as the governing ratio.

D11.A.4.1 Slenderness

For calculating member slenderness, the length of unbraced segment for compression is considered.

For analytical member design, the `MAIN` and `TMAIN` parameters are used.

D11.A.4.2 Bending

Bending capacities are calculated per NZS3404 Section 5. The allowable bending moment of members is determined as the lesser of nominal section capacity and nominal member capacity (ref. Cl.5.1).

D11.A.4.2.1 Bending Section Strength

The nominal section moment capacity, ϕM_s , is calculated about both principal x and y axes and is the capacity to resist cross-section yielding or local buckling and is expressed as the product of the yield stress of the material and the effective section modulus (ref. Cl.5.2.1). The effective section modulus is a function of section type (i.e., compact, non-compact, or slender) and minimum plate yield stress fy. The nominal member capacity depends on overall flexural-torsional buckling of the member (ref.Cl.5.3).

D11.A.4.2.2 Bending Member Strength

For sections where the web and flange yield stresses ($f_{y,web}$ and $f_{y.flange}$ respectively) are different, the lower of the two yield stresses is applied to both the web and flange to determine the slenderness of these elements.

For sections where the web and flange yield stresses (fy,web and fy.flange respectively) are different, the lower of the two yield stresses is applied to both the web and flange to determine the slenderness of these elements. Member moment capacity, φM_b , is calculated about the principal x axis only (ref. Cl.5.6). Critical flange effective cross-section restraints and corresponding design segment and sub-segments are used as the basis for calculating capacities.

The `ALM` design parameter is used to specify a_m (refer cl. 5.6.1.1).

The `SKR`, `SKT`, `SKL`, `UNT`, `UNB`, and `PBRACE` design parameters are also used for bending checks.

D11.A.4.3 Shear

Section web shear capacity, φV_v , is calculated per Cl.5.11, including both shear yield and shear buckling capacities. Once the capacity is obtained, the ratio of the shear force acting on the cross section to the shear capacity of the section is calculated. If any of the ratios (for both local Y & Z-axes) exceed 1.0 or the allowable value provided using the `RATIO` parameter, the section is considered to have failed under shear.

The following table highlights which shear capacities are calculated for different profile types.

General Profile Type	Shear Checks
I-Section (i.e., parallel to minor principal axis)	Calculated for web only

General Profile Type	Shear Checks
T-Section	
Channel	
Angle	
Tube	Calculated parallel to both z & y principal axes
Pipe	Per NZS3404 5.11.4

Only unstiffened web capacities are calculated. Stiffened webs are not considered. Bearing capacities are not considered.

The TSP design parameter is used in shear capacity calculations.

D11.A.4.4 Compression

The compressive strength of members is based on limit states per NZS3404 Section 6. It is taken as the lesser of nominal section capacity and nominal member capacity.

D11.A.4.4.1 Compression Section Strength

Nominal section capacity, φN_s , is a function of form factor (Cl.6.2.2), net area of the cross section, and yield stress of the material. Through the use of the NSC parameter, you may specify the net section area. Note that this parameter is different from that corresponding to tension. The program automatically calculates the form factor. The

$$\mathrm{k_f}$$

form factors are calculated based on effective plate widths per Cl.6.2.4, and the f_y yield stress is based on the minimum plate yield stress.

The NSC (net section factor for compression) design parameter is used for compression sectoin strength checks.

D11.A.4.4.2 Compression Bending Strength

Nominal member capacity, φN_c , is a function of nominal section capacity and member slenderness reduction factor (Cl.6.3.3). This value is calculated about both principal x and y axes. Here, you are required to supply the value of a_b (Cl.6.3.3) through the ALB parameter. The effective length for the calculation of compressive strength may be provided through the use of the parameters KY, KZ, LY, and LZ.

The PBCRES and LHT design parameters are also used for this check.

D11.A.4.5 Tension

The criteria governing the capacity of tension members are based on two limit states per NZS3404 Section 7.

The limit state of yielding of the gross section is intended to prevent excessive elongation of the member.

The second limit state involves fracture at the section with the minimum effective net area φN_t section axial tension capacities are calculated (Cl.7.2). Through the use of the NSF parameter, you may specify the net section area. STAAD.Pro calculates the tension capacity of a member based on these two limit states per Cl.7.1 and Cl.7.2 respectively of NSZ3404. Eccentric end connections can be taken into account using the KT correction factor, per

Cl.7.3. The f_y yield stress is based on the minimum plate yield stress. Parameters FYLD, FU, and NSF are applicable for these calculations.

D11.A.4.6 Combined Forces

D11.A.4.6.1 Combined Section Strength

Combined section bending and shear capacities are calculated using the shear and bending interaction method as per Cl.5.12.2.

D11.A.4.6.2 Combined Member Strength

The member strength for sections subjected to axial compression and uniaxial or biaxial bending is obtained through the use of interaction equations. Here, the adequacy of a member is also examined against both section (ref. Cl.8.3.4) and member capacity (ref.Cl.8.4.5). These account for both in-plane and out-of-plane failures. If the summation of the left hand side of the equations, addressed by the above clauses, exceeds 1.0 or the allowable value provided using the RATIO parameter, the member is considered to have failed under the loading condition.

D11.A.4.7 Torsion

STAAD.Pro does *not* design sections or members for torsion for NZS3404.

D11.A.4.8 Seismic Provisions

The program performs the following checks per the seismic provisions in section 12 of the code.

1. Minimum specified yield stress (table 12.4)
2. Maximum ratio of (fy / fu) (table 12.4)

   The member seismic category is specified using the DUCT design parameter.
3. Fabrication requirement (Sec.12.4.1.2) - Category 1 or 2 members shall be hot-rolled or fabricated by welding from hot-rolled plate, except that category 2 members may be cold-formed, provided that adequate ductility capacity of the member and its connections is established by experimental testing or rational design.
4. Element slenderness (sec.12.5.1.1) - The elements of category 1, 2, 3 and 4 shall comply with the plate-element slenderness limitations presented in Table 12.5.
5. Section symmetry requirement (sec.12.5.2) – The yielding regions of category 1 or 2 members shall be doubly symmetric sections. The yielding regions of category 3 members shall be doubly or singly symmetric sections.
6. Web slenderness of beam (sec.12.7.2.1) - The web thickness within the yielding region of a beam shall be not less than $(d1/82)\ (fy\ /\ 250)$ for a category 1 or 2 member or less than $(d1/101)\ (fy\ /\ 250)$ for a category 3 member.
7. Limit on axial force (sec.12.8.3.1) - The ratio of design axial force, N*, to design section capacity, ϕN_s , (refer to 6.2) shall not exceed the values given in (a) through (c) below:

   a. The general limit given in table 12.8.1.
   b. In addition to (a), for category 1, 2 and 3 column members, excluding brace members of concentrically and eccentrically braced frames, the following limitation on design axial compression shall apply, unless waived according to 12.8.3.2

$$N^* \le \phi N_s \left(\frac{1 + \beta_m - \sqrt{N_s / N_{oL}}}{1 + \beta_m + \sqrt{N_s / N_{oL}}} \right) \qquad \text{Eq. 12.8.3.1}$$

c. When the slenderness ratio for the member web exceeds that given in table 12.8.2 for the appropriate member category, the design axial force generated by gravity loading alone, Ng^*, shall comply with the axial force limitation equation given therein.

8. Shear-bending interaction (12.10.3.1) - When a capacity design procedure is not used, at yielding regions in category 1 or 2 beams forming part of a seismic-resisting system, when designing for load combinations including earthquake loads the nominal web shear capacity of the beams shall be taken as 80% of that calculated from 5.11.4.1 and the interaction of shear and bending moment shall satisfy:

$$M^* \leq \phi M_{sv}$$

where

$$M_{sv} = \begin{cases} M_s & \text{for } V^* \leq 0.6\phi V_w \\ M_s\left(1.38 - \frac{V^*}{1.6V_w}\right) & \text{for } 0.6\phi V_w \leq V^* \leq 0.8\phi V_w \end{cases}$$

The ratio will be calculated as – $M^* / \phi M_{sv}$

D11.A.5 Member Design

There are two methods available in STAAD.Pro for checking members against the requirements of NZS 3404:

Analytical member method (referred to as `MEMBER` design), and
Physical member method (referred to as `PMEMBER` design)

Traditionally STAAD.Pro performed code checks based on single analytical members (i.e., single members between two nodes). This implementation assumes that the design inputs (except forces and section properties) remain same throughout the length of the member. Physical member design on the other hand allows you to group single or multiple analytical members into a single physical design member for the purposes of design to NZS 3404. Thus the some of the design inputs related to member strength (unbraced lengths etc.) varies along the length of the member.

D11.A.5.1 Analytical Member Design

Thirteen equidistant cross-sections including two end sections are selected from an analytical member. For each cross-section, the member resistance checks are evaluated for each load case. The design inputs (except forces and section properties) are treated same for throughout the length of the member.

For analytical member design, by default the member is divided at 13 evenly spaced points along the member length.

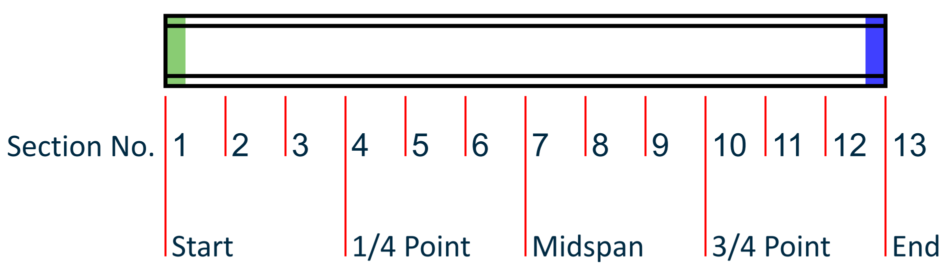

Figure 179: The default sections for design when `BEAM 1.0` is used

D11.A.5.1.1 Automated MEMBER Design Calculations

Automated Design Calculations	PMEMBER Design Parameter	Comments
α_b compression member section constant per NZS3404 6.3.3.	n/a	Calculated from table 6.3.3.
α_m moment modification factor per NZS3404 5.6.1.1 or Table 5.6.2 depending on if the segment is restrained at on/both ends.	ALM	Calculated based on moments distribution for individual segments and sub-segments.
f_u tensile strength per NZS3404 2.1.2 and AS4100 table 2.1.	FU	Based on nominal steel grade specified using SGR design parameter and element thickness.
f_y yield stress per NZS3404 2.1.1 and AS4100 table 2.1.	FYLD	Based on nominal steel grade specified using SGR design parameter and element thickness.
Residual stress category for NZS3404 Table 5.2 and 6.2.4.	IST	Based on section type.

D11.A.5.2 Physical Member Design

In case of analytical member design, all the design inputs are controlled by user input which is one-time for a whole analytical member. Specially the different unbraced lengths (UNT, UNB, LZ, LY), unbraced length factors (Kz, Ky) are considered constant throughout the length of the analytical member. But in case of a physical member, these values tend not to be constant throughout the length. The real essence of physical member design in NZS3404:1997 is the consideration of different values of unbraced lengths and unbraced length factors in different locations of same physical member to replicate the actual condition. This is achieved by auto calculation of these values from the user-provided physical bracings

In case of Physical member design in NZS3404:1997, the program does not divide the physical member into analytical member segments of equal length. Instead, each consisting analytical member is divided into 13 sections. Hence the physical member is considered as a member as a whole with “13n” sections for design checks, where n = number of component analytical members in the physical member under consideration. Clearly, in most of the cases, the distance between two sections will not be constant throughout the length of the member. In order to prevent overlapping design sections at the ends of adjoining componenet analytical members, a small gap of 0.001x the member length is used from the common joint to the design section at these locations. Doing so allows the program to capture changes in internal forces, particularly shear, at these joints within the physical member.

Additionally, PMEMBER automates:

steel grades based on section type, and
tensile stress, f_u , and yield stress, f_y , values based on plate thicknesses

Therefore it is recommend that PMEMBER design be used, even when a physical member consists of only one component analytical member.

D11.A.5.2.1 Modeling with Physical Members

You can use the physical modeling tools available in the user interface **Analytical Modeling** and **Steel Design** workflows to form physical members.

You can also define physical members using the `DEFINE PMEMBER` command. Refer to TR.16.2 Physical Members (on page 2238) for details.

D11.A.5.2.2 Section Profiles

When a physical member is checked against the code (`CODE CHECK`) in NZS3404-1997, all the component analytical members within a single physical member must have the same section assigned. If not, a code check will *not* be made and an error is displayed in the output.

When a physical member profile is selected (`SELECT`) in NZS3404-1997, all the component analytical members within a single physical member must be assigned from the same profile table. For example, if one analytical member is assigned an Australian UB150X18.0, then the other analytical members must be assigned any profile from the Austrialin UB table.

D11.A.5.2.3 Calculation for Compression Buckling

For calculation of member compression buckling capacities about the principal axis, the PMEMBER Design uses the concept of unbraced segments against compression (Lz, Ly). The unbraced segments against compression buckling are evaluated using the user defined compression bracings (PBCRES) separately for ZZ and YY axis. The types of restraints that can be provided at any location of the PMEMBER using PBCRES are: U(unbraced), T(translational), R(rotational), and TR(translational-rotational). Compression buckling restraints automate following design calculations for each segment for buckling against both the principle axis:

- Unbraced length of a segment for compression buckling – the distance between two consecutive T/R/TR type restraint. The program calculates it only when LZ or LY are not assigned.
- Effective length factor, k_e – according to figure 4.8.3.2 of NZS3404:1997 specification using type of restraint (T/R/TR) at the ends of a segment/sub-segment. The program calculates it only when KZ and KY are not assigned.

If you do not assign any compression buckling restraint to the physical member, the program will assume T type restraints at the member ends. But if a member is cantilever, then the program will keep the free end of the member unrestrained. Any user-provided input against member end restraints will override the values assumed by program.

Any value, other than 1.0, given to KZ and KY parameter will replace the automatically calculated effective length factors for the entire PMEMBER.

Any value other than 0.0 (default), given to LZ or LY parameter will replace the automatically calculated unbraced lengths for compression buckling of the entire PMEMBER.

D11.A.5.2.4 Calculation for Flexural/Flange Buckling

For calculation of member bending capacities about the principal x-axis, the PMEMBER Design uses the concept of unbraced segments against flange buckling (UNT, UNB). The unbraced segments against flange buckling are evaluated using the user defined compression bracings (PBRACE) separately for TOP and BOTTOM flange. User-defined flange restraints assigned using the PBRACE design parameter are checked to see if they are effective (i.e., if they are placed on the critical flange as per NZS3404 5.5). Flange restraints not applied to the critical flange are ineffective and hence are completely ignored.

Segment layouts for PMEMBERs may change for different load cases considered for design. Some restraints may be effective for one particular load case as they are found to apply to the critical flange, however for another load case may be found not to act on the critical flange, and found to be ineffective. In other words, the critical flange can change for each load case considered.

Typically, the critical flange will be the compression flange, except for segments with a “U” restraint at one end, in which case it will be the tension flange (as is the case for a cantilever).

Design unbraced flange segments are evaluated by “F”, “P”, “L”, “FR”, “PR”, or “U” effective section restraints. L restraints are considered only if are deemed to be “effective.” L restraints are only considered to be effective when positioned on the “critical” flange between F, P, FR, or FP restraints. If an L restraint is positioned on the non-critical flange it is ignored. Further, if an L restraint is positioned between a U and an F, P, FR, or FP restraint, it is ignored (regardless of whether it is on the critical or non-critical flange).

The PMEMBER Design uses the following steps to determine effective cross-section restraints for each load case considered:

i. first all user-defined restraints are checked to see if they are applied to the compression flange, with those that are not ignored

ii. next a check is made to see if a “U” type restraint is found at either end of the PMEMBER. If this is the case then any adjacent “L” restraints up to the next “F”, “FR”, “P” or “PR” restraint are also ignored, regardless of whether they are placed on the critical or non-critical flange. Refer NZS3404 5.4.2.3.

The compression flange in step i) of the routine above is calculated based on the bending moments at the locations of the restraints being considered.

Restraint Type	Definition	Stiffness	Description
FR	Fully and rotationally restrained	Most stiff	
F	Fully restrained	↓	
PR	Partially and rotationally restrained	↓	
P	Partially restrained	↓	
L	Laterally restrained	↓	Cannot be specified at the ends of design members.

Restraint Type	Definition	Stiffness	Description
U	Unrestrained	↓	Can only be applied at the ends of design members, and must be applied to both flanges to be effective. Both top and bottom flanges cannot be unrestrained at the same location (as this is unstable).
None		Least stiff	
C	Continuous restrained up to next restraint location		The flange is assumed to be continuously supported at that flange up to next restraint location. For continuously supported flange unbraced length is assumed to be zero.

Segment lengths are not automatically checked to determine if they provide full lateral restraint as per NZS3404 5.3.2.4.

For design of cantilevers, the free tip should have user-defined “U” restraints applied to both top and bottom flanges.

If the effective flange restraints for any load case consist of “U” or “L” restraints only, an error will be reported.

Hence flange restraints automate following design calculations for each unbraced flange segment for bending about both the principle axis:

- Unbraced length of top flange in bending compression – only when no value is assigned to `UNT`
- Unbraced length of bottom flange in bending compression – only when no value is assigned to `UNB`
- Moment modification factor, am, per NZS3404 5.6.1.1 – only when no value is assigned to `ALM`
- Load height factor, kl, given in Table 5.6.3(2) - only when no value is assigned to `SKL`
- Lateral rotation restraint factor, kr, given in Table 5.6.3(3) - only when no value is assigned to `SKR`
- Twist restraint factor, kt, given in Table 5.6.3(1) - only when no value is assigned to `SKT`

Notes:

a. If PMEMBER list is not provided, all the PMEMBERS are restrained by same configuration
b. It is not necessary to provide the restraint locations in sequence as the program sorts them automatically
c. Unless specified, PMEMBER ends are assumed to be Fully Restrained (F)
d. While designing any section of the member, effective restraints are searched on each side of the section along the critical flange
e. The types of restraints applied to the top and bottom flanges at each location determines the effective section restraints. These are outlined in the table below:

Case	Flange	Restraint on a Critical Flange	Restraint on a Non-Critical Flange	Effective Section Restraint
I		U	U	U
II	1	L	Nothing	L
	2	Nothing	L	None
III	1	P or F	Nothing or U	F
	2	Nothing or U	P or F	P
IV	1	PR or FR	Nothing or U	FR
	2	Nothing or U	PR or FR	PR
V	1	L, P or F	L, P, F, FR or PR	F
	2	FR or PR	L, P, F, FR or PR	FR

D11.A.5.2.5 Automated PMEMBER Design Calculations

The NZS3404 PMEMBER Design automates many design calculations, including those required for segment / sub-segment design.

Automated Design Calculations	PMEMBER Design Parameter	Comments
ab compression member section constant per NZS3404 6.3.3.	Not applicable	Calculated from table 6.3.3.
am moment modification factor per NZS3404 5.6.1.1 or Table 5.6.2 depending on if the segment is restrained at on/both ends.	ALM	Calculated based on moments distribution for individual segments and sub-segments.
f_u tensile strength per NZS3404 2.1.2 and AS4100 table 2.1.	FU	Based on nominal steel grade specified using SGR design parameter and element thickness.
fy yield stress per NZS3404 2.1.1 and AS4100 table 2.1.	FYLD	Based on nominal steel grade specified using SGR design parameter and element thickness.
Residual stress category for NZS3404 Table 5.2 and 6.2.4.	IST	Based on section type.
Segment and sub-segment layout for flange unbraced length.	PBRACE	Refer to the Segment or Sub-Segment for Flexural/Flange Buckling for details.
Unbraced length of top and bottom flange for flange buckling.	UNT, UNB	

Automated Design Calculations	PMEMBER Design Parameter	Comments
Segment layout for compression buckling unbraced length.	PBCRES	Refer to the Segment for Compression Buckling for details.
Effective length factor (ke) for compression buckling	KZ, KY	
Unbrace length for compression buckling	LZ, LY	
k_t twist restraint factor as per NZS3404 Table 5.6.3(1).	SKT	Based on effective end restraints for each segment / sub-segment.
k_l load height factor as per NZS3404 Table 5.6.3(2).	SKL, LHT	Based on effective end restraints for each segment / sub-segment, and LHT design parameter.
k_r lateral rotation restraint factor as per NZS3404 Table 5.6.3(3).	SKR	Based on effective end restraints for each segment / sub-segment. This is where the distinction between "F" and "FR", as well as "P" and "PR" is used.

D11.A.5.2.6 Load Height Position

When LHT is set to 1.0 to specify a top flange load height position, STAAD.Pro takes the top to be the positive local y-axis of the member.

Tip: This may not literally be the top flange for say a column or beam with a beta angle. The local member axes can be viewed in the user interface by selecting **Beam Orientation** in the **Diagrams Labels** dialog (or press **<Ctrl+O>**).

To automate kl using NZS3404 Table 5.6.3(2), the longitudinal position of the load also needs to be considered, i.e., as either "within segment" or "at segment end."

To determine which of these applies, the shear forces at the ends of each design segment / sub-segment is considered. If the shear force is found to have the same direction and magnitude at both ends, it is assumed that loads act at the segment end.

If on the other hand, the shear force at each end is found to have different directions or magnitudes, loads are assumed to act within the segment.

Tip: The above method includes an allowance for the self-weight of the member to be considered, as the self-weight always acts through the shear center.

The net sum of the end shears is also used to determine if the load is acting in the positive or negative local member y-axis direction. If LHT is set to 1.0 for top flange loading, the net sum is used to determine whether the top flange loading is acting to stabilize or destabilize the member for lateral torsional buckling. Negative local y-axis net loads act to destabilize the segments / sub-segments, whereas positive local y-axis net loads act to stabilize segments / sub-segments.

D11.A.6 Design Parameters

he design parameters outlined in the following table are used to control the design procedure. These parameters communicate design decisions from the engineer to the program and thus allow the engineer to control the design process to suit an application's specific needs. The design scope indicates whether design parameters are applicable for MEMBER Design, PMEMBER Design, or both.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements, some or all of these parameter values may be changed to exactly model the physical structure.

Table 181: New Zealand Steel Design Parameters

Parameter Name	Default Value	Design Scope	Description
CODE	-		Must be specified as NZS3404 1997 to invoke design per NZS 3404-1997. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
ALM	1.0		Moment modification factor (refer cl. 5.6.1.1) If ALM is 0.0 or not specified, it is automatically calculated based cl.5.6.1.1; otherwise the input value is used.
BEAM	1.0		Design locations: 0 = design only for end moments and those at locations specified by SECTION command. 1 = Perform design for moments at twelfth points along the beam.

Parameter Name	Default Value	Design Scope	Description
DFF	None	Analytical members only	"Deflection Length"/ Maximum Allowable local deflection. See DFF, DJ1, and DJ2 Parameters (on page 1781) See TR.40 Load Envelope (on page 2663) for deflection checks using serviceability load envelopes.
DJ1	Start Joint of member	Analytical members only	Joint No. denoting start point for calculation of "deflection length"
DJ2	End Joint of member	Analytical members only	Joint No. denoting end point for calculation of "deflection length"
DMAX	1000.0 mm		Maximum allowable depth (Applicable for member selection)
DMIN	0.0 mm		Minimum required depth (Applicable for member selection)
DUCT	0		Seismic category of member (sec. 12.2.5): 0 = Non-seismic (section 12 will not be checked) 1 = High ductile 2 = Limited ductile 3 = Nominal ductile 4 = Non-ductile
FU	500 MPa.		Ultimate strength of steel. If not specified, ultimate strength is calculated from SGR as per SGR Parameter (on page 1783).

Parameter Name	Default Value	Design Scope	Description
FYLD	248.0 MPa		Yield strength of steel. If not specified, yield strength is calculated from SGR as per SGR Parameter (on page 1783).
GLD	blank		Gravity load case number. By default, no load case will be selected as gravity load case.
IST	Refer to IST Parameter (on page 1782).		Residual stress category: 1 - SR 2 - HR 3 - CF 4 - LW 5 - HW If not specified, IST is evaluated depending upon shape. (See IST Parameter (on page 1782) for details)
KT	1.0		Correction factor for distribution of forces (refer cl. 7.2)
KY	1.0		K value for general column flexural buckling about the local Y/Z-axis. Used to calculate slenderness ratio. If specified, overrides the value calculated by program from restraint definition (PBCRES).
KZ	1.0		
LHT	0	Physical members only	Load height position as described in Table 5.6.3(2) of NZS3404:1997 0 = at Shear center 1 = At top flange (See LHT Parameter (on page 1782))

Parameter Name	Default Value	Design Scope	Description
LX	Member Length		The distance between partial or full restraints which effectively prevent twist of the section about its centroid. (sec. 8.4.4.1.2)
LY			Length for general column flexural buckling about the local Y/Z-axis. Used to calculate slenderness ratio. If specified, overrides the value calculated by program from restraint definition (PBCRES).
LZ			
MAIN	180.0		A value less than or equal to 1.0 suppresses the slenderness ratio check. checks are not explicitly required per NZS3404. Any value greater than 1.0 is used as the limit for slenderness in compression.
NSC	1.0		Net section factor for compression members = An / Ag (refer cl. 6.2.1)
NSF	1.0		Net section factor for tension members.
PBRACE	None	Physical members only	Refer to PBRACE Parameter (on page 1784) for details on the PBRACE parameter.
PBCRES	None		Refer to PBCRES Parameter (on page 1784) for details on the PBCRES parameter.
RATIO	1.0		Permissible ratio of actual load effect to the design strength.

Parameter Name	Default Value	Design Scope	Description
SGR	0		Steel Grade. 0 = Default (see note) 1 = AS 3679.1 - 350 2 = AS 3679.1 - 300 (default for standard rolled sections) 3 = AS 3679.1 - 250 4 = AS 1163 - C450 5 = AS 1163 - C350 6 = AS 1163 - C250 (default for tube sections) 7 = AS 3678 - 450 8 = AS 3678 - 400 9 = AS 3678 - 350 10 = AS 3678 - WR350 11 = AS 3678 - 300 (default for welded profiles and UPT) **Note:** Refere to SGR Parameter (on page 1783)
SKL	1.0		A load height factor given in Table 5.6.3(2). If not specified or specified as 0.0, will be automatically calculated.
SKR	1.0		A lateral rotation restraint factor given in Table 5.6.3(3). If not specified or specified as 0.0, will be automatically calculated.
SKT	1.0		A twist restraint factor given in Table 5.6.3(1). If not specified or specified as 0.0, will be automatically calculated.

Parameter Name	Default Value	Design Scope	Description
TMAIN	400.0		A value less than or equal to 1.0 suppresses the slenderness ratio check. checks are not explicitly required per NZS3404. Any value greater than 1.0 is used as the limit for slenderness in tension.
TRACK	0		Output detail 0 = report only minimum design results 1 = report design strengths in addition to TRACK 0 output 2 = provide full details of design
TSP	0.0		Spacing between transverse stiffener provided in the web. If any value less than or equal to 0.0 is specified, clear depth of web will be used.
UNB	Member Length		Unsupported length in bending compression of the bottom and top flange respectively for calculating moment resistance. If not equal to member length, overrides the value calculated by program from restraint definition (PBRACE).
UNT	Member Length		

DFF, DJ1, and DJ2 Parameters

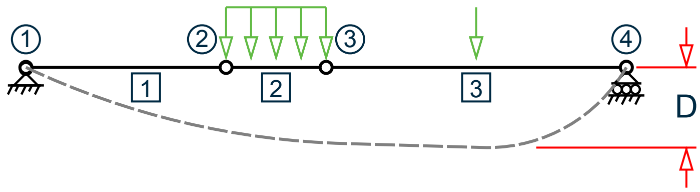
(Analytical members only) Deflection calculations are not applicable to PMEMBERs.

Compute Delta = $\sqrt{(\mathtt{DX2} - \mathtt{DX1})^2 + (\mathtt{DY2} - \mathtt{DY1})^2 + (\mathtt{DZ2} - \mathtt{DZ1})^2}$

Compute Length = distance between DJ1 & DJ2 or, between start node and end node, as the case may be.

- A straight line joining DJ1 and DJ2 is used as the reference line from which local deflections are measured.

For example, refer to the figure below where a beam has been modeled using four joints and three members. The "Deflection Length" for all three members will be equal to the total length of the beam in this case. The parameters `DJ1` and `DJ2` should be used to model this situation. Thus, for all three members here, `DJ1` should be 1 and DJ2 should be 4.



```
PARAMETERS
DFF 300. ALL
DJ1 1 ALL
DJ2 4 ALL
```

D = Maximum local deflection for members 1, 2, and 3.

- If `DJ1` and `DJ2` are not used, "Deflection Length" will default to the member length and local deflections will be measured from original member line.
- It is important to note that unless a `DFF` value is specified, STAAD.Pro will not perform a deflection check. This is in accordance with the fact that there is no default value for `DFF`.

IST Parameter

`IST` parameter is used to specify the residual stress category referred in table 5.2 and 6.2.4.

If `IST` is specified, then that value is used. But if not specified then residual stress category automated from shape of the section according to Note 1 of table 5.2.

Profile	Residual stress Category
Australian UB, UC, Angle, Channel, Tee, SHS, RHS, CHS	HR-hot-rolled or hot-finished
Australian cold formed shapes	CF-cold formed
Any other Australian shape	HW-heavily welded longitudinally
Any shape from any country other than Australia	

LHT Parameter

If the shear force is constant within the segment, longitudinal position of the load is assumed to be at the segment end.

If there is any variation of the shear force and the load is acting downward determined from shear force variation and load height parameter indicates the load is acting on top flange (flange at the positive local y axis) and restraints at the end of the segment is not FU (FRU) or PU (PRU), Kl is taken to be 1.4.

If there is any variation of the shear force and the load is acting upward determined from shear force variation and load height parameter indicates the load is acting on top flange (flange at the positive local y axis) and restraints at the end of the segment is not FU (FRU) or PU (PRU) Kl is taken to be 1.0 as the load acting at the top flange is contributing to stabilize against local torsional buckling.

SGR Parameter

NZS3404 defines the values of steel grades that are used as either normal steel or high grade steel. The following table explains the material values used when either option is specified for a particular shape:

SGR Value	Steel Grade Used	Description
0	Default	AS/NZS 3679.1 300 for rolled sections, AS 1163 C250 for hollow sections (Pipe, Tube, HSS), AS 3678 300 for welded sections (WB, WC, UPT, Tapered)
1	AS/NZS 3679.1 350	
2	AS/NZS 3679.1 300	
3	AS/NZS 3679.1 250	
4	AS 1163 C450	
5	AS 1163 C350	
6	AS 1163 C250	
7	AS 3678 450	
8	AS 3678 400	
9	AS 3678 350	
10	AS 3678 WR350	
11	AS 3678 300	

If a value for the FYLD parameter has been specified, then that value will be used. Otherwise, the SGR value will be used to determine the yield strength and tensile strength values for the steel. based on maximum thickness of the individual elements of the section. Only for shear capacity calculation web thickness is used. Similarly, Tensile Strength is determined either from FU parameter or from SGR parameter.

A check is introduced to see if yield stress is less than 100 MPa or more than 450 MPa or not. If less than 100 MPa, a warning is issued but the yield stress will not be modified. If more than 450 MPa, then also a warning is issued and the yield stress is set to 450 MPa.

Example of Member Design

The following example uses the Member design facility in STAAD.Pro. However, it is strongly recommended to use the Physical member design capabilities for NZS3404:

```
PARAMETER 1
CODE NZS3404 1997
ALB 0.0 MEMBER ALL
ALM 1.13 MEMBER ALL
BEAM 1.0 MEMBER ALL
```

```
DFF 250.0 MEMBER ALL

PBRACE Parameter

`PBRACE {TOP | BOTTOM} f1 r1 f2 r2 … f52 r52 (PMEMB` *`pmember-list`*`)`

where:

f*n* a fraction of the PMEMBER length where restraint condition is being specified. This value is any ratio between 0.0 and 1.0.

r*n* one of the possible restraint condition:

U
F
P
L
FR
PR
C

PBCRES Parameter

`PBCRES {ZZ | YY} f1 r1 f2 r2 … f52 r52 (PMEMB` *`pmember-list`*`)`

where:

f*n* a fraction of the PMEMBER length where restraint condition is being specified. This value is any ratio between 0.0 and 1.0.

r*n* one of the possible restraint condition:

U
T
R
TR

CHECK CODE PMEMBER 20 TO 25
```

Note: Parameters for PMEMBER design must be listed using member numbers. The `ALL` list option may not be used for PMEMBERs.

D11.A.7 Output Format

Results of code checking and member selection are presented in a tabular format. The term `CRITICAL COND` refers to the section of the NZS3404 specification which governs the design.

MEMBER DESIGN OUTPUT FOR PMEMBERPMEMBER for physical member, MEMBER for analytical
member     1
DESIGN Notes
------------

1. (*) next to a Load Case number signifies that a P-Delta analysis has not been
performed for
that particular Load Case; i.e. analysis does not include second-order effects.
2. φ = 0.9 for all the calculations [NZS3404 Table 3.4]
3. (#) next to Young's modulus E indicates that its value is not 200000 MPa as per
NZS3404 1.4.

DESIGN SUMMARY
--------------

D12. Norwegian Codes

D12.A. Norwegian Codes - Steel Design per NS 3472 / NPD

STAAD.Pro is capable of performing steel design based on the Norwegian code NS 3472 *Steel structures. Design rules* (3rd Edition) and NPD 1993 *Veiledning om utforming, beregning og dimensjonering av stalkonstruksjoner. Sist enderet 1.* (*Guidance on the design, calculation and dimensioning of figures constructions. Revision 1*).

Design of members per NS 3472 / NPD requires the *STAAD ECC Super Code* SELECT Code Pack.

D12.A.1 General Notes

This user manual presents a description of the design basis, parameters and theory applied to STAAD.Pro for performing code checks according to NS 3472 ref. [1] and NPD ref. [5]. The code checks include:

- stability check (buckling)
- lateral buckling check
- yield check (von Mises)
- stability check including local plate buckling of un-stiffened pipe walls according to NPD

The code check is available for the following cross-section types:

- wide flange profiles (HEA, HEB, IPE etc.)
- pipe (OD xx ID xx)
- tube (RHS, HUP)
- channel
- angle type (only RA)
- rectangular massive box (prismatic)

- user table (wide flange, I-sections, tapered I, tube, channel and RA angle)

The code check is *not* available for the following cross-section types:

- Double angles
- Tapered tubes
- Prismatic sections with too few section parameters defined
- Other sections that are not in the "available" list above

Please note the following:

- NS 3472 and NPD code checking covered in this document are available through two separate STAAD.Pro Code check packages.
- This document is not a lecture in use of NS 3472 or NPD. This document explains how, and which parts of, the Norwegian steel codes that have been implemented in STAAD.Pro.
- When L-sections are used, the Code Check requires RA angle definition.
- Weld design is not included in the Norwegian code checks.
- The prismatic section defined in the code check (rectangular massive box) is not identical to the general prismatic profile defined in the STAAD.Pro analysis package.

EDR does not accept any liability for loss or damage from or in consequence for use of the program.

D12.A.1.1 Nomenclature

NS - refers to NS 3472 ref. [1]

NS2 - refers to NS 3472 ref. [6]

NPD - refers to NPD94 ref. [5]

D12.A.2 Basis for Code Checking

This section presents general information regarding the implementation of the Norwegian codes of practice for structural steel design. This manual describes the procedures and theory used for both NS and NPD.

In general NS is used for all cross sections and shapes listed in section 1 of this manual. An exception is the treatment and check of pipe members in framed structures. NS does not give specific details about the treatment of pipes. Section 3.4 explains how this is adopted when NS is selected for code checking.

The NPD however have a more thorough check of pipe members, and consider the effect of local buckling of the pipe wall in conjunction with the stability check. In addition, the NPD code gives joint capacity formulae for brace to chord connections for pipe members.

The design philosophy and procedural logistics are based on the principles of elastic analysis and ultimate limit state design. Two major failure modes are recognized:

- failure by overstressing
- failure by stability considerations

The following sections describe the salient features of the design approach. Members are proportioned to resist the design loads without exceeding the characteristic stresses or capacities and the most economic section is selected on the basis of the least weight criteria. It is generally assumed that the user will take care of the detailing requirements like the provision of stiffeners and check the local effects like flange buckling, web crippling, etc.

You are allowed complete control over the design process through the use of the parameters listed in Table 2.1. Default values of parameters will yield reasonable results in most circumstances. However, the user should control the design and verify results through the use of the design parameters.

D12.A.2.1 Calculation of Forces and Bending Moments

Elastic analysis method is used to obtain the forces and moments for design. Analysis is done for the primary loading conditions and combinations provided by the user. The user is allowed complete flexibility in providing loading specifications and using appropriate load factors to create necessary load combinations.

D12..A.2.2 Members with Axial Forces

For tension only members, axial tension capacity is checked for the ultimate limit stress. For compression members, axial compression capacity is checked in addition to lateral buckling and ultimate limit stress. The largest slenderness ratio (λ) shall not be greater than 250 according to NS 11.7 Stability is checked as per the procedure of NS 12.3. The buckling curves of NS fig. 3 have been incorporated into the STAAD.Pro code check. The coefficient α (as per NS Table 10) can be specified in both directions through the use of parameters CY and CZ. In the absence of parameters CY and /or CZ, default a- value will be according to NS table 11.

D12.A.2.3 Members with Axial Force and Bending Moments

For compression members with bending, interaction formulae of NS table 12.3.4.2 are checked for appropriate loading situation. All compression capacities are calculated per the procedure of NS 12.3.

The equivalent moment factor β is calculated using the procedure of NS table 12. Two different approaches are used depending upon whether the members can sway or not. Conditions for sidesway and transverse loading can be specified through the use of parameters SSY and SSZ. For members that cannot sway, without transverse loading, coefficients b are calculated and proper dimensioning moments are used in the interaction formulae.

D12.A.2.4 Lateral Buckling

Lateral torsional buckling is checked as per the procedure of NS 12.3.4. The procedure for calculation of ideal buckling moment for sections with two axis of symmetry has been implemented. The coefficient can be provided by the user through the use of parameter CB. In the absence of CB, a value of 1.0 will be used. Torsional properties for cross sections (torsional constant and warping constant) are calculated using formulae from NS 3472. This results in slightly conservative estimates of torsional parameters. The program will automatically select the maximum moment in cases where Mvd is less than Mzd.

D12.A.2.5 Von Mises Yield Criterion

Combined effect of axial, bending, horizontal/vertical shear and torsional shear stress is calculated at 13 sections on a member and up to 9 critical points at a section. The worst stress value is checked against yield stress divided by appropriate material factor. The von Mises calculates as:

$$\sigma_j = \sqrt{(\sigma_x + \sigma_{by} + \sigma_{bz})^2 + 3(\tau_x + \tau_y + \tau_z)^2} \le \frac{f_y}{\gamma_m}$$

D12.A.2.6 Material Factor and Nominal Stresses

The design resistances are obtained by dividing the characteristic material strength by the material factor.

NS 3472

The material factor default value is 1.10. Other values may be input with the MF parameter. The nominal stresses should satisfy

$$\sigma_j \le \frac{f_y}{\gamma_m} = f_d$$

NPD

The general requirement is according to NPD 3.1.1. For stability the NPD 3.1.1 and 3.1.3 requires that the structural coefficient is considered.

$$S_d \le f_{kd} = \frac{f_k}{\gamma_m \cdot \gamma_{mk}(S_d)}$$

Where:

S_d = reference stress or load effect resultant
f_k = characteristic capacity
f_{kd} = design capacity
γ_m = material coefficient
γ_{mk} = structural coefficient

γ_m is default set to 1.10.

γ_{mk} shall be equal to 1.0 for frames. For pipe members γ_{mk} is a function of the reduced slenderness. In the STAAD.Pro implemented NPD code this is calculated automatically.

D12.A.2.7 Code Checking According to NPD

The following parts of Chapter 3 in the NPD guidelines have been implemented.

a. Control of nominal stresses. (NPD 3.1.2).

b. Buckling of pipe members in braced frames, including interaction with local shell buckling (NPD 3.2.2, 3.2.3).

c. Buckling of un-stiffened closed cylindrical shells, including interaction with overall column buckling (NPD 3.4.4, 3.4.6, 3.4.7 and 3.4.9).

d. Joint capacity check for gap as well as for overlap joints (NPD 3.5.2).

Check b) provides the unity check based on the beam-column buckling interaction formulae in NPD 3.2.2. The interaction between global and local buckling due to axial load and hydrostatic pressure is accounted for through computation of an axial characteristic capacity to replace the yield stress inn the beam-column buckling formulae.

Note: Check b) handles members subjected to axial loads, bending moments and hydrostatic pressure. In other words, check b) assumes that stresses resulting from shear and torsion are of minor importance, e.g., in jacket braces.

Check c) provides the unity check based on the stability requirement for un-stiffened cylindrical shells subjected to axial compression or tension, bending, circumferential compression or tension, torsion or shear. The unity check refers to the interaction formulae in NPD 3.4.4.1. The stability requirement is given in NPD 3.4.7.

Norwegian Codes - Steel Design per NS 3472 / NPD

STAAD.Pro performs a stability check on aluminum alloys according to buckling curve in ECCS (European recommendation for aluminum ally structures 1978). It is possible to select heat-treated or non heat-treated alloy from the parameter list in the STAAD.Pro input file.

For heat-treated use CY = CZ = 0.1590, and for non heat-treated use CY = CZ = 0.2420.

Tracks 1.0 and 9.0 print buckling curve H for heat-treated, and buckling curve N for non neat-treated. The yield check is the same as for steel.

D12.A.3 Design Parameters

Design parameters communicate specific design decisions to the program. They are set to default values to begin with and may be altered to suite the particular structure.

Table 182: Design Parameters for Norwegian Steel design code

Parameter Name	Default Value	Description	Reference
CODE	none	Must be specified as either NS3472 for NS or NPD for NPD (NOR may also be used for both). Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).	

Parameter Name	Default Value	Description	Reference
BEAM	0.0	Parameter `BEAM 1.0 ALL` tells the program to calculate von Mises at 13 sections along each member, and up to 8 points at each section. (Depending on what kind of shape is used.) **Note:** Must be set to 1.0	Sec. NS 12.2.2
BY	1.0	Buckling length coefficient, β for weak axis buckling (y-y) (NOTE: BY > 0.0)	Fig. NS 3 Sec. NS 12.3
BZ	1.0	Buckling length coefficient, β, for strong axis buckling (z-z) (NOTE: BZ > 0.0)	Fig. NS 3 Sec. NS 12.3
CB	1.0	Lateral buckling coefficient, Y. Used to calculate the ideal buckling moments, M_{vi}	Sec. NS2 A5.5.2 Fig. NS2 A5.5.2a)-e)
CMY	1.0	Water depth in meters for hydrostatic pressure calculation for pipe members	Valid for the NPD code only
CMZ	0.49	α_{LT} for sections in connection with lateral buckling	Sec. NS 12.3.4 Fig. NS 6.
CY CZ	Default see NS 3472	Buckling curve coefficient, a about local z-axis (strong axis). Represent the a, a0, b, c, d curve.	Fig. NS 3 Sec. NS 12.2 NS Table 11
DMAX	100.0 [cm]	Maximum allowable depth of steel section.	
DMIN	0.0 [cm]	Minimum allowable depth of steel section.	
FYLD	235	Yield strength of steel, fy (St37) [N/mm^2]	Tab. NS 3

Parameter Name	Default Value	Description	Reference
MF	1.1 (NS3472) 1.15 (NPD)	Material factor / Resistance factor, γ_m	Sec. NS 10.4.2 Sec. NPD 3.1
RATIO	1.0	Permissible ratio of the actual to allowable stresses.	Sec. NS 12.3.4.2
SSY	0.0	0.0 = No sidesway. β calculated. > 0.0 = Sidesway in local y-axis weak axis β_M=SSY	Sec. NS 12.3.4 Tab. NS 12 Sec. NPD 3.2.1.4
SSZ	0.0	0.0 = No sidesway. β calculated. > 0.0 = Sidesway in local y-axis weak axis β_M	Sec. NS 12.3.4 Tab. NS 12 Sec NPD 3.2.1.4
TRACK	0.0	Controls the level of detail in the output: 0.0 = Suppress critical member stresses. 1.0 = Print all critical member stresses, i.e., DESIGN VALUES 2.0 = Print von Mises stresses. 9.0 = Large output, 1 page for each member. Refer to D12.A.8 Tabulated Results (on page 1823) for complete list of available TRACKs and print examples.	
UNL	Member length	Effective length for lateral buckling calculations (specify buckling length). Distance between fork supports or between effective side supports for the beam	Sec. NS 12.3

The parameter CMY will, when given with negative value, define an inside pressure in pipe members. The pressure corresponds to given water depth in meters.

The parameter CB defines the φ value with respect to calculation of the ideal lateral buckling moment for single symmetric wide flange profiles, ref. NS app. 5.2.2.

D12.A.3.1 Example

D12.A.4 Stability Check According to NS 3472

The stability check is based on the assumption that both ends of the member are structural nodes. Buckling lengths and results for member with joints between the structural nodes have to be evaluated in each separate case.

Effects from local buckling or external hydrostatic pressure on pipes and tubes are not included.

The general stability criteria is: (ref. NS 12.3)

D12.A.4.1 Buckling

$$n_{max} + k^{z} \times m_{z} + k_{y} \times m_{y} \leq 1$$

D12.A.4.2 Lateral Buckling

$$\frac{n}{x_y} + k_{LT}\frac{m_z}{x_{LT}} + k_y m_y \leq 1$$

Where:

$i = z,y$

$n_{max} = n/\chi_{min}$

$n = N_f/N_d$

$\chi_{min} = \min(\chi_z,\chi_y)$

$\chi_i = N_{kd,i}/N_d$

$$k_i = 1 - \mu_i \frac{n}{\chi_i \gamma_m} \le 1.5$$

$\mu_i = {}_i(2 \cdot \beta_{Mi} - 4) \le 0.9$

β_{Mi} ref. NS Tab. 12

$$k_{LT} = 1 - \mu_{LT} \frac{n}{\chi_y \gamma_m} \le 1.0$$

$\mu_{LT} = 0.15({}_y \cdot \beta_M - 1) \le 0.9$

${}_i = \lambda_i/\lambda_1$

$\lambda_i = L_{ki}/i_i$

$$\lambda_i = \pi \sqrt{\frac{E}{f_y}}$$

$$\chi_i = \frac{1}{\phi + \sqrt{\phi^2 - \bar{\lambda}^2}}$$

$\varphi = 0.5[1 + \alpha(- 0.2) + {}^2]$

α ref. NS Tab 10 & 11

$$\chi_{LT} = \frac{1}{\phi_{LT} + \sqrt{\phi_{LT}^2 - \bar{\lambda}_{LT}^2}}$$

$$\phi_{LT} = 0.5\left[1 + \alpha\left(\bar{\lambda}_{LT} - 0.4\right) + \bar{\lambda}_{LT}^2\right]$$

α ref. NS sec. 12.3.4.1

$$\bar{\lambda}_{LT} = \sqrt{\frac{W_z f_z}{M_{cr}}}$$

$M_{cr} = \psi \cdot M_{vio}$

ψ ref. NS2 A5.5.2 Sect. a - d

$$M_{vio} = \frac{\pi}{L} \sqrt{E I_z G I_T} \sqrt{1 + \frac{\pi^2}{L^2} \frac{E C_w}{G I_T}}$$

D12.A.4.3 Determination of β_z and β_y

The equivalent moment factor β (for z and y) is calculated dependent on moment distributions as shown in the following table:

Table 183: β for different moment distributions

Moment diagram	β_M (β_{LT})
	$\beta_{M\,\psi} = 1.8 - 0.7\psi$
 	$\beta_{M\,0} = 1.3$ $\beta_{M\,0} = 1.4$
   	$\beta_M = \beta_{M,\psi} + \frac{M_0}{\Delta M}\left(\beta_{M,0} - \beta_{M,\psi}\right)$ $M_0 = \lvert M_{max} \rvert$ due to transverse load only $\Delta M = \lvert M_{max} \rvert$ if the moment has the same sign $\Delta M = \lvert M_{max} \rvert + \lvert M_{min} \rvert$ if the moment changes sign

The user can override the calculated factor with the following parameters:

β_y=SSY

β_z=SSZ

D12.A.4.4 Lateral buckling

The Ideal lateral buckling moment is calculated according to NS2 A5.5.2

$$M_{vi} = \psi M_{vio} = \psi L \ 95 \frac{E}{L} \sqrt{I_y I_x} \sqrt{1 + \frac{\pi^2}{L^2} \frac{2.6 C_w}{I_x}}$$

concern double symmetric cross sections where y is given in NS fig. A5.5.2, (input parameter CB), L = member length for lateral buckling (input parameter UNL), Cw and Ix , see section 5.

For single symmetric cross sections, the ideal lateral buckling moment is

$$M_{vix} = \phi \frac{\pi^2 E I_y}{L^2} \sqrt{\left(\frac{5a}{\pi^2} + \frac{r_x}{3} - y_s\right)^2 + C^2} - \left(\frac{5a}{\pi^2} + \frac{r_x}{3} - y_s\right)$$

Where:

$$C^2 = \frac{C_w + 0.039 L^2 I_T}{I_y}$$

α = distance from profile CoG to point where the load is acting, assumed to be on top flange.

The φ parameter (ref NS fig. A5.5.2.g) is controlled by the input parameter CB.

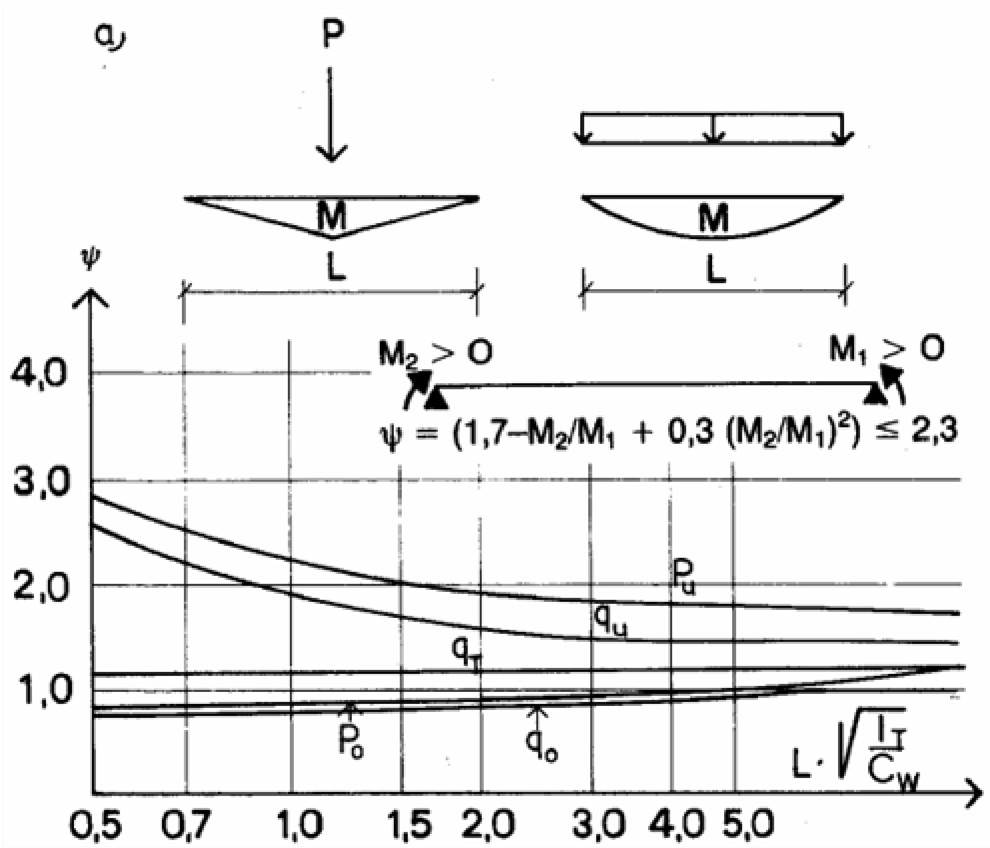

Figure 180: ψ-coefficients for a simple span beam

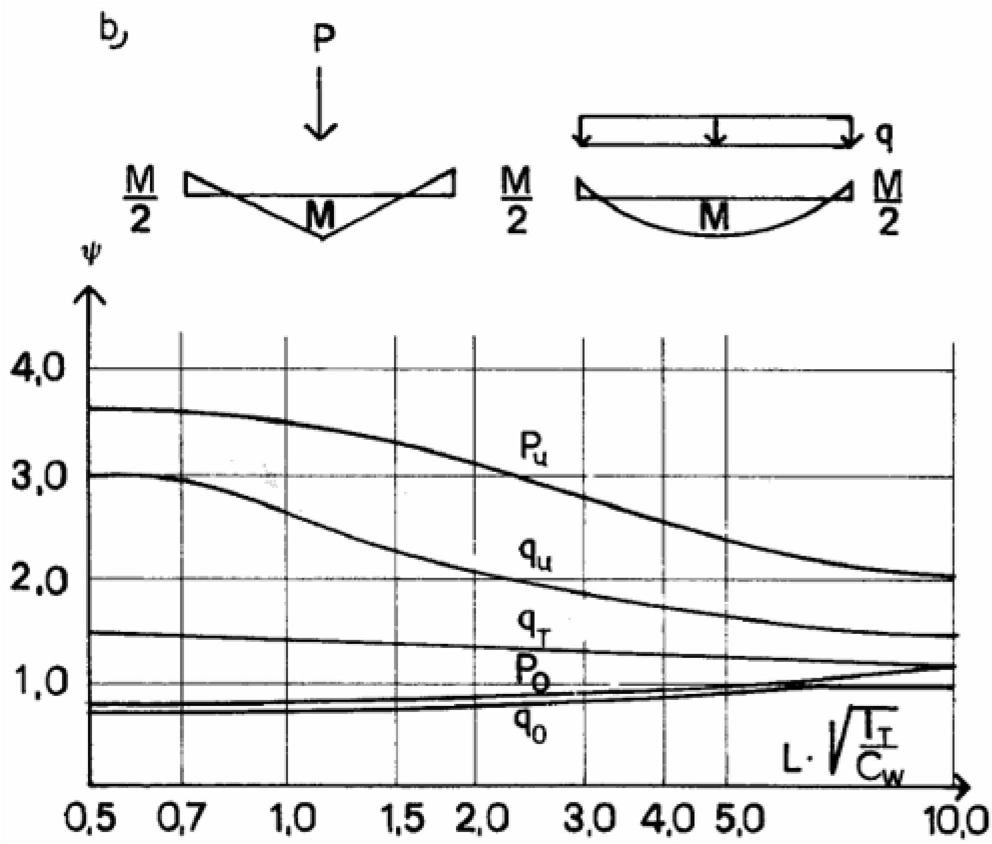

Figure 181: ψ-coefficients for a partially restrained beam

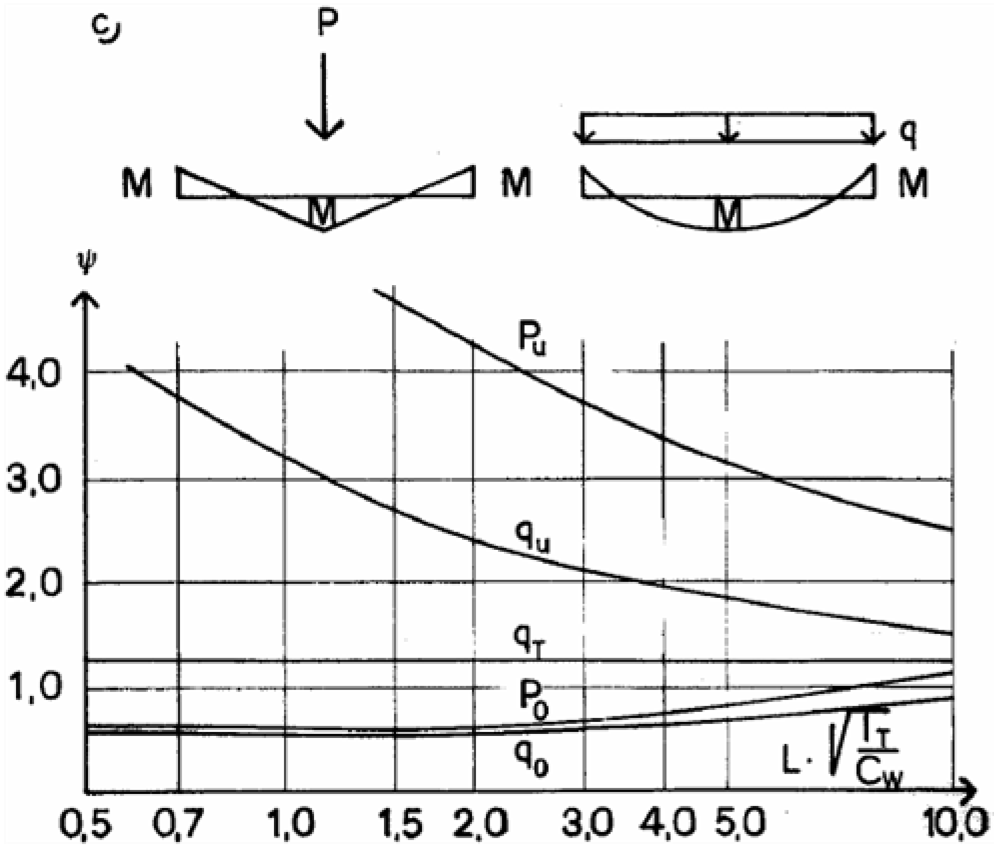

Figure 182: ψ-coefficients for a fully restrained beam

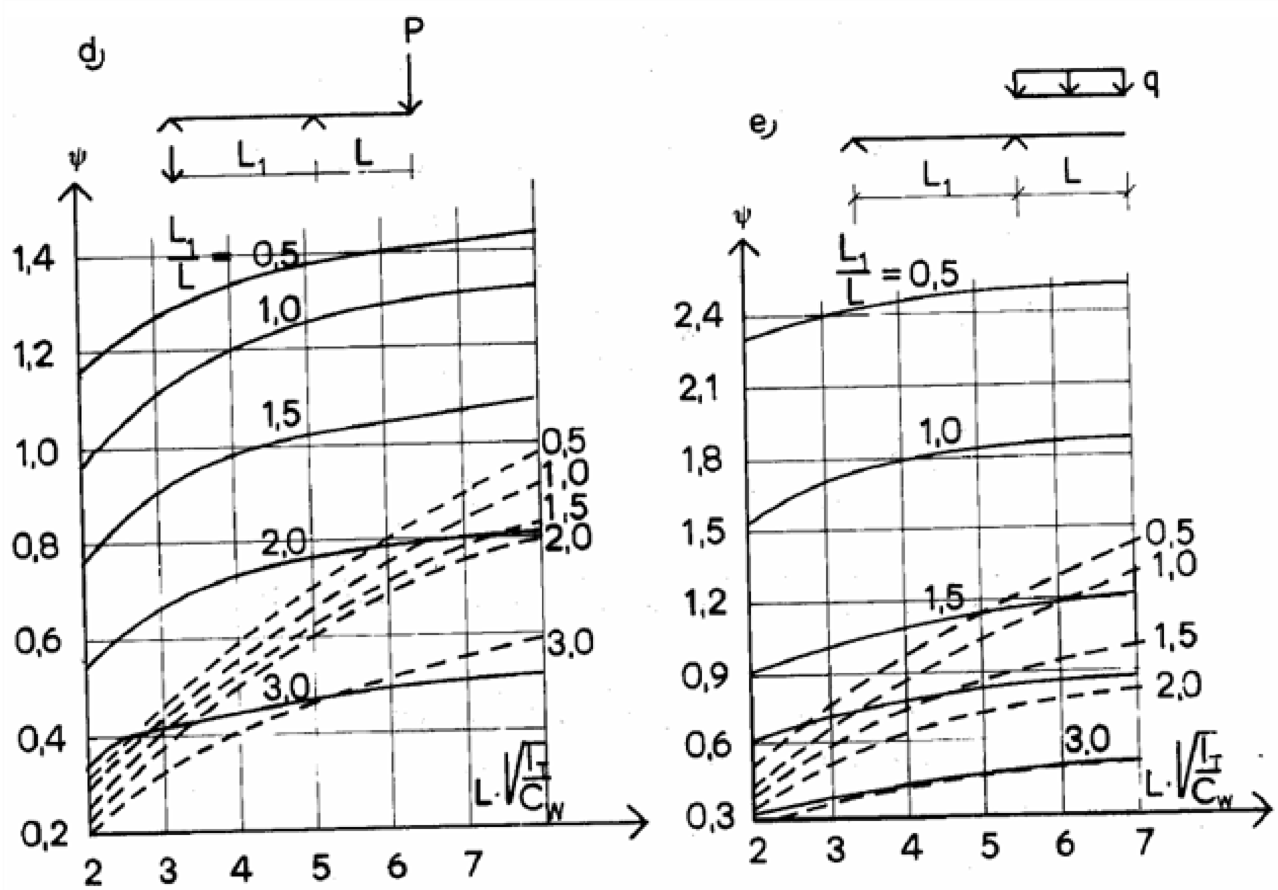

Figure 183: ψ-coefficients for the cantilevered beam with single loads and distributed loads. Dashed curves apply load on the surface.

D12.A.4.5 Stability check of pipe members

The stability criteria applied for members with pipe cross section is:

$$IR = \frac{N}{N_{kd}} + \sqrt{\left[\frac{\overline{M}_z}{M_d\left(1 - \frac{N}{N_{Ezd}}\right)}\right]^2 + \left[\frac{\overline{M}_y}{M_d\left(1 - \frac{N}{N_{Eyd}}\right)}\right]^2} \leq 1.0$$

Where:

$$\frac{N}{N_{kd}} = \max\left(\frac{N}{N_{kzd}}, \frac{N}{N_{kyd}}\right)$$

$\overline{M}_z$ and $\overline{M}_z$ are given in NS 5.4.2.

For the print output option `TRACK 9.0` $K_E \equiv 1.0$ and $M_{vd} \equiv M_d$

D12.A.4.6 Angle profiles type RA (reverse angle)

The axial contribution to the total interaction ratio is checked according to the modified EECS-method, see NS A5.4.

The stability criterion is:

$$IR = \frac{N}{N_{kd}} + \frac{\overline{M}_y}{M_{yd}\left(1 - \frac{N}{N_{Eyd}}\right)} + \frac{\overline{M}_z}{M_{zd}\left(1 - \frac{N}{N_{Ezd}}\right)} \leq 1.0$$

Where:

$$\frac{N}{N_{kd}} = \max\left(\frac{N}{N_{kzd}}, \frac{N}{N_{kyd}}\right)$$

N_{kyd} and N_{kzd} are found from NS 3472 fig. 5.4.la C-curve for y- and z-axis, respectively.

For $\bar{\lambda} \leq \sqrt{(2)}$

$$_{eff} = 0.60 + 0.57$$

For $\bar{\lambda} > \sqrt{(2)}$

$$_{eff} =$$

Where:

$$\bar{\lambda} = \frac{\lambda_k}{\pi}\sqrt{\frac{f_y}{E}}$$

$$\lambda_k = l_k/i$$

$$i = \sqrt{I / A}$$

Possible lateral buckling effects and torsional buckling (NS A5.4.5) is *not* included in the code check. This has to be evaluated by the user separately.

D12.A.4.7 Stability check of members with tapered section

Stability of members with tapered cross section is calculated as described in section 3.1. The cross section properties used in the formulae are calculated based on the average profile height. (i.e., I_z, I_y values are taken from the middle of the member.)

D12.A.4.8 Lateral buckling for tension members

When compressive stress caused by large bending moment about strong axis is greater than tension stress from axial tension force, lateral buckling is considered as defined below.

$$\sigma_a = N/A \text{ (+ tension, - compression)}$$

$$\sigma_{bz} = \pm M_z/W_z$$

$$M_{warp} = | \sigma_a + \sigma_b | W_z \text{ for } \sigma_a + \sigma_b < 0 \text{ (compression)}$$

$$IR = M_{warp}/M_{vd} + M_{y,max}/M_{yd} \leq 1.0$$

D12.A.5 Stability Check According to NPD

D12.A.5.1 Buckling of pipe members

Tubular beam-columns subjected to compression and lateral loading or end moments shall be designed in accordance with NPD 3.2.2

$$\sigma_c \gamma_{mk} + B\sigma_b^* + \sqrt{(B_z \sigma_{bz})^2 + (B_y \sigma_{by})^2} \le \frac{f_y}{\gamma_m}$$

Where:

σ_c = N/A = axial compressive stress
ν_{mk} = structural coefficient
B = bending amplification factor = 1/ (1 - μ), B is taken as the larger of B_z and B_y
B_z = bending amplification factor about the Z-axis
B_y = bending amplification factor about the Y-axis
$\mu = \sigma_c / f_E$
$f_E = \frac{\pi^2 E}{l_k^2} i^2$
$i = \sqrt{I / A}$
$\sigma_b^* = \sigma_c \left(\frac{f_y}{f_k} - 1 \right) \left(1 - \frac{f_k}{\gamma_m f_E} \right)$
l_k = kl
k = effective length factor
f_k = characteristic buckling capacity according to NS fig. 5.4.1a, curve A.

D12.A.5.2 Interaction with local buckling, NPD 3.2.3

If the below conditions are not satisfied, the yield strength will be replaced with characteristic buckling stress given in NPD 3.4.

a. members subjected to axial compression and external pressure

$$\frac{d}{t} \le 0.5 \sqrt{\frac{E}{f_y}}$$

b. members subjected to axial compression only

$$\frac{d}{t} \le 0.1 \frac{E}{f_y}$$

D12.A.5.3 Calculation of buckling resistance of cylinders

The characteristic buckling resistance is defined in accordance with NPD 3.4.4

$$f_k = \frac{f_y}{\sqrt{1 + \lambda^4}}$$

Where:

$$\lambda^2 = \frac{f_y}{\sigma_j} \left(\frac{\sigma_{ao}}{f_{ea}} + \frac{\sigma_{b0}}{f_{eb}} + \frac{\sigma_{p0}}{f_{ep}} + \frac{\tau}{f_{e\tau}} \right)$$

$$\sigma_j = \sqrt{(\sigma_a + \sigma_b)^2 - (\sigma_a + \sigma_b)\sigma_p + \sigma_p^2 + 3\tau^2}$$

$\sigma_a \ge 0$ when $\sigma_{a0} = 0$
$\sigma_a < 0$ when $\sigma_{a0} = -\sigma_a$
$\sigma_b \ge 0$ when $\sigma_{b0} = 0$

$\sigma_b < 0$ when $\sigma_{b0} = -\sigma_b$
$\sigma_p \geq 0$ when $\sigma_{p0} = 0$
$\sigma_p < 0$ when $\sigma_{p0} = \sigma_p$
σ_a = design axial stress in the shell due to axial forces (tension positive)
σ_b = design bending stress in the shell due to global bending moment (tension positive)
$\sigma_p = \sigma_\Theta$ = design circumferential stress in the shell due to external pressure (tension positive)
τ_S = design shear stress in the shell due to torsional moments and shear force.
f_{ea}, f_{eb}, f_{ep} and f_{et} are the elastic buckling resistances of curved panels or circular cylindrical shells subjected to axial compression forces, global bending moments, lateral pressure, and torsional moments and/or shear forces respectively.

D12.A.5.4 Elastic buckling resistance for un-stiffened, closed cylinders

The elastic buckling resistance for un-stiffened closed cylinders according to NPD 3.4.6 is:

$$f_e = k \frac{\pi^2 E}{12\left(1 - \nu^2\right)} \left(\frac{t}{l}\right)^2$$

where k is a buckling coefficient dependent on loading condition, aspect ratio, curvature, boundary conditions, and geometrical imperfections. The buckling coefficient is:

$$k = \psi \sqrt{1 + \left(\frac{p\xi}{\psi}\right)^2}$$

The values of ψ, ζ, and p are given in Table 4.1 for the most important loading cases.

Table 184: Table 4.1 Buckling coefficients for un-stiffened cylindrical shells

	ψ	ζ	p
Axial or Bending stress	1	$0.702\ Z$	$0.5\left(1 + \frac{r}{150t}\right)^{-0.5}$
Torsion and shear force	5.34	$0.856\ Z0.75$	0.6
Lateral pressure	4	$1.04\ Z0.5$	"
Hyrdostatic pressure	2	$1.04\ Z\ 0.5$	"

The curvature parameter is defined by

$$Z = \frac{1^2}{rt}\sqrt{1 - \nu^2}$$

For long shells the elastic buckling resistance against shear stresses is independent of shell length. For cases with:

$$\frac{1}{r} > 3.85\sqrt{\frac{r}{t}}$$

the elastic buckling resistance may be taken as:

$$f_{ep} = 0.25E\left(\frac{t}{r}\right)^2$$

D12.A.5.5 Stability requirements

The stability requirement for curved panels and un-stiffened cylindrical shells subjected to axial compression or tension, bending, circumferential compression or tension, torsion or shear is given by NPD 3.4.7:

$$\sigma_j < f_{kd}$$

where the design buckling resistance is

$$f_{kd} = \frac{f_k}{\gamma_m \gamma_{mk}}$$

D12.A.5.6 Column buckling, NPD 3.4.9

For long cylindrical shells it is possible that interaction between shell buckling and overall column buckling may occur because second-order effects of axial compression alter the stress distribution as compared to that calculated from linear theory. It is necessary to take this effect into account in the shell buckling analysis when the reduced slenderness of the cylinder as a column exceeds 0,2 according to NPD 3.4.4.1.

$\sigma_b$shall be increased by an additional compressive stress which may be taken as:

$$\Delta\sigma = B\sigma_a\left(\frac{f_y}{f_k} - 1\right)\left(1 - \frac{f_k}{f_e}\right) + \left(B - 1\right)\sigma_b$$

Where:

$$\bar{B} = \frac{1}{1 - \mu}$$

$$\bar{\lambda} = \sqrt{f_y / f_e}$$

$$f_e = \frac{\pi^2 E}{\lambda^2}$$

λ = slenderness of the cylinder as a column.

B, σ_a, σ_b, and μ are calculated in accordance with NPD 3.2.2.

D12.A.6 Yield Check

The yield check is performed at member ends and at 11 equally spaced intermediate sections along the member length.

At each section the following forces are applied:

- F_x max. axial force along member
- F_y actual shear in local y-direction at section
- F_z actual shear in local z-direction at section
- M_x max. torsional moment along member
- M_y actual bending about local y-axis at section
- M_z actual bending about local z-axis at section

For all profiles other than angle sections absolute values of the stresses are used. For

double symmetric profiles there will always be one stress point.

The stresses are calculated in several stress points at each member section. At each stress point the von Mises stress is checked as follows:

$$\sigma_j = \sqrt{\sigma_{tot}^2 + \sigma_p^2 - \sigma_{tot} \cdot \sigma_p + 3(\tau_x + \tau_y + \tau_z)^2} \le \frac{f_y}{\gamma_m}$$

Where:

$$\sigma_{tot} = | \sigma_x + \sigma_{by} + \sigma_{bz} |$$

σ_p stress from hydrostatic pressure.

D12.A.6.1 Double symmetric wide flange profile

The von Mises stress is checked at four stress points as shown in figure below.

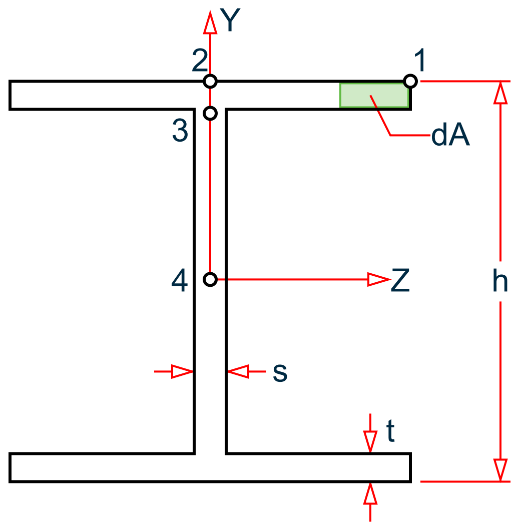

Figure 184: Stress points checked for a wide flange section

Section Properties

A_x , I_x , I_y, and I_z are taken from STAAD.Pro database
$A_y = h \times s$ Applied in STAAD.Pro print option PRINT MEMBER STRESSES

$$A_z = (2/3) \cdot b \cdot t \cdot 2$$

$$\tau_y = F_y/A_y$$

$$\tau_z = F_z/A_z$$

A_y and A_z are not used in the code check

$C_w = \frac{(h - t)^2 b^3 t}{24}$ ref. NS app. C3

$$T_y = dA \times z$$

$$T_z = dA \times y$$

Stress calculation

General stresses are calculated as:

$$\sigma = \sigma_x + \sigma_{by} + \sigma_{bz} = \frac{F_x}{A_x} + \frac{M_y}{I_y}z + \frac{M_z}{I_z}y$$

$$\tau = \tau_x + \tau_y + \tau_z = \frac{M_x}{I_x}c + \frac{V_y T_z}{I_z t} + \frac{V_z T_y}{I_y t}$$

Where the component stresses are calculated as shown in the following table:

Table 185: Stress calculations at selected stress points for a wide flange section

$h_1 = ½(h - 2 t)$

$h_2 = ½ (h - t)$

<table>
<tr><th>Point No</th><th>σ_x</th><th>σ_{by}</th><th>σ_{bz}</th><th>τ_x</th><th>τ_y</th><th>τ_z</th></tr>
<tr><td>1</td><td rowspan="4">$\frac{F_x}{A_x}$</td><td>$\frac{M_y}{I_y}\frac{b}{2}$</td><td rowspan="2">$\frac{M_z}{I_z}\frac{b}{2}$</td><td rowspan="2">$\frac{M_x}{I_x}t$</td><td>0</td><td>0</td></tr>
<tr><td>2</td><td>0</td><td>$\frac{F_y}{I_z}\frac{bth_2}{2t}$</td><td>$\frac{F_z}{I_y}\frac{tb^2}{8t}$</td></tr>
<tr><td>3</td><td>0</td><td>$\frac{M_z}{I_z}h_1$</td><td rowspan="2">$\frac{M_x}{I_x}s$</td><td>$\frac{F_y}{I_z}\frac{bth_2}{s}$</td><td>0</td></tr>
<tr><td>4</td><td>0</td><td>0</td><td>$\frac{F_y}{I_z}\frac{\left(bth_2 + 0.5h_1^2 s\right)}{s}$</td><td>0</td></tr>
</table>

In general wide flange profiles are not suitable for large torsional moments. The reported torsional stresses are indicative only. For members with major torsional stresses a separate evaluation has to be carried out. Actual torsional stress distribution is largely dependent on surface curvature at stress point and warping resistance.

D12.A.6.2 Single symmetric wide flange profile and tapered section

The von Mises stress is checked at nine stress points as shown in figure below.

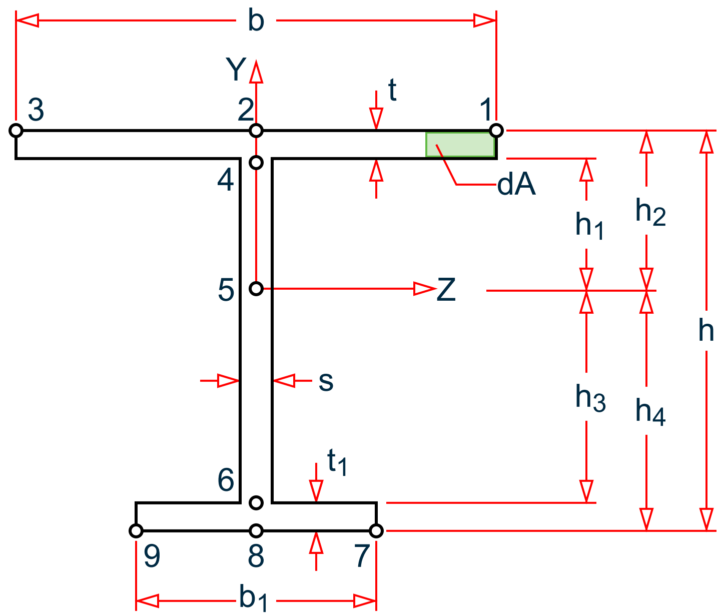

Figure 185: Stress points checked for a singly symmetric wide flange section

Section properties

A_x, I_x , I_y, and I_z are taken from STAAD.Pro database, except for tapered sections where these values are calculated for each section checked. (i.e., Iz, Iy values are taken from the middle of the member.)

$$A_z = 2/3(b \cdot t + b_1 \cdot t_1)$$

$$C_w = \frac{b^3 t \cdot b_1^3 t_1 (h - t/2 - t_1/2)^2}{12\left(b^3 t + b_1^3 t_1\right)}$$ ref. NS app. C3

Refer to D12.A.6.1 Double symmetric wide flange profile (on page 1808) for equations used in section property calculations.

Stress calculation

Refer to D12.A.6.1 Double symmetric wide flange profile (on page 1808) for equations used in general stress calculations.

Where the component stresses are calculated as shown in the following table:

Table 186: Stress calculations at selected stress points for a singly symmetric wide flange section

Point No	σ_x	σ_{by}	σ_{bz}	τ_x	τ_y	τ_z
1	$\frac{F_x}{A_x}$	$-\frac{M_y}{I_y}\frac{b}{2}$	$\frac{M_z}{I_z}h_2$	$\frac{M_x}{I_x}t$	0	0
2		0			$\frac{F_y}{I_z}\frac{bt(h_1 + t/2)}{2t}$	$\frac{F_z}{I_y}\frac{tb^2}{8t}$

Point No	**σ_x**	**σ_{by}**	**σ_{bz}**	**τ_x**	**τ_y**	**τ_z**
3		$\frac{M_y}{I_y}\frac{b}{2}$			0	0
4		0	$\frac{M_z}{I_z}h_1$	$\frac{M_x}{I_x}s$	$\frac{F_y}{I_z}\frac{bt(h_1+t/2)}{s}$	0
5		0	0		$\frac{F_y}{I_z}\frac{bt(h_1+t/2)+0.5h_1^2 s}{s}$	0
6		0	$-\frac{M_z}{I_z}h_3$		$\frac{F_y}{I_z}\frac{b_1t_1(h_3+t_1/2)}{s}$	0
7		$-\frac{M_y}{I_y}\frac{b_1}{2}$	$-\frac{M_z}{I_z}h_4$	$\frac{M_x}{I_x}t$	0	0
8		0			$\frac{F_y}{I_z}\frac{b_1t_1(h_3+t_1/2)}{2t_1}$	$\frac{F_z}{I_y}\frac{t_1b^2}{8t_1}$
9		$\frac{M_y}{I_y}\frac{b_1}{2}$			0	0

In general wide flange profiles are not suitable for large torsional moments. The reported torsional stresses are indicative only. For members with major torsional stresses a separate evaluation has to be carried out. Actual torsional stress distribution is largely dependent on surface curvature at stress point and warping resistance.

D12.A.6.3 Pipe profile

The von Mises stress is checked in three stress points as shown in figure below.

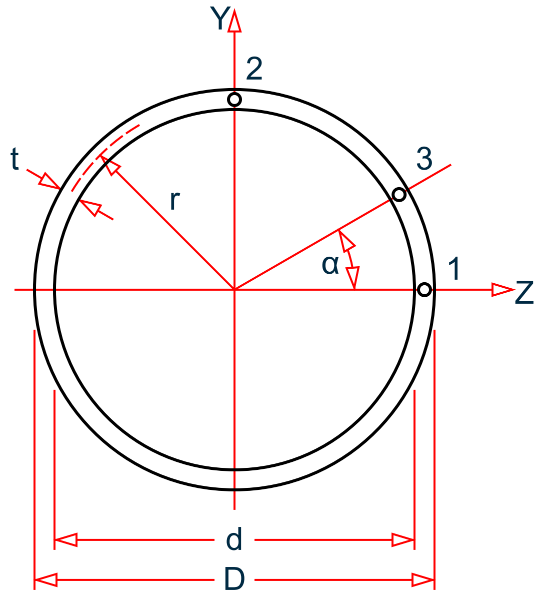

Figure 186: Stress points for a pipe section

Section properties

$d = D - 2t$
$r = 0.5 (D-t)$
$a = \tan^{-1} M_z/M_y$
$Ax = \pi/4 (D^2 - d^2)$
$A_y = A_z = 0.5A_x$
$I_x = 2I_z = \pi/32 (D^4 - d^4)$
$I_y = I_z = \pi/64 (D^4 - d^4)$

Note: In STAAD.Pro, slightly different values are used for A_y , A_z and I_x , however this has insignificant influence on the force distribution.

$A_Y = A_z = 0.6A_x$
$I_x = 2\pi R^3 t$

Stress calculation at selected stress points

Point No	σ_x	σ_{by}	σ_{bz}	τ_x	τ_y	τ_z
1	$\frac{F_x}{A_x}$	$\frac{M_y}{I_y}r$	0	$\frac{M_T}{I_x}r$	$\frac{F_y}{0.5A_x}$	0
2		0	$\frac{M_y}{I_y}r$		0	$\frac{F_y}{0.5A_x}$
3		σ_b	σ_b		τ	τ

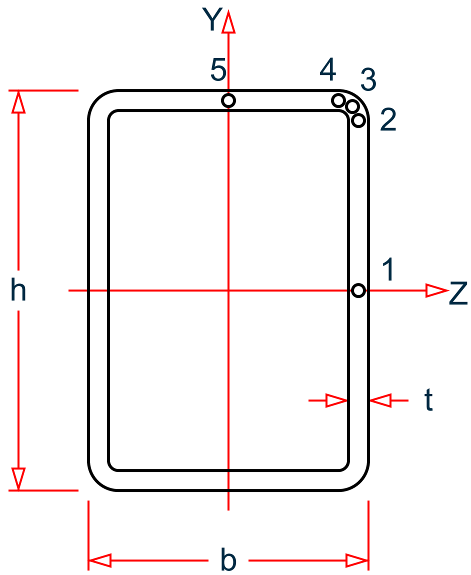
where

$$\sigma_b = \frac{\sqrt{M_y^2 + M_z^2}}{I_z} r$$

$$\tau = \frac{\sqrt{F_y^2 + F_z^2}}{0.5A_x}$$

D12.A.6.4 Tube profile

Tube sections are rectangular or quadratic hollow uniform profiles. Critical stress is checked at 5 locations as shown in figure below.



Section Properties

A_x , I_x , I_y , and I_z are taken from the STAAD.Pro database.

where

Ay = $2ht$, similar as for wide flange profiles, see Section 5.2

Az = $2(2/3)bt$; (Ay and Az are not used in code checks)

Cw = $\frac{b^2h^2t(h-b)^2}{24(h+b)}$ ref. NS app. C3

Stress calculation at selected stress points

$h_1 = h/2 - t$

$h_2 = h/2 - t/2$

$b_1 = b/2 - t$

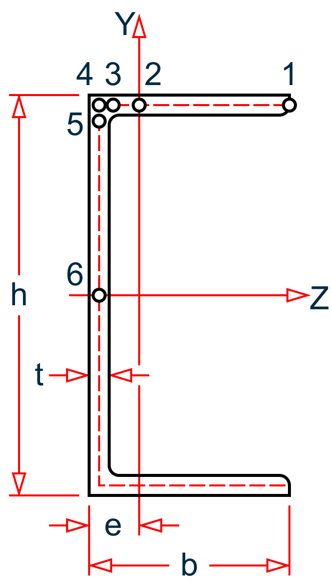
$b_2 = b/2 - t/2$

Point No	σ_x	σ_{by}	σ_{bz}	τ_x	τ_y	τ_z
1	$\frac{F_x}{A_x}$	$\frac{M_y}{I_y} b_2$	0	$\frac{M_x(h-t)(b-t)}{I_x(h+b-2t)}$	$\frac{F_y}{I_z} \frac{bth_2 + th_1^2}{2t}$	0
2		$\frac{M_y}{I_y} b_2$	$\frac{M_z}{I_z} h_1$		$\frac{F_y}{I_z} \frac{bth_2}{2t}$	$\frac{F_z}{I_y} \frac{2h_1tb_2}{2t}$
3		$\frac{M_y}{I_y} b_2$	$\frac{M_z}{I_z} h_2$		$\frac{F_y}{I_z} \frac{2b_2th_2}{2t}$	$\frac{F_z}{I_y} \frac{2h_2tb_2}{2t}$
4		$\frac{M_y}{I_y} b_1$	$\frac{M_z}{I_z} h_2$		$\frac{F_y}{I_z} \frac{2b_1th_2}{2t}$	$\frac{F_z}{I_y} \frac{htb_2}{2t}$
5		0	$\frac{M_z}{I_z} h_2$		0	$\frac{F_z}{I_y} \frac{htb_2 + tb_1^2}{2t}$

The general stress formulation is given in sec. 5.2.

D12.A.6.5 Channel profile

For channel profiles the von Mises stress is checked at 6 locations as shown in the figure below.



Cross section properties
where

A_x , S_y , S_z , I_x , I_y , and I_z	=	taken from the STAAD.Pro database
A_y	=	$2ht$, similar as for wide flange profiles
A_z	=	$2\times(2/3)bt$ (Ay and Az are not used in code checks)
e	=	$b\times(I_y/S_y)$
x	=	h-t

y	=	$b\text{-}t/2$
C_w	=	$\frac{x^2 y^3 t}{12} \frac{(2xt + 3yt)}{(xt + 6yt)}$, ref.[4] tab. 21, case 1

Stress calculations at selected stress points

$h_1 = h/2 - t$

$h_2 = h/2 - t/2$

$b_1 = e - t$

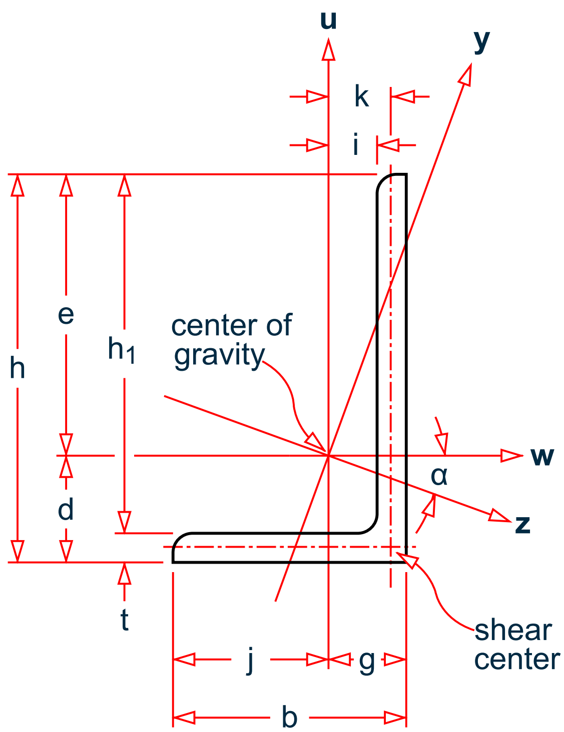
$b_2 = e - t/2$

Point No	σ_x	σ_{by}	σ_{bz}	τ_x	τ_y	τ_z
1	$\frac{F_x}{A_x}$	$\frac{M_y}{I_y}\left(b - e\right)$	$\frac{M_z}{I_z}h_2$	$\frac{M_x}{I_x}t$	0	0
2		0	$\frac{M_z}{I_z}h_2$	$\frac{M_x}{I_x}t$	$\frac{F_y}{I_z}\frac{(b - e)th_2}{t}$	$\frac{F_z}{I_y}\frac{0.5(b - e)^2 t}{t}$
3		$\frac{M_y}{I_y}b_1$	$\frac{M_z}{I_z}h_2$	$\frac{M_x}{I_x}t$	$\frac{F_y}{I_z}\frac{(b - t)th_2}{t}$	$\frac{F_z}{I_y}\frac{(b - t)t[0.5(b + t) - e]}{t}$
4		$\frac{M_y}{I_y}b_2$	$\frac{M_z}{I_z}h_2$	$\frac{M_x}{I_x}t$	$\frac{F_y}{I_z}\frac{(b - 0.5t)th_2}{t}$	$\frac{F_z}{I_y}\frac{\left(b - \frac{t}{2}\right)t\left[0.5\left(b + \frac{t}{2}\right) - e\right]}{t}$
5		$\frac{M_y}{I_y}b_2$	$\frac{M_z}{I_z}h_1$	$\frac{M_x}{I_x}t$	$\frac{F_y}{I_z}\frac{bth_2}{t}$	$\frac{F_z}{I_y}\frac{bt\left(\frac{b}{2} - e\right)}{t}$
6		$\frac{M_y}{I_y}b_2$	0	$\frac{M_x}{I_x}t$	$\frac{F_y}{I_z}\frac{bth_2 + 0.5th_1^2}{t}$	0

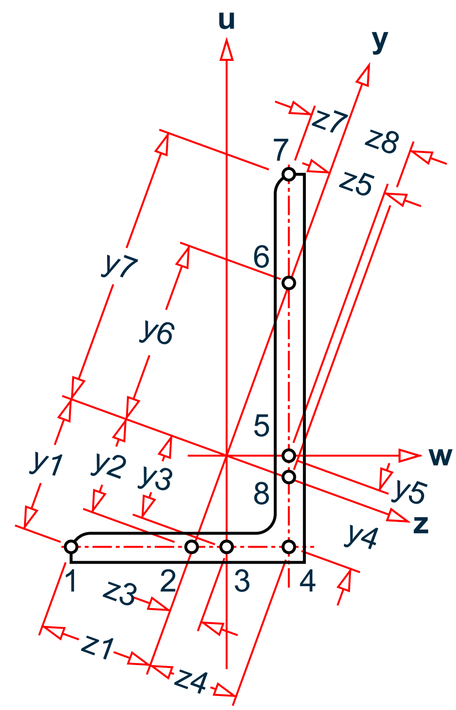
The general stress formulation is given in sec. 5.2.f

D12.A.6.6 Angle profile type RA (reverse angle)

For angle profiles the von Mises check is checked at 8 stress points as shown in figure below.



Section Dimensions



Stress Point Locations

Axes y and z are principal axes.

Axes u and w are local axes.

Cross section properties
where

A_x , I_x , I_y , and I_z	=	taken from the STAAD.Pro database
A_y	=	$\frac{2}{3}ht$, applied in STAAD.Pro print option `PRINT MEMBER STRESSES`
A_z	=	$\frac{2}{3}bt$ (Az is not used in code checks)
τ_y	=	$\frac{F_x}{A_y}$
τ_z	=	$\frac{F_x}{A_z}$
h_2	=	$0.5h_1 = t$
f	=	$h_1 e$
d	=	$\frac{th_1 h_2 + 0.5t^2 b}{A_x}$
g	=	$\frac{t^2 h_1 + tb^2}{2A_x}$

I_u	=	$\frac{h_1 t^3}{12} + htk^2 + \frac{tb^3}{12} + tb\left(\frac{b}{2} - g\right)^2$
I_w	=	$\frac{th_1^3}{12} + h_1 t(h_2 - d)^2 + \frac{bt^3}{12} + bt\left(d - \frac{t}{2}\right)^2$
I_{wu}	=	$\frac{\left(d - \frac{1}{2}\right)t}{2}\left(g^2 - j^2\right) - \frac{kt}{2}\left(e^2 - f^2\right)$
a	=	$0.5\tan^{-1}\left(\frac{2I_{uw}}{I_u + I_w}\right)$

Section forces

The section forces from the STAAD.Pro analysis are about the principle axis y and z.

The second moment of area (Ty L TZ):

$T_y = A\ Z$

$T_z = A\ Y$

Stress calculation at selected stress points

Point No	σ_x	σ_{by}	σ_{bz}	τ_x	τ_y	τ_z
1	$\frac{F_x}{A_x}$	$-\frac{M_y Z1}{I_y}$	$-\frac{M_z Y1}{I_z}$	$\frac{M_x}{I_x}t$	0	0
2		0	$-\frac{M_z Y2}{I_z}$		$\frac{F_y T_z}{I_z t}$	$\frac{F_z T_y}{I_y t}$
3		$\frac{M_y Z3}{I_y}$	$-\frac{M_z Y3}{I_z}$			
4		$\frac{M_y Z4}{I_y}$	$-\frac{M_z Y4}{I_z}$			
5		$\frac{M_y Z5}{I_y}$	$\frac{M_z Y5}{I_z}$			
6		0	$\frac{M_z Y6}{I_z}$			
7		$-\frac{M_y Z7}{I_y}$	$\frac{M_z Y7}{I_z}$			
8		$\frac{M_y Z8}{I_y}$	0		0	0

An additional torsional moment is calculated based on:

$M_T = F_y\ Z4$

$$M_T = F_z \, Y4$$

This torsion moment is included in M_x if F_y and F_Z exist.

Beta-rotation of equal & unequal legged angles

Note: The order of the joint numbers in the member incidence command specifies the direction of the local x-axis.

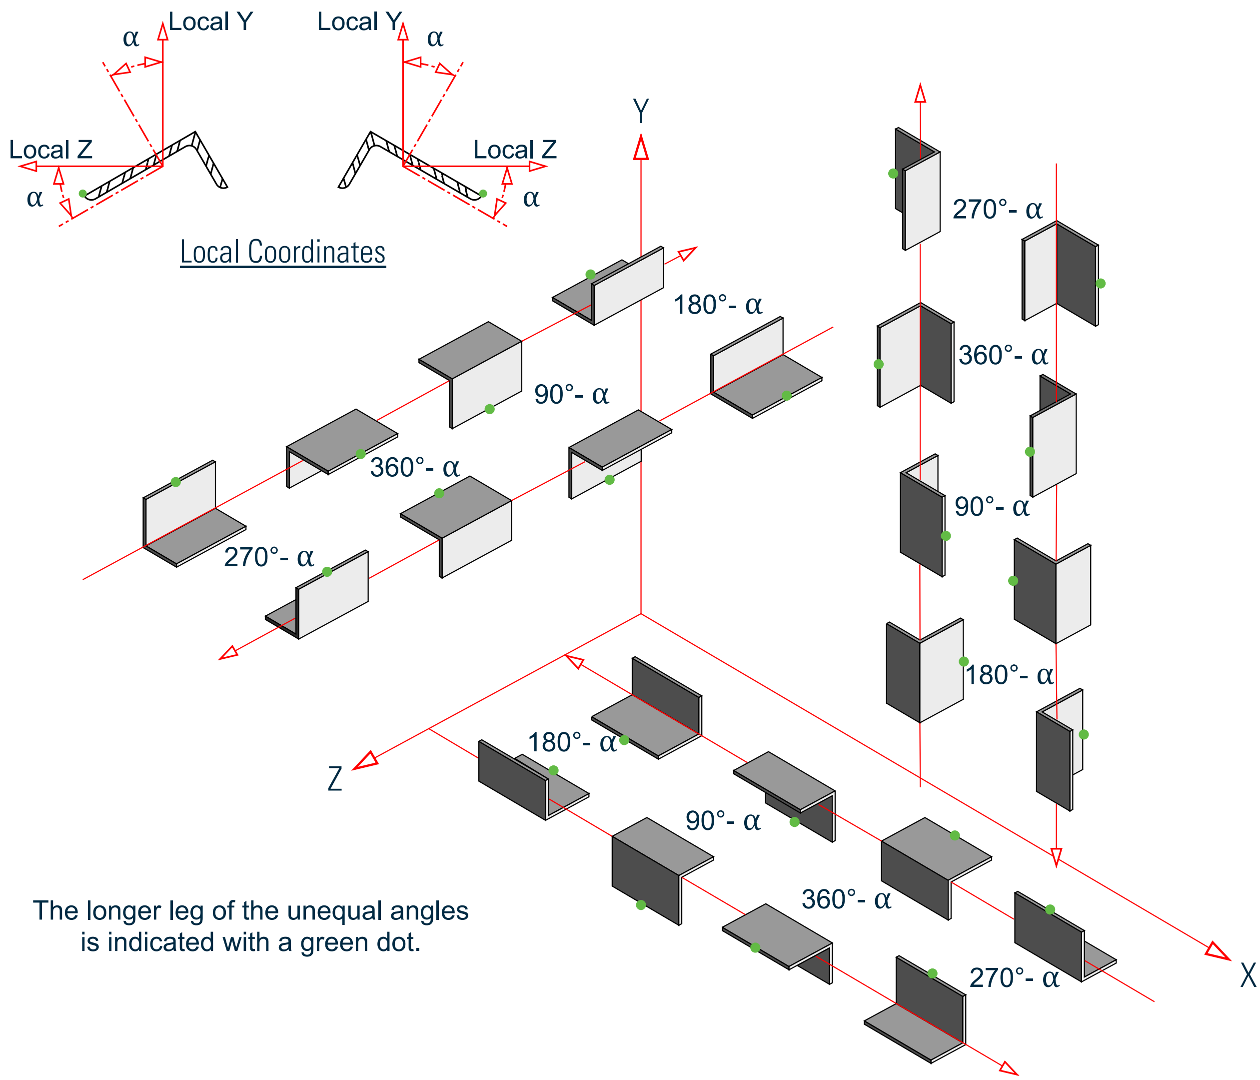


Figure 187: Beta rotation of angles

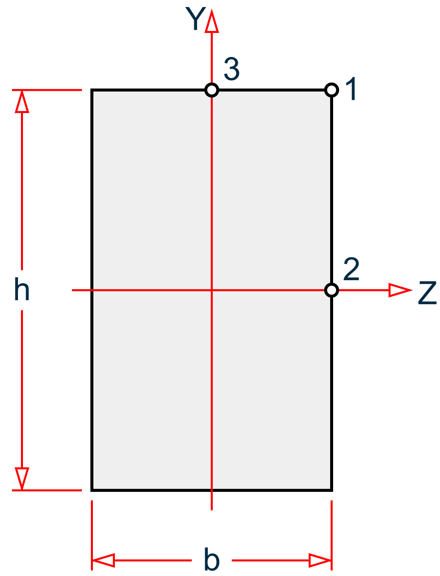
D12.A.6.7 Rectangular massive box (prismatic)

The prismatic section is assumed to be a rectangular massive box and the von Mises stress is checked at 3 locations as shown in figure below.

Note: Code check of the general purpose prismatic cross section is not available.



Note: Note that “b” may not be much greater than “h”. If that is the case, define the member with h > b and beta angle 90° instead.

Section Properties

where

A_x , A_y , A_z , I_x , I_y , and I_z , b, h	=	are user-specified. Refer to TR.20.2 Prismatic Property Specification (on page 2263).
b	=	ZD
h	=	YD
C_w	=	$\frac{1}{24}\frac{b}{2}\frac{(h-b)^2}{h+b}h^2 b^2$, ref.NS app C3.

General Stress Calculation

$$\sigma = \sigma_x + \sigma_{by} + \sigma_{bz} = \frac{F_x}{A_x} + \frac{M_y}{I_y}z + \frac{M_z}{I_z}y$$

$$\tau = \tau_x + \tau_y + \tau_z = \tau_{x,\max}\left(\frac{c}{b}\right)^2 + \frac{V_y}{A_y} + \frac{V_z}{A_z}$$

$$\tau_{x,\max} = \frac{M_x(1.5h + 0.9b)}{0.5h^2 b^2}$$

ref. [4] tab. 20, case 4 at midpoint the largest (i.e, point 2)

Stress calculation at selected stress points

Point No	σ_x	σ_{by}	σ_{bz}	τ_x	τ_y	τ_z
1	$\frac{F_x}{A_x}$	$\frac{M_y}{I_y}\frac{b}{2}$	$\frac{M_z}{I_z}\frac{h}{2}$	$\tau_{x,max}\frac{b^2}{b^2+h^2}$	0	0

Point No	σ_x	σ_{by}	σ_{bz}	τ_x	τ_y	τ_z
2		$\frac{M_y}{I_y}\frac{b}{2}$	0	$\tau_{x,max}$	$\frac{F_y}{A_y}$	0
3		0	$\frac{M_z}{I_z}\frac{h}{2}$	$\tau_{x,max}\frac{b^2}{h^2}$	0	$\frac{F_z}{A_z}$

D12.A.7 Tubular Joint Check, NPD 3.5

For pipe members, punching shear capacity is checked in accordance with the NPD sections 3.5.1 to 3.5.2, except 3.5.2.4. The chord is defined as the member with the greater diameter in the joint. If the diameters are the same the program selects the member with the greater thickness of the two. The chord members must be collinear by 5 degrees.

The punching shear run sequence is performed in two steps. The program will first identify all tubular joints and classify them as T type joints (TRACK99). The joints to be checked will be listed in a file specified in the CODE NPD parameter list, below called GEOM1. This file is used as input in the second run. The file is an editable ACSII file saved under the file name given in the CODE NPD parameter. The TRACK parameter is then set to 98 which directs the program to read from the file GEOM1 file and use it as input to the second run, i.e., the joint capacity checking. The program will check the capacity for both chord members entering the joint. The local y and z moments will be transformed into the plane defined by the joint itself and the far end joints of the brace and chord, defined as in- and out-of plane moments.

The ASCII file should be edited to reflect the correct classification of the joints, gap, can or stub dimensions, yield stress and other geometric options if required. The program will not change the brace or chord definition if this is changed or modified in the input file GEOM1. See Appendix A page xx for GEOM1 example file.

Joint classification parameters in the file GEOM1 are:

KO K joint overlapped
KG K joint with gap
TY T or Y joint
X X joint

Input example for the classification run.

```

PARAMETER
CODE NPD GEOM1
FYLD 350 ALL
TRACK 99 ALL
BEAM 1.0 ALL
CHECK CODE ALL
```

Static strength of tubular joints

The basic consideration is the chord strength. The required chord wall thickness shall be

determined when the other dimensions are given.

The following symbols are used:

T = Cord wall thickness
t = Brace wall thickness
R = Outer radius of chord
r = Outer radius of brace
Θ = Angel between chord and considered brace
D = Outer diameter of chord
d = Outer diameter of brace
a = Gap (clear distance) between considered brace and nearest load-carrying brace measured along chord outer surface
ß = r/R
g = R/T
g = a/D
f_y = Yield stress
Q_f = Factor
Q_g = See table 6.1
Q_u = See table 6.1
$Q_ß d$ = See table 6.1
N = Design axial force in brace
M_{IP} = Design in-plane bending moment in brace
M_{OP} = Design out-of plane bending moment in brace
N_k = Characteristic axial load capacity of brace (as governed by the chord strength)
M_{OPk} = Characteristic out-of-plane bending moment capacity of brace (as governed by the chord strength)
σ_{ax} = Design axial stress in chord
σ_{IP} = Design in-plane bending stress in chord
σ_{OP} = Design out-of-plane bending stress in chord

This section gives design formulae for simple tubular joints without overlap and without gussets, diaphragms or stiffeners. Tubular joints in a space frame structure shall satisfy:

$$N \le N_k / \gamma_m$$

Where:

$$N_k = Q_u Q_f \frac{f_y T^2}{\sin \Theta}$$

Q_u is given in Table 6.1 and Q_f is a factor to account for the nominal longitudinal stress in the chord.

$$Q_f = 1.0 - 0.03\gamma A^2$$

$$A^2 = \frac{\sigma_{ax}^2 + \sigma_{IP}^2 + \sigma_{OP}^2}{0.64 f_y^2}$$

Table 187: Values for Q_u

Type of joint and geometry	Type of load in brace member		
	Axial	**In-plane bending**	**Out-of-plane bending**
T and Y	2.5 + 19β	5.0√(γ)β	3.2/(1-0.81β)
X	(2.7 + 13β)Q_β		
K	0.90(2+21β)Q_β		

For $\beta > 0.6$, $Q_\beta = 0.3/[\beta(1 - 0.833\beta)]$

For $\beta \leq 0.6$, $Q_\beta = 1.0$

For $\gamma \leq 20$, $Q_g = 1.8 - 0.la/T$

For $\gamma > 20$, $Q_g = 1.8 - 4g$

but in no case shall Q_g be taken as less than 1.0.

When β ≥ 0.9, Q_f is set to 1.0. This is also applicable for moment loading. For cases with tension in the chord, Qf is set to 1.0. This is also applicable for moment loading.

The brace end moments shall be accounted for in the following cases:

- **a.** Out-of-plane bending moment when β > 0.85
- **b.** When the brace acts as a cantilever
- **c.** When the rotational stiffness of the connection is considered in the determination of effective buckling length, and / or the structural coefficient γ_{mk} = 1.00 for the beam-column design of the brace or chord. See Section 3.1.3.

The characteristic capacity of the brace subjected to in-plane bending moment shall be determined by:

$$M_{IPk} = Q_u Q_f \frac{d f_y T^2}{\sin \Theta}$$

Where Q_u is given in Table 6.1 and

$$Q_f = 1.0 - 0.045\gamma A^2$$

The characteristic capacity of the brace subjected to out-of-plane bending moment shall be determined by:

$$M_{OPk} = Q_u Q_f \frac{d f_y T^2}{\sin \Theta}$$

Where Q_u is given in Table 6.1 and

$$Q_f = 1.0 - 0.021\gamma A^2$$

For combined axial and bending loads in the brace, the following interaction equation should be satisfied:

$$\frac{N}{N_k} + \left(\frac{M_{IP}}{M_{IPk}}\right)^2 + \frac{M_{OP}}{M_{OPk}} \leq \frac{1}{\gamma_m}$$

For overlapping tubular joints without gussets, diaphragms, or stiffeners, the total load component normal to the chord, NN, shall not exceed

$$N_N = \frac{N_k}{\gamma_m}\frac{l_1}{l}\sin\Theta + \frac{2 f_y t_w l_2}{\sqrt{3}\gamma_m}$$

where (see NPD fig. 3.10)

l_l = circumference for that portion of the brace in contact with the chord (actual length)
l = circumference of brace contact with chord, neglecting presence of overlap
N_k = characteristic axial load capacity of brace
t_w = the lesser of the throat thickness of the overlapping weld or the thickness t of the thinner brace
l_2 = length as shown in NPD fig. 3.10

The above formula for the capacity of overlapping joints is valid only for K joints, where compression in a brace is essentially balanced by tension in brace(s) in the same side of the joint.

D12.A.8 Tabulated Results

This section presents a table with the various TRACKs available with respect to print out from the code check. Example prints and explanation to the information / heading given on the print out is given in Appendix A.

Table 188: Available TRACK parameter values

TRACK no.	Description
0	Brief print of member utilizations (2 lines for each member) sorted with highest utilized members first
1	Based on TRACK 3 with additional information regarding stability factors and capacities
2	Simple print of stresses, including von Mises stress
3	Brief print of member utilizations (two lines for each member)
9	Comprehensive print with detailed information about member and member utilization(one page for each member)
99	Used in connection with tubular joint check according to NPD. This TRACK identifies tubular joints to be checked and classifies all members entering the joint as T connection
98	Used in connection with tubular joint check according to NPD. This TRACK performs the joint capacity check
49	Prints member end forces for members entering each joint (at the end of the member connected to the joint)
31	Prints maximum and minimum member end forces (axial force defines max and min) at member end 1

TRACK no.	Description
32	Prints maximum and minimum member end forces (axial force defines max and min) at member end 2

D12.A.8.1 Output for member design

Output example for TRACK 0.0

Symbol	Description	Unit
MEMB	Member number	kN
FX	Axial force in the member (T = tension, C = compression)	kN·m
MYs	Start moment about the y-axis	kN·m
MYm	Mid moment about the y-axis	kN·m
MYe	End moment about the y-axis	kN·m
MYb	Buckling moment about the y-axis	kN·m
RATIO	Interaction ratio	
LOAD	The critical load case number	
TABLE	Section type (HE, IPE, TUBE, etc.)	
MZs	Start moment about z-axis	kN·m
MZm	Mid moment about the z-axis	kN·m
MZe	End moment about the z-axis	kN·m
MZb	Buckling moment about z-axis	kN·m
COND	Critical condition	
DIST	Distance from the start of the member to the critical section	m

Note: Myb and Mzb are the design moments used for max unity ratio.

Output example for TRACK 1.0

Symbol	Description	Unit
CURVE St	Buckling curve about the strong axis	
CURVE Wk	Buckling curve about the weak axis	
Beta Z	Buckling length factor about z-axis	
Beta Y	Buckling length factor about y-axis	
FYLD	Allowable yield strength	N/mm^2
Betamz	Equivalent moment factor β_m about z-axis	
Betamy	Equivalent moment factor β_m about y-axis	
Fak Z	Factor k according to 12.3.4.2 about the z-axis	
Fak Y	Factor k according to 12.3.4.2 about the y-axis	
MYD	Moment capacity about the y axis	kN·m
MZD	Moment capacity about the z axis	kN·m
MVD	Lateral buckling moment	kN·m
IR1	Interaction ratio for buckling without lateral buckling (Cl. 12.3.4.2)	
IR2	Interaction ratio for buckling with lateral buckling (Cl. 12.3.4.2)	

Symbol	Description	Unit
VON MISES	Interaction ratio for von Mises

D12.B. Norwegian Codes - Steel Design per NORSOK N-004

STAAD.Pro is capable of performing steel design based on the Norwegian code NORSOK N-004 Rev 2, October 2004. Code checks for tubular (pipe) members is performed per the code.

Please note the following:

- The code check is available for the pipe cross sections only.
- The design of conical transitions and joints with joint cans is not performed.

Design of members per NTC 1987 requires the *STAAD ECC Super Code* SELECT Code Pack.

D12.B.1 Member Resistances

The implementation of the NORSOK N-004 code in STAAD.Pro considers sections 4, 5, 6 & 7 in of that document. The details of the various clauses implemented from these sections is presented here for member checking and design.

D12.B.1.1 General Provisions

The general safety check is per Section 4. Checks are made to ensure that the design action effect (S_d) is less than or equal to the design resistance (R_d):

$$S_d \leq R_d$$

The design resistance is evaluated for each condition and this check is applied as described in the following sections.

D12.B.1.2 Steel selection and non destructive testing

Section 5 deals with the choice of “design class” for structural joints and components. The choice of design class will determine the choice of steel grade & quality and also the determination of inspection category for fatigue. The choice of design class (as per Table 5-1 of the code) is left to you and does not have any direct impact on how STAAD.Pro performs design checks.

D12.B.1.3 Ultimate Limit States

Clause 6.1 primarily deals with the section of material factors to be used in the various conditions or checks. The material factors chosen are dependent on the “section class” of a cross section. N-004 does not explicitly specify how to classify various cross sections. Therefore, the section classification is made as given in Section 5.5 of EN 1993-1-1:2005, except when specified explicitly along with member checks (See Member Subject to Axial Compression).

Also, N-004 does not specify steel grades to be used. Therefore, this STAAD.Pro uses the steel grades per EN 1993-1-1:2005 for designs per N-004.

Note: Ring stiffener design to CL. 6.3.6.2 is not included for this implementation.

D12.B.1.4 Tubular Members

Clause 6.3.1 deals with the general considerations while using tubular members.

Caution: Only tubular sections can be used with the N-004 code in STAAD.Pro. A warning is presented for any other section type.

The dimensions of the tubular sections are limited as follows:

- The thickness t ≥ 6 mm.
- The thickness t <150 mm.
- The slenderness ratio of the cross section D/t < 120.

  Where D is the diameter and t is the wall thickness of the section.
- The yield strength for tubular member ≤ 500 N/mm^2.

If any of these conditions are not met for a member selected for design, a warning will be issued by the engine and the design of that member is aborted.

> **Note:** N-004 uses “Y” to define the action effects that is in plane and ‘Z’ to define out of plane effects. This is the opposite to what STAAD uses, where ‘Z’ defines the in plane effects and ‘Y’ the out of plane effects. This document will follow the STAAD.Pro convention for the Z and Y axes.

The N-004 code also segregates members into those that are subject to hydrostatic pressure and those that are not subject to hydrostatic pressure. The program allows you to specify whether a member is subject to hydrostatic pressure or not and, if so, to specify the hydrostatic pressure for the element. By default the program will assume that all members are *not* subject to any hydrostatic pressure. The design parameter HYD is used to specify the maximum water level with respect to the origin.

If the HYD parameter is specified, the program will take that to be the water level and will evaluate the pressure distribution on each element assuming a linear increase in pressure with depth (The density of water is assumed to be 9.8 KN/m^3). Also, if the HYD parameter is specified, the program will assume that the hydrostatic loads have not been included in the analysis. For members that are subject to a combination of loads (i.e., bending plus compression) along with a hydrostatic pressure, the design will be done according to Clause 6.3.9 of the code. In the absence of any hydrostatic pressure on the member the design will be performed in accordance with Clause 6.3.8 of the code.

D12.B.1.5 Ultimate Limit State

Axial Tension

Clause 6.3.2 states that tubular members subject to axial tension shall satisfy the following condition:

$$N_{Sd} \le N_{t,Rd} = A \cdot f_y / \gamma_m$$

where

N_{Sd}	=	Design axial force (tension positive)
f_y	=	Characteristic yield strength
A	=	Cross section area
γ_m	=	Default material factor = 1.15

Axial Compression

Clause 6.3.3 states that tubular members subject to axial compression shall satisfy the following condition:

$$N_{Sd} \le N_{c,Rd} = A \cdot f_c / \gamma_m$$

where

N_{Sd}	=	Design axial force (compression positive)
f_c	=	Characteristic axial compressive strength
γ_m	=	Refer to clause 6.3.7

The design axial compressive strength for a member that is not subject to any hydrostatic pressure will be taken as the smaller of in plane or out of plane buckling strengths determined by the equations given below:

$$f_c = [1.0 - 028 \cdot {}^2]f_y \text{ when } \le 1.34$$

$$f_c = 0.9/ {}^2 \cdot f_y \text{ when } > 1.34$$

$$= \sqrt{(f_{cl}/f_E)} = k \cdot l/(\pi \cdot i)\sqrt{(f_{cl}/E)}$$

where

f_{cl}	=	Characteristic local buckling strength
$\bar{\lambda}$	=	Column slenderness parameter
f_E	=	Smaller Euler buckling strength in y or z direction
E	=	Young's modulus of elasticity = 2.1x10^5 MPa
k	=	Effective length factor, refer to Clause 6.3.8.2

l	=	Longer unbraced length in y or z direction
i	=	Radius of gyration

The characteristic local buckling strength is determined from:

$f_{cl} = f_y$ when $f_y/f_{cle} \leq 0.170$ (Plastic yielding)

$f_{cl} = [1.047 - 0.274 \cdot f_y/f_{cle}] \cdot f_y$ when $0.170 < f_y/f_{cle} \leq 1.911$ (Elastic/Plastic)

$f_{cl} = f_{cle}$ when $f_y/f_{cle} > 1.911$ (Elastic buckling)

where

f_{cle}	=	$2C_eE \cdot t / D$ (Characteristic elastic local buckling strength)
C_e	=	0.3 (Critical elastic buckling coefficient)
D	=	Outside diameter
t	=	wall thickness

For a member that is subject to pure compression, if $f_y/f_{cle} > 0.170$, the section will be classed as a CLASS 4 (slender section). In such cases, the value of the material factor (γ_m) used in the above checks is increased according to equation 6.22 (Cl. 6.3.7) of the code.

Bending

Clause 6.3.4 states that tubular members subject to pure bending alone shall satisfy:

$M_{Sd} \leq M_{Rd} = f_m \cdot W/\gamma_m$

where

M_{Sd}	=	Design bending moment
f_m	=	Characteristic bending strength
W	=	Elastic section modulus
γ_m	=	Refer to clause 6.3.7

The bending strength f_m is calculated as:

$f_m = Z/W \cdot f_y$ when $f_yD/(E \cdot t) \leq 0.0517$

$f_m = [1.13 - 2.58 \cdot f_yD/(E \cdot t)] \cdot Z/W \cdot f_y$ when $0.0517 < f_yD/(E \cdot t) \leq 0.1034$

$f_m = [0.94 - 0.76 \cdot f_yD/(E \cdot t)] \cdot Z/W \cdot f_y$ when $0.1034 < f_yD/(E \cdot t) \leq 120 \cdot f_y/E$

Shear

Clause 6.3.5 states that tubular members subject to shear shall satisfy:

$V_{Sd} \leq V_{Rd} = A \cdot f_y/(2\sqrt{3} \cdot \gamma_m)$

where

V_{Sd}	=	Design shear force
f_y	=	Yield strength
A	=	Cross section area
γ_m	=	Default material factor = 1.15

When torsional shear stresses are present, the following condition shall also be satisfied:

$M_{T,Sd} \leq M_{T,Rd} = 2 \cdot I_p f_y/(D\sqrt{3} \cdot \gamma_m)$

where

$M_{T,Sd}$	=	Design bending moment
I_p	=	Polar moment of inertia

Hydrostatic Pressure

Clause 6.3.6 states that tubular members subject to an external pressure shall primarily be checked for hoop buckling. The condition to be satisfied is:

$$\sigma_{p,Sd} \leq f_{h,Rd} = f_h/\gamma_{m)}$$

where

$\sigma_{p,Sd}$	=	$p_{Sd} \cdot D/(2 \cdot t)$
p_{Sd}	=	Design hydrostatic pressure
f_h	=	Characteristic hoop buckling strength
$\gamma_{m)}$	=	Refer to clause 6.3.7

The characteristic hoop buckling strength f_h, will be calculated as follows:

$$f_h = f_y \text{ when } f_{he} > 2.44 \cdot f_y$$

$$f_h = 0.7 \cdot f_y(f_{he}/f_y)_{0.4} \text{ when } 2.44 \cdot f_y \geq f_{he} > 0.55 \cdot f_y$$

$$f_h = f_{he} \text{ when } f_{he} \leq 0.55 \cdot f_y$$

where

=

The elastic hoop buckling strength, f_{he} , is evaluated as follows:

$$f_{he} = 2C_h E \cdot t/D$$

where

C_h	=	$0.44 \cdot t/D$ when $\mu \geq 1.6 \cdot D/t$
C_h	=	$0.44 \cdot t/D + 0.21 \cdot (D/t)^3/\mu^4$ when $0.825 \cdot D/t \leq \mu < 1.6 \cdot D/t$
C_h	=	$0.737/(\mu - 0.579)$ when $1.5 \leq \mu < 0.825 \cdot D/t$
C_h	=	0.8 when $\mu < 1.5$
μ	=	Geometric Parameter = $L/D\sqrt{(2 \cdot D/t)}$
L	=	Length of tubular member between stiffening rings, diaphragms, or end connections.

Combined Axial Tension and Bending (without Hydrostatic Pressure)

Clause 6.3.8.1 states that tubular members subject to axial tension and bending shall be designed to satisfy the following condition:

$$\left(\frac{N_{Sd}}{N_{t,Rd}}\right)^{1.75} + \frac{\sqrt{M_{y,Sd}^2 + M_{z,Sd}^2}}{M_{Rd}} \leq 1.0$$

where

$M_{y,Sd}$	=	the design bending moment about the y axis (out-of plane axis)
$M_{z,Sd}$	=	the design bending moment about the z axis (in plane axis)
N_{Sd}	=	the design axial force
M_{Rd}	=	the moment resistance (as determined by Clause 6.3.4)
$N_{t,Rd}$	=	the tension capacity of the section (as determined by Clause 6.3.2)

Combined Axial Compression and Bending (without Hydrostatic Pressure)

Clause 6.3.8.2 states that tubular members subject to axial tension and bending shall be designed to satisfy the following conditions:

$$\frac{N_{Sd}}{N_{c,Rd}} + \frac{1}{M_{Rd}}\sqrt{\left(\frac{C_{my}M_{y,Sd}}{1 - \frac{N_{Sd}}{N_{Ey}}}\right)^2 + \left(\frac{C_{mz}M_{z,Sd}}{1 - \frac{N_{Sd}}{N_{Ez}}}\right)^2} \leq 1.0$$

and

$$\frac{N_{Sd}}{N_{cl,Rd}} + \frac{\sqrt{M_{y,Sd}^2 + M_{z,Sd}^2}}{M_{Rd}} \le 1.0$$

where

N_{Sd}	=	the design axial compression
C_{my} and C_{mz}	=	the reduction factors corresponding to the Y and Z axes, respectively. You may specify a value for these using the `CMY` and `CMZ` design parameters, respectively (default0.85 for both).
N_{ey} and N_{ez}	=	the Euler buckling loads about y & z axes and are given by: $N_{Ey} = \frac{\pi^2 EA}{\left(\frac{k\ \ell}{i}\right)_y^2}$ $N_{Ez} = \frac{\pi^2 EA}{\left(\frac{k\ \ell}{i}\right)_z^2}$
k	=	the effective length factor and is given in table 6-2 of the code.
$N_{cl,\ Rd}$	=	the design axial local buckling resistance given by: $N_{cl,Rd} = \frac{f_{cl}A}{\gamma_M}$
f_{cl}	=	the characteristic local buckling strength (as determined by Clause 6.3.3)

The reduction factors used in this clause depend on the “structural element type” and will be as given in Table 6-2 of N-004. This requires the member to be classified under any one of the section types given in the table.

Combined Bending and Shear (without Hydrostatic Pressure)

Clauses 6.3.8.3 & 6.3.8.4 state that tubular members subject to beam shear force (excluding shear due to torsion) and bending moments shall satisfy:

$M_{Sd}/M_{Rd} \le \sqrt{(1.4 - V_{Sd}/V_{Rd})}$ when $V_{Sd}/V_{Rd} \ge 0.4$

$M_{Sd}/M_{Rd} \le 1.0$ when $V_{Sd}/V_{Rd} < 0.4$

If the member is subject to shear forces due to torsion along with bending moments, the condition to be satisfied is:

$M_{Sd}/M_{Red,Rd} \le \sqrt{(1.4 - V_{Sd}/V_{Rd})}$ when $V_{Sd}/V_{Rd} \ge 0.4$

$M_{Sd}/M_{Red,Rd} \le 1.0$ when $V_{Sd}/V_{Rd} < 0.4$

where

$M_{Red,Rd}$	=	$W \cdot f_{m,Red}/\gamma_m$
$f_{m,Red}$	=	$f_m\sqrt{[1 - 3(\tau_{T,Sd}/f_d)^2]}$
$\tau_{T,Sd}$	=	$M_{T,Sd}/(2\pi \cdot R^2 \cdot t)$
f_d	=	f_y/γ_m
R	=	Radius of the tubular member
γ_m	=	Refer to clause 6.3.7

Combined Loads with Hydrostatic Pressure

Clause 6.3.9 of NS-004 describes two methods to check for members subject to combined forces in the presence of hydrostatic pressure: depending on whether the hydrostatic forces were included as nodal forces in the analysis or not. If the hydrostatic forces have *not* been included in the analysis as nodal forces, Method A given in the code is used. If, however, the hydrostatic forces have been included in the analysis, then Method B in the code is used. Prior to proceeding with the checks described in the sections below, the section is verified for hoop stress limit per clause 6.3.6 (see Hydrostatic Pressure above).

The choice of method for checking members subject to combined forces and hydrostatic pressure used by STAAD.Pro will depend on the HYD parameter specified as a design parameter. If the HYD parameter has been specified, then the program will assume that the hydrostatic forces have not been included in the analysis and will perform the necessary checks as per Method A in code. If, on the other hand, the HYD parameter has not been specified, the program will use the section forces and use Method B in the code.

Combined Axial Tension, Bending, and Hydrostatic Pressure

Checks per Clause 6.3.9.1:

A. When HYD is specified:

The following condition is to be satisfied:

a. For the net axial tension condition ($\sigma_{a,Sd} \geq \sigma_{q,Sd}$)

$$\frac{\sigma_{a,Sd} - \sigma_{q,Sd}}{f_{th,Rd}} + \frac{\sqrt{\sigma^2_{my,Sd} + \sigma^2_{mz,Sd}}}{f_{mh,Rd}} \leq 1.0$$

where

$\sigma_{a,Sd}$	=	the design axial stress, excluding any axial compression from hydrostatic pressure.
$\sigma_{q,Sd}$	=	the design axial compressive stress due to hydrostatic pressure. (i.e., the axial load arising from the hydrostatic pressure being applied as nodal loads).
$\sigma_{my,Sd}$	=	the out of plane bending stress
$\sigma_{mz,Sd}$	=	the in plane bending stress
$f_{th,RD}$	=	$f_y/\gamma_m[\sqrt{(1 + 0.09 \cdot B^2 - B^{2\eta})} - 0.3B]$
$f_{mh,RD}$	=	$f_m/\gamma_m[\sqrt{(1 + 0.09 \cdot B^2 - B^{2\eta})} - 0.3B]$
B	=	$\sigma_{psd}/ f_{h,Rd}$
η	=	$5 - 4 \cdot f_h/f_y$

b. For the net axial compression condition ($\sigma_{a,Sd} < \sigma_{q,Sd}$)

$$\frac{|\ \sigma_{a,Sd} - \sigma_{q,Sd}\ |}{f_{cl,Rd}} + \frac{\sqrt{\sigma^2_{my,Sd} + \sigma^2_{mz,Sd}}}{f_{mh,Rd}} \leq 1.0$$

where

$f_{cl,Rd}$	=	f_{cl}/γ_m
f_{cl}	=	the characteristic local buckling strength (as determined by Clause 6.3.3)

Additionally, when:

$$\sigma_{c,Sd} > 0.5 \cdot f_{he}/\gamma_m$$

and

$$f_{cle} > 0.5 \cdot f_{he}$$

the following condition shall be satisfied in addition to the above check(s):

$$\frac{\sigma_{c,Sd} - 0.5\frac{f_{he}}{\gamma_M}}{\frac{f_{cle}}{\gamma_M} - 0.5\frac{f_{he}}{\gamma_M}} + \left(\frac{\sigma_{p,Sd}}{\frac{f_{he}}{\gamma_M}}\right)^2 \le 1.0$$

where

$\sigma_{c,Sd}$ = the maximum compressive stress at that section.

B. When HYD has not been specified:

$$\frac{\sigma_{ac,Sd}}{f_{th,Rd}} + \frac{\sqrt{\sigma^2_{my,Sd} + \sigma^2_{mz,Sd}}}{f_{mh,Rd}} \le 1.0$$

where

$\sigma_{ac,Sd}$ = the axial stress in the member

Combined Axial Compression, Bending, and Hydrostatic Pressure

Checks per Clause 6.3.9.2:

A. Method used when HYD has been specified:

The following condition is to be satisfied:

$$\frac{\sigma_{a,Sd}}{f_{ch,Rd}} + \frac{1}{f_{mh,Rd}}\sqrt{\left(\frac{C_{my}\sigma_{my,Sd}}{1 - \frac{\sigma_{a,Sd}}{f_{Ey}}}\right)^2 + \left(\frac{C_{mz}\sigma_{mz,Sd}}{1 - \frac{\sigma_{a,Sd}}{f_{Ez}}}\right)^2} \le 1.0$$

and

$$\frac{\sigma_{a,Sd} + \sigma_{q,Sd}}{f_{cl,Rd}} + \frac{\sqrt{\sigma^2_{my,Sd} + \sigma^2_{mz,Sd}}}{f_{mh,Rd}} \le 1.0$$

Where:

where

$\sigma_{a,Sd}$ = the design axial stress that excludes the stress from hydrostatic pressure

fch,Rd = $\frac{1}{2}\frac{f_{cl}}{\gamma_M}\left[\xi - \frac{2\sigma_{q,Sd}}{f_{cl}} + \sqrt{\xi^2 + 1.12\bar{\lambda}^2\frac{\sigma_{q,Sd}}{f_{cl}}}\right] when \bar{\lambda} < 1.34\sqrt{\left(1 - \frac{2\sigma_{q,Sd}}{f_{fl}}\right)^{-1}}$

$\frac{0.9 f_{cl}}{\bar{\lambda}^2\gamma_M} when \bar{\lambda} \ge 1.34\sqrt{\left(1 - \frac{2\sigma_{q,Sd}}{f_{fl}}\right)^{-1}}$

ξ = $1-0.28\bar{\lambda}^2$

Additionally, when:

$\sigma_{c,Sd} > 0.5 \cdot f_{he}/\gamma_m$

and

$f_{cle} > 0.5 \cdot f_{he}$

the following condition shall be satisfied in addition to the above check(s):

$$\frac{\sigma_{c,Sd} - 0.5\frac{f_{he}}{\gamma_M}}{\frac{f_{cle}}{\gamma_M} - 0.5\frac{f_{he}}{\gamma_M}} + \left(\frac{\sigma_{p,Sd}}{\frac{f_{he}}{\gamma_M}}\right)^2 \leq 1.0$$

B. Method used when HYD has *not* been specified:

The following condition is to be satisfied:

a. For the net axial tension condition ($\sigma_{ac,Sd} \geq \sigma_{q,Sd}$)

$$\frac{\sigma_{ac,Sd} - \sigma_{q,Sd}}{f_{ch,Rd}} + \frac{1}{f_{mh,Rd}}\sqrt{\left(\frac{C_{my}\sigma_{my,Sd}}{1 - \frac{\sigma_{a,Sd}}{f_{Ey}}}\right)^2 + \left(\frac{C_{mz}\sigma_{mz,Sd}}{1 - \frac{\sigma_{a,Sd}}{f_{Ez}}}\right)^2} \leq 1.0$$

and

$$\frac{\sigma_{ac,Sd}}{f_{cl,Rd}} + \frac{\sqrt{\sigma_{my,Sd}^2 + \sigma_{mz,Sd}^2}}{f_{mh,Rd}} \leq 1.0$$

(Refer to the previous section for an explanation of these terms).

b. For the net axial compression condition ($\sigma_{ac,Sd} < \sigma_{q,Sd}$)

$$\frac{\sigma_{ac,Sd}}{f_{cl,Rd}} + \frac{\sqrt{\sigma_{my,Sd}^2 + \sigma_{mz,Sd}^2}}{f_{mh,Rd}} \leq 1.0$$

(Refer to the previous section for an explanation of these terms).

Additionally, when:

$\sigma_{c,Sd} > 0.5 \cdot f_{he}/\gamma_m$

and

$f_{cle}/\gamma_m > 0.5 \cdot f_{he}/\gamma_m$

the following condition shall be satisfied in addition to the above check(s):

$$\frac{\sigma_{c,Sd} - 0.5\frac{f_{he}}{\gamma_M}}{\frac{f_{cle}}{\gamma_M} - 0.5\frac{f_{he}}{\gamma_M}} + \left(\frac{\sigma_{p,Sd}}{\frac{f_{he}}{\gamma_M}}\right)^2 \leq 1.0$$

where

$\sigma_{c,Sd}$ = the maximum compressive stress at that section.

D12.B.3 Design Parameters

Design parameters communicate specific design decisions to the program. They are set to default values to begin with and may be altered to suite the particular structure.

Table 189: Design Parameters for NORSOK N-004 design code

Parameter Name	Default Value	Description
CODE	none	Must be specified as NORSOK. **Note:** Do not use the shortened NOR, as this initiates an D12.A. Norwegian Codes - Steel Design per NS 3472 / NPD (on page 1790).
FYLD	235 [MPa]	Yield strength of steel, f_y (St37) **Note:** Note, if the SGR value is specified, then the associated value of f_y for that steel grade will be used for a member in lieu of the FYLD value.
KY	1.0	Effective length factor, k, in local Y-axis, usually minor axis.
KZ	1.0	Effective length factor, k, in local Z-axis, usually major axis.
LX		Effective length for lateral torsional buckling.
LY	Member Length	Length in local Y axis for slenderness value KL/r
LZ	Member Length	Length in local Z axis for slenderness value KL/r
CMY	0.85	Reduction factor C_m corresponding to the Y axis.
CMZ	0.85	Reduction factor C_m corresponding to the Z axis.
LSR		Length of Tubular between Stiffening Rings. This value is required to calculate Design Hoop Stress due to Hydrostatic Pressure to check Hoop Buckling as per clause 6.3.6.1.

Parameter Name	Default Value	Description
HYD	0.0	The Y-coordinate, current units, of the maximum water level with respect to the origin. **Note:** If `SET Z UP` command has been specified, then yi will be the Z co-ordinate of the max water level. For HYD > 0, the value of max. hydrostatic pressure calculated is reported for each member in a `TRACK 2.0` output.
PSD	0.0	Water pressure at each section in absence of HYD.
SGR	0	Steel Grade per EC3 (D5.C.6 Design Parameters (on page 1502)): 0 = S 235 grade steel 1 = S 275 grade steel 2 = S 355 grade steel 3 = S 420 grade steel 4 = S 460 grade steel
DMAX	100.0 [cm]	Maximum allowable depth of steel section.
DMIN	0.0 [cm]	Minimum allowable depth of steel section.
DFF	None (Mandatory for deflection check)	"Deflection length"/maximum allowable local deflection.
MAIN	0	Option to design for slenderness. 0 = Check for slenderness 1 = Do not check for slenderness Any value greater than 1.0 is used as the limit for slenderness in compression.
TMAIN	180.0	Slenderness limit in tension. Slenderness limit is checked based the `MAIN` parameter.
FU	420 [MPa]	Ultimate Tensile Strength of Steel

Parameter Name	Default Value	Description
TRACK	0	Output detail: 0 = Only a summary of the design checks performed is printed. 2 = All the details of the member checks and the various clause checks performed are printed. 3 = Prints detailed member check and joint check results.
RATIO	1.0	Permissible ratio of the actual to allowable stresses.
BEAM	0	Beam segment locations for design: 0 = design only for end moments and those at locations specified by `SECTION` command. 1 = Perform design for moments at twelfth points along the beam.
DJ1	Start Joint of member	Joint No. denoting start point for calculation of “deflection length”
DJ2	End Joint of member	Joint No. denoting end point for calculation of “deflection length”

Notes

a. C1 and C2 Parameters

The default values of these coefficients are taken from Table 6-4 of N-004 and depend on the joint and load type:

Table 190: Default values for C1 and C2 parameters

Joint Type	C1	C2
T or Y joints under brace axial load	25	11
X joints under brace axial load	20	22
K joints under balanced axial load	20	22
All joints under brace moment loading	25	30

Note: These values can be changed by setting the K, X, and Y values in the D12.B.8 External Geometry File (on page 1852).

Example

Note: This is a partial example containing only the information pertaining to the NORSOK N-004 steel design code; used at the end of the input file.

```
* Check tubular members according NORSOK N-004
CODE NORSOK
HYD 3.0 MEMB 1 TO 3
PSD 10 MEMB 7 10
SGR 2 MEMB 1 TO 3 7 10
TRACK 2 MEMB 1 TO 3 7 10
CHECK CODE MEMB 1 TO 3 7 10
```

D12.B.4 Code Checking

The purpose of code checking is to ascertain whether the provided section properties of the members are adequate as per N-004. Code checking is done using the forces and moments at specific sections of the members. If no sections are specified, the program uses the start and end forces for code checking.

When code checking is selected, the program calculates and prints whether the members have passed or failed the checks, the critical condition of NORSOK code, the value of the ratio of the critical condition (overstressed for value more than 1.0 or any other specified `RATIO` value), the governing load case, and the location (distance from the start of the number of forces in the member) where the critical condition occurs.

D12.B.5 Member Selection

STAAD.Pro is capable of performing design operations on specified members. Once an analysis has been performed, the program can select the most economical section (i.e., the lightest section which fulfills the code requirements for the specified member). The section selected will be of the same type section as originally designated for the member being designed. Member selection can also be constrained by the parameters `DMAX` and `DMIN` which limit the maximum and minimum depth of the members.

Selection of members whose properties are originally input from a user created table will be limited to sections in the user table.

D12.B.6 Tubular Joint Checking

The design of tubular joints for this implementation shall be based on section 6.4 of N-004 and will be applicable to joints formed from a connection of two or more members.

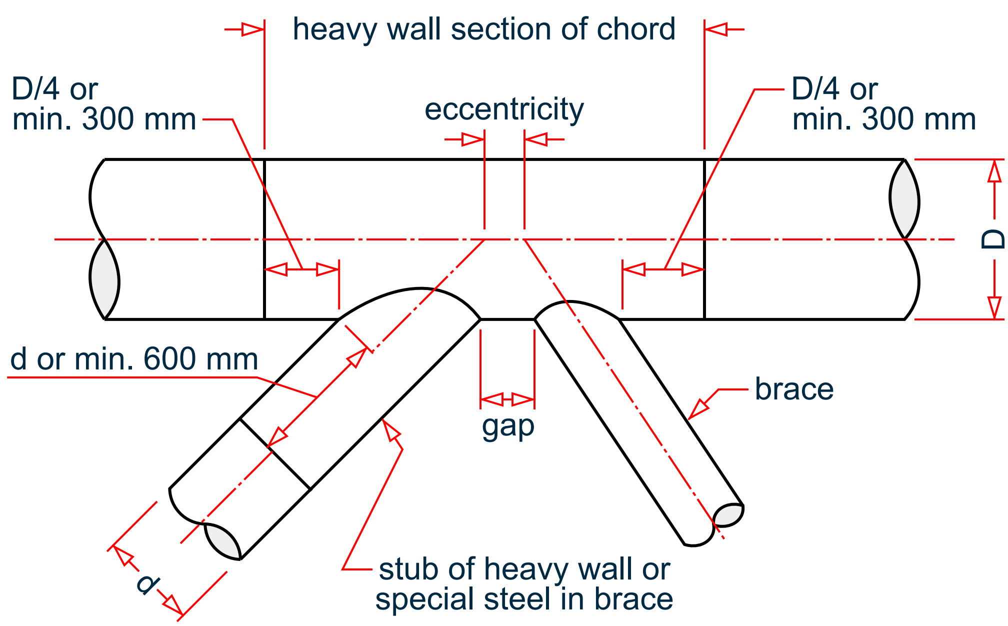

Figure 188: Typical Tubular Joint (Fig 6-1 in N004)

Prior to completing a joint design, the joint should be classified into one of the three categories given by the code. Joint classification is the process whereby a “brace” member connecting into a “chord” member is classified into one of these categories based on the axial force components in the brace. The classification normally considers all the members at a joint that lie in a plane. N-004 defines three joint classification categories: K, X, or Y (or a combination of these).

Joint Classification	Description
K	The axial force in the brace should be balanced by forces in the other braces in the same plane and on the same side of the joint. The code allows a 10% tolerance in the balancing force.
X	The axial force in the brace is reacted as a beam shear in the chord.
Y	The axial force in the brace is carried through the chord to braces in the opposite side.

Note: Typical examples of these joint types are given in Figure 6-3 of the N-004 code. It is worth noting that the joint class for each brace will be different for each load case.

Note: STAAD.Pro does not perform an automatic classification of the joints. This is left up to the engineer. All joints will initially be classified as Y in the generation of the D12.B.8 External Geometry File (on page 1852). Joints should be re-classified as necessary before performing the final joint capacity checks.

The checks for joint capacity are given in Cl. 6.4.3.2 to 6.4.3.6 and STAAD.Pro performs the checks as per these clauses. However, the program does not deal with conical joint transitions and joints with joint cans. The code also specifies checks and limits for the gaps and eccentricity of joints. This implementation will not perform such geometry checks.

The details of the checks done and the methodology will be discussed in the following sections.

Joint checks are performed as part of the `CODE CHECK` command and are displayed when either a `TRACK 0` or `TRACK 3` output design parameter is specified (with the former giving a summary and the latter giving detailed member & joint check results). Refer to D12.B.9 Examples (on page 1855) for example input and output including joint checks.

D12.B.6.1 Identification and Classification of CHORD and BRACE Members

This is a two step process where the program automatically identifies the CHORD and BRACE members at a joint and perform a default joint check. The input variables used for the initial joint checks will be generated in an external text file. You can then use this text file to edit or modify the input variables and perform a final check as necessary.

When a member is included in the `CHECK CODE` list, the program designs the member and also then proceeds to perform the joint checks at either ends of the member. It finds all members that connect to the end nodes of the member being designed and then proceeds to calculate the joint capacities based on each such connected member. The design process follows the section 6.4.3 of the code. This sections specifies certain pre-requisites for its application. If these pre-requisites are not satisfied, then the joint checks will not be performed. The following geometry checks must be satisfied in order for the joint check to be performed:

- $0.2 \leq \beta \leq 1.0$
- $10 \leq \gamma \leq 50$
- $30° \leq \theta \leq 90°$
- $g / D \geq -0.6$ (for K joints)

where

γ	=	$D / 2T$, where D = chord diameter and T = chord thickness.

The program will also produce an output file called `filename_Jnt.txt`, where "`filename`" will be the name of the `.std` input file. This format of this text file is explained in D12.B.8 External Geometry File (on page 1852).

You can then edit this text file to set up the necessary design parameters. Once the program finds of the `_JOINTS.txt` file, it will read in the necessary parameters from this file and perform the subsequent design checks. This is done by simply performing the design and analysis again for the input file.

Note: This file will be produced only once (i.e., when this file does not exist). If this file exists, it is assumed that you have already done a joint design check and hence the program reads the values from this file and uses these for joint checks.

D12.B.7 Tubular Joint Resistance

D12.B.7.1 Basic Joint Resistances

The characteristic joint resistance between a chord and a brace is given by:

$$N_{Rd} = \frac{f_y T^2}{\gamma_M \sin\theta} Q_u Q_f$$

$$M_{Rd} = \frac{f_y T^2 d}{\gamma_M \sin\theta} Q_u Q_f$$

Where:

N_{Rd} is the joint design axial resistance

M_{Rd} is the joint design bending moment resistance.
f_y is the yield strength
γ_m = Default material resistance =1.15
θ is the angle between the chord and the brace (max θ = 90 degrees)
Q_u = Strength factor which varies with the joint type and the action type in the brace. Refer to Table 6-3 and Clause 6.4.3.3 of N-004 for these equations.
$Q_f = 1.0 – \lambda A^2$

$$A^2 = C_1\left(\frac{\sigma_{a,Sd}}{f_y}\right)^2 + C_2\left(\frac{\sigma^2_{my,Sd} + \sigma^2_{mz,Sd}}{1.62 f^2_y}\right)$$

$\sigma_{p,Sd}$ is the design axial stress in the chord
$\sigma_{my,Sd}$ is the design in-plane bending stress in the chord
$\sigma_{mz,Sd}$ is the design out-of-plane bending stress in the chord
C1 is the coefficient used for the axial stress term in calculating the joint resistance. C2 is the coefficient used for the bending stress term in calculating the joint resistance. The default values of C1 and C2 are as given in Table 6-4 of N-004. The actual values used are dependent on the values of K, X, and Y specified for the joint in the D12.B.8 External Geometry File (on page 1852).
See also Figures 6-3 to 6-6 of N-004 for definition of the various terms for various joint classes.

D12.B.7.2 Strength Check for Joints

Each brace to chord joint to be checked will have to satisfy the following condition:

$$\frac{N_{Sd}}{N_{Rd}} + \left(\frac{M_{z,Sd}}{M_{z,Rd}}\right)^2 + \frac{M_{y,Sd}}{M_{y,Rd}} \le 1$$

Where:

N_{Sd} is the design axial force in the brace,
N_{Rd} is the joint design axial resistance
$M_{z,Sd}$ is the in plane bending moment in the brace
$M_{y,Sd}$ is the out of plane bending moment in the brace
$M_{z,Rd}$ is the in plane bending moment resistance
$M_{y,Rd}$ is the out of plane bending moment resistance

D12.B.8 External Geometry File

The data contained in the `filename_JOINTS.NGo` file should meet the following format. The overall process of performing punching shear checks consists of two steps which are explained in D12.B.6 Tubular Joint Checking (on page 1849).

General Format

```
LOAD LIST load_list
```

```
JOINT    NODE    K     X    Y     CHORD   CLEN       D      T      BRACE     BLEN
d           t GAP
```

```
j# n# K% X% Y% C# CLEN D T B# BLEN d t gap
```

Where:

j#	the joint number
n#	the node number
K%, X%, and Y%	The fractional contributions of K-type, X type and Y-type, respectively. Initially the joints will be classed as Y (i.e., K=0, X=0 and Y=1).
C#	the member numbers of the CHORD
CLEN	the length of chord member
D, T	Diameter and thickness of CHORD
B#	the member number of the brace
BLEN	the length of chord member
d, t	Diameter and thickness of BRACE
gap	Distance required to calculate gap factor for K bracing. Initially, the value of GAP is assumed as 0.

Note: All distances are provided in units of inches.

Example

```
LOAD LIST 1 2 4
JOINT    NODE    K     X    Y     CHORD     CLEN     D       T     BRACE
BLEN   d         t      GAP
  1      3        0    0    1       2       5.0   0.168    0.10      1
4.0    0.140   0.010   0
  2      3       0    0    1       2       5.0   0.168    0.10      16
6.043  0.075   0.005   0
```

D12.B.9 Tabulated Results

For code checking or member selection, the program produces the results in a tabulated fashion. The items in the output table are explained as follows:

Member	the member number for which the design is performed.
TABLE	the steel section name which has been checked against the N-004 code or has been selected.
RESULTS	prints whether the member has PASSed or FAILed. If the RESULT is FAIL, there will be an asterisk (*) mark on front of the member.
CRITICAL COND	the section of the N-004 code which governs the design.
RATIO	prints the ratio of the actual stresses to allowable stresses for the critical condition. Normally a value of 1.0 or less will mean the member has passed.
LOADING	the load case number which governed the design.
FX, MY, and MZ	provide the axial force, moment in local Y-axis, and the moment in local Z-axis respectively. Although STAAD does consider all the member forces and moments (except torsion) to perform design, only FX, MY and MZ are printed since they are the ones which are of interest, in most cases.

LOCATION specifies the actual distance from the start of the member to the section where design forces govern.

Note: If the parameter TRACK is set to 2.0, the program will block out part of the table and will print the allowable bending stressed in compression (FCY & FCZ) and tension (FTY & FTZ), allowable axial stress in compression (FA), and allowable shear stress (FV).

D13. Russian Codes

D13.A. Russian Codes - Concrete Design Per SNiP 2.03.01-84*

STAAD.Pro is capable of performing concrete design based on the Russian code СНиП 2.03.01-84*: *СТРОИТЕЛЬНЫЕ НОРМЫ И ПРАВИЛА БЕТОННЫЕ И ЖЕЛЕЗОБЕТОННЫЕ КОНСТРУКЦИИ* (SNiP 2.03.01-84* *Building Regulations: Concrete and Reinforced Concrete Construction*).

Design of members per SNiP 2.03.01-84* requires the *STAAD ECC Super Code* SELECT Code Pack.

D13.A.1 General

Russian Code SNiP 2.03.01–84* plain concrete and concrete structures is based on the method of limit states. Code SNiP 2.03.01–84* defines two groups of limit states.

Analysis according to the first group of limit states is performed to avoid the following phenomena:

- brittle, plastic or other type of failure,
- loss by structure of stable form or position,
- fatigue failure,
- failure due to the action of load actions and unfavorable environmental effects.

Analysis according to the second group of limit states is performed to avoid the following phenomena:

- excessive and long-term opening of cracks if they are allowed according to service conditions,
- excessive displacements.

Analysis of structures for the first group of limit states is performed with the use of the maximum (design) loads and actions. Analysis of structures for the second group of limit states is made in accordance with the operational (normative) loads and actions. Ratio between design and normative loads is called reliability coefficient for loads which is determined according to SNiP 2.01.07.-85 “Loads and actions”.

Reliability coefficient γ_n for destination according to SNiP 2.01.07.-85 shall be considered in determination of loads and their combinations.

STAAD.Pro makes it possible to calculate reinforcement for concrete members according to Russian Code SNiP 2.03.01-84*. Algorithms for calculation of reinforcement of concrete linear (beams, columns) and 2D (two dimensional; slabs, walls, shells) members are incorporated into the program. Not only Code SNiP 2.03.01-84* but also the “Guide for design of plain concrete and reinforced concrete structures from normal weight and lightweight concrete (to SNiP 2.03.01-84)” have been used in creation of these algorithms.

The program can automatically calculate reinforcement for beams of rectangular or T section and for columns of rectangular or circular section.

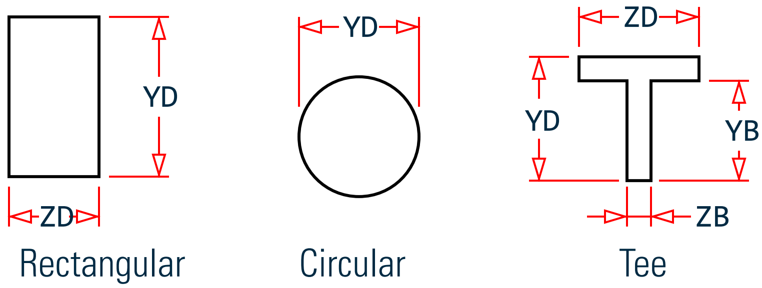

Figure 189: Section types for concrete design

Flange of T-shape beams may be situated at the top zone of the section if the angle β = 0° (`BETA 0`), or at the bottom zone of the section, if β = 180° (`BETA 180`).

D13.A.2 Design Parameters

Entry of data of cross-sections of beams and columns is made by the use of **MEMBER PROPERTIES** command, and thicknesses of 2D members are entered by **ELEMENT PROPERTY** command.

Example:

```
UNIT  MM
MEMBER  PROPERTIES
*  Columns of rectangular cross-section
1  TO  16  PRI  YD
 350.  ZD  350.
*  Columns of circular cross-section
17  TO  22  PRI  YD  350.
*  Beams of T cross-section
23  TO  40  PRI  YD  450.  ZD  550.  YB  230.  ZB  200.
UNIT  METER
ELEMENT  PROPERTY
41  TO  100 THICKNESS  0.14
101  TO  252 THICKNESS  0.16
* Flange of T beams is located at the bottom  zone of cross-section
BETA  180.  MEMB  23  TO
40
```

Commands for calculation of reinforcement are located in the input data file after the command of analysis and as a rule, after output commands to print results of calculation.

Example:

```
*  Command of analysis
PERFORM  ANALYSIS
.
.* Output command to print results of calculation  (according to user's
judgment)
.
*  Command of loading and their combinations  considered in design
```

```
LOAD  LIST  1  5  TO  9
*  Command to start reinforcement calculation  procedure
START  CONCRETE  DESIGN
CODE  RUSSIAN
.* List of parameters being used in reinforcement  calculation
.
.
BCL  20.  MEMB  17  TO   22
CL1  0.04  MEMB  1  TO   40
DD2  10.  MEMB  23  TO   40
CRA 0.036  MEMB  41  TO   252
.
.
.
* Command of beam reinforcement calculation
DESIGN  BEAM  23  TO  40
* Command of column reinforcement calculation
DESIGN  COLUMN  1  TO  22
* Command of calculation 2D elements (slabs,
 walls, shells)
DESIGN  ELEMENT  41  TO  252
* Command of interruption reinforcement calculation
END  CONCRETE  DESIGN
```

In tables 1, 2 and 3 information about parameters used for calculation of reinforcement for beams, columns and 2D (two dimensional) members is presented. Values of parameters do not depend on **UNIT** command. In the file of input data only such parameters have to be taken, the values of which differ from determined in the program.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 191: Names of parameters for Concrete design according to Russian Code -СНиП 2.03.01-84* for beams.

No.	Parameter name	Default Value	Description
1	NLT	1	Number of long-term loading case

No.	Parameter name	Default Value	Description
2	RCL	3	Class of longitudinal reinforcement: • RCL = 1, if class of reinforcement is A-I; • RCL = 2, if class of reinforcement is A-II; • RCL = 3, if class of reinforcement is A-III; • RCL = 33, if class of reinforcement is A-IIIb; • RCL = 4, if class of reinforcement is A-IV; • RCL = 5, if class of reinforcement is A-V; • RCL = 6, if class of reinforcement is A-VI; • RCL = 7, if class of reinforcement is A-VII; • RCL = 77, if class of reinforcement is K-7; • RCL = 8, if class of reinforcement is B-II; • RCL = 9, if class of reinforcement is Bp-II; • RCL = 10, if class of reinforcement is Bp-I; • RCL = 19, if class of reinforcement is K-19
2	RCL	3	Class of longitudinal reinforcement: Russian Grade: • 1 = A240; • 2 = A300; • 3 = A400; • 4 = A500; • 5 = B500; • 6 = A500SP; European Grade: • 11 = S240; • 12 = S400; • 13 = S500;

No.	Parameter name	Default Value	Description
3	USM	1.	Total product of service conditions coefficients for longitudinal reinforcement **(g_s)**
4	UB2	0.9	Specific service conditions coefficient for concrete **(g_{b2})**
5	DD1	16.	Diameter of longitudinal reinforcement bars in beam tension zone
6	DD2	16.	Diameter of shear reinforcement bars for beam;
7	BCL	15.	Compression class of concrete

No.	Parameter name	Default Value	Description
7	BCL	15.	Compression Class of concrete. • 10 = B10; • 15 = B15 • 20 = B20; • 25 = B25; • 30 = B30; • 35 = B35; • 40 = B40; • 45 = B45; • 50 = B50; • 55 = B55; • 60 = B60; • 8.10 = C8/10 • 12.15 = C12/15; • 16.20 = C16/20 • 25.30 = C25/30 • 30.37 = C30/37 • 35.45 = C35/45 • 40.50 = C50/50 • 45.55 = C45/55 • 50.60 = C50/60 • 60.75 = C60/75 • 70.85 = C70/85 • 80.95 = C80/95 • 90.105 = C90/105
8	UBM	1.	Product of service conditions coefficients for concrete, except UB2 (g_b)
9	TEM	0.	Parameter of concrete hardening conditions: • TEM=0, for natural hardening conditions; • TEM=1, for steam hardening conditions
10	CL1	0.05	Distance from top/bottom fiber of beam cross section to the center of longitudinal reinforcement bar;

No.	Parameter name	Default Value	Description
11	CL2	0.05	Distance from left/right side of beam cross section to the center of longitudinal reinforcement bar
12	WST	0.4	Ultimate width of short-term crack
13	WLT	0.3	Ultimate width of long-term crack
14	SSE	0	Limit state parameter for beam design • SSE=0, if calculation of reinforcement amount must be carried out according to the requirements of load carrying capacity (the first limit state); • SSE=1, if calculation of reinforcement amount must be carried out according to the cracking requirements (the second limit state)

No.	Parameter name	Default Value	Description
15	RSH	1	Class of shear reinforcement: • RSH = 1, if class of reinforcement is A-I; • RSH = 2, if class of reinforcement is A-II; • RSH = 3, if class of reinforcement is A-III; • RSH = 33, if class of reinforcement is A-IIIb; • RSH = 4, if class of reinforcement is A-IV; • RSH = 5, if class of reinforcement is A-V; • RSH = 6, if class of reinforcement is A-VI; • RSH = 7, if class of reinforcement is A-VII; • RSH = 77, if class of reinforcement is K-7; • RSH = 8, if class of reinforcement is B-II; • RSH = 9, if class of reinforcement is Bp-II; • RSH = 10, if class of reinforcement is Bp-I; • RSH = 19, if class of reinforcement is K-19
15	RSH	1	Class of shear reinforcement: Russian Grade: • 1 = A240; • 2 = A300; • 3 = A400; • 4 = A500; • 5 = B500; • 6 = A500SP; European grade: • 11 = S240; • 12 = S400; • 13 = S500;

No.	Parameter name	Default Value	Description
16	FWT	ZD	Design width of beam top flange. Use for beam design only with default value provided as ZD in member properties.
17	FWB	ZB	Design width of beam bottom flange. Use for beam design only with default value provided as ZB in member properties.
18	DEP	YD	Design depth of beam section. Use for beam design only with default value provided as YD in member properties.
19	SFA	0.	Face of support location at the start of the beam. Use for beam design only.
20	EFA	0.	Face of support location at the end of the beam. Use for beam design only.
21	NSE	13	Number of equally-spaced sections for beam design. Use for beam design only. Upper limit is equal to 20.

Table 192: Names of parameters for Concrete design according to Russian Code СНиП 2.03.01-84* for columns

No.	Parameter Name	Default Value	Description
1	NLT	1	Number of long-term loading case

No.	Parameter Name	Default Value	Description
2	RCL	3	Class of longitudinal reinforcement: Russian Grade: • 1 = A240; • 2 = A300; • 3 = A400; • 4 = A500; • 5 = B500; • 6 = A500SP; European Grade: • 11 = S240; • 12 = S400; • 13 = S500;
3	USM	1.	Total product of service conditions coefficients for longitudinal reinforcement **(g_s)**
4	UB2	0.9	Specific service conditions coefficient for concrete **(g_{b2})**
5	DD1	16.	Minimum diameter of longitudinal reinforcement bars for column
6	DD2	16.	Maximum diameter of longitudinal reinforcement bars for column

No.	Parameter Name	Default Value	Description
7	BCL	15.	Compression class of concrete: • 10 = B10; • 15 = B15 • 20 = B20; • 25 = B25; • 30 = B30; • 35 = B35; • 40 = B40; • 45 = B45; • 50 = B50; • 55 = B55; • 60 = B60; • 8.10 = C8/10 • 12.15 = C12/15; • 16.20 = C16/20 • 25.30 = C25/30 • 30.37 = C30/37 • 35.45 = C35/45 • 40.50 = C50/50 • 45.55 = C45/55 • 50.60 = C50/60 • 60.75 = C60/75 • 70.85 = C70/85 • 80.95 = C80/95 • 90.105 = C90/105
8	UBM	1.	Product of service conditions coefficients for concrete, except UB2 $(\mathbf{g_b})$
9	TEM	0.	Parameter of concrete hardening conditions: • TEM=0, for natural hardening conditions; • TEM=1, for steam hardening conditions
10	CL1	0.05	Distance from edge of column cross section to the center of longitudinal reinforcement bar

No.	Parameter Name	Default Value	Description
11	ELY	1.	Column's length coefficient to evaluate slenderness effect in local Y axis
12	ELZ	1.	Column's length coefficient to evaluate slenderness effect in local Z axis
13	RSH	1.	Class of shear reinforcement: Russian Grade: • 1 = A240; • 2 = A300; • 3 = A400; • 4 = A500; • 5 = B500; • 6 = A500SP; European grade: • 11 = S240; • 12 = S400; • 13 = S500;

Table 193: Names of parameters for Concrete design according to Russian Code (SNiP 2.03.01-84*) for slabs and/or walls

No.	Parameter Name	Default Value	Description
1	NLT	1	Number of long-term loading case

2	RCL	3	Class of longitudinal reinforcement: Russian Grade: • 1 = A240; • 2 = A300; • 3 = A400; • 4 = A500; • 5 = B500; • 6 = A500SP; European Grade: • 11 = S240; • 12 = S400; • 13 = S500;
3	USM	1.	Total product of service conditions coefficients for longitudinal reinforcement **(g_s)**
4	UB2	0.9	Specific service conditions coefficient for concrete **(g_{b2})**
5	SDX	16.	Diameter of reinforcing bars located in the first local (X) direction of slab/ wall
6	SDY	16.	Diameter of reinforcing bars located in the second local (Y) direction of slab/ wall

No.	Parameter Name	Default Value	Description
7	BCL	15.	Compression class of concrete: • 10 = B10; • 15 = B15 • 20 = B20; • 25 = B25; • 30 = B30; • 35 = B35; • 40 = B40; • 45 = B45; • 50 = B50; • 55 = B55; • 60 = B60; • 8.10 = C8/10 • 12.15 = C12/15; • 16.20 = C16/20 • 25.30 = C25/30 • 30.37 = C30/37 • 35.45 = C35/45 • 40.50 = C50/50 • 45.55 = C45/55 • 50.60 = C50/60 • 60.75 = C60/75 • 70.85 = C70/85 • 80.95 = C80/95 • 90.105 = C90/105
8	UBM	1.	Product of service conditions coefficients for concrete, except UB2 **(g_b)**
9	TEM	0.	Parameter of concrete hardening conditions: • TEM=0, for natural hardening conditions; • TEM=1, for steam hardening conditions

No.	Parameter Name	Default Value	Description
10	CL	0.05	Distance from top/bottom face of slab/wall element to the center of longitudinal reinforcing bars located in first local (X) direction. (Main thickness of top/bottom concrete cover for slab/ wall element)
11	CRA	0.05	Distance from top/bottom face of slab/wall element to the center of transverse reinforcing bars located in second local (Y) direction (Secondary thickness of top/bottom concrete cover for slab/wall)
12	WST	0.4	Ultimate width of short-term crack
13	WLT	0.3	Ultimate width of long-term crack

No.	Parameter Name	Default Value	Description
14	STA	0	Parameter of limit state for slab/wall design: • STA=0, if calculation of nonsymmetrical reinforcement must be carried out according to the requirements of load carrying capacity (the first limit state); • STA=1, if calculation of symmetrical reinforcement must be carried out according to the requirements of load carrying capacity (the first limit state); • STA=2, if calculation of nonsymmetrical reinforcement must be carried according to the cracking requirements (the second limit state); • STA=3, if calculation of symmetrical reinforcement must be carried according to the cracking requirements (the second limit state)
15	SELX	0.	Design length of wall member to evaluate slenderness effect in local X axis
16	SELY	0.	Design length of wall member to evaluate slenderness effect in local Y axis

No.	Parameter Name	Default Value	Description
17	MMA	0	Design parameter of slab/ wall reinforcement: • MMA=0, if reinforcement calculation must be applied by stresses in local axis; • MMA=1, if reinforcement calculation must be applied by principal stresses
18	MMB	1	Design parameter of slab/ wall reinforcement: • MMB=0, if the effect of additional eccentricity is not taken into account; • MMB=1, if the effect of additional eccentricity is taken into account
19	RSH	1.	Class of shear reinforcement: Russian Grade: • 1 = A240; • 2 = A300; • 3 = A400; • 4 = A500; • 5 = B500; • 6 = A500SP; European grade: • 11 = S240; • 12 = S400; • 13 = S500;

D13.A.3 Beams

Reinforcement for beams of rectangular and T cross-section can be calculated. In calculation of longitudinal reinforcement bending moment about local axis Z_{loc} and torsional moments are considered, but influence of longitudinal forces and bending moments in relation to local axis Y_{loc} is ignored. In calculation of transverse reinforcement shear forces parallel to local axis Y_{loc} a nd torsional moments are taken into account.

Reinforcement for beams can be calculated either from conditions of strength or from conditions of open crack width limitation (see parameter SSE).

Parameters SFA and EFA are considered only in calculation of transverse reinforcement.

In general case calculation of reinforcement for beams is carried out two times – according to strength conditions and according to conditions of open crack width limitation. In reinforcement calculations from conditions of strength design values of load have to be taken and in calculations from conditions of crack width limitation – characteristic (normative) load values are used. Both calculations can be carried out in one session with the use multiple analysis possibility of the program STAAD.Pro.

In most cases calculation of reinforcement is carried out with account only of a part of loadings. In such cases command LOAD LIST is used, in which numbers of loads considered in calculation are indicated. Number of permanent and long-term loads equal to parameter NLT must be included into the list of considered loads.

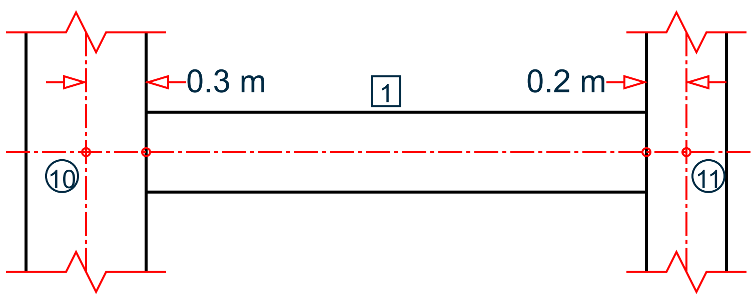
It has to be noted, that values of parameters DD1 and DD2 have influence not only on the width of opened crack but also in some cases, on design and normative reinforcement resistances.

Parameter BCL can be equal to any value of concrete compression strength class given in SNiP 2.03.01-84* and to any intermediate value as well.

It should be remembered, that accuracy of results of calculation of transverse reinforcement increases with the value of parameter NSE.

Parameters SFA and EFA are considered only in calculations of transverse reinforcement. Beam 1 is shown in Figure 2 with rigid intervals the lengths of which are: at the start of the beam 0.3m and at the end – 0.2m. In modeling of the beam the following command can be used.

```
MEMBER  OFFSET
1  START 0.3 0 0
1  END -0.2 0 0
```



When command MEMBER OFFSET is used forces corresponding to the beam the length of which is equal to the distance between points a and b are calculated and then used in calculation of reinforcement. In such case it is necessary to take into account default values of parameters SFA and EFA equal to zero.

When command MEMBER OFFSET is not used forces corresponding to the beam the length of which is equal to the distance between points *10* and *11* are calculated and then used in calculation of reinforcement. In this case it is necessary to consider values of parameters SFA=0.3 and >EFA=0,2 in reinforcement calculation.

In both cases calculated quantity of transverse reinforcement will be the same. Calculated quantity of longitudinal reinforcement in the second case will be greater.

For beam the following output is generated:

- beam number;
- method of calculation (according to conditions of strength or limitations of opened crack width);

- length and cross-sectional dimensions;
- distance from resultant of forces acting in bottom/top reinforcement to bottom/top edge of the section;
- distance from the side edge of cross-section of the beam web to the centroid of longitudinal bars located at this edge;
- concrete class;
- class of longitudinal and transverse reinforcement;
- assumed in calculations bar diameters of longitudinal and transverse reinforcement;
- calculation results of longitudinal and transverse reinforcement (in two tables).

In nine columns of the first table the following results are presented:

Table 194: Beam design output 1

Result	Description
Section	distance of the section from the “start” of the beam, *мм*
As-	cross-sectional area of longitudinal reinforcement in the bottom zone of cross-section of the beam, if angle *BETA*=0°, or in the top zone, if *BETA*=180° , *sq.cm*
As+	cross-sectional area of longitudinal reinforcement in the top zone of cross-section of the beam , if angle *BETA*=0°, or in the top zone, if *BETA*=180° , *sq.cm*
Moments (-/+)	values of bending moments, determining cross-sectional areas of longitudinal reinforcement *As*- and *As*+ , *kNm*
Load. N. (-/+)	numbers of loading versions, determining cross-sectional areas of longitudinal reinforcement
Acrc1	short-term opened crack width*, *mm*
Acrc2	long-term opened crack width*, *mm*

* Opened crack width is presented only in the case when calculation is performed according to conditions limiting opened crack width.

In ten columns of second table the following results are presented:

Table 195: Beam design output 2

Result	Description
Section	distance of the section from the “start” of the beam, *mm*
Qsw	intensity of transverse reinforcement, *kN/m*

Result	Description
Asw	cross-sectional area of transverse bars, *sq.cm*, if their step is 10, 15, 20, 25 or 30 *cm*
Q	value of shear force parallel to the local axis, *kN*
T	value of torsional moment, *kNm*
Load N.	number of loading version, determining intensity of transverse reinforcement

D13.A.4 Columns

Reinforcement for columns of rectangular or circular cross-section can be calculated. Flexibility of columns can be evaluated in two ways. In the case of usual analysis (command `PERFORM ANALYSIS`) flexibility is assessed by parameters `ELY` and `ELZ`, values of which should conform with recommendation of the Code SNiP 2.03.01-84*. If `P-DELTA` (analysis according to deformed diagram) or `NONLINEAR` (nonlinear geometry) analysis is performed, values of parameters `ELY` and `ELZ` should be close to zero, for example `ELY = ELZ`=0.01.

Longitudinal reinforcement for columns is calculated only from condition of strength. Longitudinal forces and bending moments in relation to local axes Y_{loc} and Z_{loc} are taken into account in longitudinal reinforcement calculations.

For rectangular columns the following output is generated:

- column number;
- column length and cross-sectional dimensions;
- distance of centroid of each longitudinal bar from the nearest edge of the cross-section;
- concrete class;
- longitudinal reinforcement class;
- range of longitudinal reinforcement bar diameters assumed in calculation;
- diameter of longitudinal reinforcement bars obtained in calculation;
- total quantity of longitudinal bars;
- quantity of longitudinal bars at each cross-section edge, directed parallel to the local axis Y_{loc} ;
- quantity of longitudinal bars at each cross-section edge, directed parallel to the local axis Z_{loc} .

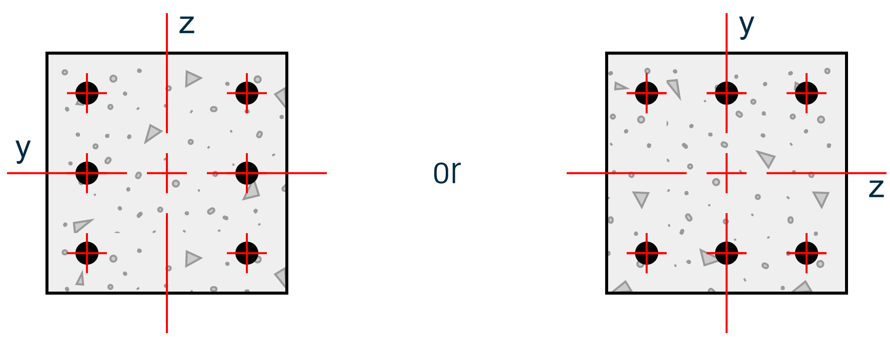
In nine columns of the table under the heading LONGITUDINAL REINFORCEMENT the following output is presented:

Table 196: Column design output 1

Result	
Section	distance of the section from the “start” of the column, *mm*
Astot	total cross-sectional area of longitudinal reinforcement, sq.cm

Result	
Asy	cross-sectional area of longitudinal reinforcement bars at each edge of section, directed parallel to the local axis Y_{loc} , sq.cm
Asz	cross-sectional area of longitudinal reinforcement bars at each edge of section, directed parallel to the local axis Z_{loc} , sq.cm
Percent	reinforcement percentage in the section
Nx, Mz, My	respective values of longitudinal force and bending moments in relation to the local axes Z_{loc} and Y_{loc} , determining cross-sectional area of longitudinal reinforcement
Load.N.	number of loading version, determining cross-sectional area of longitudinal reinforcement

Diameter of longitudinal reinforcement bars, total quantity of longitudinal bars as well as quantity of longitudinal bars at each edge of the section obtained from calculation should be considered as recommendation. In this case arrangement of reinforcement in the section depends on the orientation of the local axes and is as follows:



Calculated values of reinforcement cross-sectional areas are presented in the table and they may differ from recommended on the lower side.

When it is not possible according to detailing provisions to arrange in the column longitudinal reinforcement determined from calculation additional message is derived.

For columns of circular section the following output is generated:

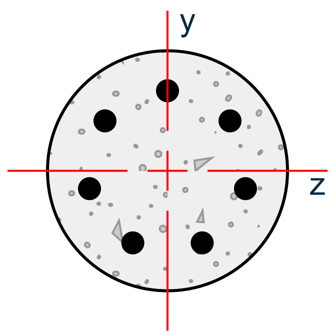
- column number;
- column length and diameter of cross-section;
- distance of centroid of each longitudinal bar to the edge of cross-section;
- longitudinal reinforcement class;
- assumed in calculation range of diameters of longitudinal reinforcement bars;
- diameter of longitudinal reinforcement bars obtained from calculation;
- quantity of longitudinal bars.

In seven columns of the table under the heading LONGITUDINAL REINFORCEMENT the following results are presented:

Section	distance of the section from the "start" of the column, *mm*
Astot	total cross-sectional area of longitudinal reinforcement, sq.cm
Per cent	percentage of longitudinal reinforcement
Nx, Mz, My	respective values of longitudinal force and bending moments in relation to local axis Z_{loc} and Y_{loc}, determining cross-sectional area of longitudinal reinforcement
Load. N.	number of loading version, determining cross-sectional area of longitudinal reinforcement

Diameter of longitudinal reinforcement bars, total quantity of longitudinal bars as well as quantity of longitudinal bars at each edge of the section should be considered as recommendation.

Arrangement of reinforcement in section in this case is shown below:



Calculated cross-sectional areas of reinforcement presented in the table may differ from recommended on the lower side.

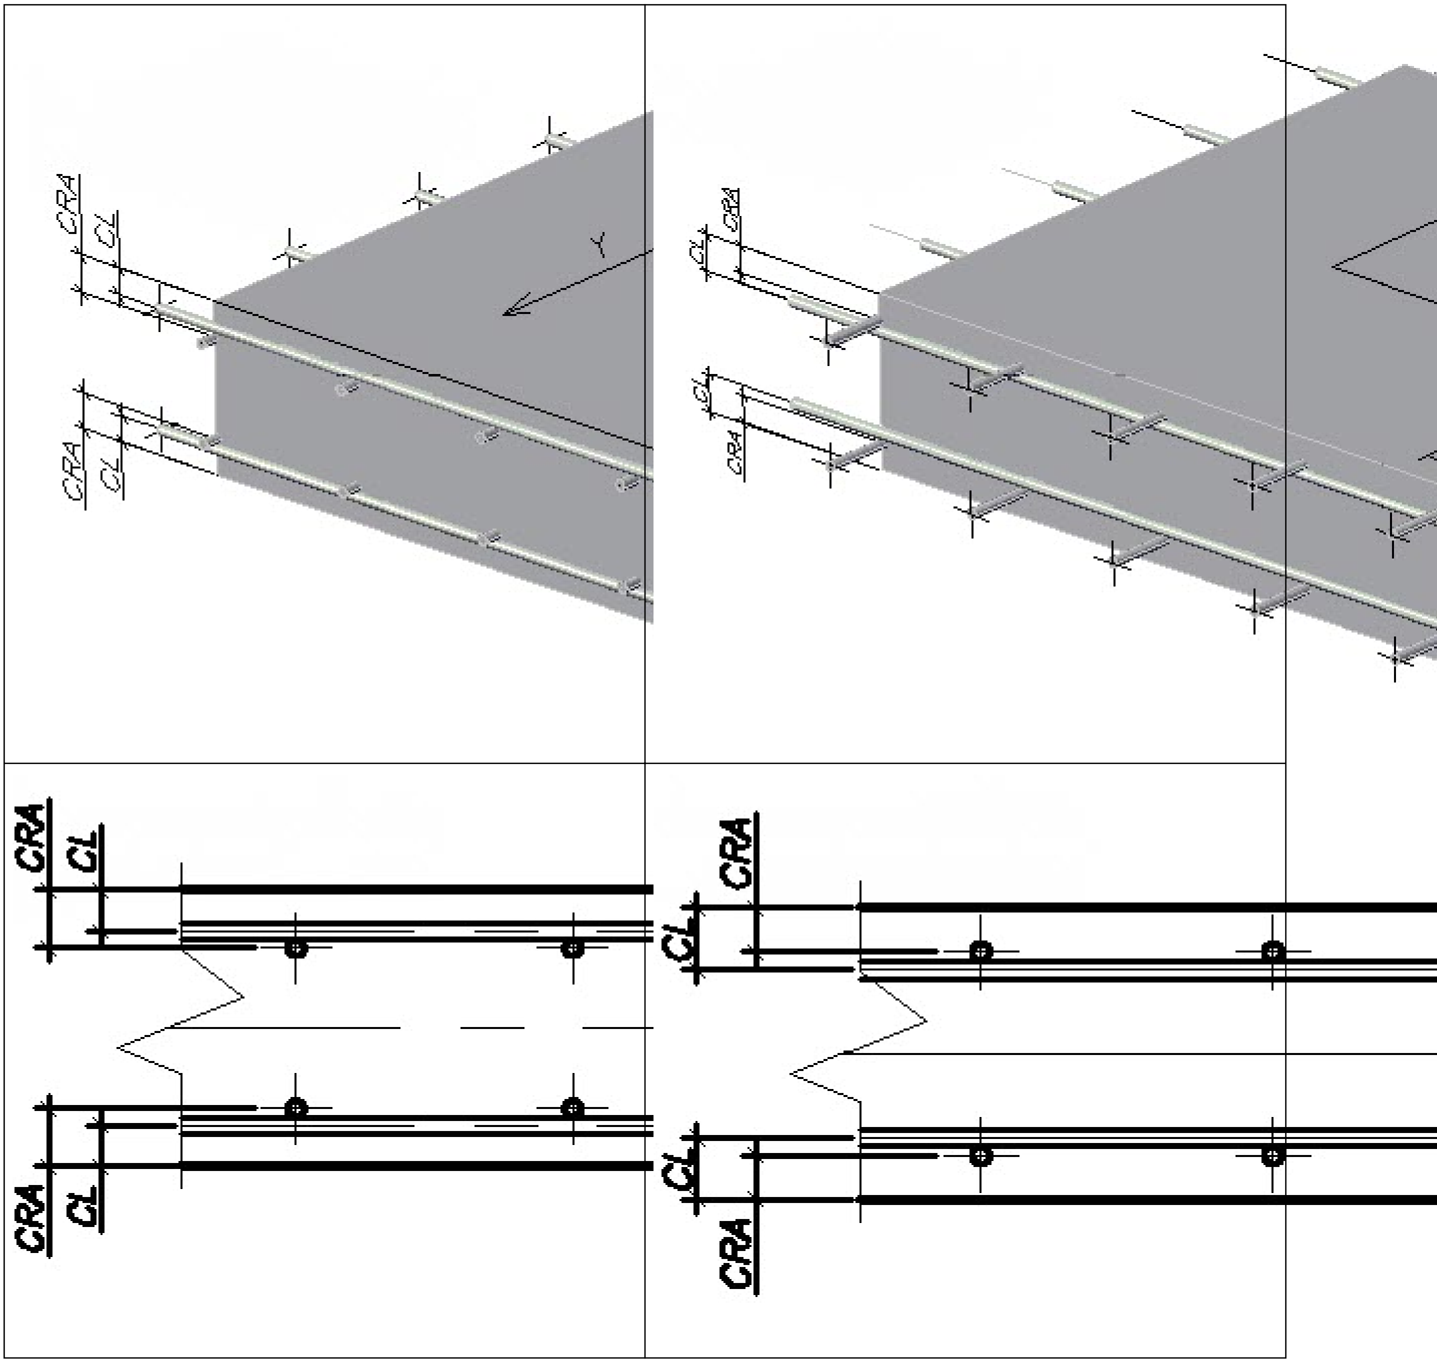
When according to detailing provisions it is not possible to arrange in the column longitudinal reinforcement obtained from calculation additional message is derived.

D13.A.5 Two Dimensional Elements (slabs, walls, shells)

In general case calculation of reinforcement for 2D members is carried out two times – according to conditions of strength and conditions of limiting opened width of cracks. If reinforcement is calculated according to conditions of strength, design values of loads have to be used, and for conditions of limiting crack width – characteristic (normative) loads are employed. Both calculations can be made in one session by using multiple analyses.

Symmetric or nonsymmetrical reinforcement of 2D members is calculated according to conditions of strength or according to conditions of limiting opened crack width (see for example **STA**).

In reinforcement calculation for 2D members it is necessary to pay attention to arrangement of local axes of member and direction of reinforcement (see for example **CL** and **CRA**).



An example of output of calculation results is presented bellow.

```
                    SLAB/WALL DESIGN RESULTS
    (by stresses in local axes for limitation of crack width)
--------------------------------------------------------------------
Element  Asx     Mx      Nx   Load. N.  Asy       My     Ny   Load N.
       sq.cm/m  kNm/m   kN/m   (X)    sq.cm/m  kNm/m   kN/m   (Y)
--------------------------------------------------------------------

```

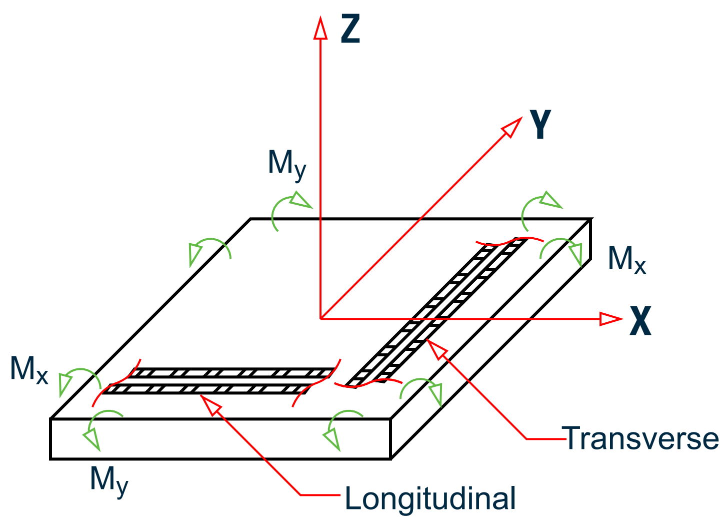
Where:

Table 197: Slab design output

Result	Description
Element	number of finite element, “TOP” - top zone of member, “BOT” - bottom zone of member (“top” zone of member is determined by positive direction of local axis, Z)
Asx	intensity of reinforcing in the longitudinal direction (parallel to the local axis, X), *sq.cm/m*
Mx	distributed bending moment in respect to the local axis, Y, *kNm/m*
Nx	distributed longitudinal force directed parallel to the axis *X*, *kNm/m*
Load N.(X)	number of loading version, determining intensity of reinforcing in the longitudinal direction
Asy	intensity of reinforcing in the transverse direction (parallel to the local axis Y), *sq.cm/m*
My	distributed bending moment in respect to the local axis X *kNm/m*
Ny	distributed longitudinal force directed parallel to the local axis *Y* *kN/m*
Load N.(Y)	number of loading version, determining intensity of reinforcing in the transverse direction



D13.B. Russian Codes - Steel Design Per SNiP 2.23-81* (Edition 1990)

STAAD.Pro is capable of performing steel design based on the Russian code СНиП II-23-81* Часть II *Нормы проектирования Стальные конструкции* (SNiP 2.23-81* Part II *Design Standards for Steel Construction*).

In STAAD.Pro V8i (SELECTseries 5) or later, design of members per SNiP 2.23-81* requires the *STAAD ECC. Super Code* SELECT Code Pack.

D13.B.1 General

Design Code SNiP Steel Structures –as is the case in the majority of modern codes– is based on the method of limit states. The following groups of limit states are defined in the Code.

- The first group is concerned with losses of general shape and stability, failure, qualitative changes in configuration of structure. Appearance of non-allowable residual deformations, displacements, yielding of materials or opening of cracks.
- The second group is concerned with states of structures making worse normal their service or reducing durability due to not allowable deflections, deviations, settlements, vibrations, etc.

Analysis of structures for the first limit state is performed using the maximum (design) loads and actions, which can cause failure of structures.

Analysis of structures for the second limit state is performed using service (normative) loads and actions. Relation between design and normative loads is referred to as coefficient of load reliability, which is defined in SNiP 2.01.07.- 85 “Loads and Actions”.

Coefficient of reliability for destination GAMA n according to SNiP 2.01.07.- 85 shall be taken in to account determining loads or their combinations.

In this version of the program only members from rolled, tube and roll-formed assortment sections and also from compound such as double angles of T-type sections, double channels are presented. Design of other members of compound section will be presented in other versions of the program.

Economy of selected section is indicated by ratio (`RATIO`) $\sigma/R_y y_c$ presented in calculation results. A section is economical when said ratio equals to 0,9 – 0,95.

D13.B.2 Built-in Russian Steel Section Library

Typical sections of members being checked and selected according to SNiP 2.01.07.- 81* are presented in the following tables.

Table 198: Typical Sections for Russian Steel Design

Section	Section Type	Designation form
I-beam (GOST 8239-89)		`ST I12`
Regular I-beam (GOST 26020-83)		`ST B1-10`
Broad-flanged I-beam (GOST 26020-83)		`ST SH1-23`
Column I-beam (GOST 26020-83)		`ST K1-20`
Channel (GOST 8240-89)		`ST C14`
Equal legs angle (GOST 8509-89)		`ST L100x100x7` `RA L100x100x7`

Section	Section Type	Designation form
Unequal legs angle (GOST 8510-89)		`ST L125x80x10` `RA L125x80x10`

Pipes (GOST 10705 and GOST 10706; welded and for gas piping)		`ST PIP102x5.5`
		or
		`ST PIPE OD 0.102 ID 0.055`

Roll-formed square and rectangular tubes (GOST 8639 and GOST 8645)		`ST TUB160x120x3`
		or
		`ST TUBE TH 0.003 WT 0.12 DT 0.16`

Table 199: Compound Sections for Russian Steel Design

Section	Section Type	Designation form
Double channels		`D C14 SP 0.01` (SP – clear distance between channel walls)

Section	Section Type	Designation form
Double equal legs angles		`LD L100x100x7 SP 0.01` (SP – clear distance between angle walls)
Double unequal legs angles with long legs back to back		`LD L125x80x10 SP 0.01` (SP – clear distance between angle walls)
Double unequal legs angles with short legs back to back		`SD L125x80x10 SP 0.01` (SP – clear distance between angle walls)

Tee with flange at the top
Note: Flange of Tee beam is at the top part of cross-section if beta angle = 0°, or at the bottom part if beta angle = 180°.
		`T I12`
		`T B1-10`
		`T SH1-23`
		`T K1-20`

For entry of cross-sectional dimensions command `MEMBER PROPERTIES RUSSIAN` is used.

D13.B.3.1 Axial Tension Members

Stress in a section of axial tension member shall not exceed design strength R_y of selected steel multiplied by coefficient of service conditions γ_c (KY and KZ), table 6 of SNiP 2.01.07.- 81*. Slenderness of tension member (CMM) shall not exceed slenderness limit indicated in table 20 of SNiP 2.01.07.- 81* (default value $\lambda_u = 200$, but another value can be defined). Net section factor (ratio A_{net}/A_{gross} (NSF)) is used for tension member to allow for reduction of design cross-section area.

D13.B.3.2 Axial Compression Members

All axial compression members are calculated as long bars, i.e., with allowance for slenderness ($\lambda = l_0/i_{min}$). The calculation is performed in accordance with the clause 5.3 of SNiP 2.01.07.- 81*, buckling coefficient φ is determined by formula 8-10. Effective bar lengths (within and out of plane) taking in to account role and location of the bar in the structure, as well as fixation of ends ($l_0 = \mu l$), are determined according to requirements of chapter 6 or addition 6 to SNiP 2.01.07.- 81* and are set by specification of members. Slenderness of compression members (CMN) shall not exceed limit values given in table 19 of SNiP 2.01.07.- 81*. Value of coefficient α being used in table 19 is taken within limits from 0,5 to 1,0. Limit slenderness value depends on stress acting in the member, section area, buckling coefficient and design resistance of steel.

Since slenderness can be different in various planes the greatest slenderness is assumed in calculations.

D13.B.3.3 Flexural members

Members subjected to the action of bending moments and shear forces are called flexural members.

Calculation of flexural members consists of verification of strength, stability and deflection.

Normal and tangential stresses are verified by strength calculation of members. Normal stresses are calculated in the outermost section fibres. Tangential stresses are verified in the neutral axis zone of the same section. If normal stresses do not exceed design steel strength and tangential stresses do not exceed design value of steel shear strength $R_s\gamma_s$ then according to clause 5.14 of SNiP 2.01.07.- 81* principal stresses are checked.

General stability of member subjected to bending in one plane are calculated in accordance with clause 5.15 of SNiP 2.01.07.- 81*, and subjected to bending in two planes – in accordance with “Guide to design of steel structures” (to SNiP 2.01.07.- 81*). Coefficient φ_b value is determined according to appendix 7 of SNiP 2.01.07.- 81*. Additional data about load (concentrated or distributed), numbers of bracing restrains of compression flanges, location of applied load are required. For closed sections it is assumed that coefficient $\varphi_b = 1.0$.

Simply supported (non-continuous) beams can be calculated in elastic as well as in elastic-plastic state according to requirements of clause 5.18 of SNiP 2.01.07.- 81*. Calculation can be selected by specification of structure in input data.

Stiffness of flexural members is verified comparing input value of deflection limit (through parameter DFF) with maximum displacement of a section of flexural member allowing for load reliability coefficient, which is specified, in input data. Limit values of deflection are determined in accordance with SNiP 2.01.07.- 85 “Loads and Actions. Addition chapter 10. Deflections and displacements”. Verification of deflection is performed only in the case of review (CHECK) problem.

D13.B.3.4 Eccentric Compression/Tension Members

Eccentric compression or tension members are subjected to simultaneous action of axial force and bending moment. Bending moment appears due to eccentric application of longitudinal force or due to transverse force.

Stress in eccentric compression/tension members is obtained as a sum of stresses due to axial force and bending.

Following the requirements of clause 5.25 of SNiP 2.01.07.- 81* resistance of eccentric compression/tension member taking into consideration condition $R_y < 530\ MPa$, $\tau < 0.5R_s$ and $N/(A_n R_y) > 0.1$ is calculated by formula 49, and in other cases-by formula 50. Calculations of stability verification are performed according to requirements of clauses 5.27, 5.30, 5.32 or 5.34.

Calculation for strength of eccentric tension members is made according to formula 50 of SNiP 2.01.07.- 81*.

When reduced relative eccentricity $m_{ef} > 20$ eccentric compression members are calculated as flexural members (N = 0), when $m_{ef} < 20$ strength by formula 49 is not verified (clause 5.24).

D13.B.4 Design Parameters

Information on parameters, data used for check and selection of sections in design of steel structures according to Russian Code is presented in the following table.

In this version of calculation according to requirements of SNiP 2.01.07.- 81* there is common database of equal legs angles and unequal legs angles, therefore solution of section selection problem may give equal legs angle as well as unequal legs angle irrespective of set at the beginning. The same is and with rectangular and square tubes.

Values of parameters do not depend on command `UNIT`. Only these values of parameters, which differ from, defined in the program need to be included in the input data file.

Review of sections (command `CHECK`) can be performed according to the first and the second group of limit states. Selection of section (command `SELECT`) can be performed only according to the first group of limit states with subsequent recalculation and verification of selected section with allowance for deflection.

Calculation for the first group of limit states involves selection of members according to strength and stability. Parameters `CMN` and `CMM` give opportunity to set slenderness limit for compression and tension members respectively for their stability calculation, or refuse consideration of slenderness by setting default parameters. In this case selection of sections will be performed with consideration only of strength check.

Check for deflection performed by setting parameter `DFF` (maximum allowable relative deflection value) different from set in the program.

In the case of application of steel not defined by SNiP and/or GOST it is necessary to set their design strength by parameters `UNL` and `PY`.

In determination of steel parameters `SBLT` and `MAIN` shall be approved (see Table 15B.4).

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 200: Parameters for Steel design according to Russian Code (SNiP II – 23 – 81*, edition 1990)

Parameter Name	Default Value	Description
CODE	-	Must be specified as `RUSSIAN 1990` Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).

Parameter Name	Default Value	Description
BEAM	1	Member design parameter: • BEAM = 0, Design members for forces at their ends or at the sections defined by SECTION command; • BEAM = 1, Calculate the major axis moment Mz at 13 points along the beam and design beam at the location of maximum Mz; • BEAM = 2, Same as BEAM=1, but additional checks are carried out at beam ends and at critical inter mediate section; • BEAM = 3, Calculate forces at 13 points and perform design checks at all locations including the ends
CB	1	Place of loading on beam: • CB = 1, for loading on top flange; • CB = 2, for loading on bottom flange
CMM	0	Slenderness limit value for tension members: • CMM = 0, if slenderness is suppressed; • CMM = 2, if ultimate slenderness value is "150"; • CMM = 2, if ultimate slenderness value is "200"; • CMM = 3, if ultimate slenderness value is "250"; • CMM = 4, if ultimate slenderness value is "300"; • CMM = 5, if ultimate slenderness value is "350"; • CMM = 6, if ultimate slenderness value is "400 Set slenderness limit value not equal to "0" for design with evaluation of buckling effect

Parameter Name	Default Value	Description
CMN	0	Slenderness limit value for compression members: • CMN = 0, if slenderness is suppressed • CMN = 1, if slenderness limit value is 180-60a • CMN = 2, if slenderness limit value is 120 • CMN = 3, if slenderness limit value is 210-60a • CMN = 4, if slenderness limit value is 220-40a • CMN = 5, if slenderness limit value is 220 • CMN = 6, if slenderness limit value is 180-60a • CMN = 7, if slenderness limit value is 210-60a • CMN = 8, if slenderness limit value is 200 • CMN = 9, if slenderness limit value is 150 Set slenderness limit value not equal to "0" for design with evaluation of buckling effect
DFF	0.	Allowable limit of relative local deflection (Member length/ Deflection Ratio): Default value 0 is valid if design is applied without deflection limitation. Set for deflection check only
DMAX [m]	1.	Maximum allowable section depth
DMIN [m]	0.	Minimum allowable section depth
GAMC1	1.0	Specific service condition coefficient for buckling design

Parameter Name	Default Value	Description
GAMC2	1.0	Specific service condition coefficient for strength design
GMF	1.0	Ratio between design and characteristic load value
KY	1.0	Coefficient of effective length in respect to local axis Y (in plane XZ)
KZ	1.0	Coefficient of effective length in respect to local axis Z (in plane XY)
LEG	4	Type and position of loading on beam: • LEG = 1, for loading concentrated in the middle span; • LEG = 2, for loading concentrated in the quarter of the span; • LEG = 3, for loading concentrated at the end of bracket; • LEG = 4, for loading uniformly distributed on beam; • LEG = 5, for loading uniformly distributed on bracket
LY [m]	Member length	Effective length in respect to local axis Y (in plane XZ) Default is selected member's length
LZ [m]	Member length	Effective length in respect to local axis Z (in plane XY) Default is selected member's length

Parameter Name	Default Value	Description
MAIN	1	Standard of steel grade (GOST): • MAIN = 1, if Standard of steel grade is GOST27772-88; • MAIN = 2, if Standard of steel grade is GOST10705-80; • MAIN = 3, if Standard of steel grade is GOST10706-76; • MAIN = 4, if Standard of steel grade is GOST8731-87; • MAIN = 5, if Standard of steel grade is TY14-3-567-76
NSF	1.0	Net section factor for tension members or web section area weakening factor for bending members
PY [MPa]	0	Design steel strength (yield strength): If parameters MAIN according to Standard of steel grade (GOST) and by SGR according to Steel grade (STAL) are not defined
RATIO	1.0	Permissible ratio of the actual capacities.
SBLT	0	Number of lateral bracing restraints along the span: • SBLT = 0, if beam not fixed; • SBLT = 1, one restraint in the middle of the span; • SBLT = 2, 3, etc. number of uniformly spaced lateral supports along the span
SGR	1	Steel grade (STAL). Refer to Table 12B.4 below.

Parameter Name	Default Value	Description
TB	0	Indication of elastic or elastic-plastic calculation: • TB = 0, for elastic calculation • TB = 1, for elastic-plastic calculation Set for members under bending or non-axial compression/tension only.
TRACK	0	Output parameter: • TRACK = 0, for suppressed output information; • TRACK = 1, for extended output information; • TRACK = 2, for advanced output information
UNL [MPa]	0	Design steel strength (ultimate strength): If parameters MAIN according to Standard of steel grade (GOST) and by SGR according to Steel grade (STAL) are not defined

Table 201: Steel types for design of steel structures according to SNiP 2.01.07.-81* (table 51 and 51a)

SGR Value	Steel	Parameter MAIN	GOST	For members*
1	C235	1	GOST 27772-88	GT, F
2	C245	1	“	GT, F
3	C255	1	“	GT, F

17	20	4	GOST 8731-87	Tube
18	16G2AF	5	TY 14-3-567-76	Tube

*GT – members from sheet and roll-formed tubes

F – rolled section steel

D13.B.5 Member Selection and Code Check

Both code checking and member selection options are available in SNiP 2.23-81*.

Output of selection and check results are given in suppressed, extended and advanced forms. Form of output results depends on value of parameter TRACK.

Results are presented in tables. Three versions of output results are possible: suppressed – results according the critical strength condition (TRACK=0), extended - results according to all check conditions (TRACK=1) and advanced – complete information on results of member design (TRACK=2).

In tables of results common data for all TRACKs are indicated:

(TRACK=2)

In tables of results common data for all TRACKs are indicated:

number of member;
type and number of cross-section;
result obtained (ACCEPTED – requirements are met, FAILURE – are not met);
abbreviated name of normative document (code, standard) (SNiP);
number of check clause;
safety of strength (ratio between design and normative values);
number of the most unfavorable loading;

value of longitudinal force acting in the member with subscript indicating its direction ("C" – compression, "P" – tension);

bending moments in relation to local member axes Z and Y;

distance to section, in which the most unfavorable combination of forces acts.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

Note: The output for the Russian code uses the axes system from STAAD.Pro, except where details of the equations from the code are printed, in which case the axes system is as defined in the code.

D13.B.5.1 Example of TRACK 0 output

In suppressed form (`TRACK 0`) results are presented according to the critical check for given member with indication of SNiP clause number, according to which strength safety of the member is minimum.

```
=========================================================================
MEMBER     CROSS          RESULT/   CRITICAL COND/    RATIO/    LOADING/
           SECTION NO.      FX            MZ            MY      LOCATION
=========================================================================
   1         I60            PASS      SNiP- 5.18       0.68       1

                        0.000E+00     -4.650E+02    0.000E+00   3.000E+00
   1         I60            PASS      SNiP- DISPL      0.36       1
                        0.000E+00     -4.650E+02    0.000E+00   3.000E+00
```

D13.B.5.3 Example of a TRACK 2 output

In advanced form (`TRACK=2`) in addition to tabled results supplementary information is presented.

Material characteristics:

Steel;

Design resistance;

Elasticity modulus;

Section characteristics:

Length of member;

Section area;

Net area;

Inertia moment (second moment of area) (I);

Section modulus (W);
First moment of area (S);
Radius of gyration;
Effective length;
Slenderness;
Results are presented in two columns, Z and Y respectively.
Design forces:
Longitudinal force;
Moments;
Shear force.

Signs “+” and “-“ indicate direction of acting longitudinal force, bending moments and shear forces in accordance with sign rules assumed in program STAAD.

Check results in advanced form are presented with values of intermediate parameters by formulas in analytical and numerical expression with indication of SNiP clause.

```

```

Conventional notations assumed in presentation of results: “+”, “-“, “/”, “*”,”**”, “SQRT”, their respective meanings (i.e., addition, subtraction, division, multiplication, raising to the second power (squared), and square root). Conventional notations of stresses, coefficients and characteristics of steel resistance comply with accepted in the SNiP standard. Only Greek letters are changed by their names (e.g., , γ_c-GAMAC; α-ALPHA; β-BETA, η-ETA, φ-PHI, etc.).

D13.C. Russian Codes - Steel Design Per SP 16.13330.2011

STAAD.Pro is capable of performing steel design based on the Russian code Сп 16.13330.2011 *стальные конструкции* (SP 16.13330.2011 *Steel Structures*).

Note: This code supersedes SNiP II-23-81*.

D13.C.1 General

Design Code SP *Steel Structures* –as is the case in the majority of modern codes– is based on the method of limit states. The following groups of limit states are defined in the Code.

- The first group concerns losses of general shape and stability, failure, and qualitative changes in configuration of the structure (i.e., ultimate limit states). Appearance of non-allowable residual deformations, displacements, yielding of materials or opening of cracks.

  Analysis of structures for the first limit state is performed using the maximum (design) loads and actions, which can cause failure of structures.
- The second group concerns states of the structure which worsen their service or reduce durability due to exceeding allowable deflections, deviations, settlements, vibrations, etc. (i.e., service conditions)

  Analysis of structures for the second limit state is performed using service (normative) loads and actions. Relation between design and normative loads is referred to as coefficient of load reliability, which is defined in SNiP 2.01.07.- 85 “Loads and Actions”.

The coefficient of reliability for destination GAMA n according to SP 20.13330.2011 shall be taken in to account determining loads or their combinations.

According to the European standards, the strength of steel is represented by the characteristic value. To obtain the design value, the steel reliability coefficient `GAMM` is used. The default value of `GAMM` is 1.0.

Note: If there are doubts about the conformance of the European steel type and the standard, it is necessary that the steel type designation used by the `ENSGR` parameter be set the same as the standard selected in the `ENMAIN` parameter. If the chosen steel type is *not* present in the chosen standard, then the program exits with the error code `MEMBER NO.145 STEEL S275 IS NOT PRESENT IN EN 10025-6 * ERROR *` The calculation will be terminated if the thickness of the designed member web or flange thickness is outside the limits of the steel standard. The error code will be issued: `MEMBER NO. 1000 CURRENT THICKNESS IS OUT OF EN 100219-1 * ERROR *`

Only members from rolled, tube, and roll-formed assortment sections, and compound sections (such as double angles of T-type sections, double channels) are may be designed in STAAD.Pro.

Economy of selected section is indicated by ratio the ration (which can be set using the `RATIO` parameter) $\sigma / R_y y_c$ presented in calculation results. A section is economical when said ratio equals to 0.9 – 0.95.

D13.C.2 Member Capacities

D13.C.2.1 Axial Tension Members

Stress in a section of an axial tension member shall not exceed design strength R_y of the selected steel multiplied by the coefficient of service conditions, γ_c (input by the `GAMC1` and `CAMC2` parameters), take from table 1 of SP 16.13330.2011.

The slenderness of tension members shall not exceed the slenderness limit, λ_u indicated in table 33 of SP 16.13330.2011 as equal to 150. This limit may be specified using the `CMM` parameter, which defaults to 150.

The net section factor (the ratio of A_{net}/A_{gross}) is specified by the `NSF` parameter and is used for tension members to allow for the reduction of design cross-section area.

D13.C.2.2 Axial Compression Members

All axial compression members are calculated as long bars (i.e., with allowance for slenderness - $\lambda = l_0/i_{min}$, where l_0 is the effective length of the element). Calculation is performed in accordance with clause 7.1.1 of SP 16.13330.2011, with the buckling coefficient ϕ determined by equation 8. Effective lengths of elements (within and out-of plane) take into account role and location of the bar in the structure, as well as fixity of the ends ($l_0 = \mu_1$), are determined according the requirements of section 10.3 of SP 16.13330.2011 and are set by the user specification of the members. Slenderness parameters, $\mu_{x(z)}$ and μ_y are set using the parameters `KZ` and `KY`, respectively. If the slenderness parameters of an element is not precisely known, then the effective length can be specified using the `LY` and `LZ` parameters, instead. The ultimate slenderness of compression members shall now exceed the limit values given in table 32 of SP 16.13330.2011, or a user-specified value provided through the `CMN` parameter. The value of the coefficient α used in Table 32 is taken within the limits of 0.5 and 1.0. The limiting slenderness value in compression elements depends on stress acting the member, buckling coefficient, and design resistance of the steel.

Since the slenderness can be different in various planes, the greatest slenderness ratio is assumed in calculations. A warning is given if the slenderness ratio of a compression element exceeds the limit, but the calculations are continued. If the slenderness ratio exceeds the limit value, the output line containing the slenderness check is preceded by a # (pound or hash symbol).

The calculations of single members are performed in this manner. If the member is subjected to axial forces and bending moment (e.g., due to self weight), then the calculation of load bearing capacity will be done taking into account the axial force and bending moments and the buckling resistance only under the axial compression according to clause 7.1 of SP 133330.2011. Local buckling of the web and flanges of centrally loaded members is checked. Stiffener ribs are recommended if necessary.

D13.C.2.3 Flexural Members

Member subjected to bending moments and shear forces are called flexural members.

There are three classes of flexural elements:

1. **Elastic** - in cross-section, the stress in the extreme compression fiber of the steel member –assuming an elastic distribution of stresses– can reach the yield strength. $\sigma \le R_y$, where σ is the absolute value of the stress.
2. **Elasto-plastic** - in on part of the cross-section, the stresses are $\sigma \le R_y$ and in another $\sigma = R_y$.
3. **Plastic state** (i.e., conditional plastic hinge) - across the entire cross-section, the stresses are $\sigma = R_y$.

The parameter `TB` is used to specify either class 1 (elastic) or class 2 (elasto-plastic).

The calculation of flexural members consists of verification of strength, stability, and deflection.

Normal and tangential stresses are verified by strength calculations of members. Normal stresses are calculated in the outermost section fibers. Tangential stresses are verified in the neutral axis zone of the same section. If the normal stresses do not exceed design steel strength and tangential stresses do not exceed the design value of steel shear strength, $R_s\gamma_s$, then according to clause 8.2.1 of SP 16.13330.2011 the principal stresses are checked.

For elements subjected to biaxial bending moments according to clauses 8.2.1 and 8.4.1 of SP 16.13330.2011

D13.C.2.4 Eccentrically Compressed/Tensioned Members

Eccentrically compressed or tensioned members are subjected to simultaneous action of axial force and bending moment. Bending moment appears to eccentrically applied longitudinal force or due to transverse force.

		or
		`ST TUBE TH 0.003 WT 0.12 DT 0.16`

Table 203: Compound Sections for Russian Steel Design

Section	Section Type	Designation form
Double channels		`D C14 SP 0.01` (SP – clear distance between channel walls)
Double equal legs angles		`LD L100x100x7 SP 0.01` (SP – clear distance between angle walls)
Double unequal legs angles with long legs back to back		`LD L125x80x10 SP 0.01` (SP – clear distance between angle walls)
Double unequal legs angles with short legs back to back		`SD L125x80x10 SP 0.01` (SP – clear distance between angle walls)

Section	**Section Type**	**Designation form**

Tee with flange at the top
Note: Flange of Tee beam is at the top part of cross-section if beta angle = 0°, or at the bottom part if beta angle = 180°.
		`T I12`
		`T B1-10`
		`T SH1-23`
		`T K1-20`

For entry of cross-sectional dimensions command `MEMBER PROPERTIES RUSSIAN` is used.

Refer to D13.B.2 Built-in Russian Steel Section Library (on page 1890) for an example.

D13.C.4 Design Parameters

Table 204: Design parameters for design of steel members per SP 16.13330.2011

Parameter Name	**Default Value**	**Description**
CODE	-	Must be specified as `RUSSIAN 2011` Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
BEAM	1	Member design parameter: 0. Design member for forces at their ends or at the sections defined by the SECTION command (TR.41 Section Specification (on page 2665)). 1. Calculate the major axis moment, Mz, and 13 points along the beam and design the beam the location of the maximum Mz value. 2. Same as BEAM = 1, but additional checks are carried out at beam ends and at critical intermediate sections. 3. Calculate forces at 13 points and perform design checks at all locations, including at ends

Parameter Name	Default Value	Description
BMT		Bimoment for design of eccentrically loaded members per clause 8.4 or members subjected to two bending moments per clause 8.2.
CB	1	Location of loading on the beam: 1. top flange 2. bottom flange
CMM	0	Slenderness limit for tension members: 0. suppress slenderness check 1. 150 2. 200 3. 250 4. 300 5. 350 6. 400
CMN	0	Ultimate slenderness for compression members. Limits as per SP 16.13330.2011 clause 10.4, Table 32: 0. suppress slenderness check 1. 180-60a 2. 120 3. 210-60a 4.220-40a 5. 220 6. 180-60a 7. 210-60a 8. 200 9. 150 where a = alpha calculated as defined in SP 16.13330.2011 Table 32.
DFF	None	"Deflection Length" / Maximum allowable local deflection
DJ1	Start Jointof member	

Parameter Name	Default Value	Description
DJ2	End Joint of member	
DMAX	1,000 in	Maximum allowable section depth
DMIN	0	Minimum allowable section depth
ENMAIN	1	The number of the steel standard taken from Table 3.1 in EN 1993-1-1: 2005
ENSGR	1	The number of the steel grade from Table 3.1 in EN 1993-1-1: 2005. D5.C.6 Design Parameters (on page 1502) for values. Also, see Note 1 below.
GAMC1	1.0	Specific service condition coefficient for buckling design
GAMC2	1.0	Specific service condition coefficient for strength design
GAMM	1.0	Specific partial coefficient for steel for European . Refer to D13.C.1 General (on page 1905) for details.
GMF	1.0	Ratio between design and characteristic load value
KY	1.0	Coefficient of effective length in respect to local axis Y (in plane XZ)
KZ	1.0	Coefficient of effective length in respect to local axis Z (in plane XY)
LEG	4	Describes the type of and position of loading on the beam: 1. concentrated in middle of the span 2. concentrated in the quarter of the span 3. concentrated at the end of bracket 4. uniformly distributed along beam 5. uniformly distributed on bracket

Parameter Name	Default Value	Description
LY	Member Length	Effective length in respect to local axis Y (in plane XZ)
LZ	Member Length	Effective length in respect to local axis Z (in plane XY)
MAIN	1	Standard of steel grade (GOST): 1. GOST27772-88 2. GOST10705-80 3. GOST10706-76 4. GOST8731-87 5. TY14-3-567-76
NSF	1.0	Net section factor for tension members or web section area weakening factor for bending members
PY	0	Design steel strength (yield strength) **Note:** Used when parameters `MAIN` and `SGR` are not defined for Russian steel materials or `ENMAIN` and `ENSGR` for European steel materials. See Note 1 below.
RATIO	1.0	Permissible ratio of the actual capacities.
SBLT	0	Number of lateral bracing restraints along the span: 0. beam is not fixed laterally 1. singe restraint at mid-span 2. or higher is the number of uniformly spaced lateral restraints along the span

Parameter Name	Default Value	Description
SGR	1	Steel grade (STAL): See Note 1 below. 1. S235 2. S245 3. S255 4. S285 5. S345 6. S345K 7. S375 8. S390 9. S440 10. S590 11. S590K 12. VSt3kp 13. VSt3ps 14. VSt3sp 15. VSt3ps4 16. St3ps4 17. 20
TB	1	Indication of stress strain state per Cl 4.2.7: 1. 1st Class (Elastic) 2. 2nd Class (Elasto-plastic) 3. 3rd Class (Plastic) The engineer shall consider the appropriate class of the member, as it is used in multiple checks under Ch.8. for elastic or elastic-plastic calculation for bending members (non-axially compressed or tensioned): Cl 8.2.1, Cl. 8.2.3, Cl. 8.4.1, Cl. 8.4.4, and Cl 8.4.6.

Parameter Name	Default Value	Description
TRACK	0	Output details: 0. suppressed output information 1. extended output information for the critical section under the critical load case 2. full output information for the critical section under the critical load case 3. extended output information for all sections under all load cases.
UNL	0	Design steel strength (ultimate strength) **Note:** Used when parameters MAIN and SGR are not defined.

Notes

1. It is common practice to design only Russian or European shapes to the SNiP codes. For Russian steel sections, the steel design strength value, Ry, of a particular steel grade can be obtained from Table C.5 of SP 16.13330.2011 and is used for the SGR parameter. For European sections, the ENSGR and ENMAIN parameters are used accordingly. The ENSGR parameter is valid only with a corresponding value of the ENMAIN parameter when specifying European steel grades. If steel sections from other countries must be used, the PY parameter is used to specify the steel strength.

D13.C.5 Member Selection and Code Check

Both code checking and member selection options are available in SP 16.13330.2011.

Output of selection and check results are given in suppressed, extended and advanced forms. Form of output results depends on value of parameter TRACK.

Results are presented in tables. Three versions of output results are possible: suppressed – results according the critical strength condition (TRACK=0), extended - results according to all check conditions (TRACK=1) and advanced – complete information on results of member design (TRACK=2).

In tables of results common data for all TRACKs are indicated:

(TRACK=2)

In tables of results common data for all TRACKs are indicated:

number of member;
type and number of cross-section;
result obtained (ACCEPTED – requirements are met, FAILURE – are not met);

abbreviated name of normative document (code, standard) (SNiP);
number of check clause;
safety of strength (ratio between design and normative values);
number of the most unfavorable loading;
value of longitudinal force acting in the member with subscript indicating its direction (“C” – compression, “P” – tension);
bending moments in relation to local member axes Z and Y;
distance to section, in which the most unfavorable combination of forces acts.

Note: Slenderness criteria is not reported in the Design Results table of Post-processing mode because Slenderness check is performed to check overall limit; not a guiding criteria for member check.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

Note: The output for the Russian code uses the axes system from STAAD.Pro, except where details of the equations from the code are printed, in which case the axes system is as defined in the code.

D13.C.5.1 Example of TRACK 0 output

In suppressed form (TRACK 0) results are presented according to the critical check for given member with indication of SP 16 clause number, according to which strength safety of the member is minimum.

D13.C.5.3 Example of a TRACK 2 output

In advanced form (TRACK=2) in addition to tabled results supplementary information is presented.

Material characteristics:
Steel;
Design resistance;
Elasticity modulus;
Section characteristics:
Length of member;
Section area;
Net area;
Inertia moment (second moment of area) (I);
Section modulus (W);
First moment of area (S);
Radius of gyration;
Effective length;
Slenderness;
Results are presented in two columns, Z and Y respectively.
Design forces:
Longitudinal force;
Moments;
Shear force.

Signs "+" and "-" indicate direction of acting longitudinal force, bending moments and shear forces in accordance with sign rules assumed in program STAAD.

Check results in advanced form are presented with values of intermediate parameters by formulas in analytical and numerical expression with indication of SNiP clause.

Conventional notations assumed in presentation of results: “+”, “-“, “/”, “*”,”**”, “SQRT”, their respective meanings (i.e., addition, subtraction, division, multiplication, raising to the second power (squared), and square root). Conventional notations of stresses, coefficients and characteristics of steel resistance comply with accepted in the SP standard. Only Greek letters are changed by their names (e.g., , γ_c-GAMAC; α-ALPHA; β-BETA, η-ETA, φ-PHI, etc.).

D13.D. Russian Codes - Concrete Design Per SP 63.1330.2012

STAAD.Pro is capable of performing concrete design for beams, columns, slabs, and walls based on the Russian code Сп63.1330.2012 *Бетонные и железобетонные конструкции. Основные положения* (SP 63.1330.2012 *Concrete and Reinforced Concrete Structures. Basic Provisions*).

Note: This code supersedes SNiP 2.03.01-84*.

Design of members per SP 63.1330.2012 requires the *STAAD ECC Super Code* SELECT Code Pack.

Note: This feature requires STAAD.Pro 2007.11 or greater.

D13.D.1 General

Russian Code SP 63.1330.20121 *Concrete and Reinforced Concrete Structures - Basic Provisions* is based on the method of limit states. This code defines two groups of limit states.

Analysis according to the first group of limit states is performed to avoid the following phenomena:

- brittle, plastic or other type of failure,
- loss by structure of stable form or position,

Analysis according to the second group of limit states is performed to avoid the following phenomena:

- excessive opening of cracks (if they are allowed according to service conditions)

Analysis of structures for the first group of limit states is performed for the maximum (design) loads and actions. Analysis of structures for the second group of limit states is made in accordance with the operational (normative) loads and actions. Ratio between design and normative loads is called reliability coefficient for loads which is determined according to SNiP 2.01.07.-85 *Loads and actions*.

STAAD.Pro calculates reinforcement for concrete members. Algorithms for calculation of reinforcement of concrete linear (beams, columns) and 2D (two dimensional) (slabs, walls, shells) members are incorporated into STAAD.Pro. In addition to SP5 2.13330.2011, the *Guide for design of plain concrete and reinforced concrete structures from normal weight and lightweight concrete (to SNiP 2.03.01-84)* has been incorporated in the calculation algorithms.

The program can automatically calculate reinforcement for beams of rectangular or T section and for columns of rectangular or circular section.

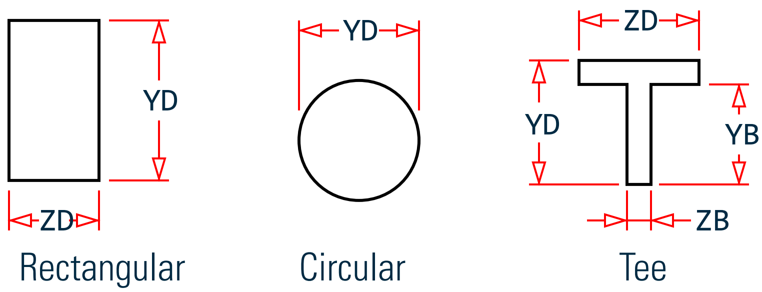

Figure 190: Section types for concrete design

Flange of T-shape beams may be situated at the top zone of the section if the angle β = 0° (`BETA 0`), or at the bottom zone of the section, if β = 180° (`BETA 180`).

D13.D.2 Design Parameters

Values of parameters do not depend on the `UNIT` command.

Commands for calculation of reinforcement are located in the input data file after the command of analysis and as a rule, after output commands to print results of calculation.

Table 205: Parameters for concrete design according to Russian Code SP 63.1330.2012

Parameter Name	Default Value	Description
CODE	-	Must be assigned as `RUSSIAN` Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
BCL	15	Compression class of concrete

Parameter Name	Default Value	Description
CL	0.05	(Slabs/Walls) Distance from top/ bottom face of slab/wall element to the center of the longitudinal reinforcing bars located in the first local (x) direction (i.e., main thickness of top/bottom concrete cover for slab/wall elements)
CL1	0.05	(Beams) Distance from the top or bottom edge of the beam cross section to the center of longitudinal reinforcement (Columns) Distance from the edge of the column cross section to the center of the longitudinal reinforcing bars
CL2	0.05	(Beams) Distance from left/right side of the beam cross section to the center of longitudinal reinforcement
CRA	0.05	(Slabs/Walls) Distance from top/ bottom face of slab/wall element to the center of the transverse reinforcing bars located in the second local (y) direction (i.e., secondary thickness of top/bottom concrete cover for slab/wall elements)
DD1	16	(Beams) Diameter of the longitudinal reinforcement bars in the beam tension zone (Columns) Minimum diameter of longitudinal reinforcement bars for the column
DD2	16	(Beams) Diameter of the shear reinforcement bars for the beam (Columns) Maximum diameter of longitudinal reinforcement bars for the column

Parameter Name	Default Value	Description
DEPTH	YD	(Beams) Design depth of beam the section. Used for design only, with the default value taken as the YD dimension in the member properties.
EFA	0	(Beams) Face of support location at the end of the beam
ELY	1	(Columns) Length coefficient to evaluate slenderness effects in the local Y axis
ELZ	1	(Columns) Length coefficient to evaluate slenderness effects in the local Z axis
FWB	ZB	(Beams) Design width of the beam's bottom flange. Used for design only, with the default value taken as the ZB dimension in the member properties.
FWT	ZD	(Beams) Design width of the beam's top flange. Used for design only, with the default value taken as the ZD dimension in the member properties.
MMA	0	(Slabs/Walls) Design parameter of slab/wall reinforcement: 0. reinforcement calculation applied by stresses in local axis 1. reinforcement calculation applied by principal stresses
MMB	1	(Slabs/Walls) Design parameter of slab/wall reinforcement: 0. the effect of additional eccentricity is *not* considered 1. the effect of additional eccentricity is considered
NLT	1	Load case ID number of the long-term load case

Parameter Name	Default Value	Description
NSE	13	(Beams) Number of equally spaced sections used for beam design. The upper limit is 20.
RCL	3	Class of longitudinal reinforcement: 1. A240 2. A400 3. A500 4. A600
RSH		(Beams) Class of shear reinforcement: 1. A240 2. A400 3. A500 4. A600
SDX	16	(Slabs/Walls) Diameter of reinforcing bars located in the first local (X) direction
SDY	16	(Slabs/Walls) Diameter of reinforcing bars located in the second local (Y) direction
SELX	0	(Slabs/Walls) Design length of wall member to evaluate slenderness effects in local X axis
SELY	0	(Slabs/Walls) Design length of wall member to evaluate slenderness effects in local Y axis
SFA	0	(Beams) Face of support location at the start of the beam

Parameter Name	Default Value	Description
SSE		(Beam) Limit state parameter for beam design: 0. reinforcement amount calculated for required load capacity (i.e., the first limit state) 1. reinforcement amount calculated for cracking requirements (i.e., the second limit state)
STA	0	(Slabs/Walls) Parameter of limit state for slab/wall design: 0. non symmetric reinforcement amount calculated for required load capacity (i.e., the first limit state) 1. symmetric reinforcement amount calculated for required load capacity (i.e., the first limit state) 2. non symmetric reinforcement amount calculated for cracking requirements (i.e., the second limit state) 3. symmetric reinforcement amount calculated for cracking requirements (i.e., the second limit state)
TEM	0	Parameter of concrete hardening conditions: 0. normal concrete 1. fine-grain concrete 2. (Beams and Columns) fine-grain, steam hardened concrete
UB2	0.9	(Slabs/Walls) Specific service conditions coefficient for concrete, γ_b
UBM	1	Product of service conditions coefficients for concrete, except for γ_b in the case of slabs or walls (see UB2)

Parameter Name	Default Value	Description
USM	1	(Beams and Columns) Total product of service conditions coefficients for longitudinal reinforcement, γ_s
WLT	0.3	(Beams and Slabs/Walls) Ultimate width of long-term crack
WST	0.4	(Beams and Slabs/Walls) Ultimate width of short-term crack.

D13.D.3 Beams

Reinforcement areas are calculated for beams of rectangular and T cross section. When calculating the longitudinal reinforcement bending moment about the local axis Z and torsional moments are considered; the influence of longitudinal forces and bending moments in relation to local axis Y is ignored. When calculating transverse reinforcement shear forces parallel to local axis Y and torsional moments are considered.

Reinforcement for beams can be calculated either for strength conditions or from crack width limits using the `SSE` parameter.

In general, the calculation of reinforcement for beams is carried out two times: once according to strength conditions and again according to crack width limitation. In reinforcement calculations for strength conditions (i.e., the first limit state), design load values must be used. In reinforcement calculations for crack width limitation (i.e., the second limit state), characteristic (i.e., normative or service) load values are used. Using the multiple analysis capability of STAAD.Pro allows you to carry out both calculations in a single analysis and design run.

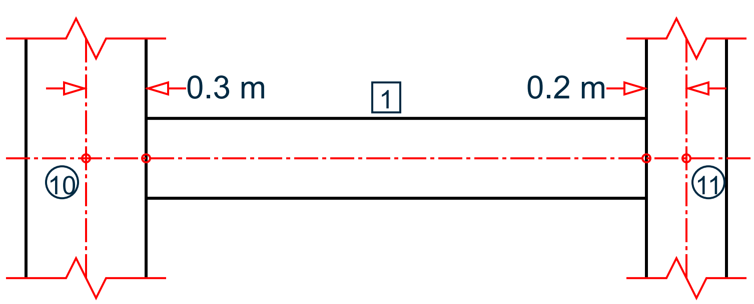
In most cases, calculation of reinforcement is carried out with only a partial number of load cases. In such cases, the `LOAD LIST` command is used to indicate the load case numbers. The load case number indicated by the `NLT` parameter –used to indicate the load cases for permanent and long-term loads– must be included in the list of considered loads.

The parameter `BCL` can be equal to any value of concrete compression strength class given in SNiP 2.03.01-84*, as well as any intermediate value.

It should be noted that the accuracy of results in calculating transverse reinforcement increases with the value of the `NSE` parameter.

Parameters `SFA` and `EFA` are considered only in the calculation of transverse reinforcement. Beam 1 shown in the following figure has rigid end-links of 0.3m at the start of the beam and 0.2m at the end of the beam. In the STAAD input file, this is modeled as:

```
MEMBER OFFSET
1 START 0.3 0 0
1 END -0.2 0 0
```



When the `MEMBER OFFSET` command is used, the forces used in calculation of reinforcement are for a beam whose length is taken from point a to point b (i.e., between the faces of the supporting columns) in the figure. In this case, it is necessary to use the default values of the parameters `SFA` and `EFA` (zero).

When the `MEMBER OFFSET` command *not* is used, the forces used in calculation of reinforcement are for a beam whose length is taken from node 10 to node 11. In this case, it is necessary to assign the distances to the design parameters `SFA` and `EFA`.

```
CODE RUSSIAN
SFA 0.3 1
EFA 0.2 1
```

Note: The sign is positive for the `EFA` parameter, as it is assumed to be taken away from the gross beam length.

In both cases, the calculated quantity of transverse reinforcement is the same. The calculated quantity of longitudinal reinforcement in the second case will be greater.

For beams, the following output is generated:

beam number;
method of calculation (according to conditions of strength or limitations of opened crack width);
length and cross-sectional dimensions;
distance from resultant of forces acting in bottom/top reinforcement to bottom/top edge of the section;
distance from the side edge of cross-section of the beam web to the centroid of longitudinal bars located at this edge;
concrete class;
class of longitudinal and transverse reinforcement;
assumed in calculations bar diameters of longitudinal and transverse reinforcement;
calculation results of longitudinal and transverse reinforcement (in two tables).

In nine columns of the first table the following results are presented:

Section – distance of the section from the “start” of the beam, мм;
As- – cross-sectional area of longitudinal reinforcement in the bottom zone of cross-section of the beam, if angle BETA=0°, or in the top zone, if BETA=180°, sq.cm;
As+ – cross-sectional area of longitudinal reinforcement in the top zone of cross-section of the beam , if angle BETA=0°, or in the top zone, if BETA=180°, sq.cm;
Moments (-/+) – values of bending moments, determining cross-sectional areas of longitudinal reinforcement As* and As* , kNm;
Load. N. (-/+) – numbers of loading versions, determining cross-sectional areas of longitudinal reinforcement;
Acrc1 – short-term opened crack width, mm;
Acrc2 – long-term opened crack width, mm.

Opened crack width is presented only in the case when calculation is performed according to conditions limiting opened crack width.

In ten columns of second table the following results are presented:

Section – distance of the section from the “start” of the beam, mm;
Qsw – intensity of transverse reinforcement, kN/m;
Asw – cross-sectional area of transverse bars, sq.cm, if their step is 10, 15, 20, 25 or 30 cm;
Q – value of shear force parallel to the local axis, kN;

T – value of torsional moment, kNm;
Load N. – number of loading version, determining intensity of transverse reinforcement.

D13.D.4 Columns

Reinforcement for columns of rectangular or circular cross section can be calculated. The flexibility of columns can be evaluated in two ways.

- In the case of linear analysis (i.e., the `PERFORM ANALYSIS` command), the effective length is evaluated using the `ELY` and `ELZ` parameters, conforming to provisions of SP5 2.13330.2011.
- If a `P-DELTA` or `NONLINEAR` (i.e. nonlinear geometry) analysis is performed, the values of the `ELY` and `ELZ` parameters should be close to zero (e.g., ELY = ELZ = 0.01).

Longitudinal reinforcement for columns is calculated only for the strength condition. Longitudinal forces and bending moments in relation to local axes Y and Z are taken into account in longitudinal reinforcement calculations.

For rectangular columns, the following output is generated:

column number;
column length and cross-sectional dimensions;
distance of centroid of each longitudinal bar from the nearest edge of the cross-section;
concrete class;
longitudinal reinforcement class;
range of longitudinal reinforcement bar diameters assumed in calculation;
diameter of longitudinal reinforcement bars obtained in calculation;
total quantity of longitudinal bars;
quantity of longitudinal bars at each cross-section edge, directed parallel to the local axis Y ;
quantity of longitudinal bars at each cross-section edge, directed parallel to the local axis Z.

In nine columns of the table under the heading LONGITUDINAL REINFORCEMENT, the following output is presented:

Section – distance of the section from the “start” of the column, mm;
Astot – total cross-sectional area of longitudinal reinforcement, sq.cm;
Asy – cross-sectional area of longitudinal reinforcement bars at each edge of section, directed parallel to the local axis Y , sq.cm;
Asz – cross-sectional area of longitudinal reinforcement bars at each edge of section, directed parallel to the local axis Z , sq.cm;
Percent – reinforcement percentage in the section;
Nx, Mz, My – respective values of longitudinal force and bending moments in relation to the local axes Z and Y , determining cross-sectional area of longitudinal reinforcement;
Load.N. – number of loading version, determining cross-sectional area of longitudinal reinforcement.

D13.D.5 2DElements: Slabs, Walls, and Shells

In general, the calculation of reinforcement for two dimensional elements (i.e., slabs, walls, and shells) is performed two times: once according to conditions of strength and again according to limiting of width of cracks. In reinforcement calculations for strength conditions (i.e., the first limit state), design load values must be used. In reinforcement calculations for crack width limitation (i.e., the second limit state), characteristic (i.e., normative or service) load values are used. Using the multiple analysis capability of STAAD.Pro allows you to carry out both calculations in a single analysis and design run.

Symmetric or non symmetric reinforcement of elements is calculated according to either first or second limit states by using the STA parameter.

It is necessary to pay close attention to the arrangement of local axis of the element with respect to the direction of reinforcement for the calculation of reinforcement. This is controlled using the CL and CRA parameters, as shown in the following figure.

D13.E. Russian Codes - Steel Design per SP 16.13330.2017

STAAD.Pro is capable of performing steel design based on the Russian code Сп 16.13330.2017 *стальные конструкции* (SP 16.13330.2017 *Steel Structures*).

D13.E.1 General

Design Code SP *Steel Structures* –as is the case in the majority of modern codes– is based on the method of limit states. The following groups of limit states are defined in the Code.

- The first group concerns losses of general shape and stability, failure, and qualitative changes in configuration of the structure (i.e., ultimate limit states). Appearance of non-allowable residual deformations, displacements, yielding of materials or opening of cracks.

  Analysis of structures for the first limit state is performed using the maximum (design) loads and actions, which can cause failure of structures.
- The second group concerns states of the structure which worsen their service or reduce durability due to exceeding allowable deflections, deviations, settlements, vibrations, etc. (i.e., service conditions).

  Analysis of structures for the second limit state is performed using service (normative) loads and actions. Relation between design and normative loads is referred to as coefficient of load reliability, which is defined in SP 16.13330.2017.

The coefficient of reliability for destination `GAMA n` according to SP 20.13330.2017 shall be taken into account determining loads or their combinations.

According to SP 16.13330.2017, the strength of steel is represented by the characteristic value. To obtain the design value, the steel reliability coefficient `GAMM` is used. The default value of `GAMM` is 1.0.

Only members from rolled, tube, and roll-formed assortment sections, and compound sections (such as double angles of T-type sections, double channels) are may be designed in STAAD.Pro.

Various checks are made according to SP 16.13330 Design Code, particularly implementing Clauses:

- 7.1. Calculation of elements in central tension and compression with solid sections

- Cl. 7.1.1 Eq. (5)
- Cl. 7.1.3 Eq. (7)
- 7.3. Stability check of walls and flanges of center-compressed elements with solid sections
- 8. Calculation of elements in bend
    - Strength calculation of bending elements with solid sections
        - Cl. 8.2.1 Eq. (41), (42), (43), (44) – for 1st Class Elements
        - Cl. 8.2.3 Eq. (50), (51), (53), (54), (55) – for 2nd and 3rd Class Elements
    - Calculation of general stability of bending elements with solid sections
        - Cl. 8.4.1 Eq (69), (70)
- 9. Calculation of elements in sinuous central force
    - Strength calculation of elements with solid sections
        - Cl. 9.1.1 Eq. (105), (106)
        - Cl. 9.1.2
    - Calculation of stability of elements with solid sections
        - Cl. 9.2.1
        - Cl. 9.2.2 Eq. (109)
        - Cl. 9.2.4 Eq. (111)
        - Cl. 9.2.5 Eq. (112), (113), (114)
        - Cl. 9.2.7
        - Cl. 9.2.8
        - Cl. 9.2.9 Eq. (116), (117)
        - Cl. 9.2.10 Eq. (120), (121), (122)
- 10.4. Ultimate Slenderness of Elements
    - Cl. 10.4.1
- Steel Grades are determined from Appendix C, Tables C.3, C.4, C5.
- Coefficients for the calculation of the stability of centrally- and eccentrically- compressed elements are determined from Appendix E (normative), Tables E.1, E.2, E.3, E.4, E.6.
- Coefficients for calculation of constructional elements with regard to the development of plastic deformations are determined from Appendix F (normative), Table F.1
- Stability coefficient ϕb at a bend is calculated according to Appendix G (obligatory).

Also, the Selection of steel of hot rolled sections, plates, tubes and pipes is implemented.

D13.E.2 Member Capacities

D13.E.2.1 Axial Members in Tension

Stress in a section of an axial tension member shall not exceed design strength Ry of the selected steel multiplied by the coefficient of service conditions, γ_c (input by the `GAMC1` and `CAMC2` parameters), take from table 1 of SP 16.13330.2017.

The slenderness of tension members shall not exceed the slenderness limit, λ_u indicated in table 33 of SP 16.13330.2017 as equal to 150. This limit may be specified using the `CMM` parameter, which defaults to 150.

The net section factor (the ratio of A_{net}/A_{gross}) is specified by the `NSF` parameter and is used for tension members to allow for the reduction of design cross-section area.

D13.E.2.2 Axial Compression Members

All axial compression members are calculated as long bars (i.e., with allowance for slenderness - $\lambda = l_0 / i_{min}$, where l_0 is the effective length of the element). Calculation is performed in accordance with clause 7.1.1 of SP 16.13330.2017, with the buckling coefficient ϕ determined by equation 8. Effective lengths of elements (within and out-of plane) take into account role and location of the bar in the structure, as well as fixity of the ends (l_0 = μ_1), are determined according the requirements of section 10.3 of SP 16.13330.2017 and are set by the user specification of the members. Slenderness parameters, $\mu x(z)$ and μy are set using the parameters `KZ` and `KY`, respectively. If the slenderness parameters of an element is not precisely known, then the effective length can be specified using the `LY` and `LZ` parameters, instead. The ultimate slenderness of compression members shall now exceed the limit values given in table 32 of SP 16.13330.2017, or a user-specified value provided through the `CMN` parameter. The value of the coefficient α used in Table 32 is taken within the limits of 0.5 and 1.0. The limiting slenderness value in compression elements depends on stress acting the member, buckling coefficient, and design resistance of the steel.

Since the slenderness can be different in various planes, the greatest slenderness ratio is assumed in calculations. A warning is given if the slenderness ratio of a compression element exceeds the limit, but the calculations are continued. If the slenderness ratio exceeds the limit value, the output line containing the slenderness check is preceded by a "#" (pound or hash symbol).

The calculations of single members are performed in this manner. If the member is subjected to axial forces and bending moment (e.g., due to self weight), then the calculation of load bearing capacity will be done taking into account the axial force and bending moments and the buckling resistance only under the axial compression according to clause 7.1 of SP 133330.2017. Local buckling of the web and flanges of centrally loaded members is checked. Stiffener ribs are recommended if necessary.

Note: Wall cross section area Aw used in SP 16.13330.2017 code is the area of web excluding thickness of flange(s).

D13.E.2.3 Flexural Members

Member subjected to bending moments and shear forces are called flexural members.

There are three classes of flexural elements:

- Elastic - in cross-section, the stress in the extreme compression fiber of the steel member –assuming an elastic distribution of stresses– can reach the yield strength. $\sigma \leq R_y$, where σ is the absolute value of the stress.
- Elasto-plastic - in on part of the cross-section, the stresses are $\sigma \leq R_y$ and in another $\sigma = R_y$.
- Plastic state (i.e., conditional plastic hinge) - across the entire cross-section, the stresses are $\sigma = R_y$.

The parameter `TB` is used to specify either class 1 (elastic), class 2 (elasto-plastic), or class 3 (plastic), with elastic being the default.

The calculation of flexural members consists of verification of strength, stability, and deflection.

Normal and tangential stresses are verified by strength calculations of members. Normal stresses are calculated in the outermost section fibers. Tangential stresses are verified in the neutral axis zone of the same section. If the normal stresses do not exceed design steel strength and tangential stresses do not exceed the design value of steel shear strength, $R_s \gamma_s$, then according to clause 8.2.1 of SP 16.13330.2017 the principal stresses are checked.

For elements subjected to biaxial bending moments according to clauses 8.2.1 and 8.4.1 of SP 16.13330.2017.

Stability check as per clause 8.4.4 should be performed for I shaped section only. If stability is not ensured as per 8.4.4 for I shaped sections, then a check as per clause 8.4.1 is performed. For other types of sections, the program skips clause 8.4.4 and checks per clause 8.4.1.

D13.E.2.4 Eccentrically Compressed/Tensioned Members

Eccentrically compressed or tensioned members are subjected to simultaneous action of axial force and bending moment. Bending moment appears to eccentrically applied longitudinal force or due to transverse force.

D13.E.3 Supported Section Profiles

STAAD.Pro can check many standard sections in SP 16.13330.2017.

D13.E.3.1 Built-in Russian Steel Section Library

These profiles use the SGR to specify the grade of steel.

Table 207: Typical Sections for Russian Steel Design

Section	Section Type	Designation form
I-beam (GOST 8239-89)		`ST I12`
Regular I-beam (GOST 26020-83)		`ST B1-10`
Broad-flanged I-beam (GOST 26020-83)		`ST SH1-23`
Column I-beam (GOST 26020-83)		`ST K1-20`
Channel (GOST 8240-89)		`ST C14`

Section	Section Type	Designation form
Equal legs angle (GOST 8509-89)	 	`ST L100x100x7` `RA L100x100x7`
Unequal legs angle (GOST 8510-89)	 	`ST L125x80x10` `RA L125x80x10`

Pipes (GOST 10705 and GOST 10706; welded and for gas piping)		`ST PIP102x5.5`
		or
		`ST PIPE OD 0.102 ID 0.055`

Section	Section Type	Designation form

Roll-formed square and rectangular tubes (GOST 8639 and GOST 8645)		`ST TUB160x120x3`
		or
		`ST TUBE TH 0.003 WT 0.12 DT 0.16`

Table 208: Compound Sections for Russian Steel Design

Section	Section Type	Designation form
Double channels		`D C14 SP 0.01` (SP – clear distance between channel walls)
Double equal legs angles		`LD L100x100x7 SP 0.01` (SP – clear distance between angle walls)
Double unequal legs angles with long legs back to back		`LD L125x80x10 SP 0.01` (SP – clear distance between angle walls)
Double unequal legs angles with short legs back to back		`SD L125x80x10 SP 0.01` (SP – clear distance between angle walls)

Section	Section Type	Designation form

Tee with flange at the top
Note: Flange of Tee beam is at the top part of cross-section if beta angle = 0°, or at the bottom part if beta angle = 180°.
		`T I12`
		`T B1-10`
		`T SH1-23`
		`T K1-20`

For entry of cross-sectional dimensions command `MEMBER PROPERTIES RUSSIAN` is used.

Refer to D13.B.2 Built-in Russian Steel Section Library (on page 1890) for an example.

D13.E.3.2 Standard European Profiles

The following profile types are supported using the `ENSGR` parameter to specify steel grade.

- Wide Flange: IPE, HD, HE, HL, HP, DIL, IPE
- Channel: U, UPE, UPN
- Angle: L
- Circular Hollow: CHC, Pipe
- Rectangular Hollow: RHS, SHS, Tube

D13.E.3.3 Other Supported Standard Profiles

The following profiles are supported using the `PY` parameter to specify steel yield strength in place of steel grade.

- Wide Flange
- Channel
- Angle
- Circular Hollow
- Rectangular Hollow

D13.E.3.4 User Table Profiles

The following UPT shapes are supported either using the `PY` parameter to specify steel yield strength or the `SGR` or `ENSGR` in place of steel grade.

- Wide Flange
- Channel
- Angle
- Double Angle
- Tee
- Pipe
- Tube

Not supported: ISection, General, or Prismatic

D13.E.4 Design Parameters

Table 209: Design parameters for design of steel members per SP 16.13330.2017

Parameter Name	Default Value	Description
CODE	-	Must be specified as: `RUSSIAN` or `RUSSIAN 2017` Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
BMT		Bimoment for design of eccentrically loaded members per clause 8.4 or members subjected to two bending moments per clause 8.2.
CB	1	Location of loading on the beam: 1) top flange 2) bottom flange
CMM	0	Slenderness limit for tension members: 0) suppress slenderness check 1) 150 2) 200 3) 250 4) 300 5) 350 6) 400 **Note:** Slenderness check for member is performed against `CMM` or `CMN` parameters depending on the tension/compression nature of axial force. If the member is not subjected to axial force, slenderness check is not performed as there is no relevant clause in the SP 16.13330.2017.

Parameter Name	Default Value	Description
CMN	0	Ultimate slenderness for compression members. Limits as per SP 16.13330.2017 clause 10.4, Table 32: 0) suppress slenderness check 1) 180-60a 2) 120 3) 210-60a 4) 220-40a 5) 220 6) 180-60a 7) 210-60a 8) 200 9) 150 where a = alpha calculated as defined in SP 16.13330.2017 Table 32. **Note:** Slenderness check for member is performed against `CMM` or `CMN` parameters depending on the tension/compression nature of axial force. If the member is not subjected to axial force, slenderness check is not performed as there is no relevant clause in the SP 16.13330.2017.
DFF	None	"Deflection Length" / Maximum allowable local deflection
DJ1	Start Joint of member	
DJ2	End Joint of member	
DMAX	1,000 in	Maximum allowable section depth
DMIN	0	Minimum allowable section depth
ENSGR	1	The number of the steel grade from Table 3.1 in EN 1993-1-1: 2005. D5.C.6 Design Parameters (on page 1502) for values. Also, see Note 1 below.
FU	0	Design steel strength (ultimate strength) **Note:** Used when the `SRG` parameter is not defined.
GAMC1	1.0	Specific service condition coefficient for buckling design
GAMC2	1.0	Specific service condition coefficient for strength design

Parameter Name	Default Value	Description
GAMM	1.0	Specific partial coefficient for steel, γ_m, for European or Russian steel. Refer to Table 3 in the SP 16.13330.2017 code. 1) Gamma(n) = 1.025 2) Gamma(n) = 1.05
GMF	1.0	Ratio between design and characteristic load value
KY	1.0	Coefficient of effective length in respect to local axis Y (in plane XZ)
KZ	1.0	Coefficient of effective length in respect to local axis Z (in plane XY)
LEG	4	Describes the type of and position of loading on the beam: 1) concentrated in middle of the span 2) concentrated in the quarter of the span 3) concentrated at the end of bracket 4) uniformly distributed along beam 5) uniformly distributed on bracket
LY	Member Length	Effective length in respect to local axis Y (in plane XZ)
LZ	Member Length	Effective length in respect to local axis Z (in plane XY)
NSF	1.0	Net section factor for tension members or web section area weakening factor for bending members
PY	0	Design steel strength (yield strength) **Note:** Used when parameters `MAIN` and `SGR` are not defined for Russian steel materials or `ENMAIN` and `ENSGR` for European steel materials. See Note 1 below.
SBLT	0	Number of lateral bracing restraints along the span: 0) beam is not fixed laterally 1) single restraint at mid-span 2) or higher is the number of uniformly spaced lateral restraints along the span

Parameter Name	Default Value	Description
SGR	1	Steel grade: See Note 1 below. Grades from Table C5: hot-rolled profiles except of type K, SH, and B of I section beams (See Note 2 below) 1) S245* (4-40 mm) 2) S255* (4-40 mm) 3) S345* (4-40 mm) 4) S345K* (4-10 mm) 5) S355*; S355-1* (8-40 mm) 6) S390* (8-40 mm) Grades from Table C3: sheets, wide strips, plates, pipes, and tubes 7) S235 (2-4 mm) 8) S245 (2-20 mm) 9) S255 (2-40 mm) 10) S345 (2-160 mm) 11) S345K (4-10 mm) 12) S355 (8-160 mm) 13) S355-1; S355-K (8-60 mm) 14) S355P (8-40 mm) 15) S390; S390-1 (8-50 mm) 16) S440 (8-50 mm) 17) S550 (8-50 mm) 18) S590 (8-50 mm) 19) S690 (8-50 mm) Grades from Table C4: I-beams with parallel flange faces, type K, SH, and B 20) S255B; S255B-1 (0-100 mm) 21) S345B (0-60 mm) 22) S345B-1 (0-60 mm) 23) S355B (0-100 mm) 24) S355B-1 (0-60 mm) 25) S390B (31-100 mm) 26) S440B (0->100 mm)
STP	1	Section type: 1) Rolled section 2) Welded section

Parameter Name	Default Value	Description
TB	1	Indication of stress strain state per Cl 4.2.7: 1) 1st Class (Elastic) 2) 2nd Class (Elasto-plastic) 3) 3rd Class (Plastic) The engineer shall consider the appropriate class of the member, as it is used in multiple checks under Ch.8. for elastic or elastic-plastic calculation for bending members (non-axially compressed or tensioned): Cl 8.2.1, Cl. 8.2.3, Cl. 8.4.1, Cl. 8.4.4, and Cl 8.4.6.
TRACK	0	Output details: 0) design summary only 1) extended output information for the critical section under the critical load case 2) full output information for the critical section under the critical load case 3) design summary only (Russian language) 4) extended output information for the critical section under the critical load case (Russian language) 5) full output information for the critical section under the critical load case (Russian language)

Notes

1. It is common practice to design only Russian or European shapes to the Russian steel codes. For Russian steel sections, the steel design strength value, Ry, is obtained from Tables C.3, C.4, and C.5 of SP 16.13330.2017 determined by the assigned the SGR parameter. For European sections, the ENSGR should be used instead. If steel sections from other countries are used, the PY parameter should be used to specify the steel strength.
2. SGR parameter values marked with an “*” are from Table C.5. These grades are also repeated in Table C.3 with different labels.

D13.E.5 Member Selection and Code Check

Both code checking and member selection options are available in SP 16.13330.2017.

Output of selection and check results are given in suppressed, extended and advanced forms. Form of output results depends on value of parameter TRACK.

Results are presented in tables. Three versions of output results are possible: suppressed – results according the critical strength condition (TRACK=0), extended - results according to all check conditions (TRACK=1) and advanced – complete information on results of member design (TRACK=2).

In tables of results common data for all TRACKs are indicated:

(TRACK=2)

In tables of results common data for all TRACKs are indicated:

- number of member;
- type and number of cross-section;
- result obtained (`ACCEPTED` – requirements are met, `FAILURE` – are not met);
- abbreviated name of normative document (code, standard) (SNiP);
- number of check clause;
- safety of strength (ratio between design and normative values);
- number of the most unfavorable loading;
- value of longitudinal force acting in the member with subscript indicating its direction ("C" – compression, "T" – tension);
- bending moments in relation to local member axes Z and Y;
- distance to section, in which the most unfavorable combination of forces acts.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

Note: The output for the Russian code uses the axes system from STAAD.Pro, except where details of the equations from the code are printed, in which case the axes system is as defined in the code.

D13.E.5.1 Example of TRACK 0 output

In suppressed form (`TRACK 0`) results are presented according to the critical check for given member with indication of SP 16 clause number, according to which strength safety of the member is minimum.

D13.E.5.3 Example of a TRACK 2 output

In advanced form (TRACK=2) in addition to tabled results supplementary information is presented.

Material characteristics:

Steel;

Design resistance;

Elasticity modulus;

Section characteristics:

Length of member;

Section area;

Net area;

Inertia moment (second moment of area) (I);
Section modulus (W);
First moment of area (S);
Radius of gyration;
Effective length;
Slenderness;
Results are presented in two columns, Z and Y respectively.
Design forces:
Longitudinal force;
Moments;
Shear force.

Signs “+” and “-” indicate direction of acting longitudinal force, bending moments and shear forces in accordance with sign rules assumed in program STAAD.Pro.

Check results in advanced form are presented with values of intermediate parameters by formulas in analytical and numerical expression with indication of SP code clause.

```

Conventional notations assumed in presentation of results: “+”, “-”, “/”, “*”,“**”, “SQRT”, their respective meanings (i.e., addition, subtraction, division, multiplication, raising to the second power (squared), and square root). Conventional notations of stresses, coefficients and characteristics of steel resistance comply with accepted in the SP standard. Only Greek letters are changed by their names (e.g., , γ_c-GAMAC; α-ALPHA; β-BETA, η-ETA, φ-PHI, etc.).

D14. South African Codes

D14.A. South African Codes - Concrete Design per SABS-0100-1

STAAD.Pro is capable of performing concrete design based on the South African code SABS-0100-1 2000 *Code of Practice for Structural Use of Concrete Part1: Design*. Design can be performed for beams (flexure, shear, and torsion) and columns (axial load + biaxial bending). Given the width and depth (or diameter for circular columns) of a section, the program calculates the required reinforcement.

D14.A.1 Design Parameters

The program contains a number of parameters which are needed to perform and control the design to SABS 0100-1. These parameters not only act as a method to input required data for code calculations but give the engineer control over the actual design process. Default values of commonly used parameters for conventional design practice have been chosen as the basis. Table 17A.1 contains a complete list of available parameters with their default values.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 210: South African Concrete Design SABS 0100-1 Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified as `SABS0100`. Design code to follow. See TR.53.2 Concrete Design-Parameter Specification (on page 2685).
BRACE	0.0	Column bracing: 0. Column braced in both directions. 1. Column braced about local Y direction only 2. Column unbraced about local Z direction only 3. Column unbraced in both Y and Z directions
CLB	20mm	Clear Cover for outermost bottom reinforcement

Parameter Name	Default Value	Description
CLS	20mm	Clear Cover for outermost side reinforcement
CLT	20mm	Clear Cover for outermost top reinforcement
DEPTH	YD	Depth of concrete member, in current units. This value default is as provided as YD in MEMBER PROPERTIES.
ELY	1.0	Member length factor about local Y direction for column design.
ELZ	1.0	Member length factor about local Z direction for column design.
FC	30N/mm^2	Concrete Yield Stress / cube strength, in current units.
FYMAIN	450 N/mm^2	Yield Stress for main reinforcement, in current units.
FYSEC	450N/mm^2	Yield Stress for secondary reinforcement a, in current units. Applicable to shear bars in beams
MAXMAIN	50mm	Maximum required reinforcement bar size Acceptable bars are per MINMAIN above.
MINMAIN	8mm	Minimum main reinforcement bar size Acceptable bar sizes: 6 8 10 12 16 20 25 28 32 36 40 50 60
MINSEC	8mm	Minimum secondary bar size a. Applicable to shear reinforcement in beams

Parameter Name	Default Value	Description
TRACK	0.0	Output detail 0. Critical Moment will not be printed with beam design report. Column design gives no detailed results. 1. For beam gives min/max steel % and spacing. For columns gives a detailed table of output with additional moments calculated. 2. Output of TRACK 1.0 List of design sag/hog moments and corresponding required steel area at each section of member
WIDTH	ZD	Width of concrete member, in current units. This value default is as provided as ZD in MEMBER PROPERTIES.

D14.A.2 Member Dimensions

Concrete members that are to be designed by STAAD.Pro must have certain section properties input under the `MEMBER PROPERTIES` command.

The following example demonstrates the required input:

```
UNIT  MM
MEMBER  PROPERTIES
*RECTANGULAR  COLUMN 300mm WIDE X 450mm DEEP
1 3  TO 7 9 PRISM YD 450. ZD 300.
*CIRCULAR  COLUMN 300mm diameter
11 13  PR YD 300.
* T-SECTION  - FLANGE 1000.X 200.(YD-YB)
* - STEM 250(THICK) X 350.(DEEP)
14 PRISM  YD 550. ZD 1000. YB 350. ZB 250.
```

In the above input, the first set of members are rectangular (450mm depth x 300mm width) and the second set of members, with only depth and no width provided, will be assumed to be circular with 300mm diameter. Note that area (AX) is not provided for these members. If shear area areas (AY & AZ) are to be considered in analysis, the user may provide them along with YD and ZD. Also note that if moments of inertias are not provided, the program will calculate them from YD and ZD. Finally a T section can be considered by using the third definition above.

D14.A.3 Beam Design

Beam design includes flexure, shear and torsion. For all types of beam action, all active beam loadings are scanned to create moment and shear envelopes and locate the critical sections. The total number of sections considered is thirteen. From the critical moment values, the required positive and negative bar pattern is developed. Design for flexure is carried out as per clause no. 4.3.3.4.

Shear design as per SABS 0100 clause 4.3.4 has been followed and the procedure includes computation of critical shear values. From these values, stirrup sizes are calculated with proper spacing. If torsion is present, the program will also consider the provisions of SABS 0100 clause 4.3.5. Torsional reinforcement is separately reported.

A `TRACK 2` design output is presented below.

```

-----------------------------------------------------------------------------

TORSION REINFORCEMENT : Not required
```

D14.A.4 Column Design

Columns are designed for axial force and biaxial bending at the ends. All active loadings are tested to calculate reinforcement. The loading which produces maximum reinforcement is called the critical load and is displayed. The requirements of SABS 0100-1 clause 4.7 are followed, with the user having control on the effective length in each direction by using the ELZ and ELY parameters as described in table 12A.1. Bracing conditions are controlled by using the BRACE parameter. The program will then decide whether or not the column is short or slender and whether it requires additional moment calculations. For biaxial bending, the recommendations of 4.7.4.4 of the code are considered.

Column design is done for square, rectangular and circular sections. For rectangular and square sections, the reinforcement is always assumed to be arranged symmetrically. This causes slightly conservative results in certain cases.

Using parameter `TRACK 1.0`, the detailed output below is obtained. `TRACK 0.0` would merely give the bar configuration, required steel area and percentage, column size and critical load case.

```

D14.B. South African Codes - Steel Design per SANS10162-1:1993

The South African Steel Design facility in STAAD.Pro is based on the SAB Standard SAB0162-1: 1993, *Limit States Design of Steel Structures*. A steel section library consisting of South African Standards shapes is available for member property specification.

D14.B.1 General

The design philosophy embodied in this specification is based on the concept of limit state design. Structures are designed and proportioned taking into consideration the limit states at which they would become unfit for their intended use. Two major categories of limit-state are recognized - ultimate and serviceability. The primary considerations in ultimate limit state design are strength and stability, while that in serviceability is deflection. Appropriate load and resistance factors are used so that a uniform reliability is achieved for all steel structures under various loading conditions and at the same time the chances of limits being surpassed are acceptably remote.

In the STAAD implementation, members are proportioned to resist the design loads without exceeding the limit states of strength, stability and serviceability. Accordingly, the most economic section is selected on the basis of the least weight criteria as augmented by the designer in specification of allowable member depths, desired section type, or other such parameters. The code checking portion of the program checks whether code requirements for each selected section are met and identifies the governing criteria.

The next few sections describe the salient features of the STAAD implementation of SAB0162-1: 1993. A detailed description of the design process along with its underlying concepts and assumptions is available in the specification document.

D14.B.2 Analysis Methodology

Elastic analysis method is used to obtain the forces and moments for design. Analysis is done for the primary and combination loading conditions provided by the user. The user is allowed complete flexibility in providing loading specifications and using appropriate load factors to create necessary loading situations. Depending upon the analysis requirements, regular stiffness analysis or P-Delta analysis may be specified. Dynamic analysis may also be performed and the results combined with static analysis results.

Refer to TR.37 Analysis Specification (on page 2620) for additional information.

D14.B.3 Member Property Specifications

For specification of member properties, the steel section library available in STAAD.Pro may be used. The next section describes the syntax of commands used to assign properties from the built-in steel table. Member properties may also be specified using the User Table facility. For more information on these facilities, refer to G.6 Member Properties (on page 2113) .

D14.B.4 Built-in Steel Section Library

A steel section library consisting of South African Standards shapes is available for member property specification.

The following information is provided for use when the built-in steel tables are to be referenced for member property specification. These properties are stored in a database file. If called for, the properties are also used for member design. Since the shear areas are built into these tables, shear deformation is always considered during the analysis of these members.

Refer to G.6.2 Built-In Steel Section Libraries (on page 2116) for additional information.

D14.B.4.1 I Shapes

The following example illustrates the specification of I- shapes.

```
1 TO 15 TABLE ST IPE-AA100
```

D14.B.4.2 H shapes

Designation of H shapes in STAAD is as follows.

For example,

```
18 TO 20 TABLE ST 152X37UC
```

D14.B.4.3 PG shapes

Designation of PG shapes in STAAD is as follows.

```
100 TO 150 TABLE ST 720X200PG
```

D14.B.4.4 Channel Sections (C & MC shapes)

C and MC shapes are designated as shown in the following example.

```
3 TABLE ST 127X64X15C
```

D14.B.4.5 Double Channels

Back to back double channels, with or without spacing between them, are specified by preceding the section designation by the letter D. For example, a back to back double channel section `PFC140X60` without spacing in between should be specified as:

```
100 TO 150 TABLE D PFC140X60
```

A back-to-back double channel section 140X60X16C with spacing 0.01 unit length in between should be specified as:

```
100 TO 150 TABLE D 140X60X16C  SP 0.01
```

Note: The specification SP after the section designation is used for providing the spacing. The spacing should always be provided in the current length unit.

D14.B.4.6 Angles

To specify angles, the letter L succeeds the angle name. Thus, a 70X70 angle with a 25mm thickness is designated as 70X70X8L. The following examples illustrate angle specifications.

```
100 TO 150 TABLE ST 70X70X8L
```

Note: This specification is for "standard" angles, designated by ST. In this specification, the local z-axis corresponds to the Y'-Y' axis shown in the section table. Another common practice of specifying angles assumes the local y-axis to correspond to the Y'-Y' axis. To specify angles in accordance with this convention, use the reverse angle designation, RA. Refer to G.4.2 Local Coordinate System (on page 2088) for details on the local axis systems for standard (ST) and reverse (RA) angles.

Refer to the following example for details.

```
100 TO 150 TABLE RA 45X45X3L
```

D14.B.4.7 Double Angles

To specify double angles, the specification ST should be substituted with LD (for long leg back-to-back) or SD (short leg back-to-back). For equal angles, either SD or LD will serve the purpose. Spacing between angles may be provided by using the word SP followed by the value of spacing (in current length unit) after section designation.

```
100 TO 150 TABLE LD 50X50X3L
3 TABLE LD 40X40X5L SP 0.01
```

The second example above describes a double angle section consisting of 40X40X5 angles with a spacing of 0.01 length units.

D14.B.4.8 Tees

Tee sections obtained by cutting W sections may be specified by using the T specification instead of ST before the name of the W shape. For example:

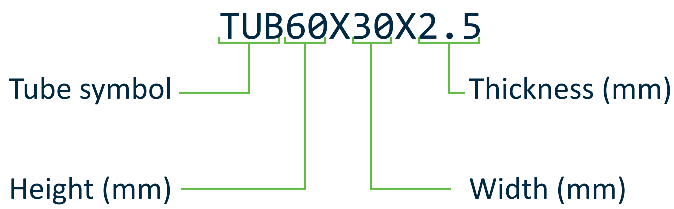
```
100 TO 150 TABLE T IPE-AA180
```

will describe a T section cut from a IPE-AA180 section.

D14.B.4.9 Rectangular Hollow Sections

These sections may be specified in two possible ways. Those sections listed in the SAB tables may be specified as follows.

```
100 TO 150 TABLE ST TUB60X30X2.5
```



In addition, any tube section may be specified by using the DT(for depth), WT(for width), and TH(for thickness) specifications. For example:

```
100 TO 150 TABLE ST TUBE  TH 3 WT 100 DT 50
```

will describe a tube with a depth of 50mm, width of 100mm. and a wall thickness of 3mm. Note that the values of depth, width and thickness must be provided in current length unit.

D14.B.4.10 Circular Hollow Sections

Sections listed in the SAB tables may be provided as follows:

```
100 TO 150 TABLE ST PIP34X3.0CHS
```

In addition to sections listed in the SAB tables, circular hollow sections may be specified by using the OD (outside diameter) and ID (inside diameter) specifications.

For example:

```
100 TO 150 TABLE ST PIPE  OD 50 ID 48
```

will describe a pipe with an outside diameter of 50 length units and inside diameter of 48 length units. Note that the values of outside and inside diameters must be provided in terms of current length unit.

D14.B.4.11 Example

A sample input file to demonstrate usage of South African shapes:

D14.B.5 Section Classification

The SAB specification allows inelastic deformation of section elements. Thus, local buckling becomes an important criterion. Steel sections are classified as plastic (Class 1), compact (Class 2), noncompact (Class 3), or slender element (Class 4) sections depending upon their local buckling characteristics (See Clause 11.2 and Table 1 of SAB0162-1:1993). This classification is a function of the geometric properties of the section. The design procedures are different depending on the section class. STAAD.Pro determines the section classification for the standard shapes and user specified shapes. Design is performed for sections that fall into the category of Class 1,2, or 3 sections only. Class 4 sections are not designed by STAAD.Pro.

D14.B.6 Member Resistances

The member resistances are calculated in STAAD.Pro according to the procedures outlined in section 13 of the specification. These depend on several factors such as members' unsupported lengths, cross-sectional properties, slenderness factors, unsupported width to thickness ratios and so on. Note that the program automatically takes into consideration appropriate resistance factors to calculate member resistances. Explained here is the procedure adopted in STAAD.Pro for calculating the member resistances.

All the members are checked against allowable slenderness ratio as per Cl.10.2 of SAB0162-1: 1993.

D14.B.6.1 Axial

Parameters FYLD, FU, and NSF are applicable for these calculations.

D14.B.6.2 Axial Compression

The compressive resistance of columns is determined based on Clause 13.3 of the code. The equations presented in this section of the code assume that the compressive resistance is a function of the compressive strength of the gross section (Gross section Area times the Yield Strength) as well as the slenderness factor (KL/r ratios). The effective length for the calculation of compression resistance may be provided through the use of the parameters KX, KY, KZ, LX, LY, and LZ (see D14.B.7 Design Parameters (on page 1960)). Some of the aspects of the axial compression capacity calculations are:

1. For frame members not subjected to any bending, and for truss members, the axial compression capacity in general column flexural buckling is calculated from Cl.13.3.1 using the slenderness ratios for the local Y-Y and Z-Z axis. The parameters KY, LY, KZ, and LZ are applicable for this.
2. For single angles, asymmetric or cruciform sections are checked as to whether torsional-flexural buckling is critical. But for KL/r ratio exceeding 50,as torsional flexural buckling is not critical, the axial compression capacities are calculated by using Cl.13.3. The reason for this is that the South African code doesn't provide any clear guidelines for calculating this value. The parameters KY, LY, KZ, and LZ are applicable for this.
3. The axial compression capacity is also calculated by taking flexural-torsional buckling into account. Parameters KX and LX may be used to provide the effective length factor and effective length value for flexural-torsional buckling. Flexural-torsional buckling capacity is computed for single channels, single angles, Tees and Double angles.
4. While computing the general column flexural buckling capacity of sections with axial compression + bending, the special provisions of 13.8.1(a), 13.8.1(b) and 13.8.1(c) are applied. For example, Lambda = 0 for 13.8.1(a), K=1 for 13.8.1(b), etc.)

D14.B.6.3 Bending

The laterally unsupported length of the compression flange for the purpose of computing the factored moment resistance is specified in STAAD with the help of the parameter UNL. If UNL is less than one tenth the member length (member length is the distance between the joints of the member), the member is treated as being continuously laterally supported. In this case, the moment resistance is computed from Clause 13.5 of the code. If UNL is greater than or equal to one-tenth the member length, its value is used as the laterally unsupported length. The equations of Clause 13.6 of the code are used to arrive at the moment of resistance of laterally unsupported members. Some of the aspects of the bending capacity calculations are:

1. The weak axis bending capacity of all sections except single angles is calculated as:

   For Class 1 & 2 sections

   $$Phi*Py*Fy$$

   For Class 3 sections

   $$Phi*Sy*Fy$$

   Where:

   Phi = Resistance factor = 0.9
   Py = Plastic section modulus about the local Y axis
   Sy = Elastic section modulus about the local Y axis
   Fy = Yield stress of steel
2. Single angles sections are not designed by STAAD, as the South African code doesn't provide any clear guidelines for calculating this value.
3. For calculating the bending capacity about the Z-Z axis of singly symmetric shapes such as Tees and Double angles, SAB0162-1: 1993 stipulates in Clause 13.6(b), page 31, that a rational method.

D14.B.6.4 Axial compression and bending

The member strength for sections subjected to axial compression and uniaxial or biaxial bending is obtained through the use of interaction equations. In these equations, the additional bending caused by the action of the axial load is accounted for by using amplification factors. Clause 13.8 of the code provides the equations for this purpose. If the summation of the left hand side of these equations exceeds 1.0 or the allowable value provided using the RATIO parameter (see D14.B.7 Design Parameters (on page 1960)), the member is considered to have FAILed under the loading condition.

D14.B.6.5 Axial tension and bending

Members subjected to axial tension and bending are also designed using interaction equations. Clause 13.9 of the code is used to perform these checks. The actual RATIO is determined as the value of the left hand side of the critical equation.

D14.B.6.6 Shear

The shear resistance of the cross section is determined using the equations of Clause 13.4 of the code. Once this is obtained, the ratio of the shear force acting on the cross section to the shear resistance of the section is calculated. If any of the ratios (for both local Y & Z axes) exceed 1.0 or the allowable value provided using the RATIO parameter (see D14.B.7 Design Parameters (on page 1960)), the section is considered to have failed under shear. The code also requires that the slenderness ratio of the web be within a certain limit (See Cl. 13.4.1.3, page 29 of SABS 0162-1:1993). Checks for safety in shear are performed only if this value is within the allowable limit. Users may by-pass this limitation by specifying a value of 2.0 for the MAIN parameter.

D14.B.7 Design Parameters

The design parameters outlined in table below may be used to control the design procedure. These parameters communicate design decisions from the engineer to the program and thus allow the engineer to control the design process to suit an application's specific needs.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements, some or all of these parameter values may be changed to exactly model the physical structure.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 211: South African Steel Design Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified SANS10162-1:1993. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).

Parameter Name	Default Value	Description
BEAM	0	0 - Perform design at ends and those locations specified in the section command. 1 - Perform design at ends and 1/12th section locations along member length.
CB	1.0	Greater than 0.0 and less than 2.5,Value of Omega_2 (C1.13.6) to be used for calculation Equal to 0.0: Calculate Omega_2
CMY	1.0	1 - Do not calculate Omega-1 for local Y axis. 2 - Calculate Omega-1 for local Y axis
CMZ	1.0	1 - Do not calculate Omega-1 for local Z axis. 2 - Calculate Omega-1 for local Z axis
DFF	0	Default is 0 indicating that deflection check is not performed
DJ1	0	Start node of physical member for determining deflected pattern for deflection check and should be set along with DFF parameter
DJ2	0	End node of physical member for determining deflected pattern for deflection check and should be set along with DFF parameter
DMAX	1000	Maximum allowable depth
DMIN	0	Minimum required depth
FU	345Mpa	Ultimate strength of steel
FYLD	300Mpa	Yield strength of steel
KT	1.0	K value for flexural torsional buckling

Parameter Name	Default Value	Description
KY	1.0	K value in local Y-axis, usually minor axis
KZ	1.0	K value in local Z-axis, usually major axis
LT	Member length	Length for flexural torsional buckling
LY	Member length	Length in local Y axis for slenderness value KL/r
LZ	Member length	Length in local Z axis for slenderness value KL/r
MAIN	0	Flag for controlling slenderness check 0 - For Check for slenderness. 1 - For Do not check for slenderness
NSF	1.0	Net section factor for tension members
RATIO	1.0	Permissible ratio of applied load to section capacity Used in altering the RHS of critical interaction equations
SSY	0	Sidesway parameter 0 - Sideway about local Y-axis. 1 - No sideway about local Y-axis.
SSZ	0	Sidesway parameter 0 - Sideway about local Z-axis. 1 - No sideway about local Z-axis.

Parameter Name	Default Value	Description
TRACK	0	Track parameter 0. Print the design output at the minimum detail level. 1. Print the design output at the intermediate detail level. 2. Print the design output at maximum detail level
UNB	Member Length	Unsupported length in bending compression of bottom flange for calculating moment resistance
UNT	Member Length	Unsupported length in bending compression of top flange for calculating moment resistance

D14.B.8 Code Checking

The purpose of code checking is to determine whether the current section properties of the members are adequate to carry the forces obtained from the most recent analysis. The adequacy is checked as per the SANS10162-1:1993 requirements.

Code checking is done using forces and moments at specified sections of the members. If the BEAM parameter for a member is set to 1 (which is also its default value), moments are calculated at every twelfth point along the beam. When no section locations are specified and the BEAM parameter is set to zero, design will be based on member start and end forces only. The code checking output labels the members as PASSed or FAILed. In addition, the critical condition, governing load case, location (distance from the start joint) and magnitudes of the governing forces and moments are also printed. Using the TRACK parameter can control the extent of detail of the output.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

Example

Sample input data for South African Code Design

D14.B.9 Member Selection

The member selection process involves determination of the least weight member that PASSes the code checking procedure based on the forces and moments of the most recent analysis. The section selected will be of the same type as that specified initially.

For example, a member specified initially as a channel will have a channel selected for it. Selection of members whose properties are originally provided from a user table will be limited to sections in the user table. Member selection cannot be performed on members listed as `PRISMATIC`.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

D14.B.10 Tabulated Results of Steel Design

Results of code checking and member selection are presented in a tabular format. The term CRITICAL COND refers to the section of the SANS10162-1:1993 specification, which governed the design.

If the TRACK parameter is set to 1.0, the output will be displayed as follows:

```
                SSSSSSSSSSSSSSSSSSSSSSSSSSSSSSSSSSSSSS
                       STAAD.PRO CODE CHECKING

D14.C. South African Codes - Steel Design Per SANS 10162-1:2011

STAAD.Pro is capable of performing steel design based on the South African code SANS 10162-1:2011 *Design of steel structures*.

D14.C.1 General

The design philosophy embodied in this specification is based on the concept of limit state design. Structures are designed and proportioned taking into consideration the limit states at which they would become unfit for their intended use. Two major categories of limit-state are recognized - ultimate and serviceability. The primary considerations in ultimate limit state design are strength and stability, while that in serviceability is deflection. Appropriate load and resistance factors are used so that a uniform reliability is achieved for all steel structures under various loading conditions and at the same time the chances of limits being surpassed are acceptably remote.

In the STAAD implementation, members are proportioned to resist the design loads without exceeding the limit states of strength, stability, and serviceability. Accordingly, the most economic section is selected on the basis of the least weight criteria as augmented by the designer in specification of allowable member depths, desired section type, or other such parameters. The code checking portion of the program checks whether code requirements for each selected section are met and identifies the governing criteria.

The next few sections describe the salient features of the STAAD implementation of SANS 10162-1:2011. A detailed description of the design process along with its underlying concepts and assumptions is available in the specification document.

D14.C.2 Analysis Methodology

Elastic analysis method is used to obtain the forces and moments for design. Analysis is done for the primary and combination loading conditions provided by the user. You are allowed complete flexibility in providing loading specifications and using appropriate load factors to create necessary loading situations. Depending upon the analysis requirements, regular stiffness analysis or P-Delta analysis may be specified. Dynamic analysis may also be performed and the results combined with static analysis results.

Refer to TR.37 Analysis Specification (on page 2620) for additional information.

D14.C.3 Member Property Specifications

For specification of member properties, the steel section library available in STAAD.Pro may be used. The next section describes the syntax of commands used to assign properties from the built-in steel table. Member properties may also be specified using the User Table facility. For more information on these facilities, refer to G. 6 Member Properties (on page 2113) .

D14.C.4 Built-in Steel Section Library

A steel section library consisting of South African Standards shapes is available for member property specification.

Refer to D14.B.4 Built-in Steel Section Library (on page 1955) for details on using the built-in library of South African steel shapes.

D14.C.5 Section Classification

The SANS 10162 specification allows inelastic deformation of section elements. Thus, local buckling becomes an important criterion. Steel sections are classified as plastic (Class 1), compact (Class 2), noncompact (Class 3), or slender element (Class 4) sections depending upon their local buckling characteristics (See Clause 11.2 and Table 1 of SANS 10162-1:2011).

The design procedures are different depending on the section class. STAAD.Pro determines the section classification for the standard shapes and user specified shapes.

Class 4 sections are those with ratios exceeding those listed for Class 3. This classification is a function of the geometric properties of the section. Design is performed accordingly for sections in Class 1, Class 2, and Class 3.

Class 4 sections per SANS 10162-1:2011 are *not* designed in STAAD.Pro. If a member design is requested for a section of this type, the analysis file will list reason for failure as “Class 4”.

D14.C.6 Member Resistances

The member resistances are calculated in STAAD.Pro according to the procedures outlined in section 13 of the specification. These depend on several factors such as members’ unsupported lengths, cross-sectional properties, slenderness factors, unsupported width to thickness ratios and so on. Note that the program automatically takes into consideration appropriate resistance factors to calculate member resistances. Explained here is the procedure adopted in STAAD.Pro for calculating the member resistances.

All the members are checked against allowable slenderness ratio as per Cl.10.2 of SANS 10162-1:2011.

D14.C.6.1 Resistance Factor

The strength resistance factor, ϕ used for structural steel is 0.90 per Section 13.1. This factor is applied to the equations directly in capacity calculations.

D14.C.6.2 Axial Tension

The factored tensile resistance, T_r , developed by a member subjected to an axial tensile force shall be taken as least of the following per Section 13.2:

$$T_r = \phi A_g f_y$$

$$T_r = 0.85\phi A_{ne} f_u$$

Parameters FYLD, FU, and NSF are applicable for these calculations.

D14.C.6.3 Flexural Buckling - Axial Compression

Per section 13.3.1, the factored axial compressive resistance, C_r , of doubly symmetric sections conforming to the requirements of clause 11 for class 1, 2, or 3 sections shall be taken as:

$$C_r = \phi A f_y (1+\lambda^{2n})^{-1/n}$$

where

n	=	1.34 for hot-rolled, fabricated structural sections, and hollow structural sections manufactured according to SANS 657-1
λ	=	$= \frac{kl}{r}\sqrt{\frac{f}{\pi^2 E}} = \sqrt{\frac{f}{f_e}}$

Doubly symmetric sections which may be governed by torsional-flexural buckling shall also meet the requirements of 13.3.2.

The parameters KY, LY, KZ, and LZ are applicable for this.

D14.C.6.4 Torsional or Torsional-Flexural Buckling

Per section 13.3.2, the factored compressive resistance, C_r , of asymmetric, singly symmetric, and cruciform or other bisymmetric sections not covered under 13.3.1 shall be computed using the expressions given in 13.3.1 with a value of $n = 1.34$ and the value of f_e taken as lesser of F_{ex} and F_{eyz} for single symmetric section, with the y axis taken as the axis of symmetry.

$$f_{eyz} = \frac{f_{ey} + f_{ez}}{2\Omega}\left[1 - \sqrt{1 - \frac{4 f_{ey} f_{ez} \Omega}{(f_{ey} + f_{ez})^2}}\right]$$

where

f_{ey}	=	$\frac{\pi^2 E}{\left(\frac{K_y L_y}{r_y}\right)^2}$
f_{ez}	=	$\left(\frac{\pi^2 E C_w}{K_Z^2 L_Z^2} + GJ\right)\frac{1}{A\bar{r}_0^2}$
Ω	=	$1 - \left(\frac{x_0^2 + y_0^2}{\bar{r}_0^2}\right)$

x_0, y_0	=	= the principal coordinates of the shear center with respect to the centroid of the cross-section.
$\bar{r}_0^2$	=	$= x_0^2 + y_0^2 + r_x^2 + r_y^2$

For asymmetric sections, f_e is the smallest root of:

$$\left(f_e - f_{ex}\right)\left(f_e - f_{ey}\right)\left(f_e - f_{ez}\right) - f_e^2\left(f_e - f_{ey}\right)\left(\frac{x_0}{\bar{r}_0}\right)^2 - f_e^2\left(f_e - f_{ex}\right)\left(\frac{y_0}{\bar{r}_0}\right)^2 = 0$$

where

f_{ex} = $\dfrac{\pi^2 E}{\left(\frac{K_x L_x}{r_x}\right)^2}$

The parameters KY, LY, KZ, and LZ are applicable for this.

D14.C.6.5 Shear

Per section 13.4.1, the factored shear resistance, V_r , developed by the web of a flexural member, shall be taken as

$$V_r = \phi A_v f_s$$

where

A_v = = the shear area $t_w h$

a. $f_s = 0.66 f_y$ when $\dfrac{h_w}{t_w} \le 440\sqrt{\dfrac{k_v}{f_y}}$

where

k_v = = the shear buckling coefficient defined as:

$$= 4 + \frac{5.34}{(s/h_w)^2} \text{ if } s/h_w < 1$$

$$= 5.34 + \frac{4}{(s/h_w)^2} \text{ if } s/h_w \ge 1$$

b. $f_s = f_{cri}$ when $440\sqrt{\dfrac{k_v}{f_y}} < \dfrac{h_w}{t_w} \le 500\sqrt{\dfrac{k_v}{f_y}}$

where

f_{cri} = $= 290\dfrac{\sqrt{f_y k_v}}{(h_w / t_w)}$

k_v = = is as defined in (a)

c. $f_s = f_{cri} + f_t$ when $500\sqrt{\dfrac{k_v}{f_y}} < \dfrac{h_w}{t_w} \le 620\sqrt{\dfrac{k_v}{f_y}}$

where

f_t = the tension field post-buckling stress defined as:

$= k_a(0.50 f_y - 0.866 f_{cri})$

k_a = the aspect coefficient defined as:

$$= \frac{1}{\sqrt{1 + (s/h_w)^2}}$$

d. $f_s = f_{cre} + f_t$ when $620\sqrt{\frac{k_v}{f_y}} < \frac{h_w}{t_w}$

where

f_t	=	the tension field post-buckling stress defined as:
		$= k_a(0.50f_y - 0.866f_{cre})$
f_{cre}	=	$= \frac{180,\ 000k_v}{(h_w / t_w)^2}$
k_v	=	as defined in (a)

D14.C.6.6 Bending

The laterally unsupported length of the compression flange for the purpose of computing the factored moment resistance is specified using the parameters UNB and UNT.

Laterally Supported Members

Per section 13.5, the factored moment resistance, M_r , developed by a member subjected to uniaxial bending moments about a principal axis and where continuous lateral support is provided to the compressive flange shall be taken as:

a. For class 1 and class 2 sections:

$$M_r = \phi Z_{pl} f_y = \phi M_p$$

b. For class 3 sections:

$$M_r = \phi Z_e f_y = \phi M_y$$

Laterally Unsupported Members

Per section 13.6, where continuous lateral support is not provided to the compression flange of a member subjected to uniaxial strong axis bending, the factored moment resistance, M_r , may be taken as follows:

a. For doubly symmetric class 1 and class 2 sections, except closed square and circular sections:

i. When $M_{cr} > 0.67M_p$,

$$M_r = 1.15\phi M_p\left(1 - \frac{0.28M_p}{M_{cr}}\right)$$

but not greater than ϕM_p .

ii. When $M_{cr} \le 0.67M_p$,

$$M_r = \phi M_{cr}$$

where

M_{cr}	=	= the critical elastic moment of the unbraced member,
		$= \frac{\omega_2 \pi}{KL}\sqrt{EI_y GJ + \left(\frac{\pi E}{KL}\right)^2 I_y C_w}$
KL	=	= the effective length of the unbraced portion of the beam, in mm.
ω_2	=	$= 1.75 + 1.05\kappa + 0.3\kappa^2 \le 2.5$ for unbraced lengths subjected to end moments, or
		$= 1.0$ when the bending moment at any point within the unbraced length is larger than the end moment or when the re is no effective lateral

support for the compression flange at one of the ends of the unsupported length.

Note: The value for ω_2 can be specified using the CB parameter. Otherwise, it is calculated as indicated here.

κ = = the ratio of the smaller factored moment to the larger factored moment at opposite ends of the unbraced length, positive for double curvature and negative for single curvature.

C_w = = the ratio of the smaller factored moment to the larger factored moment at opposite ends of the unbraced length, positive for double curvature and negative for single curvature.

Note: Alternatively, E may be specified directly.

b. For doubly symmetric class 3 sections, except closed square and circular sections, and for channels:

i. When $M_{cr} > 0.67M_p$,

$$M_r = 1.15\phi M_y\left(1 - \frac{0.28M_y}{M_{cr}}\right)$$

but not greater than ϕM_y for class 3 sections and the value given in 13.5(c)(iii) for class 4 sections.

ii. When $M_{cr} \leq 0.67M_y$,

$$M_r = \phi M_{cr}$$

where M_{cr} and ω_2 are as defined in 13.6(a).

c. For closed sections and circular sections, M_{cr} shall be determined in accordance with section 13.5.

d. For biaxial bending, the member shall meet the following criterion:

$$\frac{M_{ux}}{M_{rx}} + \frac{M_{uy}}{M_{ry}} \leq 1.0$$

e. For monosymmetric sections, a rational method of analysis should be used.

Note: STAAD.Pro uses AISC LRFD guidelines for the design of channels, double angles, tees, and single angle sections.

i. For tees and double angles:

$$= \frac{\pi\sqrt{EI_yGJ}}{L_b}\left(B + \sqrt{1 + B^2}\right)$$ (AISC LRFD equation F1-15)

where

B = $-2.3(d / UNL)\sqrt{I_y / J}$

minus sign considered for conservative side

ii. For channel sections:

When $M_{cr} \leq 0.67M_y$:

$$M_r = 1.15\phi M_y\left[1 - 0.28\frac{M_y}{M_{cr}}\right] \leq 0.9M_y$$

When $M_{cr} > 0.67M_y$

$$M_r = 0.9M_{cr}$$

iii. For angle sections:

When $M_{ob} \le M_y$:

$$M_n = M_{ob}\left[0.92 - 0.17\frac{M_{ob}}{M_y}\right]$$

When $M_{ob} > M_y$

$$M_n = M_y\left[1.92 - 1.17\sqrt{\frac{M_y}{M_{ob}}}\right] \le 1.5M_y$$

where

M_{ob} = $= 4.9E\frac{I_z}{l^2}CB\left[\sqrt{\beta_w^2 + 0.052(lt / r_z)^2} + \beta_w\right]$ for unequal leg angles.

Note: β_w is conservatively assumed as zero.

$= CB\frac{0.46Eb^2t^2}{l}$ for equal leg angles.

I_z = minor principal axis moment of inertia
r_z = radius of gyration for minor principal axis
β_w = 0 (conservative assumption)
CB = The design parameter corresponding to ω_2 .
b = width of the angle leg
t = thickness of the angle

D14.C.6.7 Member Strength and Stability

Class 1 and Class 2 I-Shaped Sections

Members required to resist both bending moments and an axial compressive force shall be proportioned so that:

$$\frac{C_u}{C_r} + \frac{0.85U_{1x}M_{ux}}{M_{rx}} + \frac{\beta U_{1y}M_{uy}}{M_{ry}} \le 1.0$$

where

C_u and M_u = = the maximum load effects in compression and bending, respectively, including stability effects as defined in Cl. 8.7.
β = $= 0.6 + 0.4\lambda_y \le 0.85$
λ_y = = the nondimensional slenderness parameter about the y-y axis

The capacity of the member shall be examined for:

a. cross-sectional strength (members in braced frames only), with $\beta = 0.6$, in which case:

C_r is as define din Cl. 13.3 with the value of $\lambda = 0$.
M_r is as defined in Cl. 13.5 (for the appropriate class of section), and
U_{1x} and U_{1y} are as defined in 13.8.4 but not less than 1.0, and

b. overall member strength, in which case:

C_r is as define din Cl. 13.3 with the value of $K = 1$, except that for strong-axis bending, $C_r = C_{rx}$ (see aslo 10.3.2),
M_r is as defined in Cl. 13.5 (for the appropriate class of section), and
U_{1x} and U_{1y} are as defined in 13.8.4 for members in braced frames, and

U_{1x} and U_{1y} are taken as 1.0 for members in unbraced frames, and

c. lateral torsional bucking strength, when applicable, in which case:

C_r is as define din Cl. 13.3, and is based on weak-axis or torsional-flexural buckling (see also 10.3.3),
M_{rx} is as defined in 13.6 (for the appropriate class of section),
M_{ry} is as defined in 13.5 (for the appropriate class of section),
U_{1x} and U_{1y} are as defined in 13.8.4 for members in braced frames, and
U_{1x} is as defined in 13.8.4 but not less than 1.0, for members in braced frames, and
U_{1y} is as defined in 13.8.4 for members in braced frames

There parameters SSY and SSZ are used to indicate the sidesway in the local Y and Z axes, respectively.

In addition, the member shall meet the following criteria:

$$\frac{M_{ux}}{M_{rx}} + \frac{M_{uy}}{M_{ry}} \leq 1.0$$

where

M_{rx} and M_{ry}	=	= as described in 13.5 or 13.6, as appropriate

All Other Sections

Members required to resist both bending moments and an axial compressive force shall be proportioned so that:

$$\frac{C_u}{C_r} + \frac{U_{1x} M_{ux}}{M_{rx}} + \frac{U_{1y} M_{uy}}{M_{ry}} \leq 1.0$$

where all terms are as defined in 13.8.2

The capacity of the member shall be examined for the following cases in a parallel manner to that in 13.8.2:

a. cross-sectional strength (members in braced frames and tapered members only),
b. overall member strength, and
c. lateral-torsional buckling strength.

Section Values of U_1

In lieu of a more detailed analysis, the value of U1 for the axis under consideration, accounting for the second-order effects due to the deformation of a member between its ends, shall be taken as:

$$U_1 = \frac{\omega_1}{1 - C_u / C_e}$$

where

ω_1	=	= for the axis under consideration as defined in 13.8.4
C_e	=	$= \frac{\pi^2 EI}{L^2}$ for the axis under consideration

D14.C.6.8 Combined Axial Tension and Bending

Members required to resist both bending moments and an axial tensile force shall be proportioned such that:

a. $\frac{T_u}{T_r} + \frac{M_u}{M_r} \leq 1.0$

where

M_r	=	ϕM_p for class 1 and class 2 sections

$= \phi M_y$ for class 3 and class 4 sections

b. $\frac{M_u}{M_r} - \frac{T_u Z_{pl}}{M_r A} \leq 1.0$ for class 1 and class 2 sections,

$\frac{M_u}{M_r} - \frac{T_u Z_e}{M_r A} \leq 1.0$ for class 3 and class 4 sections

where

M_r = as defined in 13.5 or 13.6

D14.C.7 Design Parameters

The design parameters outlined in table below may be used to control the design procedure. These parameters communicate design decisions from the engineer to the program and thus allow the engineer to control the design process to suit an application's specific needs.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements, some or all of these parameter values may be changed to exactly model the physical structure.

Note: Once a parameter is specified, its value stays at that specified number until it is specified again. This is the way STAAD.Pro works for all codes.

Table 212: South African Steel Design Parameters

Parameter Name	Default Value	Description
CODE	-	Must be specified `SANS10162-1:2011`. Design code to follow. See TR.48.1 Parameter Specifications (on page 2676).
BEAM	0	0 - Perform design at ends and those locations specified in the section command. 1 - Perform design at ends and 1/12th section locations along member length.
CAN	0	Deflection check for cantilever members. 0 - False 1 - True

Parameter Name	Default Value	Description
CB	1.0	Greater than 0.0 and less than 2.5,Value of ω_2 (C1.13.6) to be used for calculation Equal to 0.0: Calculate ω_2
CMY	1.0	Values between 0.4 – 1 used for ω_{1y} (C1.13.8.5). Input beyond the values consider as 1.
CMZ	1.0	Values between 0.4 – 1 used for ω_{1z} (C1.13.8.5). Input beyond the values consider as 1.
DFF	0	Default is 0 indicating that deflection check is not performed
DJ1	0	Start node of physical member for determining deflected pattern for deflection check and should be set along with `DFF` parameter
DJ2	0	End node of physical member for determining deflected pattern for deflection check and should be set along with `DFF` parameter
DMAX	1,000	Maximum allowable depth
DMIN	0	Minimum required depth
FU	345 Mpa	Ultimate strength of steel
FYLD	300 Mpa	Yield strength of steel
KT	1.0	K value for flexural torsional buckling
KY	1.0	K value in local Y-axis, usually minor axis
KZ	1.0	K value in local Z-axis, usually major axis
LT	Member length	Length for flexural torsional buckling
LY	Member length	Length in local Y axis for slenderness value KL/r

Parameter Name	Default Value	Description
LZ	Member length	Length in local Z axis for slenderness value KL/r
MAIN	0	Flag for controlling slenderness check 0 - For Check for slenderness. 1 - For Do not check for slenderness
NSF	1.0	Net section factor for tension members
RATIO	1.0	Permissible ratio of applied load to section capacity Used in altering the RHS of critical interaction equations
SSY	0	Sidesway parameter 0 - Sideway about local Y-axis. 1 - No sideway about local Y-axis.
SSZ	0	Sidesway parameter 0 - Sideway about local Z-axis. 1 - No sideway about local Z-axis.
STIFF	Member length	Center-to-center distance between transverse web stiffeners.
TRACK	0	Track parameter 0. Print the design output at the minimum detail level. 1. Print the design output at the intermediate detail level. 2. Print the design output at maximum detail level
UNB	Member Length	Unsupported length in bending compression of bottom flange for calculating moment resistance

Parameter Name	Default Value	Description
UNT	Member Length	Unsupported length in bending compression of top flange for calculating moment resistance

D14.C.8 Code Checking and Member Selection

D14.C.8.1 Code Checking

The purpose of code checking is to determine whether the current section properties of the members are adequate to carry the forces obtained from the most recent analysis. The adequacy is checked as per the SAB0162-1: 1993 requirements.

Code checking is done using forces and moments at specified sections of the members. If the BEAM parameter for a member is set to 1 (which is also its default value), moments are calculated at every twelfth point along the beam. When no section locations are specified and the BEAM parameter is set to zero, design will be based on member start and end forces only. The code checking output labels the members as PASSed or FAILed. In addition, the critical condition, governing load case, location (distance from the start joint) and magnitudes of the governing forces and moments are also printed. Using the TRACK parameter can control the extent of detail of the output.

Refer to D1.B.1.3 Code Checking (on page 1141) for general information on Code Checking. Refer to TR.49 Code Checking Specification (on page 2677) for details the specification of the Code Checking command.

D14.C.8.2 Member Selection

The member selection process involves determination of the least weight member that PASSes the code checking procedure based on the forces and moments of the most recent analysis. The section selected will be of the same type as that specified initially.

For example, a member specified initially as a channel will have a channel selected for it. Selection of members whose properties are originally provided from a user table will be limited to sections in the user table. Member selection cannot be performed on members listed as `PRISMATIC`.

Refer to D1.B.1.4 Member Selection (on page 1142) for general information on Member Selection. Refer to TR. 49.1 Member Selection Specification (on page 2678) for details the specification of the Member Selection command.

7

Postprocessing and Reports

This section describes how to review output, perform post-processing tasks, generate reports, and plot from STAAD.Pro.

P. To view analysis results

There are several ways to open analysis results in the STAAD.Pro Editor.

1. Either:

   On the **Utilities** ribbon tab, select the **View Analysis Output** tool in the **Utilities** group.

   
   or

   Drag a STAAD output file (file extension `.anl`) icon from Windows Explorer and drop it on to the STAAD.Pro Editor icon.

   or

   In the Windows Explorer, double-click the icon for the file, `Bentley.Staad.Editor.exe`.

   

2. If you opened the STAAD.Pro Editor, then:
   - **a.** select **File** > **Open.**
   - **b.** Select **STAAD Analysis Output Files (*.anl)** in the file type drop-down list.
   - **c.** Navigate to and select a STAAD output file and the click **Open**.

The output results open in the STAAD.Pro Editor application.

Note: You may need to change the character encoding used depending on the design code selected.

P. Postprocessing Workflow

This workflow offers graphical result verification and visualization facilities. A comprehensive custom report generation facility is also incorporated. The customized reports may contain tabular results as well as graphics.

P. To create a animated video file from analysis results

AVI files are a mechanism by which a dynamic result, such as, a deflection diagram in animation, may be captured and recorded. In an animated view, the movement from one extremity to the other is captured as several frames. Presently, this facility is available in STAAD for deflection, section displacement, mode shape and plate stress contour diagrams.

1. Perform a successful analysis on a STAAD input file.
2. On the **Utilities** ribbon tab, select the **Create AVI File** tool in the **Utilities** group.
   The **Create AVI File** dialog opens.
3. (Optional) Change the values of the **Total No. of Frames** and **Frame Rate /sec** to alter the speed and length of the animation.
4. Select a result to animate: **Deflection**, **Sectional Displacement**, **Mode Shape**, or **Stress Contour**.

   Note: Mode Shape and Stress Contour are not active if the required data of that type are not present in the STAAD file, such as a modal extraction, or finite elements.
5. Click **OK**.
   A **Save As** dialog opens.
6. Click **Save**.
   The **Video Compression** dialog opens.
7. (Optional) Select the means of **Video Compression** (codec) to use and change settings for the selection as needed.
8. Click **OK**.
   A message indicating the status of the AVI creation opens.
9. Click **OK**.

   The AVI Video window opens and begins playing the saved animation.

P. Nodal Results

This section describes how to display and review analysis results for nodes.

P. To display displacements

To view the displaced shape along with nodal and beam displacements for the current load case, use the following procedure.

1. Either:

   Select the **Displacements** page in the **Postprocessing** workflow

   or

Select the **Deflection** tool in the **View Results** group on the **Results** ribbon tab

The nodal displacements are shown for the current load case. The **Node Dispalcements** and **Beam Relative Displacement Detail** tables open.

2. (Optional) Select different **Load** in the **View Results** group on the **Results** ribbon tab.
   The displaced shape updates with the selected load.

Related Links

- *P. Node Displacements table* (on page 2002)

P. To display the deflect shape

To display the deflected shape of the structure including beam section displacements, use the following procedure.

Tip: This displays a more accurate estimation of the section displacements than using just the nodal displacements, but can also take longer to render on large models.

1. On the **Results** ribbon tab, select the **Displacement** tool in the **View Results** group.

   The deflected shape is drawn for the current load case.
2. (Optional) Select different **Load** in the **View Results** group on the **Results** ribbon tab.
   The displaced shape updates with the selected load.

Related Links

- *P. Node Displacements table* (on page 2002)

P. To display the support reaction values

To display the support reaction values for the current load case, use the following procedure.

1. Either:

   select the **Reactions** page in the **Postprocessing** workflow

   or

   select the **Layouts** > **Reaction** tool in the **View Results** group on the **Results** ribbon tab

   The six values —namely, the three forces along global X, Y and Z, and the three moments Mx, My and Mz, in the global axis system— are displayed in the annotation box for each support node.

   The **Support Reactions** table opens.
2. (Optional) Select different **Load** in the **View Results** group on the **Results** ribbon tab.
   The reaction values update with the selected load.
3. To reposition an annotation box to aid visibility:
   a. On the **Select** ribbon tab, select the **Text** tool in the **Cursors** group.

The mouse pointer changes to the text selection cursor. 

b. Click-and-drag on any annotation (while holding down the left mouse button) it to the desired location in the View window.
The leading arrow is redrawn from the support to the new annotation position.

c. Press **<Esc>** to return to the default selection mode.

You can use the **Annotation** tool to control the reactions displayed.

Related Links

- *P. Support Reactions table* (on page 2003)

P. To graphically display reactions at each support

1. Select the **Reactions** page in the Postprocessing workflow.
   The reactions are labeled for the current load.
2. On the **Results** ribbon tab, select the **Annotate** tool in the **Configuration** group.

   The **Annotation** dialog opens.
3. Select the Reactions tab.
4. Select the **Show Line** option.
5. (Optional) Change the scale for force and moment if needed.
6. Click **Annotate** to display the reactions as scaled load arrows.
7. Click **Close**.

Related Links

- *Annotation dialog* (on page 2997)
- *Annotation dialog* (on page 2997)

P. To display load versus displacement graph

To display the load level versus displacement curve for a selected node and load case, use the following procedure.

Load versus displacement is only available after a geometric nonlinear analysis is performed on the STAAD.Pro model.

1. Select the **Layouts** > **Node Displacement** tool in the **View Results** group on the **Results** ribbon tab.
   The **Node Displacement Curve** and **Node Displacements** table open.
2. Either:

   use the **Node Cursor** tool in the **Cursors** group on the **Select** ribbon tab to select a node in the graphical view

   or

   select a node in the **Node Displacements** table

The plot for the selected node is displayed. If you select multiple nodes, then the graph will display the plot for the lowest node number.

3. Select a **Load** in the **View Results** group on the **Results** ribbon tab.

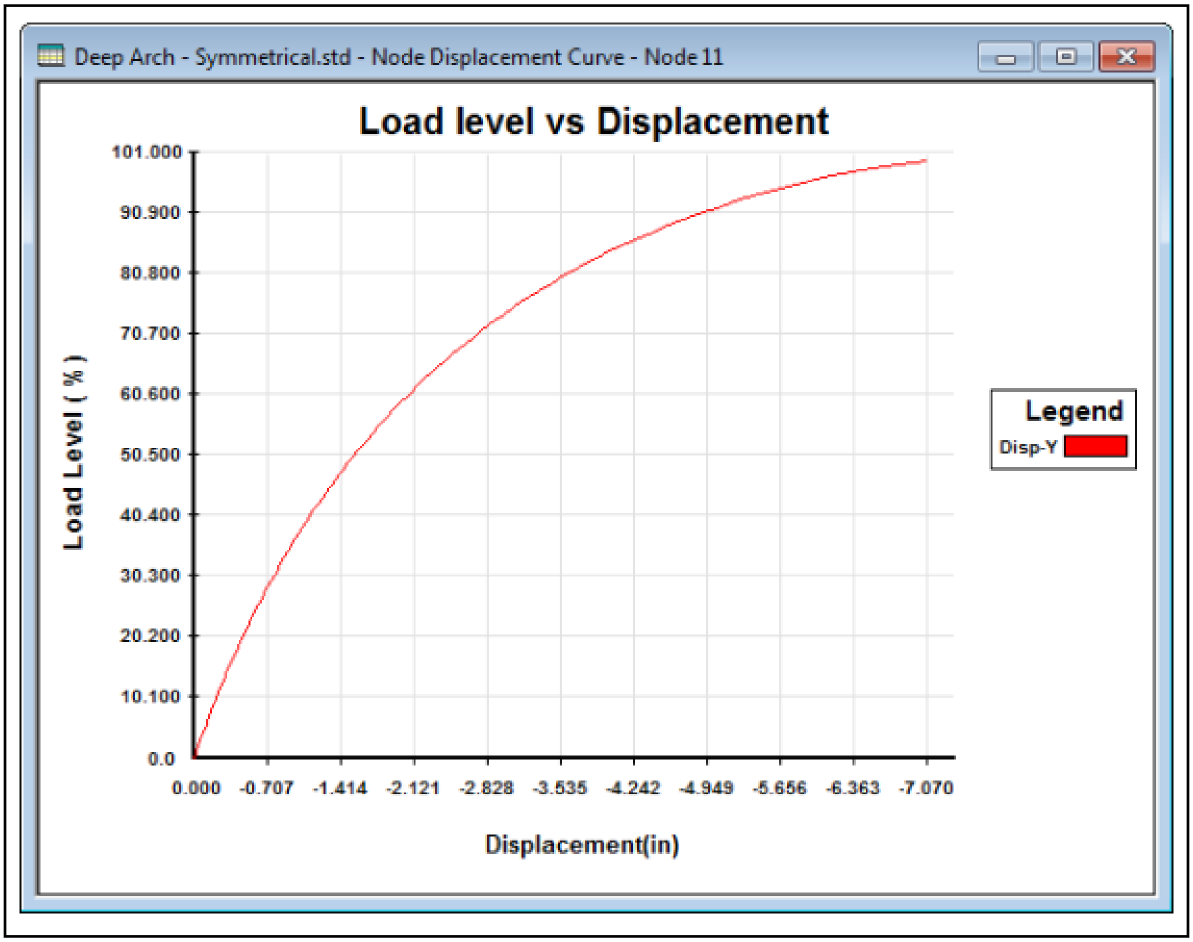
   A nonlinear analysis must be performed for the selected load case.
4. (Optional) Specify the **Select Load Step** in the **Node Displacements** table.

   > **Note:** The maximum number of load steps for the current load case is displayed on the right-hand side of the table controls.
5. (Optional) Check the **Limit Maximum Load Step for Graph** option in the **Node Displacements** table to limit the maximum load step displayed in the graph.
6. To change the degree of freedom plotting on the graph:
   a. Right-click anywhere on the **Node Displacements** curve window.
   b. Select **Geometry** from the pop-up menu.
   The **Diagram** dialog opens.
   c. Select the displacement degree of freedom you want displayed on the graph.

   You can select multiple degrees of freedom to plot simultaneously.
   d. Click **OK**.

   The graph and legend update to include the selected curves.
7. (Optional) To include the current graph in a report:
   a. Right-click anywhere on the **Node Displacements** curve window.
   b. Select **Take Picture** from the pop-up menu.
   A **Picture #** dialog opens to name the image.
   c. (Optional) Type an **ID** and **Caption**.
   d. Click **OK**.

   The picture is added to the picture album for inclusion in reports.



P. To display base pressure results

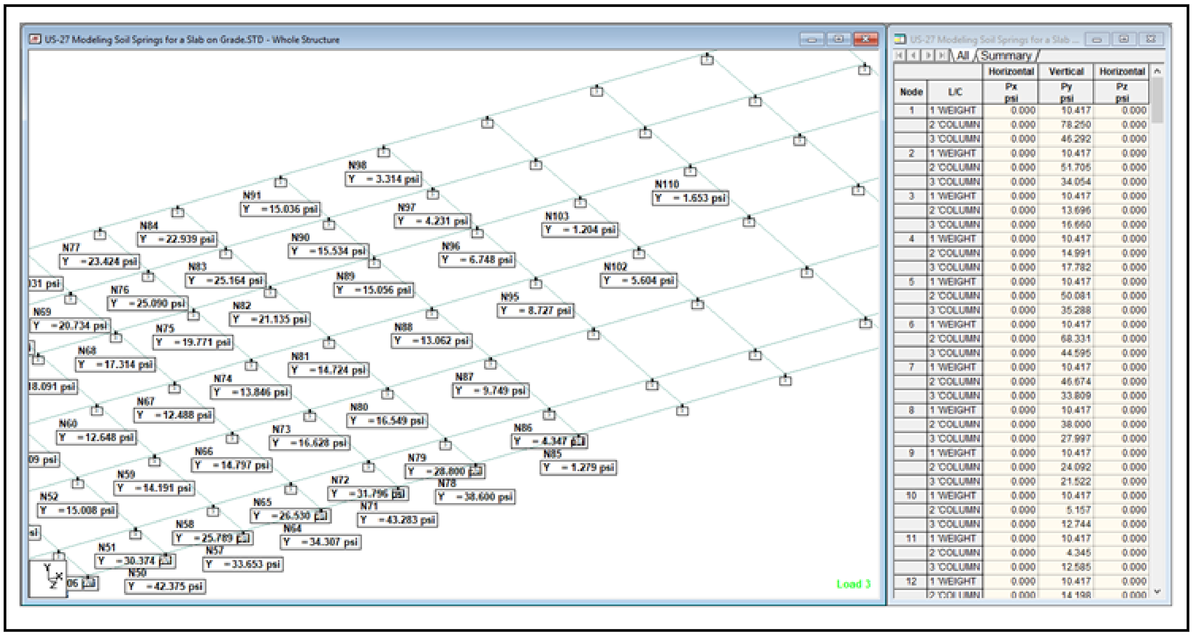
To display soil pressure at support node locations for slabs consisting of plate elements which have been generated using elastic mat or plate mat commands, use the following procedure.

This feature is only available for analyzed models that include these mat support conditions.

1. Select the **Layouts** > **Base Pressure** tool in the **View Results** group on the **Results** ribbon tab.
   The vertical pressure value at each support node is displayed. The **Base Pressure** has tabs to display the pressure values at each supported node for all load cases, along with a summary tab.

   Tip: You may need to zoom in to see individual labels for some models.

2. (Optional) Select a different **Load** in the **View Results** group on the **Results** ribbon tab.
   The labels update to reflect the base pressure for the selected load case.



P. To display nodal instabilities

To graphically examine nodes and degrees of freedom on the structure where instability conditions have been reported in the output, use the following procedure.

This feature is only available when instabilities have been detected during the analysis.

1. Select the **Layouts** > **Instability** tool in the **View Results** group on the **Results** ribbon tab.

   The locations of instabilities are highlighted on the structure in large blue circles. The Unstable Joint table provides information on the joint number and the degree of freedom associated with an instability at that joint. An unstable condition is marked with a "1".

You can apply restraints at these joints in unstable directions in an attempt to stabilize the joint.

P. Beam Results

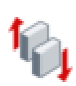
This section describes how to display and review analysis results for members.

P. To display results diagrams on the members

To display the results diagrams drawn on to the members, use the following procedure.

1. On the **Results** ribbon tab, select one of the graphical results tools in the **View Results** group:

Displacement



FY

MY

Utilization Ratio

FX

MZ

FX

MX

Beam Stress

> **Tip:** Alternatively, you can select the **Layout** > **Beam Forces** tool in the **View Results** group on the **Results** ribbon tab to display the major axis bending graphs on the members (**MZ**).

The selected diagram is drawn on the members.

> **Note:** The selected tool is shaded to indicate it is active.

2. (Optional) Either:

   repeat step 1 to select different diagrams as needed

   or

   select the active diagram tool to hide the diagram

   > **Tip:** Multiple diagrams may be displayed simultaneously.

3. To change the scale of any diagrams:
   a. On the **Results** ribbon tab, select the **Scale** tool in the **Configuration** group.

   
   The **Diagrams** dialog opens to the **Scales** tab.
   b. Change the scale factor for the relevant item in the Results Scales group.

   > **Tip:** Smaller values result in more exaggerated diagram sizes.

   c. Click **Apply** to update the diagram.
   d. Click **OK** to close the dialog.

P. To view stress contour of a beam

To display the full section stress contour on a beam, use the following procedure.

Stress contours can be displayed for sections that have predefined dimensions (e.g., catalog and prismatic sections) and general sections with stress distances defined.

1. On the **Results** ribbon tab, select the **Layouts** > **Beam Stress** tool in the **View Results** group.
   The **3D Beam Stress Contour** dialog opens.
2. In the **Whole Structure** view window, click on any member to select it.

The **Select Section Plane** dialog opens.

The **3D Beam Stress Contour** displays a rendered view of the member with the stress contours on the surface on the left and the current cross-section stress contour on the right. Compression is display in blue and tension in red.

The table displays the corner stress values at points along the member length.

3. Use the slider in the **Select Section Plane** dialogs to update the cross section stress contour display.
4. (Optional) In the **Select Section Plane** dialog, type a Y Point and Z Point value to display the cross-section stress at an arbitrary point within the section.

P. To view stress contour of a General UPT beam

To display the full section stress contour on a beam that uses a general UPT profile, use the following procedure.

Stress contours can be displayed for general UPT sections that do not yet have stress distances defined by defining those in the Postprocessing workflow.

1. On the **Results** ribbon tab, select the **Layouts** > **Beam Stress** tool in the **View Results** group.
   The **3D Beam Stress Contour** dialog opens.
2. In the **Whole Structure** view window, click on any member which uses a General UPT profile to select it.
3. Either:

   select the **Define Section Profile** tool in the **Model** group on the **Beam** ribbon tab

   or

   right-click and then select **Define Section Profile** from the pop-up menu

   The **Define Section Profile** dialog opens.
4. Type the local Y and Z coordinates of the extreme fibers for stress results.

   Tip: You can also “swap” the top and bottom sides ( ) or left and right sides ( ) in order to facilitate entering stress points by clicking the corresponding tools.
5. Click **OK**.
6. Use the slider in the **Select Section Plane** dialogs to update the cross section stress contour display.
7. (Optional) In the **Select Section Plane** dialog, type a Y Point and Z Point value to display the cross-section stress at an arbitrary point within the section.

Related Links

- *Define Section Profile dialog* (on page 3049)

P. To display steel design utilization ratios

To display member utilization values and color-coded design results on the structure, use the following procedure.

The utilization ratios for members are only available for steel design performed in the batch mode.

The utilization ratio is for the load envelope used for design and is not affected by the current load case in the Postprocessing workflow.

Note: For AISC 360-16, multiple parameter blocks (multiple steel designs) can be reviewed in the user interface.

1. (Optional) On the **Results** ribbon tab, select the parameter block or maximum design from the **Design Parameters** drop-down list.

   If an input file contains multiple parameter blocks (steel design parameter sets) or multiple design commands (steel code check or member selections) within a single parameter block, then the results are available in the Postprocessing workflow. Parameter sets are numbered and multiple design commands in the same parameter block are given as decimals.

   Note: This feature is compatible with AISC 360-16 only in this release.
2. O

   on the **Results** ribbon tab, select the **Layouts** > **Utilization** tool in the **View Results** group.

   or

   on the **Results** ribbon tab, select the **Utilization Ratio** tool in the **View Results** group

   The utilization ratio label is shown next to each member included in the steel design.

   Note: Members are color coded: green for passing design, blue for failing less than 50% over utilization, and red for failing more than 50% over utilization.

   The **Design Results** table includes a tab for **All** members as well as for **Failed** members.
3. (Optional) Change the color coded limits:
   a. On the **Results** ribbon tab, select the **Structure** tool in the **Configuration** group.
   The **Diagrams** dialog opens.
   b. Select the **Design Results** tab.
   c. In the color-coding table, change the **To** cell values for the green and blue rows.

   For example, you may want to change the green (passing) utilization ratio to 1.003 and the blue (nearly passing) utilization ratio to 1.05 to get a “feel” for where the members are nearly adequate.
   d. Click **Apply**.
   The diagram color coding updates accordingly.
   e. Click **OK**.

P. To display bending and shear diagrams

To display the bending (both major and minor axes) and shear diagrams, use the following procedure.

1. On the **Results** ribbon tab, select the **Layouts** > **Graphs** tool in the **View Results** group.
   The **Beam Graphs** windows open.
2. Select a member in the view window.
3. Select the current **Load** on the **Results** ribbon tab in the **View Results** group.
4. Change the diagrams displayed in any of the **Beam Graphs** windows:
   a. Right-click and select **Diagrams** from the pop-up menu.
   The **Diagram** dialog opens.
   b. Set the checkbox for the graphs you want to add to the window.
   c. Click **OK**.

   The diagrams are updated.

P. Plate Results

This section describes how to display and review analysis results for plate elements.

P. To display plate results contours

To display analysis results of plate elements as contour lines on the plates, use the following procedure.

Plate stresses can be displayed as contour lines along the plate elements graphically for a variety of stress types.

1. Either:

   on the **Results** ribbon tab, select the **Plate Stress** tool in the **View Results** group

   or

   select the **Plate Results** page in the Postprocessing workflow bar
   The **Diagrams** dialog opens to the Plate Stress Contour tab.

   The tables in the Plate Results page also display results data for many of the stress types.
2. (Optional) Select the **Load Case**.

   Tip: The current load case in the Results ribbon tab will be selected.
3. Select the **Stress Type** to display.
   STAAD.Pro can display a variety of component element stresses or stress combinations.
4. Select the display options for the contours.
5. Click **Apply**.
6. Make any different selections to change the contour display as needed and then click **Apply** again to update the view.
7. Click **OK**.
   The dialog closes.

- *Diagrams dialog* (on page 2751)

P. To display plate results along a cut line

To view the plate stresses along an arbitrary line cut across plate elements, use the following procedure.

Note: Cut lines are not supported for models containing plate offsets.

1. On the **Results** ribbon tab, select the **Layouts** > **Results Along Line** tool in the **View Results** group.
   The **Results Along Line** dialog and layout open.
2. In the **Results Along Line** dialog, click **Cut by a Line**.
3. In the view window, click the start and end points of the line.

4. Click a third point to define the cut direction.

   A perpendicular line is rubber banded to the mid-point of the line drawn in step 3.

   The line is added to the list and the in Max Absolute results along the line are displayed in the graph and table.
5. Customize the stress results:
   a. (Optional) Type a **Name** for the line.
   b. Select the **Stress Type** from the drop-down list.

      Options Max Absolute through Tressca Bottom (i.e., options with "(Line)") represent values across indiviual elements.
      Options St-Line through Qt-Line represent values that have been mathematical processed to be continuous across element boundaries and have forces in equlibrium along the cut line.

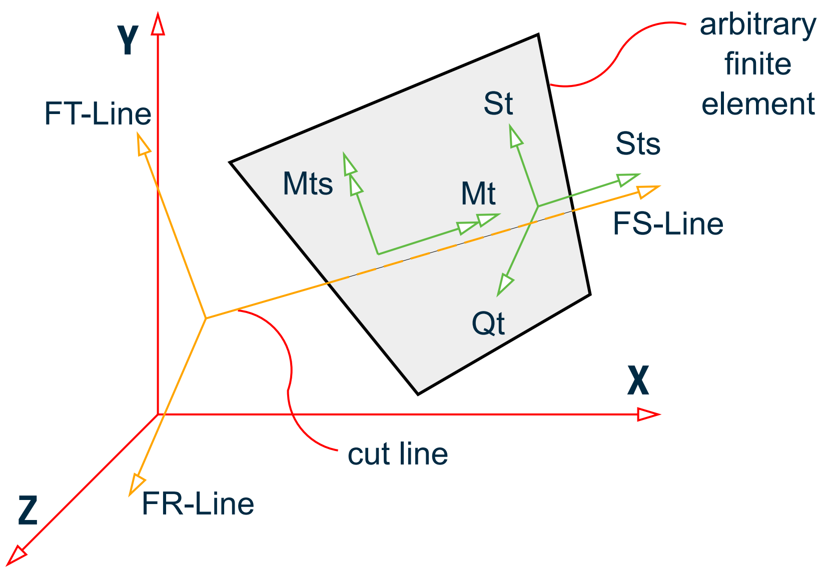

Figure 193: Stresses along a cut line for "-Line" stress types

St Normal stress perpendicular to the cut line, σ_t.

Sts Shear stress along the cut line, τ_t.

Mt Bending moment along the cut line, M_t.

Mts Bending Moment about the T axis. This is in the plane of the plate and perpendicular to the cut line (i.e. the S axis).

Qt Out-of-plane shear, Q_t

   c. Type a **Max No Div** to specify the number of equal divisions displayed in the graph.

      Tip: Higher values result in a clearer graph, with 10-20 being a normal range.

   d. Click **Update**.
6. (Optional) Add the cut line results to the report:
   a. Click **Create Report**.
      The **Report Title** dialog opens.
   b. Check the **Save Report** option.

c. Click **OK**.

The graph displays the selected stress values along the cut line using the number of divisions per element specified.

Forces listed in the table when these results are selected are given in the in a coordinate system relative to the cut line (i.e., “FS” is along the cut line, “FT” is in the plane of the element, and “FR” is normal to the element). This is indicated by the “-Line” suffix of the results.

The table has two tabs: **Stresses** and **Total Force**. In the case of “-Line” stress types, the forces are given in the local cut line coordinate system:

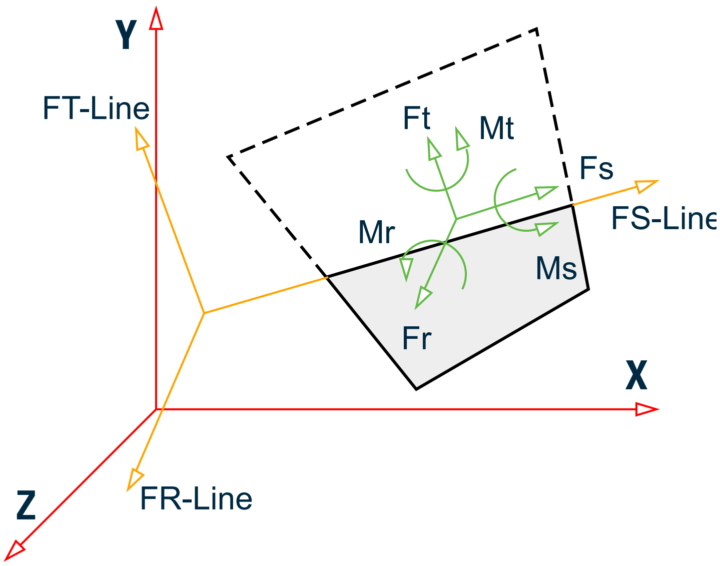

Figure 194: Forces along a cut line for “-Line” stress types

Fs Resultant force along the cutline

Ms Resultant moment about the cutline

Ft Resultant force perpindicular to the culine in the plane of the plate

Mt Resultant moment about the line perpindicular to the cutline in the plane of the plate

Fr Resultant force perpindicular to the cutline out of the plane of the plate

Mr Resultant moment about the line perpindicular to the cutline out of the plane of the plate

P. Solid Results

This section describes how to display and review analysis results for solid elements.

P. To display solid results contours

To display analysis results of solid elements as contour lines on the solid faces, use the following procedure.

Solid stresses can be displayed as contour lines along the solid element faces graphically for a variety of stress types.

1. Either:

   on the **Results** ribbon tab, select the **Solid Stress** tool in the **View Results** group

   

   or

   select the **Solid Results** page in the Postprocessing workflow bar

   The **Diagrams** dialog opens to the Solid Stress Contour tab.

   The tables in the Solid Results page also display results data for many of the stress types for both solid corners and solid centers.

   Note: The stress values displayed in the Postprocessing workflow tables are “smoothed” by averaging stresses from adjacent elements. Therefore, they may not be equal to those corner stresses reported in the STAAD.Pro `.anl` for the same model.
2. (Optional) Select the **Load Case**.

   Tip: The current load case in the Results ribbon tab will be selected.
3. Select the **Stress Type** to display.

   STAAD.Pro can display a variety of component element stresses or stress combinations.
4. Select the display options for the contours.
5. Click **Apply**.
6. Make any different selections to change the contour display as needed and then click **Apply** again to update the view.
7. Click **OK**.
   The dialog closes.

- *P. Solid Center Stress table* (on page 2011)

P. Dynamic Results

P. To display mode shapes

To display the mode shape diagram and a table of mode shape data, use the following procedure.

Mode shapes are available for models with dynamic load cases.

Tip: You can limit the number of modes included in the Postprocessing results in the **Results Setup** dialog **Modes** tab.

1. Either:

   on the **Results** ribbon tab, select the **Mode Shape** tool in the **Dynamics** group

or

on the **Results** ribbon tab, select the **Layouts** > **Mode Shape** tool in the **Dynamics** group

or

select the **Dynamics** page in the **Postprocessing** workflow bar

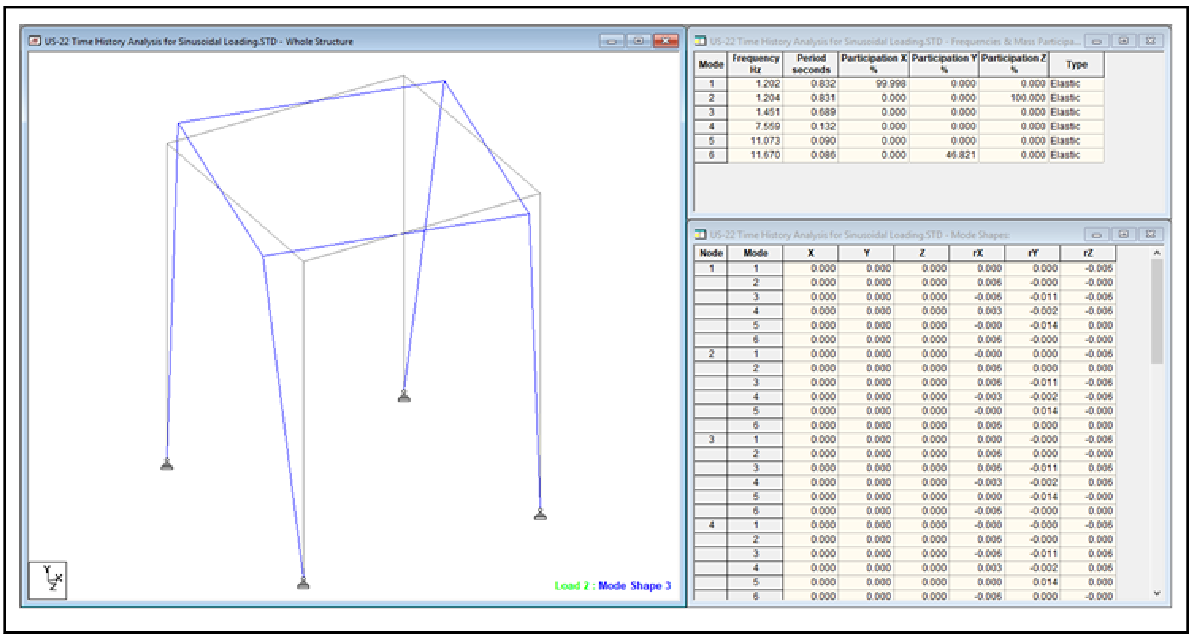
The **Mode Shape** tool is only active if the current load is a dynamic load case.

The mode shape for the currently selected mode and load case is displayed.

If you selected the Layout or the Page control, the **Frequencies & Mass Participation** and **Mode Shapes** tables are also displayed.

2. (Optional) Select a different **Load** in the **View Results** group on the **Results** ribbon tab.
3. (Optional) Select a different **Mode** in the **Dynamics** group on the **Results** ribbon tab.

   This option is only active if the current load is a dynamic load case.



You can control the color and display of the mode shapes diagram from the **Load and Results** tab of the **Diagrams** dialog.

Related Links

- *Diagrams dialog* (on page 2751)

P. To display time history graphs

To display data of time versus displacement, velocity, or acceleration, use the following procedure.

Time history plots are only available for STAAD.Pro models with time history loads.

1. Select the time history response plot you want to view:

To view...	Select...
Displacement data	the **Layouts** > **Displacement** tool in the **Dynamics** group
Velocity data	the **Layouts** > **Velocity** tool in the **Dynamics** group
Acceleration data	the **Layouts** > **Acceleration** tool in the **Dynamics** group

A set of three plots opens.

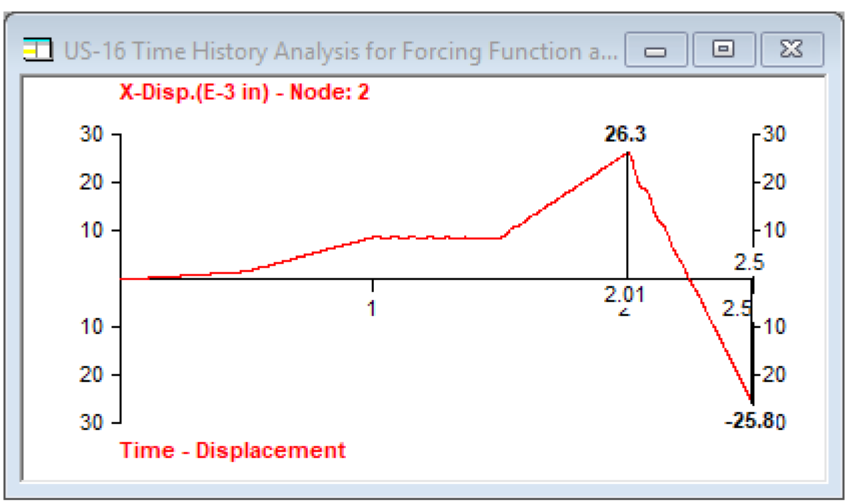
If you do not have any node groups defined in the model, you will asked if you want to define any now. If you opt to not create any now, you must select the Analytical workflow to define node groups.

2. Either:

To graph data for...	Select...
a single node	the node in the graphical view
a node group that defines a floor	the name of the node group in the **Select Groups** dialog **Tip:** You can use the **Group** tool in the **Attributes** group on the **Select** ribbon tab to display the **Select Groups** dialog.

Selecting a node group will display calculated average time history results for the desired response. This feature can be used to generate floor spectra at each floor level in a structure which can then be used as input for other dynamic analysis such as analysis of vibrating machinery existing on the floor.

3. To select the global direction of action displayed on the y-axis for a plot:
   a. Right-click on the graph and select **Diagrams** from the pop-up menu.
      The **Diagram** dialog opens.
   b. Select global direction for the action.
      More than one global direction can be displayed on a plot.
   c. (Optional) Click the color block beside a global direction to specify a different color for the plot.
   d. Click **OK**.

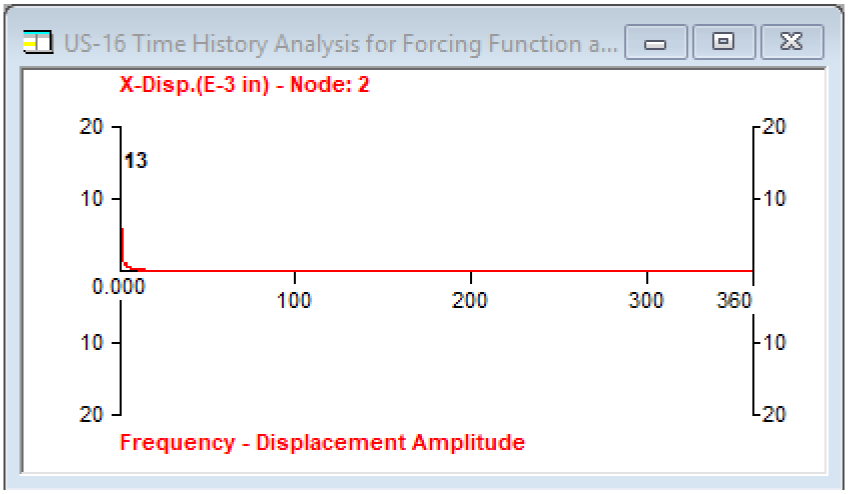


4. To change the x-axis of a graph to display frequency instead of time:

This option performs a time-domain to frequency-domain transformation of the nodal displacement response due to time-varying load. STAAD.Pro graphs the amplitude information from a Fourier transform.

a. Right-click on the graph and select **Diagrams** from the pop-up menu.
   The **Diagram** dialog opens.
b. Select **Frequency Domain** and then click **OK**.

The graph updates to display frequency.



5. (Optional) To save the current set data to an external file:
   a. Right-click on the graph and then select **Save data in a text file** from the pop-up menu.
      A Windows **File Open** dialog opens.
   b. Select a location to save the data.
   c. Type a **File Name** and then click **Save**.

   The plot data is saved in a plan text file (file extension `.txt`).
6. You can use pictures of the graph in other reports or external programs by right-clicking on the graph and selecting:

Select...	To...
Copy Picture	copy the graph to the Windows clipboard
Take Picture	save the image for use in reports for later use. A Picture dialog will open for a label and caption. Click **OK** to save the graph to the report Picture Album.

P. To display floor spectrum results

To display the generated floor spectra results for a time history load case, use the following procedure.

These results are only available for a STAAD.Pro model with a time history load and a generated floor spectrum command.

1. On the **Results** ribbon tab, select the **Layouts** > **Floor Spectrum** tool in the **Dynamics** group.
   The **Floor Spectrum Graph** window and **Floor Spectrums** table open.

   Tip: The peak acceleration value is labeled.
2. On the **Floor Spectrums** table, select the **Floor Spectrum Set** from the drop-down list.
   The tabulated values and the graph update to display the selected set.
3. (Optional) You can change the display of the graphed data by right-clicking on the graph and selecting:

Select...	To...
Linear Graph	display the response spectrum graph with linear axes
Log-Log Graph	display the response spectrum graph with logarithmic axes (default display)
Show Points	display the individual calculated points on the plot

4. (Optional) To save the current set data to an external file:
   a. Right-click on the graph and then select **Save data in a text file** from the pop-up menu.
      A Windows **File Open** dialog opens.
   b. Select a location to save the data.
   c. Type a **File Name** and then click **Save**.

   The plot data is saved in a plan text file (file extension `.txt`).
5. You can use pictures of the graph in other reports or external programs by right-clicking on the graph and selecting:

Select...	To...
Copy Picture	copy the graph to the Windows clipboard
Take Picture	save the image for use in reports for later use. A Picture dialog will open for a label and caption. Click **OK** to save the graph to the report Picture Album.

P. To display buckling analysis results

To display the calculated buckling factors and buckling modes from a buckling analysis, use the following procedure.

You must perform a successful buckling analysis of a structure using the Eigen method to access this feature.

1. On the **Results** ribbon tab, select the **Layouts** > **Buckling** tool in the **Dynamics** group
   The **Buckling Factors** table and with the **Buckling Modes** table open. The first buckling mode is displayed on the structure.
2. Select a row corresponding to a Mode number in the **Buckling Factors** table
   The graphical display shows the selected buckling mode shape.

P. Reports

STAAD.Pro can generate the following specialized reports.

P. To generate a node displacement report

1. In the **Postprocessing** mode, use the **Node Cursor** tool to select nodes for inclusion in the report.
2. On the Results ribbon tab, select **Reports** > **Node Displacements** in the **Reports** group.

The **Node Displacement** dialog opens.

3. (Optional) Select the sorting criteria you want to use in the report.
4. (Optional) Select the **Load Cases** on the **Loading** tab you want to include in the report.
5. Specify the report metadata:
   a. Select the **Report** tab.
   b. Type the **Title** for the report.
   c. (Optional) Check the **Save Report** option and type an **Id** value if you want to change it.
6. Click **OK**.

Related Links

- *Node Displacement dialog* (on page 3001)

P. To generate transfer forces report

To generate transfer forces for a selected set of beams and columns to include in your report, use the following procedure.

1. In the **Postprocessing** workflow, use the **Beam Cursor** tool to select all the members framing into a connection.
2. On the Results ribbon tab, select **Reports** > **Column Transfer Force** in the **Reports** group.

   The **Transfer Force for Selected Members** dialog opens.
3. (Optional) Click any load cases you to *exclude* from the transfer forces report.

   By default, all load cases will be included.
4. Click **Insert to Table**.
   The **Transfer Force Report** table opens.
5. Click **Close**.

The **Transfer Force Report** can be found within the **Reports** group on the **Items** tab in the **Report Setup** dialog.
Related Links

- *Transfer Forces for Selected Members dialog* (on page 3002)

P. To generate a floor vibration report

To generate a floor vibration report per the procedures of Chapters 3 and 4 of the AISC Steel Design Guide Series No. 11, use the following procedure.

Floor vibration reports are performed for composite decks only. You must define and run an analysis for a composite deck structure in order to generate a floor vibration report.

1. On the **Results** ribbon tab, select the **Reports** > **Floor Vibration Report** tool in the **Reports** group.

   

   The **Floor Vibration Report** dialog opens.
2. Select the composite deck name from the **Select** drop-down list and then select the **Load Case**.
3. Either:

   select the closes description for the type of building in the **Bldg Type** drop-down list in order to select a predefined Beta value

   or

   type the **Beta** value directly
4. Click **Check**.
   The results of the vibration check are displayed.

P. Floor Vibrations Engineering Theory

The fundamental natural frequency of the joist mode and the girder mode can be determined from equation 3.3 on page 11 of the design guide:

$$f_{j/g} = 0.18\ (g/\Delta)^{1/2} \qquad 1$$

where

$f_{j/g}$	=	fundamental natural frequency of the joist or the girder mode
g	=	acceleration due to gravity
Δ	=	midspan deflection of the member due to the weight supported.

For the combined mode, the fundamental natural frequency can be determined from equation 3.4 on page 11 of the design guide:

$$f_n = 0.18\ [g/\ (\Delta_j + \Delta_g)\ ]_{1/2} \qquad 2$$

where

f_n	=	fundamental natural frequency for the combined mode
g	=	acceleration due to gravity
Δ_j	=	joist deflection due to the weight supported
Δ_g	=	girder deflection due to the weight supported

Δ_j and Δ_g are the local deflection of the joist and the girder determined from a secondary operation after the analysis. The stiffness analysis will yield the global deflection values for the girder beams. A line joining the start and the end nodes of the girder beam in its deflected position is created as a base line. Relative to this base line, the deflection values are zero for the start and end nodes. The local deflection values of the intermediate points of the girder beam are evaluated from the global deflection values relative to this base line.

It is this local deflection that is used in calculating the fundamental natural frequency as shown in the earlier equations. Further, the local deflection is also used in calculating the equivalent uniform loading on the joist and the girder, wj and wg, as shown in the equation on page 21 of the AISC Design Guide:

3

where

$I_{j/g}$	=	moment of inertia of the effective joist or girder section
$L_{j/g}$	=	joist or girder span
E_g	=	modulus of elasticity of steel

In addition to the terms f_j , Δ_j , w_j shown above , the following additional terms —D_s , D_j , B_j , and W_j — which are explained below, are also reported for the joist mode.

where

D_s	=	the transformed slab moment of inertia per unit width and is determined from the equation at the bottom right corner of page 17 of the AISC Design Guide:
d_e	=	effective depth of the concrete slab, usually taken as the depth of the concrete above the form deck plus one-half the depth of the form deck
N	=	dynamic modular ratio = $E_s\ /\ 1.35\ E_c$
E_c	=	modulus of elasticity of concrete
D_j	=	the joist or the or beam transformed moment of inertia per unit width, and is determined from the equation shown at the top left of page 18 of the AISC Design Guide:
		= I_j/S
S	=	joist or beam spacing

B_j	=	the effective width for the beam or joist panel mode and is determined from equation 4.3a on page 17 of the AISC Design Guide:
		$= C_j (D_s / D_j)^{1/4} L_j \leq 2/3\times$ floor width
C_j	=	1.0 for interior panels
		2.0 for edge panels
W_j	=	the weight of the beam panel and is calculated from equation 4.2 on page 17 of the AISC Design Guide and page 21 left side:
		$W_j = w_j B_j L_j$ (x 1.5 if continuous)

For the girder mode, the terms reported include f_g , Δ_j , w_g which were explained earlier, and, D_g , B_g , and W_g which are described below.

where

D_g	=	the girder transformed moment of inertia per unit width described on page 18 of the AISC Design Guide:
		$= I_g/L_j$ for all but edge girders
		$= I_g/2L_j$ for edge girders
B_g	=	the effective width for the girder panel mode and is determined by equation 4.3b on page 18:
		$= C_g (D_g / D_j)^{1/4} L_g \leq 2/3\times \mathit{floor\ width}$ for interior panels
		$= 2/3\ L_g$ for edge panels
C_g	=	defined on page 18 as:
		= 1.6 for girders supporting joists connected to girder flange (e.g., joist seats)
		= 1.8 for girders supporting beams connected to the girder web.
W_g	=	the weight of the girder panel and is calculated by equation 4.2 on page 17 and described on page 21:
		$= w_g B_g L_g$ (x 1.5 if continuous)

For the combined mode of vibration the parameters reported are f_n , W, β, Peak Acceleration and Acceleration Limit.

f_n is calculated from equation 2 shown above.

W is the equivalent panel weight in the combined mode and is calculated from the equation shown on page 21 of the AISC Design Guide:

W

β is the value of the damping ratio as per Table 4.1 on page 18 of AISC Design Guide.

The peak acceleration due to walking excitation is then determined from the equation 4.1 on page 17 and on page 21 of the AISC Design Guide:

where

a_p	=	peak acceleration value due to walking excitation
P_0	=	a constant force representing excitation and is determined as per Table 4.1 of the Design Guide.
f_n	=	fundamental natural frequency in combined mode

The acceleration limit is determined from Table 4.1 on page 18 of the Design Guide.

P. Reviewing Pushover Analysis Results

This section describes how to view some of the specific results from a pushover analysis.

Once a successful pushover analysis is performed, pushover results are available in the **Postprocessing** worfklow.

P. To review pushover load steps

To review the pushover load applied at each load step, use the following procedure.

1. On the **Results** ribbon tab, select the **Layouts** tool drop-down in the **Dynamics** group.
2. Select the **Loads** tool in the **Pushover** group.
   The **Load Value** table opens.
3. Either type a integer or use the arrows in the **Select Load Step** field.
   The pushover loads at each node and base shear are displayed for this load step.

P. To view capacity curve and determine target displacement

To determine the performance point of a pushover analysis for a given performance level, use the following procedure.

The capacity curve displays the plot of the base shear versus the displacement at control joint.

1. On the **Results** ribbon tab, select the **Layouts** tool drop-down in the **Dynamics** group.
2. Select the **Graphs** tool in the **Pushover** group.
   The Capacity Curve graph (on page 2013) and table opens.
3. Right-click on the **Capacity Curve** graph and select **Determine Target Displacement** from the pop-up menu.
   The **Define Modification Factor C0** dialog opens.
4. Specify the Modification Factor C0:
   a. Either:

To...	Do the following...
use a table value	select the **Select from Table** option and then select a C0 factor value in the table
use an interpolated value	select the **Define** option and then select or type the specific building parameters using the options

   The **Modification Factor C0** value to be used is displayed in the dialog.
   b. Click **Next.**

   The **Define Cm to Calculate Modification Factor C1** dialog opens.
5. Specify the Modification Factor C1:
   a. Select the Damping ratio (in percent) from the drop-down list.

   b. Select the effective mass factor, Cm, to use by clicking the value in the table.
      The **Cm** value to be used is displayed in the dialog.
   c. Click **Next**.

   The **Define Modification Factor C2** dialog opens.
6. Specify the Modification Factor C2:
   a. Select the **Structure Performance Level** from the drop-down list.
   b. Select the **Framing Type** from the drop-down list.
      The **Modification Factor C2** value to be used is displayed in the dialog.
   c. Click **Finish**.

   The calculated target displacement and base shear at target displacement values are displayed on the **Capacity Curve** graph.
7. (Optional) Right-click on the **Capacity Curve** graph and select **Show Idealized Capacity Curve** from the pop-up menu.
   The idealized capacity curve is shown in blue on the graph, along with the curve parameters. These include the slopes of the linear portions of the idealized capacity curve along with the base shear and deflection at the inflection point.
8. (Optional) Repeat steps 3 through 6 and select a different **Structure Performance Level** as needed.

P. To display pushover node results

To display the nodal displacements and support reactions for a pushover analysis, use the following procedure.

1. On the **Results** ribbon tab, select the **Layouts** tool drop-down in the **Dynamics** group.
2. Select the **Node Results** tool in the **Pushover** group.
   The **Node Displacements** and **Support Reactions** tables open.
3. Either type a integer or use the arrows in the **Select Load Step** field.
   The tables display the results for this load step. The view window displays the deflected shape of the structure for this load step.

P. To review pushover beam results

Once a successful pushover analysis is performed, pushover results are available in the **Postprocessing** worfklow.

1. On the **Results** ribbon tab, select the **Layouts** tool drop-down in the **Dynamics** group.
2. Select the **Loads** tool in the **Pushover** group.
   The **Beam Hinge Results** and **Beam Force Detail** tables open.
3. Either type a integer or use the arrows in the **Select Load Step** field.
   The values in the tables are updated for this load step. The

The hinges are graphically displayed on the structure for each load step using the color coding for acceptance criteria:

- (Green) Initial Hinge format at the top of the elastic range, represents Immediate Occupancy.
- (Blue) Hinge in the Life Safety range
- (Purple) Hinge in the Collapse Prevention range.
- (Red) Hinge greater than Collapse Prevention range.

P. Node Results - Layouts

Layout	Purpose
Displacement	Displays the nodal and beam sectional displacements, along with the P. Node Displacements table (on page 2002) and P. Beam Relative Displacement Detail table (on page 2003). This has the same effect as selecting the **Displacements** page in the Postprocessing workflow.
Reaction	Displays the support reactions, along with the P. Support Reactions table (on page 2003) and P. Statics Check Results table (on page 2004). This has the same effect as selecting the **Reactions** page in the Postprocessing workflow.
Instability	Displays unstable joints if any were detected in the analysis along with the P. Unstable Joints table (on page 2004). **Note:** This tool is only active if instabilities are detected during the analysis.
Base Pressure	Displays the soil pressure at support node locations for slabs consisting of plate elements generated using either the elastic mat or plate mat commands along with the P. Base Pressure table (on page 2004). **Note:** This tool is only active if `ELASTIC MAT` or `PLATE MAT` commands are present in the input file.

P. **Node Displacements** table

Displays the displacements and rotations for each node for the selected load case. For geometric nonlinear analysis, you can select the load step for which you want to display the displacements.

Opens when the **Displacements** page is selected in the **Postprocessing** workflow.

Select Load Step	Select the Load Step value to display in the view window, **Node Displacement Curve** dialog, and the **Node Displacements** table. The Maximum Number of Load Steps for the current load case is displayed on the right-hand side of the table controls.
Limit Maximum Load Step for Graph	Select this option to limit the Load Level scale on the Node Displacement Curve to the Selected Load Step.

All tab

This tab presents all nodal displacements in tabular form for all load cases and all degrees of freedom.

Summary tab

The Summary tab shown below, presents the maximum and minimum nodal displacements (translational and rotational) for each degree of freedom. All nodes and all Load Cases specified during the Results Setup are considered. Maximum values for all degrees of freedom are presented with the corresponding Node of occurrence and Load Case number (L/C).

Related Links

- *P. To display displacements* (on page 1979)
- *P. To display the deflect shape* (on page 1980)

P. **Beam Relative Displacement Detail** table

Used to view numerical values for sectional displacements along the length of members.

Opens when the **Displacements** page is selected in the **Postprocessing** workflow.

Note: You can set custom increments for beam results for using the **Increments** input on the Results Setup dialog (on page 2999).

All Relative Displacement tab

Displays the displacements of members at intermediate section points. All specified members and all specified load cases are included. The table shows displacements along the local axes of the members, as well as their resultants.

Max Relative Displacement tab

Displays the summary of maximum sectional displacements. This table includes the maximum displacement values and location of its occurrence along the member, for all specified members and all specified load cases. The table also provides the ratio of the span length of the member to the resultant maximum section displacement of the member.

P. **Support Reactions** table

Used to display values of support reactions in tabular format. Three tabs help organize the results: All, Summary, and Envelope.

Opens when the **Reactions** page is selected in the **Postprocessing** workflow.

All tab

Displays the reactions at support nodes for all load cases.

Summary tab

Displays the maximum and minimum support reactions (translational and rotational) for each degree of freedom. All nodes and all Load Cases specified during the Results Setup are considered. Maximum values for all degrees of freedom are presented with the corresponding Node of occurrence and Load Case number (L/C).

Envelope tab

Displays maximum and minimum support reaction envelopes along with the Load Case number that caused the reaction. All degrees of freedom and all specified Load Cases are considered.

Related Links

- *P. To display the support reaction values* (on page 1980)

P. **Statics Check Results** table

Displays the global force and moment load and reaction totals.

Opens when the **Reactions** page is selected in the **Postprocessing** workflow.

Note: You can set custom increments for beam results for using the **Increments** input on the Results Setup dialog (on page 2999).

P. **Unstable Joints** table

Used to view the nodes and degrees of freedom associated with instabilities.

Opens when the **Layouts** > **Instability** tool in the **View Results** group on the **Results** ribbon tab is selected.

The locations of instabilities are highlighted on the structure in large blue circles. The Unstable Joint table provides information on the joint number and the degree of freedom associated with an instability at that joint. An unstable condition is marked with a “1”.

P. **Base Pressure** table

Displays the numeric values for base pressure at support nodes.

Opens when the **Layouts** > **Base Pressure** tool in the **View Results** group on the **Results** ribbon tab is selected.

All tab

Displays a table containing pressures, along global X, Y and Z directions for all load cases, at each support node where a spring is generated.

Summary tab

Displays a table containing a) the maximum and minimum pressure along each of the 3 global directions b) the support node where they occur c) the load case responsible for that value.

P. Beam Results - Layouts

Layout	Purpose
Beam Forces	Displays the force diagram on the structure for the selected load case along with the P. Beam End Forces table (on page 2005) and **Beam Force Detail** table. This has the same effect as selecting the **Beam Results** page in the Postprocessing workflow.
Beam Stress	Displays the member stress diagram on the structure (same as the **Beam Stress** tool), along with the **3D Beam Stress Contour** view and P. Beam Combined Axial and Bending Stress table (on page 2007).
Utilization	Displays the design code based utilization ratio, for code checks and member selection operations, in annotated form on the structure diagram (same as the **Utilization** tool) along with the P. Design Results table (on page 2008).
Graphs	Displays the current loading on the structure in the main view along with a set of three Beam Graph windows which display force or bending diagrams for the currently selected member.

P. **Beam End Forces** table

This table displays the numerical values of the forces that are applied on to a beam from the nodes that define its start and end. There are thus two rows of data per member per load case. The range of beams and load cases that are included in the table are selected from the Results Setup dialog,(see Results Setup dialog (on page 2999)).

The units for the data are defined in the **Display Options** dialog > Force Units sheet as the Force unit for the FX, FY and FZ results and Moment for the MX, MY and MZ results. Note that it is possible to select an alternative unit for forces or moments by right-clicking over a value and selecting the unit from the options in the pop-up menu 'Change Unit for this column'

This table, along with the **Beam Force Detail** table is opened when the **Beam Results** page is selected. The table has three tabs which allows the data to be displayed thus:

Opens when the **Beam Results** page is selected.

All tab

The results for all load cases and beams selected in the Results Setup dialog are displayed. Each result being the force on the node as applied to the beam.

Summary tab

This tab presents maximum and minimum End Force results for each degree of freedom. All specified members and all load cases are considered.

In order to account for the fact that the direction of the forces is inverted at the far end of the beam to induce an equivalent force on the beam, the signs of the force at the far end of the beam are first inverted and the maximum/minimum values are then determined.

For example consider a beams which have been loaded in two load cases such that the first is in compression by 10kN and in the second is in tension by 5kN. This would be reported in the All results tab thus:

Beam	L/C	Node	Fx (kN)	Fy (kN)	Fz (kN)	Mx (kNm)	My (kNm)	Mz (kNm)
1	1 Compression	1	10.000	0.000	0.000	0.000	0.000	0.000
		2	-10.000	0.000	0.000	0.000	0.000	0.000
	2 Tension	1	-5.000	0.000	0.000	0.000	0.000	0.000
		2	5.000	0.000	0.000	0.000	0.000	0.000

As the values of the far end results are inverted, the value of Max FX reports the maximum compression and Min FX reports the maximum tension thus:

	Beam	L/C	Node	Fx kN	Fy kN	Fz kN	Mx kip-in	My kip-in	Mz kip-in
Max Fx	1	1 Compression	1	10.000	0.000	0.000	0.000	0.000	0.000
Min Fx	1	2 Tension	1	-5.000	0.000	0.000	0.000	0.000	0.000

Note: The inversion of the far end results applies to all degrees of freedom to provide similar insights on the forces experienced on the beam.

Envelope tab

This tab reports the details for each beam which load case provides the most positive and most negative effect for each degree of freedom, (i.e. 8 results per beam).

This is displayed on 4 rows,

1. On the start node:
   a. The most positive effect in each degree of freedom.
   b. The load case that produce the most positive effect.
   c. The most negative effect in each degree of freedom.
   d. The load case that produce the most negative effect.
2. On the far node:
   a. The most positive effect in each degree of freedom.
   b. The load case that produce the most positive effect.
   c. The most negative effect in each degree of freedom.
   d. The load case that produce the most negative effect.

If there is no load case that produces a positive or negative effect, that is indicated with “-” as the load case.

P. **Beam Combined Axial and Bending Stress** table

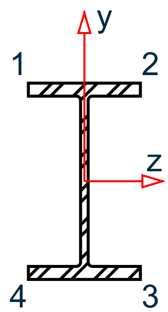
Presents the combined bending stress results at key cross-section points along the member length for each load case.

Opens when the **Layouts** > **Beam Stress** tool in the **View Results** group on the **Results** ribbon tab is selected.

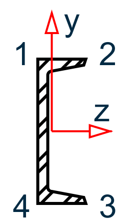
All tab

This tab presents combined axial and bending stress at four corners of the member cross section at the specified number of intermediate sections. The Maximum Compressive and Maximum Tensile stresses are also listed. The result is given for all selected Load Cases.

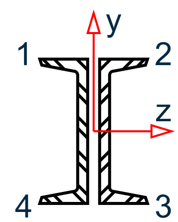
The points on the cross-section where the stresses are reported are identified by the numbers 1, 2, 3, and 4. The locations of these points are identified in the following figure by section type.



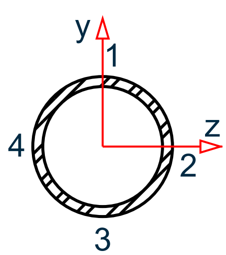
I shape



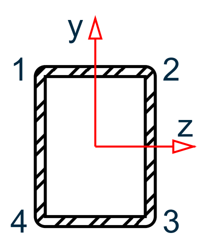
channel



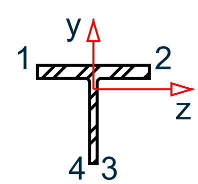
double channel



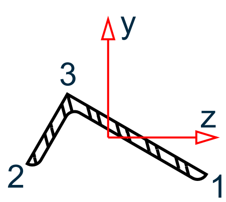
pipe



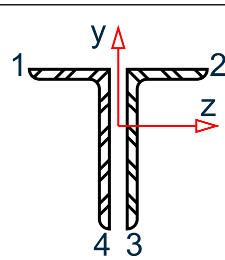
tube



T shape



single angle



double angle

Max Stresses tab

This tab presents the Maximum Compressive and Maximum Tensile Stresses for all Members for all selected Load Cases. The stresses at all intermediate sections and at both ends are considered. The point of occurrence (position along length) of the Maximum stress is listed in the Length column. The corner of the beam at which the stress occurs is listed under the Corner column.

Profile Stress Points tab

The forces and stresses (Combined Axial and Bending Stresses) can be obtained at certain selected points on a cross section and can be added to the table. Type in the **Dist** value, local Y distance on the cross section (**Stress Pt(Y)**), and the local Z distance on the cross section (**Stress Pt(Z)**).

P. **Design Results** table

This table presents the results from a steel or aluminum design in a tabular form.

Opens when the page is selected.

The results given are the **Design Property** designated by a member selection, **Utilization Ratio** for the member from a code check or member selection operation, cross sectional areas about the member's local axes, **Ay**, **Az**, **Ax**, web depth **Dw**, flange width **Bf**, and moments of inertia about the member's local axes, **Iz**, **Iy** and **Ix**.

All tab

This table displays the following:

a. The member number
b. The cross-section name used for the initial analysis and for the final design result is displayed. In the event of multiple operations, the cross-section used in the last operation is displayed.
c. Actual and allowable design ratios. When a `RATIO` parameter has been specified, this is listed as the allowable value.
d. The normalized ratio is given, which is the actual ratio divided by the allowable. This is the critical value that indicates the suitability of the member. Normally, a value higher than 1.0 indicates the extent to which the member is over-stressed and a value below 1.0 indicates the reserve capacity available.
e. The member property values of the section used in the design operation.

Failed Members tab

Shows the values for only those members which have failed from the standpoint of the code requirements. These usually have a utilization ratio higher than 1.0.

P. Plate Results - Layouts

Layout	**Purpose**
Plate Stress	Displays the graphical plate stress contour diagram superimposed on the elements along with the P. Plate Corner Stress table (on page 2009) and P. Plate Center Stress table (on page 2009). This item will also open the Diagrams dialog to the Plate Stress Contour tab.

Layout	Purpose
Results Along a Line	Opens the **Results Along Line** dialog along with the line graph and **Result along selected line** table.

P. **Plate Corner Stress** table

This table displays the stresses at corner nodes of plate elements.

Opens when the **Plate Results** page is selected.

Shear, Membrane and Bending tab

Displays all Shear, Membrane, and Bending Stresses for all specified plates and for all specified Load Cases. Stresses corresponding to all the nodal points of the plates are tabulated.

Stress Envelope

Displays the maximum positive plate stress and maximum negative plate stress values (shear, membrane, and bending) at each corner node for the envelope.

P. **Plate Center Stress** table

This table displays the stresses at the center of plate elements.

Opens when the **Plate Results** page is selected.

Shear, Membrane and Bending tab

This tab presents all Shear, Membrane and Bending Stresses for all specified Plates for all specified Load Cases.

Stress Summary tab

This table provides results of maximum Shear, Membrane and Bending stresses. The Plate element number and associated Load Case number are listed.

Stress Envelope

Displays the maximum positive plate stress and maximum negative plate stress values (shear, membrane, and bending) at each plate center for the envelope.

Principal and Von Mis tab

This table provides Principal and Von Mises Stresses for all specified Plates for all specified Load Cases similar to the Shear, Membrane and Bending tab.

Principal Summary tab

This table provides results of maximum Principal and Von Mises stresses in each row. The Plate element number and the associated Load Case number are also listed.

Principal Envelope

Displays the maximum positive and maximum negative Principal and Von Mises stresses values at each plate center for the envelope.

Global Moments tab

Depending on the various parameters specified by the user, for those plates whose plane is parallel to the selected global plane, the local axis moments MX, MY and MXY can be transformed into a moment about the selected global axis and plotted.

Combined Stress

P. Solid Results - Layouts

Layout	**Purpose**
Plate Stress	Displays the graphical Solid Stress Contour diagram superimposed on the elements along with the P. Solid Corner Stress table (on page 2010) and the P. Solid Center Stress table (on page 2011). This has the same effect as selecting the **Solid Results** page in the Postprocessing workflow. This item will also open the Diagrams dialog to the Solid Stress Contour tab.

P. **Solid Corner Stress** table

This table presents stresses at corner nodes of solid elements.

Opens when:

- the **Solid Results** page is selected in the Postprocessing workflow
- the **Solid Stress** tool is selected from the **View Results** group on the **Results** ribbon tab

- the **Layouts** > **Solid Stress** tool is selected from the **View Results** group on the **Results** ribbon tab

'

Note: The stress values displayed in the Postprocessing workflow tables are “smoothed” by averaging stresses from adjacent elements. Therefore, they may not be equal to those corner stresses reported in the STAAD.Pro `.anl` for the same model.

Shear, Member and Bending tab

This tab presents all Shear, Membrane and Bending Stresses for all specified solids for all specified Load Cases.

(Shear, Membrane and Bending) Summary tab

This table provides results of maximum Shear, Membrane and Bending stresses. The solid element number, node number and associated Load Case number are listed.

Principal and Von Mis tab

This table provides Principal and Von Mises Stresses for all solids for all Load Cases similar to the Shear, Membrane and Bending tab.

(Principal and Von Mis) Summary tab

This table provides results of maximum Principal and Von Mises stresses in each row. The solid element number and the associated Load Case number are also listed.

Related Links

- *P. To display solid results contours* (on page 1990)

P. **Solid Center Stress** table

This table presents stresses at center of solid elements.

Opens when:

- the **Solid Results** page is selected in the Postprocessing workflow
- the **Solid Stress** tool is selected from the **View Results** group on the **Results** ribbon tab

- the **Layouts** > **Solid Stress** tool is selected from the **View Results** group on the **Results** ribbon tab

'

Note: The stress values displayed in the Postprocessing workflow tables are “smoothed” by averaging stresses from adjacent elements. Therefore, they may not be equal to those corner stresses reported in the STAAD.Pro `.anl` for the same model.

Shear, Member and Bending tab

This tab presents all Shear, Membrane and Bending Stresses for all specified solids for all specified Load Cases.

(Shear, Membrane and Bending) Summary tab

This table provides results of maximum Shear, Membrane and Bending stresses. The solid element number, node number and associated Load Case number are listed.

Principal and Von Mis tab

This table provides Principal and Von Mises Stresses for all solids for all Load Cases similar to the Shear, Membrane and Bending tab.

(Principal and Von Mis) Summary tab

This table provides results of maximum Principal and Von Mises stresses in each row. The solid element number and the associated Load Case number are also listed.

P. Geometric Nonlinearity - Layouts

Layout	Purpose
Loads	Displays the deflected shape for the selected load case and load step, along with the **Node Displacements Curve** graph and **Node Displacement** table.
Graph	Opens the Load Level vs Section Forces diagram and **Beam Force Detail** table.

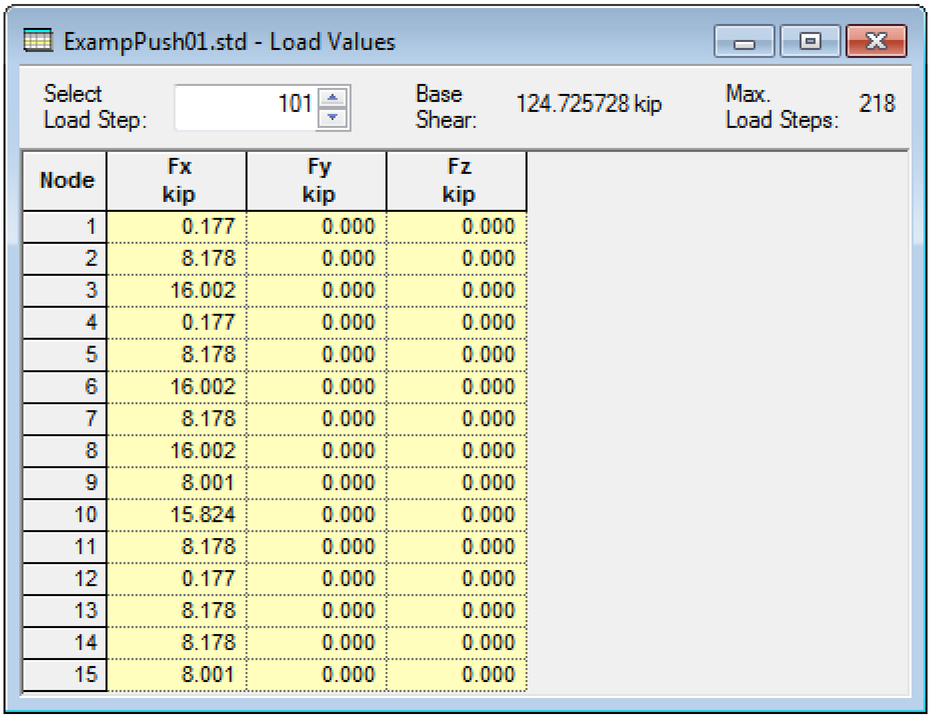
P. Pushover - Layouts

The pushover analysis results layouts in the post-processing mode are described here. These pages are available only upon a successful pushover analysis.

Layout	Purpose
Loads	Opens the (Pushover) Load Values table (on page 2012), which displays the nodal load values and total base shear for the selected load step, along with the **Capacity Curve** table. The magnitude and direction of the loads in the current load step are displayed in the view window.
Graph	Opens the Capacity Curve graph (on page 2013), which displays displacement vs. force for the pushover analysis. The **Capacity Curve** table contains the roof or control joint displacement and base shear values recorded for each load step.
Node Results	Displays nodal displacements and rotations in the (Pushover) Node Displacements table (on page 2014) and the support reactions in the (Pushover) Support Reactions table (on page 2015) for the selected load step. The deflected shape is overlaid on the structure in the view window.
Beam Results	Opens the (Pushover) Beam Hinge Results table (on page 2016) which displays the status of the beam and hinge conditions along each beam's length. The (Pushover) Beam Force Details table (on page 2017) displays the cross-sectional forces and moments at sections along each beam's length are displayed for the selected load step. The status of beams and hinges are displayed in the view window.

(Pushover) **Load Values** table

Displays the nodal load values and total base shear for the selected load step.



Node	Fx kip	Fy kip	Fz kip
1	0.177	0.000	0.000
2	8.178	0.000	0.000
3	16.002	0.000	0.000

13	8.178	0.000	0.000
14	8.178	0.000	0.000
15	8.001	0.000	0.000

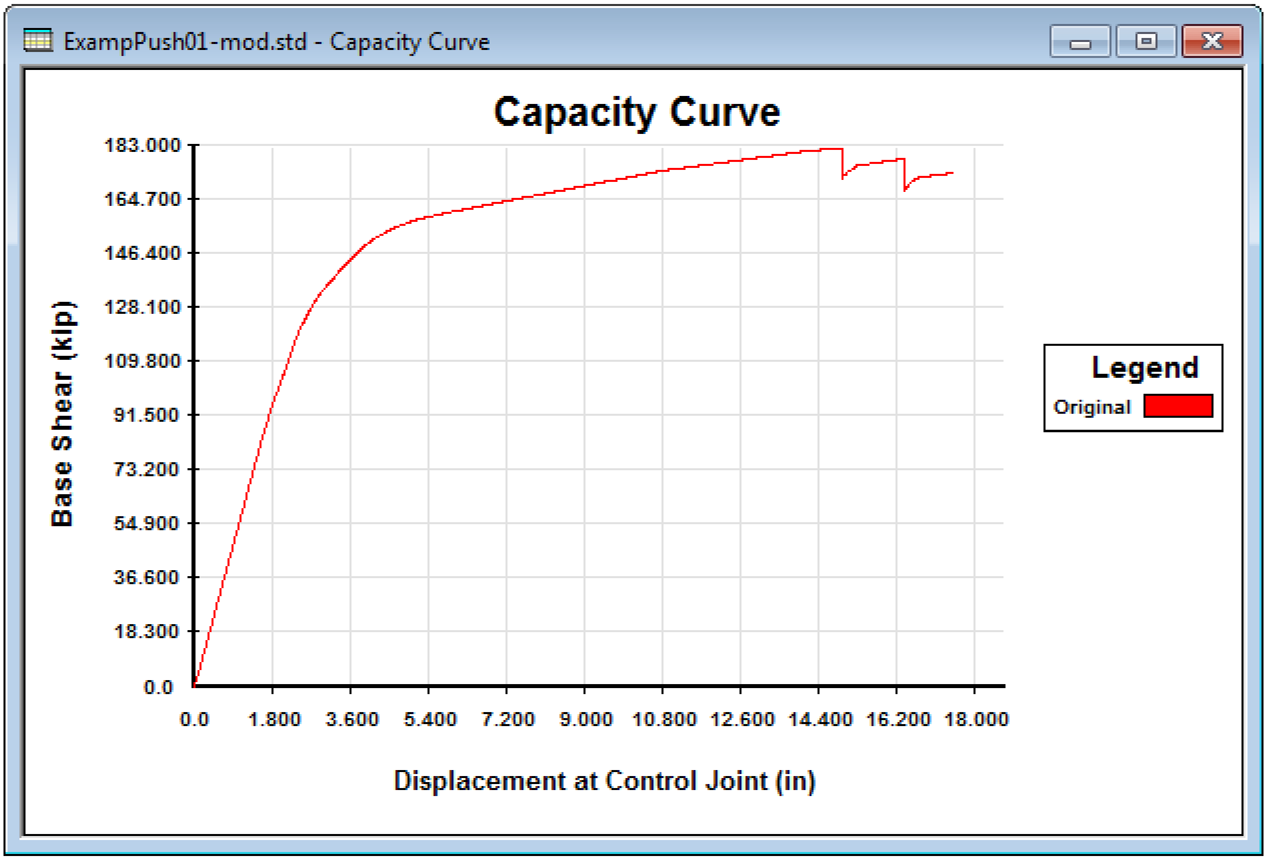
Figure 195: Load Values table

Select Load Step	Use the arrow controls or type the number of the load step. The tabulated load values, base shear, and view window load display update automatically.

Capacity Curve graph

Displays the displacement versus base shear graph for the pushover analysis. The displacement at control joint is given if a control joint was specified as a solution control method. Otherwise, the displacement is taken largest Y nodes (i.e., the "roof" level).

Opens when the **Pushover | Capacity Curve** page is selected.



The individual values of the curve are displayed in the **Capacity Curve** table.

Figure 198: Beam Hinge Results table

Select Load Step Use the arrow controls or type the number of the load step. The tabulated section forces & moments, base shear, and view window hinge display update automatically.

table The table displays the overall beam status as well as the location and status of any hinges which have formed. Up to three hinges may be listed. The hinge location (Section) and Status are displayed in physical order, from start to end node, of their location along the beam.

The table contains the following columns:

- Status - The material status of the beam for current load step. Linear indicates no hinges have formed in the beam. Nonlinear indicates that one or more hinges have formed. Inactive means that three hinges have formed or that one or hinges are beyond the collapse prevention (CP) limit.
- Dir (Local) - the direction of bending for resulting in the formation of hinges.
- Hinge Section & Status - The location along the length of the hinge and the acceptance criteria status. The location and status of hinges are displayed graphically on the structure in the view window.

(Pushover) **Beam Force Details** table

Displays the cross section forces and moments at 1/12th points along the beam's length for the current load step.

P. Generating Reports

P. To setup report contents

To select the items to include in a STAAD.Pro report, use the following procedure.

1. Select the **File** ribbon tab.
   The STAAD.Pro Backstage view opens.
2. Select the **Report** tab and then click **Setup**.
   The **Report Setup** dialog opens.
3. Select the **Items** tab and then specify the sections to include in the report.

   The list on the right contains the included report items in the order they will appear in the report.

   a. Select a report category in the drop-down list.
      The list of available items updates.

b. Either:

Select one or more items in the available list and then click **>** to add to the report.

Tip: Hold **<Ctrl>** to click on multiple items. Hold **<Shift>** to select a series of adjacent items.

or

Click **>>** to include all items within the report category in the report.

c. Repeat steps 3a and 3b to include items from additional report categories.

4. (Optional) Use the up and down buttons to reorder items in the report list.
5. (Optional) Click **Print** to output the report immediately.
   The Print dialog opens to select the system printer.
6. Click **OK**.

You can limit the report contents by load cases, modes (for dynamic results), and ranges of objects.

- *Report Setup dialog* (on page 2697)

P. To add a custom header and logo to reports

To add custom header text and a logo for your organization to your reports, use the following procedure.

1. Select the **File** ribbon tab.
   The STAAD.Pro Backstage view opens.
2. Select the **Report** tab and then click **Setup**.
   The **Report Setup** dialog opens.
3. Select the **Name and Logo** tab.
4. In the text field, type the custom header text.
5. (Optional) Customize the text placement and appearance:
   a. Click **Font** to select a font face, style, and size.
   b. Select the font **Alignment**.
      This is active when the logo is aligned to right or left.
6. Click **File** to locate and select a bitmap image (file extension `.bmp`) to use for your header logo.

P. Steel AutoDrafter Workflow

The Steel AutoDrafter workflow extracts planar drawings and material take-off from a structural steel model prepared in STAAD.Pro.

Steel AutoDrafter produces plans at any level and sections in any of the orthogonal directions.

Note: The model needs to be analyzed and saved before using Steel AutoDrafter workflow.

Note: Steel AutoDrafter requires models with Y-up orientation only. Z-up models are not supported.

Overview

RR 21.03.00-3.1 Static Seismic Loads per IBC 2015 / ASCE 7-10

- *RR 21.03.00-3.1 Static Seismic Loads per IBC 2015 / ASCE 7-10* (on page 136)

P. To open the Steel AutoDrafter workflow

You must perform an analysis before using the Steel AutoDrafter workflow.

1. Perform a successful analysis.
2. Select **Steel AutoDrafter** in the **Workflows** panel.

The **Steel AutoDrafter** ribbon tab and the Steel AutoDrafter workflow **Layout** page open.

Related Links

- *Steel AutoDrafter tab* (on page 3003)

P. To configure units in Steel AutoDrafter

To change the system of units for the interface as well as in drawings and material take-off, use the following procedure.

1. On the **Steel AutoDrafter** ribbon tab, select the **Drawing Style Manager** tool in the **Edit** group.

   

   The **Drawing Style Manager** dialog opens.
2. Select the **Appearance** tab.
3. Select the **Drawing Unit** to use.

   Metric

   or

   English
4. Click  **OK**.

Grids, material take-offs, etc. are all now provided in the selected system of units.

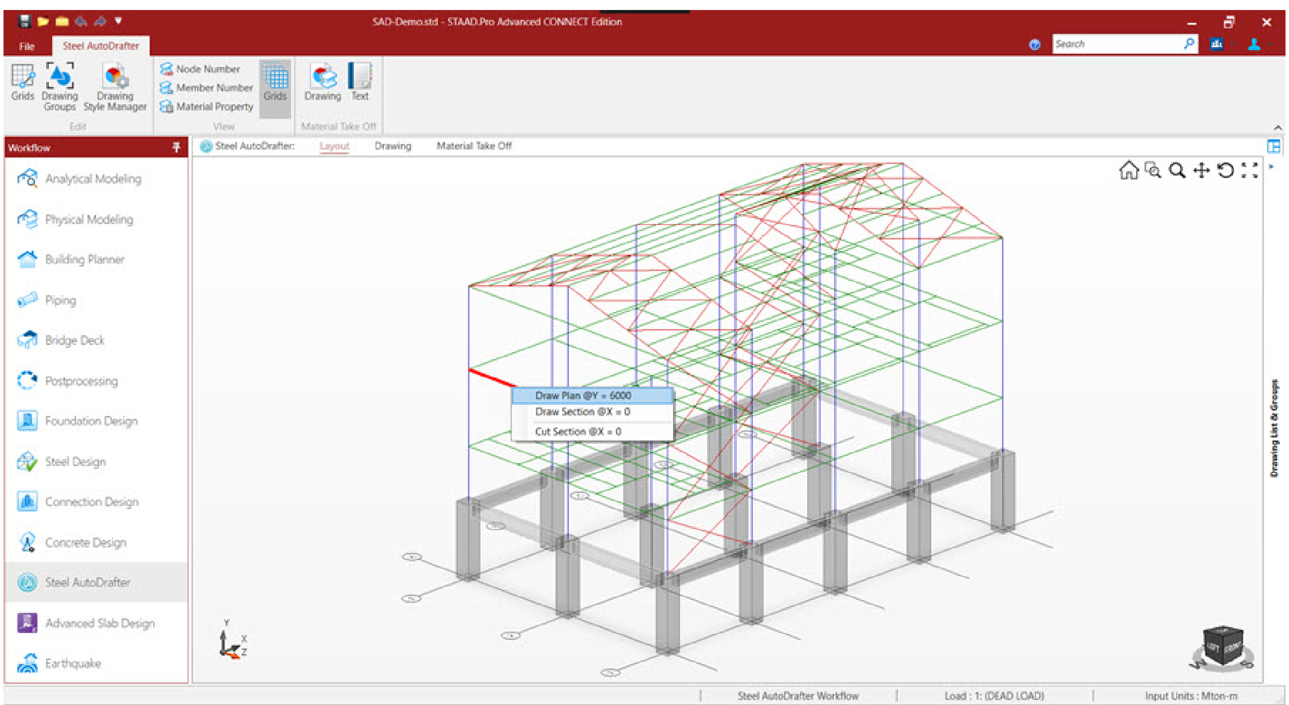
- *Drawing Style Manager dialog* (on page 3006)
- *Member Labels* (on page 3007)

P. Drawing



Drawing Logic

For built-up section made of two members, batten plates are drawn as indicative.

For connection between concrete and steel, indicative base plates are shown.

For elevation Bracing's the angle is adjusted as per the change of center line of the beams as per top of steel (TOS).

For bottom chord of the trusses the node between bottom chord and the top chord is adjusted as per the size of the bottom chord member. Accordingly the inclination of the top chord is adjusted without changing the top of truss. Similarly the lengths of the members connecting bottom chord and top chord are adjusted.

Similar to a truss, for inclined portals an indicative joint with connection plates is shown between the column and the portal member.

For moment connections there is no gap provided between the connecting members. For other connections an indicative gap is shown between the connecting members.

Shapes

These shapes are supported:

- Standard rolled steel sections, including T (Tee section) and DT (double tee) sections, are supported
- Section cover plates, TC (top cover plate), BC (bottom cover plate), and TB (top & bottom cover plates), are supported

The following prismatic shapes are also supported:

- Solid Circle (defined with YD),
- Solid Rectangle (defined with YD and ZD),
- Tee (defined with TD, ZD, YB and ZB),
- Trapezoidal (defined with YD, ZD and ZB),
- General (displayed as a rectangular solid using the values of YD and ZD),
- Tapered I (displayed using the average dimensions of web and flange),
- Tapered Tube (displayed using the average dimensions).

Note: The circle, rectangle, trapezoidal, tee, and general sections will be shown as concrete sections. The tapered I and tapered tube will be shown as steel sections.

User-provided table (UPT) shapes:

- All user table sections, such as wide-flange, channel, angle, double angle, etc.
- Shapes imported from Free Sketch as general shapes

These shapes are *not* supported:

- Other shapes with varying cross-sections (not listed under Prismatic sections above)
- Cold-formed steel sections, timber sections, and aluminum sections
- Composite sections (CM),
- American castellated sections, solid rods, and cables, steel joists,
- Dutch plates, strips, solid round sections, and solid square sections

Notes

Drawing generated are as per the members on a given plane, Any members that cut across different planes are not shown.

Curved members are currently not supported.

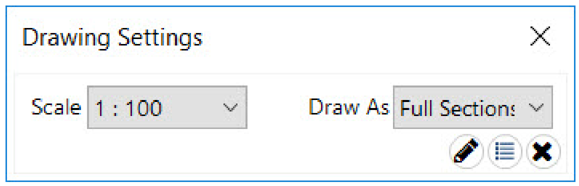
In case if the section defined in STAAD.Pro is not identified by Steel AutoDrafter, Then the member will not be displayed in drawing.

P. To add a plan drawing

To create a plan drawing of members at the same elevation, use the following procedure.

1. Select a horizontal member in the **Layout** page.

   The Y coordinate of the member is used to define the level of the plan. All members at this elevation are included.
2. Right-click and then select **Draw Plan @Y = *elevation*** from the pop-up menu.
   The **Drawing Settings** dialog opens.



3. Select the **Scale** for your drawing from the drop-down list.

   The Scale of drawing can be set as 1:25, 1:50, 1:80, or 1:100.
4. Select either **Full Sections** or **Part Sections** from the **Draw As** drop-down list.

   This will control the extents of how members are drawn.

   - **Full Section -** All edges of the section are drawn for the full length of the member
   - **Part Section -** All edges of the section are drawn for the part length of the member
5. Either:

   click **Draw** to generate the drawing

   or

   click **Add to Drawing List** to add this drawing to the Drawing List tab

The top of steel (TOS) for beams is adjusted as Y coordinate of the floor. Accordingly the center line of the beam is shifted down by half the beam depth.

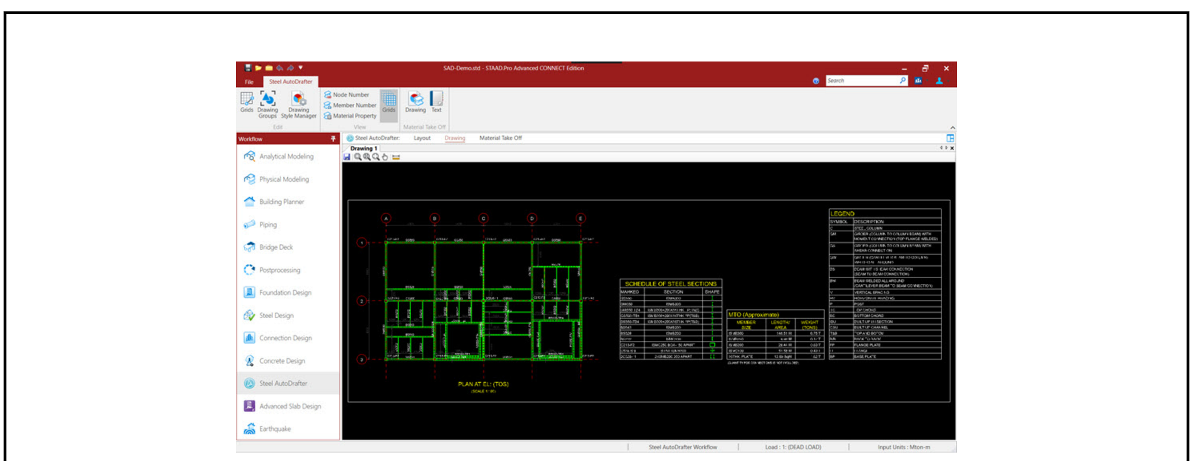


Figure 200: Full section example

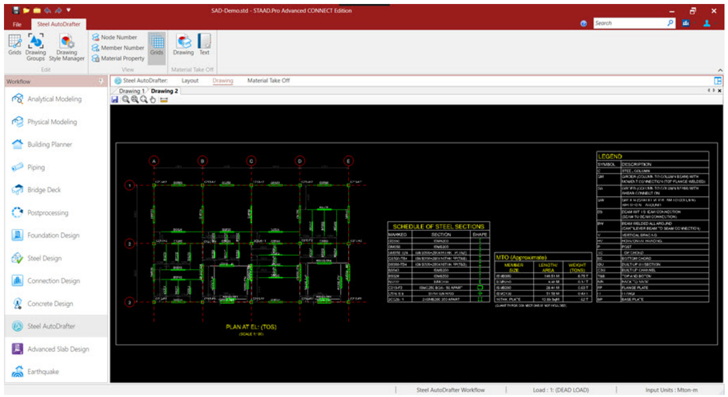

Figure 201: Part section example

Tip: Alternatively, you can use the options in the **Drawing List** tab to select **Plan** from the **Type** drop-down list to create a plan drawing at a selected **Location.**

If you selected to add this drawing to the drawing list, then click the  **Draw** tool below the list on the **Drawing List** tab to generate all of your drawings.

P. To add a section drawing

To add a new section drawing at a vertical or diagonal member, use the following procedure.

In Steel AutoDrafter, a standard "section" drawing is used draw either a elevation or a full section across the entire structure.

1. Select either a vertical or diagonal member in the **Layout** page.

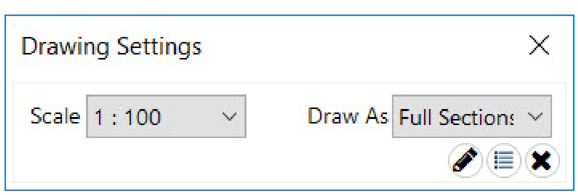
   The Z or X coordinate of this member is used to define the plane of the section. All members in this plane are included.
2. Right-click and then select one of the following options from the pop-up menu:

   Draw Section @X = ***Location***

   or

   Draw Section @Z = ***Location***

   The **Drawing Settings** dialog opens.



3. Select the **Scale** for your drawing from the drop-down list.

   The Scale of drawing can be set as 1:25, 1:50, 1:80, or 1:100.
4. Select either **Full Sections** or **Part Sections** from the **Draw As** drop-down list.

   This will control the extents of how members are drawn.

   - **Full Section -** All edges of the section are drawn for the full length of the member
   - **Part Section -** All edges of the section are drawn for the part length of the member
5. Either:

   click **Draw** to generate the drawing

   or

   click **Add to Drawing List** to add this drawing to the Drawing List tab

> **Tip:** Alternatively, you can use the options in the **Drawing List** tab to select **Section @X** or **Section @Z** from the **Type** drop-down list to create a plan drawing at a selected **Location.**

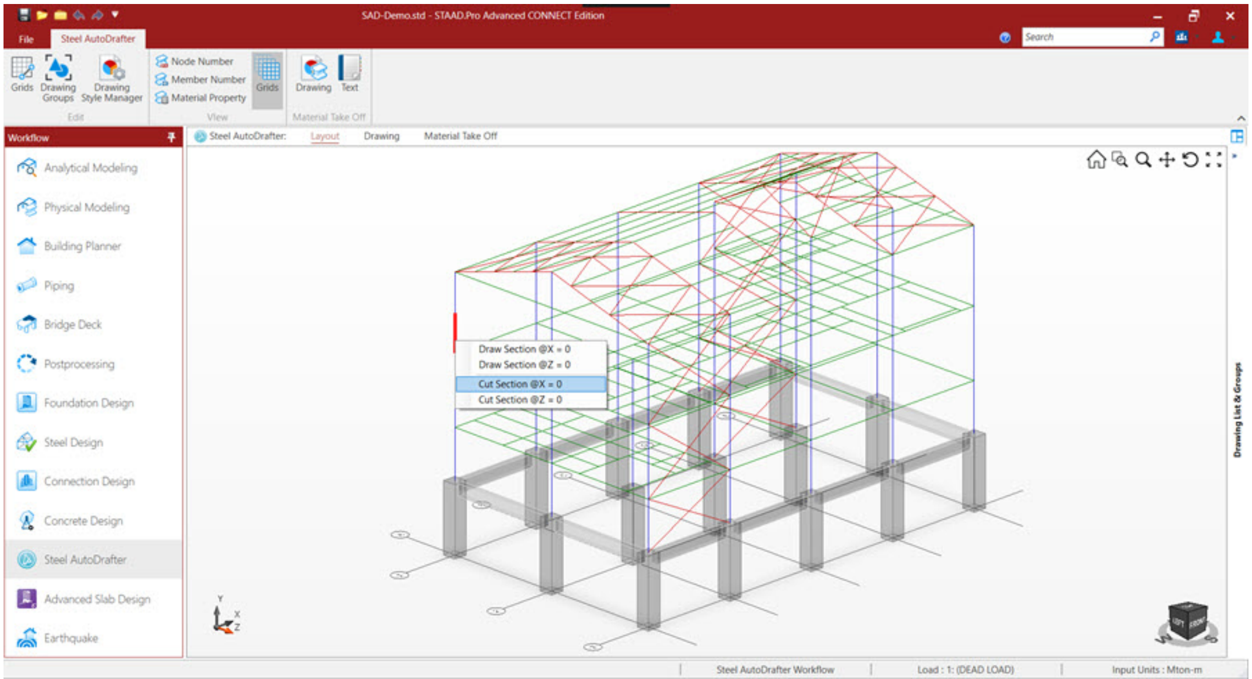
If you selected to add this drawing to the drawing list, then click the **Draw** tool below the list on the **Drawing List** tab to generate all of your drawings.

P. To create a drawing group

To create groups (physical members) for inclined members such as bracing, truss chords, portals, etc., use the following procedure.

Steel AutoDrafter will identify physical members automatically for vertical and horizontal members.

1. Right-click on a member and select **Cut Section @*`<grid or plane>`***.



The **Section View** dialog opens.

2. Select the group type tool corresponding to the group of members you want to create:

Tool	Description
	Top chord - can include purlins
	Bottom chord
	Portal - can include purlins at a specified spacing
	Bracing
	Inclined Column

The mouse pointer changes to a selection box.

3. Select the members to be grouped graphically:

click on them individually

or

click-and-drag a window box around the members

Tip: Use the view control tools to assist in selecting members.

Members in the selection set are highlighted in red.

4. Right-click anywhere in the **Section View** dialog view area and then select **Create Group** from the pop-up menu.

   For Portal and Top Chord groups, the **Create Group for <group type>** dialog opens. For other groups, the group is created.
5. (Optional) For Portal and Top Chord groups, select the **Purlin Section** shape and section size to use and then click **OK**.

   Note: Purlins are not part of the analysis but this allows you to add these to the drawings for accuracy.
6. Repeat Steps 2 through 5 to create additional groups.
7. Click the **Draw** tool.

   The **Drawing Settings** dialog opens.
8. Select the **Scale** for your drawing from the drop-down list.

   The Scale of drawing can be set as 1:25, 1:50, 1:80, or 1:100.
9. Select either **Full Sections** or **Part Sections** from the **Draw As** drop-down list.

   This will control the extents of how members are drawn.

   - **Full Section -** All edges of the section are drawn for the full length of the member
   - **Part Section -** All edges of the section are drawn for the part length of the member
10. Either:

    click **Draw** to generate the drawing

    or

    click **Add to Drawing List** to add this drawing to the Drawing List tab

Tip: To delete a group, right-click on the group name in either the **Section View** dialog or in the **Drawing Groups** tab of the **Drawing List & Groups** panel and then select **Delete** from the pop-up menu.

Related Links

- *Section View dialog* (on page 2026)

Section View dialog

Used to create groups (physical members) for inclined members in a section.

Opens when **Cut Section** ***@grid or plane*** is selected from the right-click pop-up menu of a selected member in the view area.

A list of group at the current section selection is displayed on the left side tree.

Tip: A list of all groups in the model can be viewed on the **Drawing Groups** tab of the **Drawing Lists & Groups** panel.

The view area of the dialog displays the members in the current section. You can manipulate this section view using the view controls to the right.

View Area Right-click Pop-up Menu

Create Group (available when you have selected members to place in a group type) For bottom chord, bracing, and inclined column group types, the group is created.

For top chord or portal group types, the **Create Group for <group type>** dialog opens to specify purlin parameters.

Show Node Number Toggles the display of node numbers in the dialog view area.

Show Member Number Toggles the display of member numbers in the dialog view area.

Show Member Property Toggles the display of member section sizes in the dialog view area.

Top chord - can include purlins

Bottom chord

Portal - can include purlins at a specified spacing

Bracing

Inclined Column

Opens the **Drawing Settings** dialog, which is used to select the drawing scale, member extents drawn, and if the drawing is to generated immediately or saved to the drawing list.

Related Links

- *P. To create a drawing group* (on page 2024)

P.To open a drawing in MicroStation

To open the current drawing in MicroStation, use the following procedure.

You must have either MicroStation or Bentley PowerDraft installed to use this feature.

Note: If you have MicroStation PowerDraft installed instead of MicroStation, you will have that product's icon instead of the MicroStation icon in the drawing toolbar.

1. Open a drawing in the Steel AutoDrafter workflow.
2. On the drawing toolbar, select the **Open in MicroStation** tool.

You are prompted to save the drawing file (`.dxf` file extension).

The drawing opens in MicroStation.

Tip: The resulting `.dxf` can be opened within any compatible program.

P. To edit grid labels

To toggle the display of grids and elevation marks or to change the label for each, use the following procedure.

Steel AutoDrafter identifies the grids from column (vertical elements) centers from the analysis file.

Note: The model in STAAD.Pro is required to be created using Y up axes system.

Tip: Grid can be imported from another `adfx` file using the import grid option provided. The `adfx` file will be available along with the relevant STAAD.Pro file in the same folder. Click  **Import** to select a `adfx` file.

1. On the **Steel AutoDrafter** ribbon tab, select the **Grids** tool in the **Edit** group.

   
   The **Grid Manager** dialog opens.
2. To toggle the display of a grid line or elevation mark, use the check box associated with that grid or elevation mark.
3. To edit the label of a grid or elevation mark, type the label in **Mark** cell associated with that grid or elevation mark.
4. Click  **OK**.

Related Links

- *Grid Manager dialog* (on page 3005)

P. Built-Up Sections in Steel AutoDrafter

Steel AutoDrafter recognises and draws built-up sections. These sections have to be defined in STAAD.Pro, using a particular format within the user table section.

Section	User Table Prop Name
Angle Star	AS-ISA75X75X8-10
I/H Star	IS-ISMB500
Built Up I	IBU-DPT-WD-WT-FT
Built Up Channel	CBU-DPT-WD-WT-FT
Two I/H Sxn	2I-ISMB250-100

where

DPT	=	total depth of the section
WD	=	total width of section

WT	=	web thickness
FT	=	flange thickness

“10” in the Angle Star represents the clear gap between the two angles.
“100” in the 2I represents the clear gap between the two sections.

Example of creating user table in STAAD as per above format:

```
START USER TABLE
TABLE 1
UNIT CM MTON
GENERAL
IEU-750-250-12-20
185.2 75 1.2 25 2 169049 5218.56 85.28 4507.98 417.48 0 0 0 0 0 0
IS-ISMB200
61.6 20 0.57 10 1 2257 14 225.7 451.4 0 0 0 0 0 0
AS-ISA75X75X6-8
17.32 15 0.58 15 0.58 192.58 148.6 1.97 33.62 28.02 12.99 12.99 51.47 -
44.04 19690.9 13.84
2I-ISMB200-200
64.66 20 1.62 30 1.07 6766 4470.8 21.85 451.067 447 48.49 48.49 656.48 -
517.95 218592 16.76
END
```

P. Drawing List & Groups panel

Drawings that are to be created can be added to the Drawing List using any of the following options. Groups of members in drawings can be managed here.

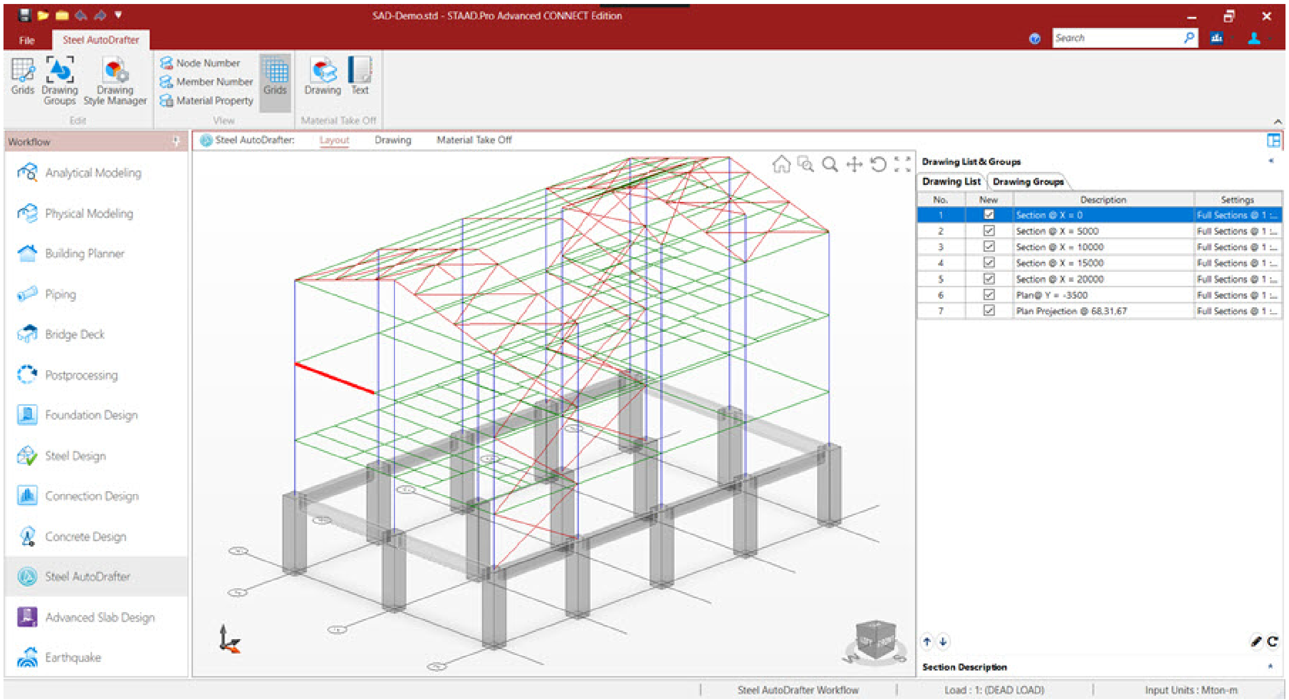
Drawing List tab

Section Description	This is used to add drawings to the list.

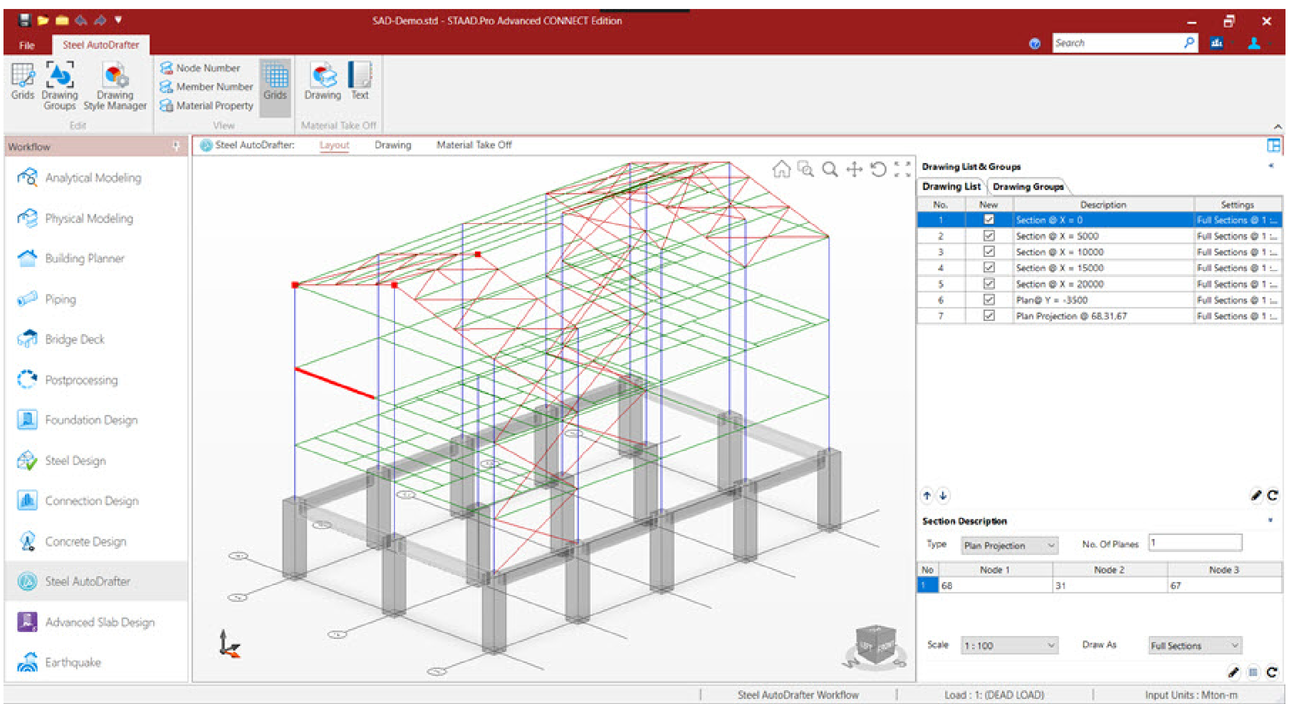
- By selecting a member in the view area and then selecting the required drawing from the options in the Drawings List tab.
- By using the options in the Section Description.
- A projected view can be created by selecting three nodes.

Drawings added to the list can all be generated at once using the draw options

New Option in the list can be used to generate drawings together in a single sheet. (Default each drawing is generated in a new sheet)



Selection of points for projected view



P. To generate a material take-off

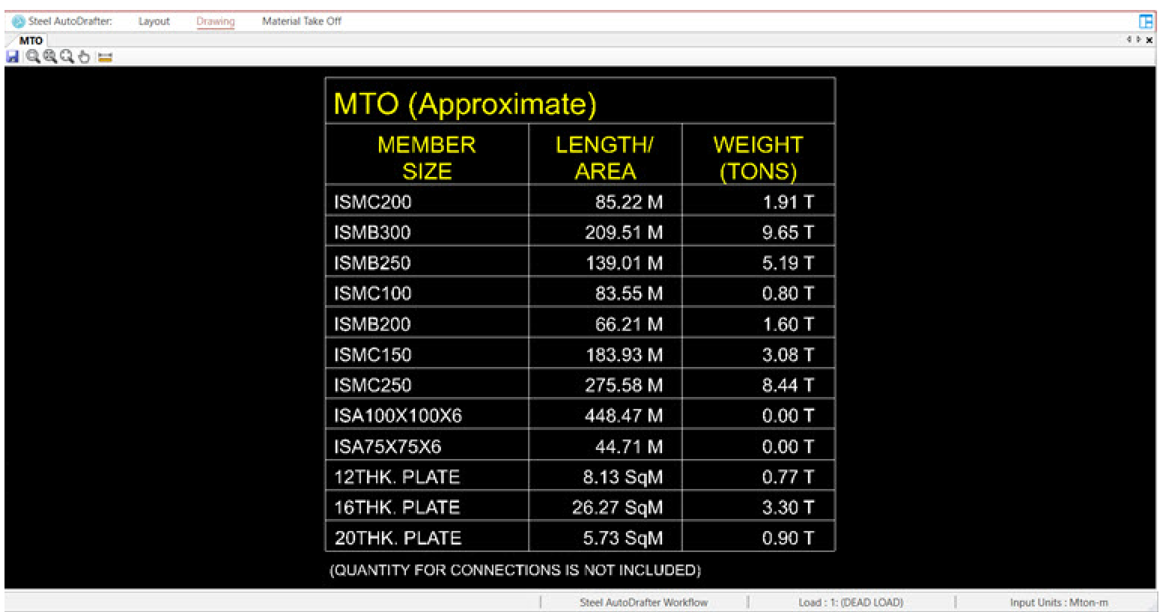
1. Steel AutoDrafter generates material take-offs for the entire structure in two formats:

Format	Select...
drawing	the **Drawing** tool in the **Material Take Off** group on the **Steel AutoDrafter** ribbon tab 
text	the **Text** tool in the **Material Take Off** group on the **Steel AutoDrafter** ribbon tab 

The material take-off opens in the selected format. The drawing format will open in the **Drawing** page. The text format will open in the **Material Take Off** page.

2. (Optional) Click the **Save** tool in the page toolbar to save the material take-off to an external file.

   The drawing is saved as a `.dxf` file and the text is saved as an `.html` file.



MTO (Approximate)

P. Earthquake workflow

This STAAD.Pro workflow is used to check if the structure conforms to the basic geometric recommendations made in Eurocode 8 (EC8). This workflow is in addition to the normal post-processing workflow which gives the various analysis results. These checks are intended to give you a "feel" for the structure and are not mandatory to proceed to the design phase.

Eurocode 8: Part 1 [EN 1998-1-1:2004] contains specific requirements and recommendations for building structures that are to be constructed in seismic regions. Essentially, these fundamental requirements have been provided to ensure that the structures can sustain the seismic loads without collapse and also –where required– avoid suffering unacceptable damage and can continue to function after an exposure to a seismic event.

Tip: The program feature assumes Y as vertical and that seismic forces act in the global X and Z directions.

P. Using the Earthquake Workflow

To perform the geometry checks per Eurocode 8, STAAD.Pro must first calculate the center of mass for each defined floor. Specifying a response spectrum loading accomplishes this.

All the analysis methods for design and evaluation of the performance of a structure mentioned in Eurocode, as listed in the following, are all available in STAAD.Pro:

- Linear modal response spectrum analysis (i.e., a linear elastic analysis used in conjunction with an EC8 response spectrum load)
- Nonlinear static analysis (i.e., a pushover analysis)
- Nonlinear dynamic analysis (i.e., a time-history analysis)

Note: In order to make use of the EC8 response spectrum load, a linear modal response spectrum analysis should be used. This is required to locate the center of mass which is needed to perform the associated geometry checks.

Loads are distributed by element stiffness to all members during analysis. Thus, for the purposes of Eurocode 8, all members are assumed to be "primary seismic" elements.

Note: The EC8 response spectrum load must be specified in the model in order to perform any further checks, design, or detailing per Eurocode 8.

Related Links

- *M. To add an EC8 response spectrum* (on page 867)

P. To open the Earthquake workflow

You must perform an analysis on a model with a load cases including an EC8 response spectrum load.

1. Perform a successful analysis.
2. Select **Earthquake** in the **Workflows** panel.

The **EC8 Stiffness** page opens along with the **Floors** dialog, **Storey Stiffness** table, and **Soft Storeys** table.

Tip: You can nominally use the pages in the Earthquake workflow in any order. However, it is recommended that you work through the checks in a left-to-right order (i.e., EC8 Stiffness, EC8 Plans, and then EC8 Elevations).

P. To check stiffness of a structure per EC8

To review the stiffness of a structure per Eurocode 8 requirements, use the following procedure.

This set of checks is to enables you to judge whether the stiffness characteristics of the structure meet the recommendations set by EC 8. This implementation will:

i. Display the center of mass and center of stiffness graphically for each floor to inform you of some inherent eccentricities and their variation along the height of the building.
ii. Calculate the total stiffness of every story in each direction and provide you with a ratio of the stiffnesses in the two directions. This aides you to judge whether the structure conforms to the condition in EC8 that the stiffness should be similar in both directions.
iii. Check to see if there are any soft stories in the structure and will highlight them in the GUI. A soft story is defined as a story that has a stiffness in a particular direction that is less than 70% of the stiffness of the story above.

1. Select the **EC8 Stiffness** page in the **Earthquake** page control bar.
   The center of mass and center of stiffness are drawn at each floor level.
2. For a particular floor, you can expand the entry in the **Floors** dialog to review the location of these items.

   The selected floor and centers of mass or stiffness are highlighted in the view area.
3. The stiffness ratios are reported in the Storey Stiffness table for each floor as well as for the total structure.
4. Any soft stories detected by the program are listed in the Soft Storey table.

> **Note:** The stiffness of only the vertical elements are considered while working out the total stiffness of a story in a particular direction as the seismic loads are primarily resisted by the vertical elements in a structure.

P. To check for plan irregularities

To check for plan irregularities per Eurocode 8 such as re-entrant corners, slenderness, and torsional radius, use the following procedure.

This set of checks is to enable you to be able to classify the building as being 'regular in plan.' Checks will be performed and the results will be displayed graphically in the GUI. The program primarily checks for the main three plan regularity conditions set out in EC-8 viz.

- **i.** Checks for re-entrant corners in floor slabs – The program performs checks on each floor slab and reports whether the condition set out in EC-8 for re-entrant corners has been satisfied.
- **ii.** Check for slenderness of structure – The program calculates a “slenderness ratio” for the structure based on the maximum dimensions on plan and reports whether the EC-8 criteria are satisfied.
- **iii.** Checks for torsional radius: **-** The program calculates the torsional radius for each floor and checks against the conditions set out in EC-8.

1. Select the **EC8 Plans** page in the **Earthquake** page control bar.
   The **Check Regularity in Plan** dialog opens along with the **Slab Re-Entrant Corners** and **Torsional Radius Check** tables.

   > **Tip:** You may have to re-arrange the dialog and tables to display all windows.
2. To check for re-entrant corners:
   a. In the **Check Regularity in Plan** dialog, expand **Clause 4.2.3.2(3) - [Re-Entrant Corners]**.
      A child entry is present for each floor in the structure.
   b. Select each floor to review any detected re-entrant corners.
      The details of any detected re-entrant corners are displayed in the **Slab Re-Entrant Corners** table.
3. To check for structure slenderness, expand **Clause 4.2.3.2(5) - [Slenderness]** in the **Check Regularity in Plan** dialog.
   The slenderness ratio and status for the structure is reported.
4. To check torsional radius, select the **Torsional Radius Check** table.
   The ratio of each torsional radius check for each floor along with the status of the check is reported here.

P. To check for elevation irregularities

To check for elevation irregularities as defined by EC8, use the following procedure.

This set of checks enables you to classify the building as a 'regular in elevation' structure. Checks will be performed and the results will be displayed graphically.

1. Select the **EC8 Elevations** page in the **Earthquake** page control bar.
   The **Earthquake Elevation Criteria** dialog opens along with the **Elevation Regularity** table.
2. In the **Earthquake Elevation Criteria** dialog, select to check elevation along **X- Axis** or **Z- Axis.**
3. Select the appropriate elevation criteria which applies to your structure.

   > **Note:** Refer to clause 4.2.3.3 and Figure 4.1 in Eurocode 8 (EN 1998-1:2004) for additional information.
4. Click **Perform Checks**.
   The calculated values and results of this check are displayed in the **Elevation Regularity** table.

5. Repeat steps 2 through 4 to check the other direction or for other criteria if needed.

P. Pages in the Earthquake Workflow

The Pages in the Earthquake workflow page control bar are described below in brief. Detailed description of these pages is available in the pages to follow.

Earthquake Page	Description
EC8 Stiffness	Used evaluate whether the stiffness characteristics of the structure meet the recommendations set by EC 8.
EC8 Plan	Used to classify the building as being “regular in plan.” Checks will be performed and the results will be displayed graphically in the GUI. The program primarily checks for the main three plan regularity conditions set out in EC-8.
EC8 Elevations	Used to classify the building as a “regular in elevation” structure. Checks will be performed and the results will be displayed graphically.

P. EC8 Stiffness page

Used evaluate whether the stiffness characteristics of the structure meet the recommendations set by EC 8.

Note: The stiffness of only the vertical elements are considered while working out the total stiffness of a story in a particular direction as the seismic loads are primarily resisted by the vertical elements in a structure.

When the Eurocode 8 **|** Stiffness Checks page is selected, the **Floors** dialog, **Story Stiffness** table, and **Soft Story** table open. The active view window displays the Whole Structure with the Center of Mass and Center of Gravity plotted for each floor. This is used to inform you of some inherent eccentricities and their variation along the height of the building.

P. **Floors** dialog

Displays the Center of Mass (CM), Center of Stiffness (CS), and Eccentricity (difference between CM and CS) for each defined floor in the structure. This information is graphically plotted onto the structure diagram in the Whole Structure view window.

Opens when the **Eurocode 8 | Stiffness Checks** page is selected.

Tip: You can select on of the entries in the **Floors** dialog to have the corresponding item highlighted in the **Whole Structure** view window.

P. Story Stiffness table

The program calculates the total stiffness of every story in each direction and provides you with a ratio of the stiffnesses in the two directions. This aides you to judge whether the structure conforms to the condition in EC8 that the stiffness should be similar in both directions.

Opens when the **Eurocode 8 | Stiffness Checks** page is selected.

P. Soft Story table

The program will check if there are any soft stories in the structure and will display any detected soft story and the direction in this table. These stories will also be highlighted in the active View window. A soft story is defined as a story that has a stiffness in a particular direction that is less than 70% of the stiffness of the story above.

Opens when the **Eurocode 8 | Stiffness Checks** page is selected.

P. EC8 Plan page

Used to classify the building as being "regular in plan." Checks will be performed and the results will be displayed graphically in the GUI. The program primarily checks for the main three plan regularity conditions set out in EC-8.

When the EC8 Plan page is selected, the **Check Regularity in Plan** dialog opens and the active view window displays the Whole Structure.

Selecting various structure elements listed in the **Check Regularity in Plan** dialog will open either the **Torsional Radius Check** table or the **Slab Re-Entrant Corners** table.

P. Check Regularity in Plan dialog

Displays the results of the following checks for the main three plan regularity conditions set out in EC-8:

i. Checks for re-entrant corners in floor slabs

The program performs checks on each floor slab and reports whether the condition set out in EC-8 for re-entrant corners has been satisfied.

ii. Check for slenderness of structure

The program calculates a "slenderness ratio" for the structure based on the maximum dimensions on plan and reports whether the EC-8 criteria are satisfied.

iii. Checks for torsional radius

The program calculates the torsional radius for each floor and checks against the conditions set out in EC-8. These are summarized in the **Check Regularity in Plan** dialog and the **Torsional Radius Check** table will display details.

Opens when the **Eurocode 8 | Plan Regularity** page is selected.

P. Torsional Radius Check table

The program calculates the torsional radius for each floor and checks against the conditions set out in EC-8.

Opens when the **Eurocode 8 | Plan Regularity** page is selected.

P. Slab Re-Entrant Corners table

The program performs checks on each floor slab and reports whether the condition set out in EC-8 for re-entrant corners has been satisfied. The details of any corners detected which fail this check are displayed here. The geometry which fails is highlighted in the active view window.

Opens when the **Eurocode 8 | Plan Regularity** page is selected.

P. Eurocode 8 | Elevation Regularity page

Used to classify the building as a “regular in elevation” structure. Checks will be performed and the results will be displayed graphically.

When the Eurocode 8 **|** Elevation Regularity page is selected, the **Earthquake Elevation Criteria** dialog and **Elevation Regularity** table open.

The structure diagram is displayed in the Whole Structure view window. When a Elevation Regularity check is performed, the elevation profile is displayed on the structure diagram.

P. Earthquake Elevation Criteria dialog

Used to specify global seismic direction and the elevation criteria per Eurocode 8 against which a Elevation check will be performed.

Opens when the **Eurocode 8 | Elevation Regularity** page is selected.

Control	Description
Choose elevation along	Select the global axis along which the seismic forces are acting for this check.
Choose elevation criteria	Select the criteria which best describes the elevation variation per Clause 4.2.3.3 and Figure 4.1 of EN 1998-1:2004 (EC8).
Perform Checks	Click this button once the appropriate criteria is selected for a direction. The program will evaluate the elevation geometry against code requirements. The results of this evaluation will populate the Elevation Regularity table and the profile checked will be displayed onto the structure diagram in the active view window.

P. Elevation Regularity table

Reports the status of a Elevation Regularity check performed based on criteria set in the **Earthquake Elevation Criteria** dialog.

Opens when the **Eurocode 8 | Elevation Regularity** page is selected.

P. Plotting from STAAD.Pro

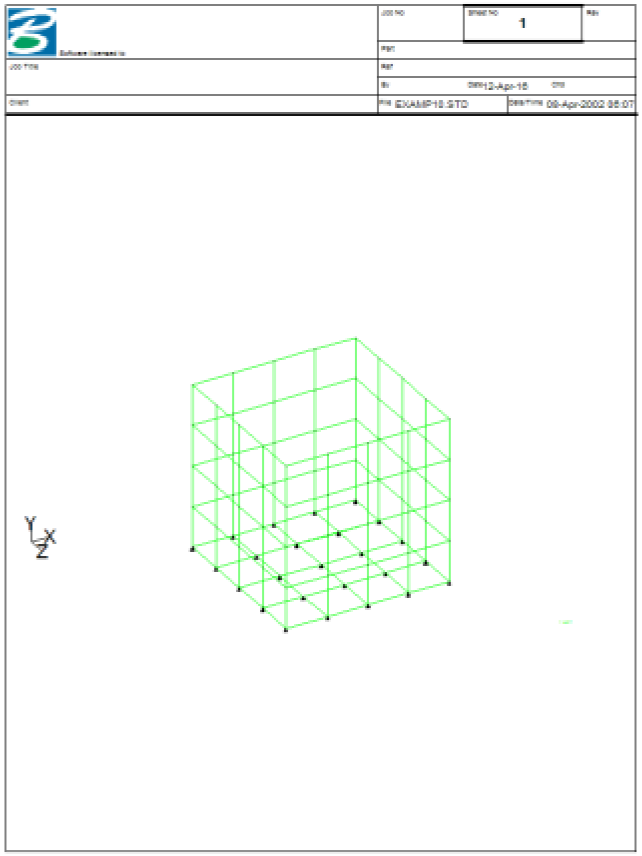
Explained below are five methods for plotting the drawing of the STAAD model and STAAD result diagrams.

P. Plot Using the Print Current View Tool

1. (Optional) Right-click in the view window and then select the **Print Preview Current View** from the pop-up menu.

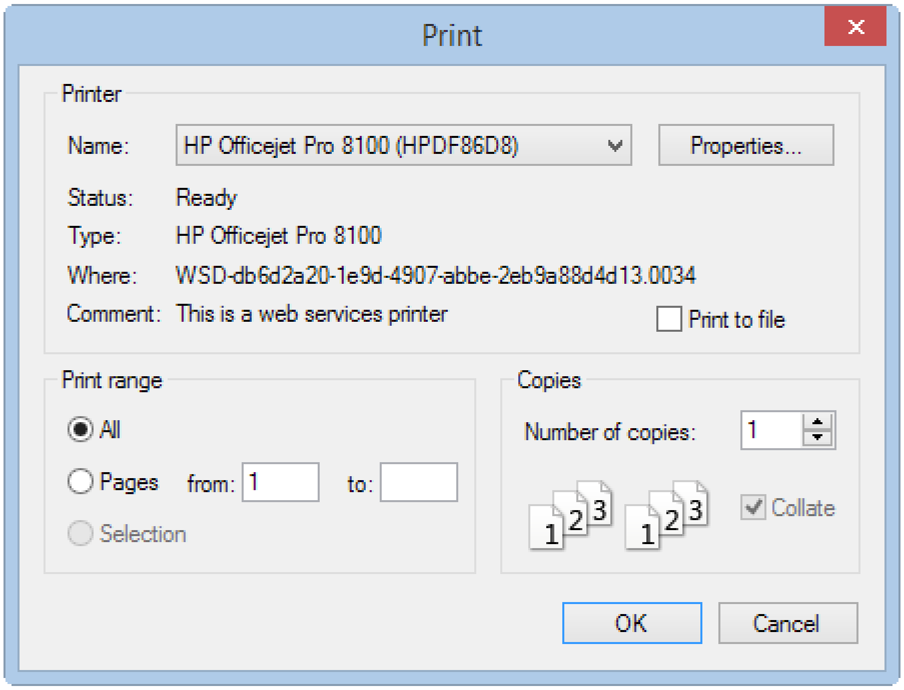
   This is used to preview the image as it will appear on paper.

   The **Print Preview** window opens to display the view in a report format.



2. Select **Print** in the Print Preview toolbar.

   The standard Windows **Print** dialog opens, which is used to select the printer or plotter where you wish to send the image.



3. Select the desired printer and click **OK.**

P. Plot Using the Take Picture Tool

1. On the **Utilities** ribbon tab, select the **Take Picture** tool in the **Utilities** group.

The **Picture #** dialog opens.

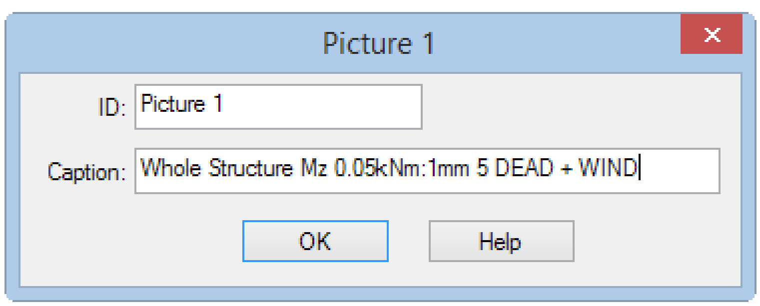


Figure 204: The Picture # dialog with the ID and Capture automatically generated

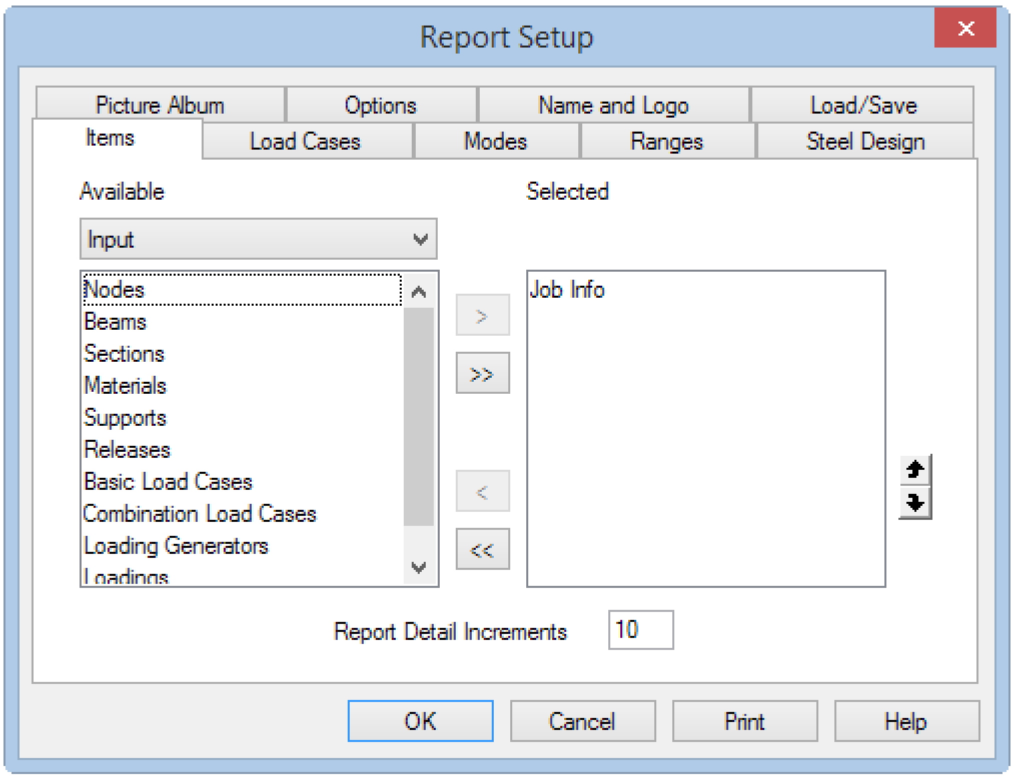
2. (Optional) Type a Picture **ID**

   The ID is incremented automatically.
3. (Optional) Type a **Caption**

Note: For most View window contents, the caption will be automatically completed with a description of the contents.

4. Click **OK**.
   This picture is saved for use in reports.
5. Open the Report Setup:
   a. Select the **File** ribbon tab.
      The Backstage view opens.
   b. Select the **Report** tab and then **Setup**.

   The **Report Setup** dialog opens.



Note: The Available items list is filtered by the drop-down selection list above it. This allows you to sort your reports.

6. On the **Items** tab, select **Pictures** from the available list of items.
7. Add one or more pictures to the Selected list by clicking [>].
8. (Optional) Select the **Picture Album**

Tip: You can manage pictures taken using the **Take Picture** tool here.

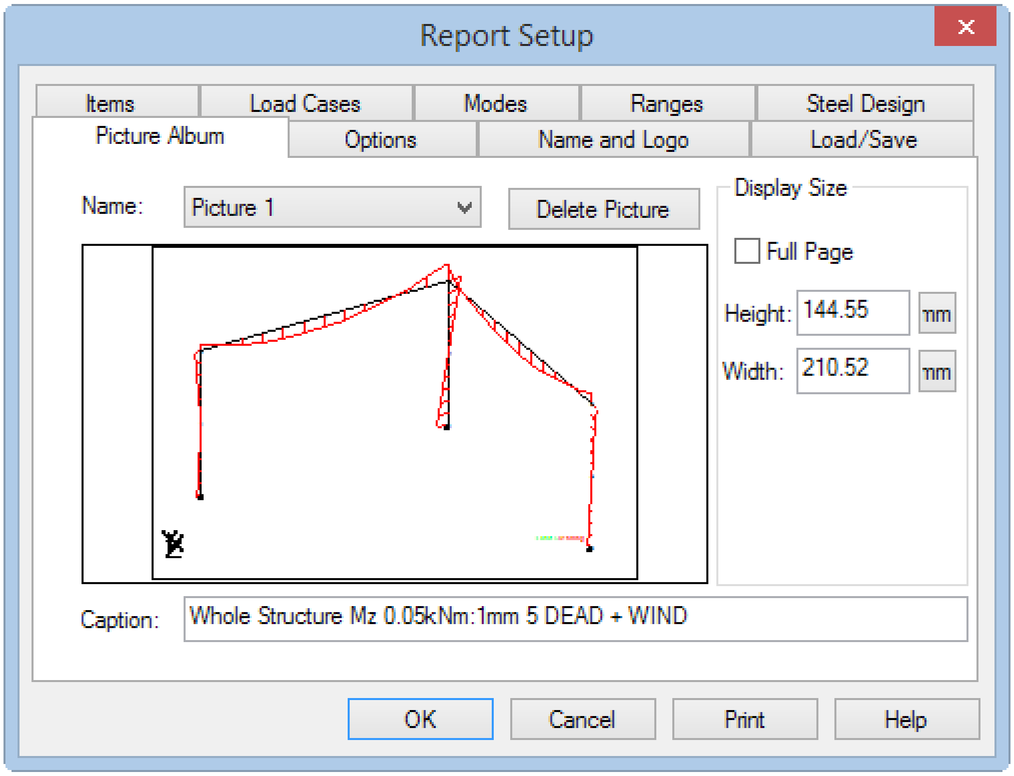


Figure 205:

9. (Optional) Select the **Full Page**
10. Click **OK**.
11. Select **File** > **Print Report**.
    The diagram will be plotted.

Alternatively, Select **File** > **Export Report** > **MS Word File** to create a report you can print from Microsoft Word.

In the **Save As** dialog, specify a name for the file and click **Save**. In the template dialog, select the **Normal** template (or use any custom Word templates you have created).

Figure 206:

Microsoft Office Word builds the file with the picture in it. Once this task is completed, the new file is opened in Microsoft Office Word.

P. Plot Using the Export View Option

STAAD.Pro has a facility to export the drawing to a graphic image file.

Use the program to generate the diagram or plot you want to export.

1. Select the **Export View** tool on the **Print** toolbar. 
   The **Save As** dialog opens.
2. Select the graphic format you want to use for your image file (i.e., Bitmap, JPEG, TIFF, GIF, etc.)
3. Type a file name and save the file.

P. Plot Using the Copy Picture Option

1. Highlight the window containing the diagram that you wish to plot.

   This can be done by making sure the title bar of that window has the color which indicates that it is in focus.
2. Select **Edit** > **Copy Picture**.
3. Open a graphics program capable of cropping the graphics image to your needs (e.g., Microsoft Paint, Corel PaintShop Pro, Adobe Photoshop, etc.).
4. Paste the clipboard contents into an empty file in this program.

   The drawing from the STAAD window is pasted in that program.

Alternatively, you can also copy graphic contents of the View window by using the **<PrtSc>** (Print Screen key).

8 Data Files and Interoperability

This section describes how to manually edit STAAD.Pro input files, import and export data, and interact with STAAD.Pro using external applications.

Note: You can also interact with STAAD.Pro via an API. Refer to OpenSTAAD (on page 7000) for more information.

I. STAAD.Pro Editor

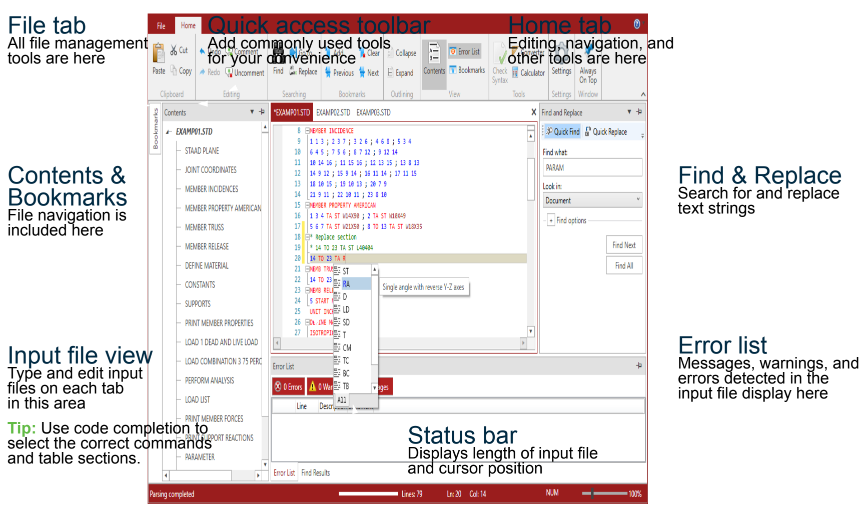
This section describes the various facilities available in the STAAD.Pro Editor. The tools and menus in the editor are described here.

Related Links

- *P. To view analysis results* (on page 1978)

I. Getting Started

I. Quick Overview



Related Links

- *I. File tab* (on page 2055)
- *I. Home tab* (on page 2056)

I. To start the editor from STAAD.Pro

When the STAAD.Pro Editor is opened from within STAAD.Pro, the model that is currently open is saved, the STAAD input file automatically parsed and a check on the data is performed. If any issues detected are then reported in an error message that identifies the number of Errors/Warning detected. The details of the issues are then reported in the Error List panel. For more details for the messages. Refer to I. To check for syntax errors (on page 2048) for details.

> **Note:** Note that when the STAAD.Pro Editor is opened from within STAAD.Pro, it is not possible to open an additional STAAD input file or start a new file. This is only possible when starting the STAAD.Pro Editor externally. Refer to I. To start the editor externally (on page 2044).

1. Open a STAAD file in STAAD.Pro.
2. On the **Utilities** ribbon tab, select the **Command File Editor** tool in the **Utilities** group.

   The STAAD.Pro Editor window opens with the current STAAD input file.

I. To start the editor externally

STAAD.Pro Editor can be run seperately from STAAD.Pro.

> **Note:** STAAD.Pro Editor is *not* capable of checking for errors when run externally from STAAD.Pro. Additionally, STAAD.Pro Editor cannot perform an analysis on an input file. This must always be done using STAAD.Pro.

1. In Windows Explorer, navigate to the Editor folder in the STAAD.Pro installation folder.
   This is typically
   `C:\Program Files\Bentley\Engineering\STAAD.Pro CONNECT Edition\STAAD\Editor.`
2. Either:

   double-click the `Bentley.Staad.Editor.exe` `Bentley.TCL.Editor.exe` file

   or

   drag-and-drop a STAAD input file (file extension `.std` onto the STAAD.Pro Editor icon.

> **Tip:** You can create a Windows shortcut to the STAAD.Pro Editor program file and add it to your Start menu, desktop, or Windows task bar.

> **Tip:** You can right-click on an `.std` and select **Open with** to add the STAAD.Pro Editor to the program list associated with a STAAD input file.

To select the character encoding

To manually select the character encoding used in the editor, use the following procedure.

You may typically only need to change the encoding to view some analysis output files. The auto-detect setting will work for STAAD input files.

For example, to correctly view the design results for steel design per the Russian SP 16.13330.2017 code, you must select "Cyrillic (Windows) (1251: windows-1251)" as the method of encoding.

1. On the **Home** ribbon tab in the STAAD.Pro Editor, select the **Settings** tool in the **Settings** group.

   
   The **Settings** dialog opens.
2. On the **General** tab, select the appropriate encoding system from the **Default Encoding** drop-down list.
3. Click **OK**.
   You are prompted to reload the file if one is open.
4. Click **Yes**.

I. To Pin a Panel

The **Contents**, **Bookmarks**, **Find and Replace**, and **Error List** panels call be "pinned" to stay open. Alternatively, to free up screen space, they can be "unpinned" to display only when selected.

1. Either:

   click the tab name of the panel you want to display

   or

   click the corresponding took name in the Searching or View groups on the **Home** ribbon tab
   The panel opens.
2. Click the pin icon in the top, right-hand corner of hte panel.
   The panel is now pinned in place.

Tip: Clickin the pin icon again will hide the panel once you click elsewhere.

Related Links
- *I. Bookmarks* (on page 2049)

I. STAAD Input Files

These are text files which list structure geometry, material properties, loading data, analysis commands, design commands, and other related structure input data which the STAAD.Pro analysis and design engine interprets upon running an analysis.

These files are the primary files created in the STAAD.Pro graphical interface and can be edited directly using the STAAD.Pro Editor.

Tip: STAAD input files use the `.std` file extension.

STAAD Command Language and Syntax

The advantage of using the STAAD.Pro Editor over other plain text editors is that the syntax of the STAAD command language is natively understood and will be appropriately marked (this functionality may be customized in the STAAD.Pro Editor **Settings** dialog). The following represents an overview of the language structure:

- English based - Input commands use full English words (though these may be shortened in many instances) or common engineering nomenclature.
- Case insensitive - Input data is not case sensitive.
- Line continuation - Lines containing lists may be continued to the next line by ending the line with a blank and a hyphen. Some lists have special rules or considerations.
- Comments - Lines may be marked as a comment (information which is ignored by the program) by including an asterisk (*) as the first non-blank character in any line. By default, comment lines will appear in green in the STAAD.Pro Editor window.

Refer to TR.1 Command Language Conventions (on page 2197) for additional information on the STAAD Command Language.

I. To create a new STAAD input file

1. Either:

   Select the **New** tool on the **File** ribbon tab.

   or

   Press **<Ctrl+N>**.

   A new STAAD input file opens with the empty template.

You can now start typing STAAD commands. To check syntax or to run the STAAD input file, you must use STAAD.Pro.

I. To open an existing STAAD input file

Tip: Multiple input files can be open simultaneously. Each file is displayed on a separate tab across the top of the text editor.

1. Either:

   Select the **Open** tool on the **File** ribbon tab.

   or

   Press **<Ctrl+O>**.

   The **Select STAAD File** dialog opens. The controls are similar to a typical Windows File open dialog.
2. Navigate to and select the STAAD input file you want to edit.
3. Click **Open**.

I. To save chagnes to a STAAD input file

1. Either:

   select the **Save** tool on the **File** ribbon tab

or

press **<Ctrl+S>**.

> **Tip:** Select the **Save As** tool on the **File** ribbon tab to save the file with a different file name or in a different location.

If this is a newly create STAAD input file, you will be prompted to type a file name and select a location to save the file.

2. (Optional) Click **Save** if you are saving for the first time or saving as a new file.

I. Getting Help

When you are typing, press **<F1>** to open the Technical Reference help to the topic pertaining to the current input command.

To open the general STAAD.Pro help, click the **Help** tool () on the right side of the ribbon bar.

I. Editing Input Files

I. Typing Commands

Code Completion

As you type commands, the STAAD.Pro Editor will offer suggestions to complete the command you are typing in the form of a drop-down list. This list is context-sensitive based on the preceding commands.

As you continue typing, the list will respond by narrowing to complete the word you are typing. You can use your mouse or the arrow keys to select a command from the list. Press **<Enter>** or **<Tab>** to accept the highlighted command keyword.

Table Sizes

Similarly, within a `MEMBER PROPERTY` *`country`* block, the corresponding country section tables are available for selecting sections. After typing `TABLE` and any additional specification options, the table sections will open as a drop-down list. You can continue typing to narrow the list or use your mouse to select one of the shape tabs for that table.

Context-Sensitive Command Help

Pressing **<F1>** opens the Technical Reference help to the topic corresponding to the current input command.

I. To add a comment

To change one or more lines in the input file to a comment, do the following.

Comments can be used to add notes or remarks in the input. They also can be used to turn 'off' commands so they are ignored by the analysis and design engine.

1. Either:

   place your cursor anywhere on the line you want to comment

or

select text across mulitple lines

2. Either:

   select the **Comment** tool in the **Editing** group on the **Home** ribbon tab

   or

   right-click and select **Comment Selection**

If...	Then...
No content was selected in Step 1	the current line is made a comment
Multiple lines were selected in Step 1	all the lines in the selection are made comments

Tip: You can remove comments using the **Uncomment** tool n the **Editing** group on the **Home** ribbon tab or by selecting **Uncomment Selection** in the right-click menu.

I. To check for syntax errors

Note: In order to check for errors, STAAD.Pro must be running. If you have launched the STAAD.Pro Editor externally, this feature is disabled.

Note: Input file data is also parsed when STAAD.Pro is first opened as well as when the STAAD.Pro Editor is first opened. You will be notified of any errors at that time.

1. Select the **Check Syntax** tool in the **Tools** group on the **Home** ribbon tab.
   A message opens to indicate if no errors are detected.

When the file is checked, if any issues are detected, the details are reported in the **Error list** panel. The data there is displayed in four colums:

i. An icon which indicates the type of issue detected: error, warning, or message.
ii. The line number on which the detected issue occurs. Double-click on the issue will point the input view to this line number.

   Note: If a line number cannot be identified by the program, then this will be blank.

iii. A description that provides details of why the issue has been identified and possible assistance in determining a resolution.
iv. A copy of the data in the line what has been identified as an issue.

You can review individual errors or warnings in the **Error List** panel.

I. Navigation

Multiple Files Open

You can open multiple STAAD input file simultaneously. Each file is displayed on a separate tab across the top of the text editor panel by the filename. The currently selected tab is active and all operations are performed on this file only.

Blocks

Blocks can be nested. For example, `DEFINE MATERIAL START` is a block, and each `ISOTROPIC` material within that block is a sub-block. The current block is indicated by a vertical bar to the right of the commands.

Clicking the minus sign will collapse the block down to the fist command. Once a block is collapsed, a plus sign is displayed and the first command is displayed in a box.

Tip: Select the **Collapse** tool in the **Outlining** group on the **Home** ribbon tab to collapse all blocks in the current input file.

Contents Panel

The top-level blocks are listed, in order, in the Contents pane.

Double-clicking an entry in the contents moves the cursor to that point in the text editor.

I. To go to a line

To move the cursor to a particular line in the input file, do the following:

1. Select the **Go to** tool in the **Searching** group on the **Home** ribbon tab.
   The **Go To Line** dialog opens.
2. Type the **Line Number**.
3. Click **OK**.
   The cursor is placed at the beginning of the indicated line.

   Note: A message indicates if the specified line number is higher than the number of lines in the file.

I. Bookmarks

You can add bookmarks at any point in an input file to quickly return to that point.

To add a bookmark

1. Either:
   - select the **Add** tool in the **Bookmarks** group on the **Home** ribbon tab, or
   - right-click and select **Toggle Bookmark** from the pop-up menu.

To navigate to the next or previous bookmark in the file, select the **Next** or **Previous** tool in the **Bookmarks** group on the **Home** ribbon tab.

To jump to a specify bookmark, double-click the name in the **Bookmark** panel.

To remove *all* the bookmarks in the file, select the **Clear** tool in the **Bookmarks** group on the **Home** ribbon tab.

Related Links

- *I. To Pin a Panel* (on page 2045)

I. Find and Replace

I. To find something

1. Either:

   select the **Find** tool in the **Searching** group on the **Home** ribbon tab

   or

   press **<Ctrl+F>**

   The **Quick Find** tab on the **Find and Repalce** pane opens.
2. Type a string to match in the **Find what** field.
3. (Optional) Select the **Look in** and **Find options** to specify the extents of the search and how the string should be matched, respectively.
4. Click **Find Next**.
   The next matching string is selected in the input file.

Related Links

- *I. Search Methods* (on page 2051)

I. To replace something

1. Either:

   select the **Replace** tool in the **Searching** group on the **Home** ribbon tab

   or

   press **<Ctrl+H>**

   The **Quick Find** tab on the **Find and Repalce** pane opens.
2. Type a string to match in the **Find what** field.
3. (Optional) Select the **Look in** and **Find options** to specify the extents of the search and how the string should be matched, respectively.
4. Type a replacement string in the **Replace with** field.
5. Either:

   click **Find Next** to highlight the next matching string

   or

   click **Replace** to replace the currently highlighted match

   or

   click **Replace All** to automatically replace all the matching strings in the file

Related Links

- *I. Search Methods* (on page 2051)

I. To find all occurances of a string

1. Press **<Ctrl+I>**.
2. Start typing a string.
   As you type, all occurances of the input string are highlighted in the file. The cursor jumps to the next occorance of the string.

I. Search Methods

STAAD.Pro Editor can use a variety of methods for matching strings when searching an input file.

In either the **Quick Find** or **Quick Replace** tabs on the **Find and Replace** panel, expand the **Find options** section to display the avaialable matching options.

Look in	Select either the **document** (entire file) or **selection** to limit the search extents.
Match case	Select use case-sensitive matching in the search string.
Match whole word	Select to match entire words (separated by white space) only. (e.g., searching for `JOI` will find "JOI" but not "JOINTS").
Search type	

Normal	Match the input string literally, using the options selected above.
Regular Expressions	Use regular expressions (also referred to as regex or regexp) in the search string. For additional
Wildcard	Use standard Windows wildcards to substitute a single character for one or more other characters in the search string. "?" represents a single character, and "*" represents any combination of characters
Acronym	
Shorthand

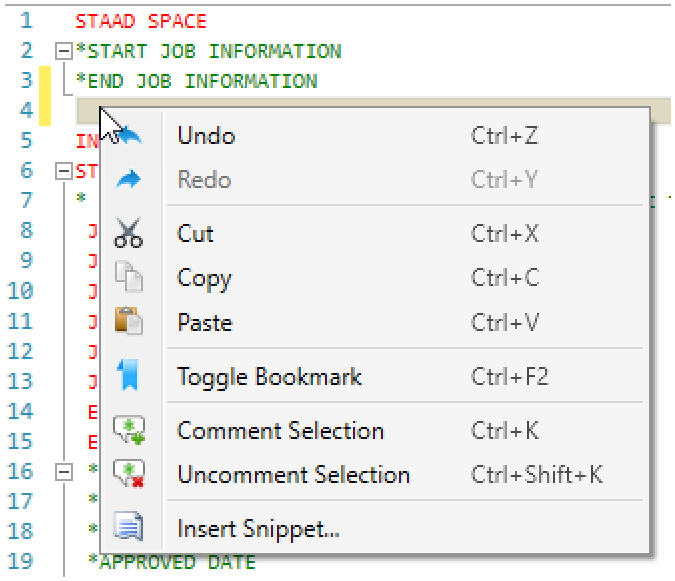
- *I. To replace something* (on page 2050)

I. Snippets

Code snippets are short sections which you commonly need to insert into different input files. Saving this code as a separate snippet allows you to easily access these portions of predefined code.

I. To insert a code snippet

1. Place your cursor at the point you want to insert a code snippet.
2. Right-click and select **Insert Snippet** from the pop-up menu.



The inline snippet tool opens.

3. Either:

   Use the arrow keys or mouse to select the name of the snippet you want to insert.

   Tip: If you have organized snippet files into multiple folders, select the folder first.

   or

   Start typing to select the snippet by the Shortcut string in the snippet file.

4. Double-click with the mouse, press **<Enter>**, or press **<Tab>** to select and place the snippet.
   The text is inserted.

I. To create a code snippet

To create a custom code snippet using a sample as a template, do the following:

Some familiarity with editing XML files (e.g., HTML) is helpful to create snippet files, but not necessary. Further, no special tools or software are required, but a plain text editor which can validate XML is recommended.

1. In Windows Explorer, navigate to the .../`STAAD/Editor/Snippets/Std/` folder in your STAAD.Pro installation folder.
2. Make a copy of one of the existing snippet files (file extension `.snippet`).

   You can place snippets in the same folder or create a new folder within .../`STAAD/Editor/Snippets/` to orgnanize snippet files as needed.
3. Rename this copy to something meaningful.
4. Open the reanmed file in a plain text editor.

5. Change the header information:
   a. Type a new title within the <Title> element.
   b. (Optional) Type a your name or your organization's name within the <Author> element.
   c. Type a tool tip description within the <Description> element.
   d. Type a shortcut string within the <Shortcut> element.

   Note: Do *not* edit any of the XML tags or attibutes. Only change the plain text inside elements.
6. (Optional) If you want to add replacement strings in the snippet, create a <Literal> element inside the <Declarations> section for each.
7. Type or paste the actual snippet STAAD input code into the CDATA section, between the inner-most square brackets.

   Example:
   ```
   <![CDATA[snippet contents here]]>
   ```
   The contents here will be copied directly when the snippet is used (except for variables), including line breaks and commented lines.

   Tip: There is no syntax checking in the snippet file itself, so it is best practice to copy and paste the STAAD input snippet code from a STAAD input file you have checked for errors.
8. Save and close the snippet file.

I. Creating a New Code Snippet

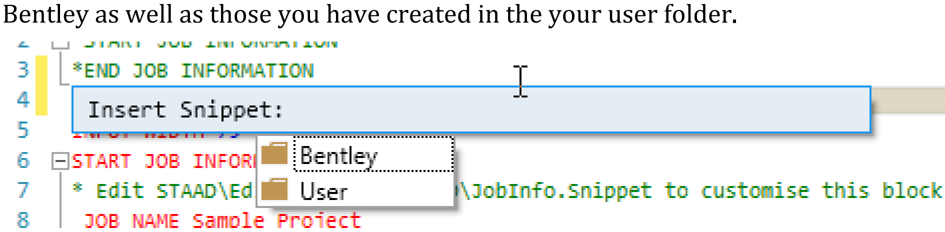
Code snippet files (file extension .snippet) are XML files which contain one or more code snippets to insert along with metadata about the snippet, such as tool tips, titles, etc. They can be created or edited in any plain-text editor.

Tip: It is easiest to copy an existing snippet file, rename it, and edit as needed.

You can save it in a separate folder to organize your snippets. This will add a folder section to your Insert Snippet menu. Otherwise, you can simply save them in the /STAAD/Editor/Snippets/Std/ folder.

The application comes with a few sample snippet files in the installation. However, to add your own Snippets, add the .snippet file to the folder \Users*(user name)*\AppData\Local\Bentley\Engineering\STAAD.Pro CONNECT Edition\Default \Editor\Snippets.

When you select Insert Snippet from the right-click pop-up menu, you will then be provided folders for the samples from Bentley as well as those you have created in the your user folder.



Code Snippet Syntax

When editing a snippet file, you should note that there are two primary components to the XML: the `<Header>` and the `<Snippet>`. The Header contains the metadata about the code snippet, including the `<Title>` text and `<Description>`, which is used as a tool tip in the STAAD.Pro Editor.

The actual code inserted when the snippet is used by the STAAD.Pro Editor is contained in a CDATA section within the `<Code>` section.

```
<Code Language="STD">
  <![CDATA[UNIT FEET KIP]]>
</Code>
```

Tip: If you want line returns before or after the inserted code, you can place those at the beginning or end of the CDATA text. Whitespace (i.e., spaces, tabs, or line returns) *outside* of the CDATA section have no effect on the inserted snippet.

```
<Code Language="STD">
  <![CDATA[
  UNIT FEET KIP
  ]]>
</Code>
```

Snippet Replacements

You can create replacement strings in a snippet which will be highlighted for the snippet user. These are added in the `<Declarations>` section within the `<Snippet>` section.

Each replacement definition has the following structure:

```
<Literal>
   <ID>name</ID>
   <ToolTip>Tool tip text.</ToolTip>
   <Default>Default text</Default>
</Literal>
```

Where:

`name` is the replacement name to use within the snippet code.

`Tool tip text.` is the string to show as a tool tip in the STAAD.Pro Editor

`Default text` is the text that will be inserted (and highlighted) in the STAAD.Pro Editor when the snippet is used

To use the replacement within the snippet code, just place dollar signs ("$") before and after the *`name`* value.

Snippet Editing Tools

You can use an IDE such as Microsoft Visual Studio, but any plain text editor is capable of editing code snippet files. An editor that is capable of checking XML syntax is recommended, though.

Tip: Notepad++ is a free text editor which, when the XML Tools plugin is installed, is capable of checking XML syntax.

- *I. Quick Overview* (on page 2043)

I. Settings dialog

This dialog is used to control display settings for the STAAD.Pro Editor.

General tab

Display options	**Display Line Number**	Set this option to include line numbers to the left of the command lines in the editor. Line numbers are not printed.
	Highlight Current Line	Set this option to highlight the entire line where the cursor is located in the editor.
	Outline Group	Set this option to have sections of the input file “grouped” together in the editor.
	Color Coded Text	Set this option to highlight input using different colors by keyword, values, etc. in the input file. Printed input files will use the same color coding. **Note:** The output file (`.ANL`) does not use color coding for the input echo. Only warnings, errors, and messages will be displayed in color when the information is indicated for this.
Default Encoding	Select the default character encoding system used by the viewer.	
Editor options	These options are only available in the Editor mode.	
	Enable IntelliSense	Set this option to enable code-completion for input file editing.
	Enable Snippets	Set this option to enable the snippets functionality in the right-click pop-up menu in the editor. Snippets allow you quickly add predefined blocks of code to your input file.

Fonts and Colors tab

File Type	Select the file extension corresponding to the type of file you want to style.
Font	Select an installed Windows font from the drop-down list to use for the text editor.
Size	Select a font size from the drop-down list to use for the text editor.
Items	Select one of the text window display items from this list. The color can be selected from the **Item Color** drop-down pallet.
Item Color	Click the down arrow to select a color for the selected **Items**.

Print tab

Header	Set this option to include a header with the selected options:	
	Logo	(Input files only) Set this checkbox to include the file path in the **Company Logo File** field. Click **Browse** to locate an image file.
	Job Information	(Input files only) Set this option to include the `JOB NAME`, `JOB CLIENT`, and `ENGINEER NAME` job information values from the `START JOB INFORMATION` command block.

Date/Time (Output files only) Select the time stamp to use for the file.

Footer Set this option to include a footer with the selected options:

Path and Filename Set this option to include the file path, file name, and timestamp of the file in the footer of each page of the printout.

Page Number Set this option to include page numbers in the footer of each page of the printout.

Margins Set the page margins around the page here.

I. Keyboard Shortcuts

Exit the programs.	**<Alt+F4>**
Opens the help topic for the current input command.	**<F1>**
Select all the contents in the current input file.	**<Ctrl+A>**
Copy the current selection to the clipboard.	**<Ctrl+C>**
Open the **Quick Find** tool to search the document.	**<Ctrl+F>**
Open the **Quick Replace** tool to find and replace strings in the document.	**<Ctrl+H>**
Highlight all occurances of a typed string.	**<Ctrl+I>**
Delete the current line.	**<Ctrl+L>**
Start a new input file.	**<Ctrl+N>**
Open an existing STAAD input file.	**<Ctrl+O>**
Open the **Print** dialog.	**<Ctrl+P>**
Save changes made to the current input file. If the file has not been saved previously, you will be prompted to type a file name and select a location.	**<Ctrl+S>**
Reverse the order of the previous two characters before the cursor.	**<Ctrl+T>**
Paste the clipboard contents at the cursor location.	**<Ctrl+V>**
Cut the selection from the document to the clipboard.	**<Ctrl+X>**
Undo the last redo action.	**<Ctrl+Y>**
Undo the last action.	**<Ctrl+Z>**

I. Integrated Structural Modeling

STAAD.Pro can exchange structure information with Bentley Integrated Structural Model (ISM) repositories.

I. ISM Sync Tools Overview

STAAD.Pro can send structural data to and from an ISM repository through a set of ISM Syncing tools. These tools allow both creation and updating of STAAD.Pro models as well as ISM repositories. Further, these flexible tools allow you to begin models and move data as your workflow dictates.

If you need to ...	... use this tool	Description
Create a new ISM repository from an existing STAAD.Pro model	 **Create Repository**	transfers the current model opened in STAAD.Pro and generates a new ISM repository. This is the most common way in which an ISM repository is initially created.
Create a new STAAD.Pro model from an existing ISM repository	 **New From Repository**	creates a new STAAD.Pro model from an existing ISM repository. This is used to transfer model data from other tools used in the workflow.
Update an existing repository to reflect changes made in a STAAD.Pro model	 **Update Repository**	will coordinate changes made to the model in STAAD.Pro and coordinate some or all of those changes with an existing ISM repository.
Update an existing STAAD.Pro model to reflect changes in an ISM repository	 **Update From Repository**	used to update a STAAD.Pro model with some or all of the changes which have been made to the ISM repository.

Not all tools are available at all times. For example,

- If ISM is not installed these items will be grayed out and not available.
- If ISM is installed but no STAAD.Pro model is loaded, only **New From Repository** will be available.

iTwin Analytical Synchronizer

The program provided by ISM for accepting or rejecting model data changes is called " iTwin Analytical Synchronizer ". iTwin Analytical Synchronizer provides the user with a powerful set of tools for moving data between the applications used in a daily workflow. Even relatively small structural models have enormous amounts of data and ISM allows this data to be re-used with ease. Care must be taken that only desired data is transferred between applications.

When accepting changes made by client applications to an ISM Repository, some attention must be paid to what changes are actually being made. A small change in a client application can have unintended repercussions, if accepted. A repository is intended to represent the data that is *common* to all the client applications. Some client application models will use only a subset of the repository data but changes made to them can affect the entire repository if these changes are accepted when a repository update action is performed.

Note: This brief overview is not intended as a sufficient description on using the full capabilities of iTwin Analytical Synchronizer. Please refer to the iTwin Analytical Synchronizer product documentation for more detailed information.

- *ISM tab* (on page 2702)

I. What is ISM?

Bentley's Integrated Structural Model (ISM) is a technology for sharing structural engineering project information among structural modeling, analysis, design, drafting, and detailing applications. ISM is similar to Building Information Modeling (BIM), but focuses on the information that is important in the design, construction, and modification of the load bearing components of buildings, bridges, and other structures.

I. Purpose of ISM

There are two related purposes for ISM:

1. The transfer of structural information between applications.
2. The coordination of structural information between applications.

To provide for the first purpose (transferring information), ISM provides a means of defining, storing, reading and querying ISM models.

To provide for the second purpose (coordination of information), ISM additionally provides capabilities to detect differences between ISM models and to selectively (based on user selection) update either an ISM repository or an application's data to provide a user-controlled level of consistency between the two data sets.

I. ISM and Application Data

ISM is not intended to store all of the information that all of its client applications contain. Rather, it is intended to store and communicate a *consensus* view of data that is *common* to two or more of its client applications, such as STAAD.Pro.

STAAD.Pro continues to hold and maintain its own private copy of project data. Some of the application data will duplicate that of the associated ISM repository. The application data may even conflict with that in the ISM repository. STAAD.Pro (or the user) may decide that a conflict gives the best data for the different uses in STAAD.Pro versus ISM.

I. Backups

STAAD.Pro has an auto-saving and backup managing feature to prevent accidental data loss.

I. To enable auto-recovery

To turn on the auto-recovery feature and set the frequency of auto-recovery backups, use the following procedure.

This feature will automatically create backups based on a specified time interval (default of 5 minutes) of your entire STAAD project, including physical models. In the event of a program crash or if the program is simply closed without saving changes, the program will detect the auto recovery files and prompt you to open from that recovery state when you re-open the associated STAAD model.

The auto-recovery process will only run if changes are detected in the files since your last save action.

1. From the Start page, select the **Configure** tool.
   The **Application Configuration** dialog opens.
2. Select the **Options** tab.
3. Check the option to **Save AutoRecover information every X minutes**.
4. (Optional) Type the how often (in minutes) you want the program to save recovery state for open files.

   The default of 5 minutes is recommended. Intervals shorter than this can degrade performance.
5. Click **OK**.

Tip: If you find that the auto-recovery process is causing performance issues when running (which may occur in large models), then you can toggle it off in the Quick Access toolbar. This will not stop a current auto-recovery process, but will prevent it from running subsequently until toggled back on again.

- *GS. Quick Access Toolbar* (on page 62)

I. To create a restore point

To create a restore point used to backup your entire STAAD project, use the following procedure.

A restore point is a backup of all files associated with a STAAD input model, including a physical model if one is present. The option to include analysis output files is also available when creating a restore point.

1. Select the **File** ribbon tab.
   The STAAD.Pro Backstage view opens.
2. Select the **Backup/Restore** tab and then click **Create Restore Point**.
3. (Optional) Provide the restore point details:
   a. Type a **Name** for the restore point.

      The name value will be populated and incremented automatically if you don't type a differenet value.
   b. Type a **Description** to provide additional information for this restore point.
   c. Check the option to **Include Analysis Data** if required.
4. Click **Create**.
   A message dialog informs you the restore point was created.
5. Click **Ok**.

You restore your model to this point at any time.
Related Links

- *Backup/Restore tab* (on page 2695)

I. To restore a model from a backup

To restore a model from a previously created restore point, use the following procedure.

1. Select the **File** ribbon tab.
   The STAAD.Pro Backstage view opens.
2. Select the **Backup/Restore** tab and then click **Restore Model**.
3. Select the restore point and then click the **Restore** tool associated with that backup.
   A message dialog opens to confirm you want to overwrite the model with the restore point data.
4. Click **Yes**.
   The model opens with the data from the restore point and a message dialog opens to confirm the restore point was successfully loaded.

Related Links
- *Backup/Restore tab* (on page 2695)

I. To compare backups

To compare two restore points or a restore point with the current model state, use the following procedure.

Your model must have one or more restore points created.

1. Select the **File** ribbon tab.
   The STAAD.Pro Backstage view opens.
2. Either:

To...	Select...
compare the current model state with a previous restore point	select a restore point and then click **Compare with the Current Model**
compare two restore points	hold **<Ctrl>** and click on the two restore points of interest. Then click **Compare Models**.

   The **Backup and Restore - Compare Models** window opens to compare the input file data from the selected model states.
3. (Optional) To restore the contents of one of the selected files, click either: **Restore Left** or **Restore Right**.
4. Close the **Backup and Restore - Compare Models** window.

Related Links
- *Backup/Restore tab* (on page 2695)

I. Archives

Archive files can be used to collect all of the files within a STAAD.Pro into a single file, which is useful for records or sending project files to others.

STAAD.Pro projects consist of multiple files, such as the input file (file extension `.std`), analysis results (file extension `.anl`, etc.

An archive file uses the extension `.stz`.

Related Links

- *I. To share a STAAD.Pro project in ProjectWise* (on page 2076)

I. To create an archive

To create an archive file for a STAAD project, use the following procedure.

You cannot create an archive when a STAAD input file is open in the program.

1. Select the **Archive** tab on the Start page.
2. Select **Create**.

   

3. Select the **File Name** of the STAAD input file you want to archive.

   Click **Browse** to navigate to the file using a Windows open dialog.
4. Type the **File Name** of the archive file.
5. (Optional) Select a **Location** where you want the archive file created.

   The default location is the same folder containing the STAAD input file.
6. (Optional) Select the files associated with the input file you want included in the archive.

   All files are selected by default.
7. Click **Create**.

You can repeat this process and overwrite an existing archive file to update with any changes made to the STAAD input file, analysis results, etc.

Related Links

- *GS. Start Page* (on page 54)

I. To open an archive file

To open an archive file in STAAD.Pro, use the following procedure.

1. Select the **Open** tab on the **Start** page.
2. Select the Archive tab as the source type.

   

   > **Tip:** You can open recent Archive files with one click. These are listed on the **Archive** tab along the top of the Open tab

   The Windows **Open** dialog opens.

3. Select the **File Name** of the archive file (file extension `.stz`) you want to open.

   Tip: Click the **[...]** button to navigate to the folder where the archive is saved.
4. Select the **Location** where you want to store the extracted project files.
5. Click **Open**.

You can work with the STAAD input file and associated files within the archive as you normally would. Select **File** > **Close** to close the archive when you are finished.
Related Links
- *GS. Start Page* (on page 54)

I. To extract an archive

To extract the files within an archive, use the following procedure.

You cannot extract an archive when a STAAD input file is open in the program.

1. Select the **Archive** tab on the Start page.
2. Select **Create**.

3. Select the **File Name** of the archive file you want to extract.
   Click **Browse** to navigate to the file using a Windows open dialog.
4. (Optional) Select a **Location** to where you want the files within the archive extracted.
   The default location is the same folder containing the archive file.
5. (Optional) Select the files in the archive you want to extract.
   All files are selected by default.
6. Click **Extract**.

Bentley CONNECT Features

ProjectWise Project Association

STAAD.Pro CONNECT Edition allows you associate a file with a ProjectWise Project.

A ProjectWise Project is a single definition of a project for your entire organization and represents a one-to-one relationship with the contracted work being done by your organization.

Note: In order to utilize this feature in STAAD.Pro, you must:

1. Have the Bentley CONNECTION Client running. The CONNECTION Client is typically installed with STAAD.Pro.

2. Register with Bentley Cloud Services.
3. Sign in using your credentials with the CONNECTION Client.

For additional details on the benefits of using ProjectWise Projects, please visit https://www.bentley.com/connect/.

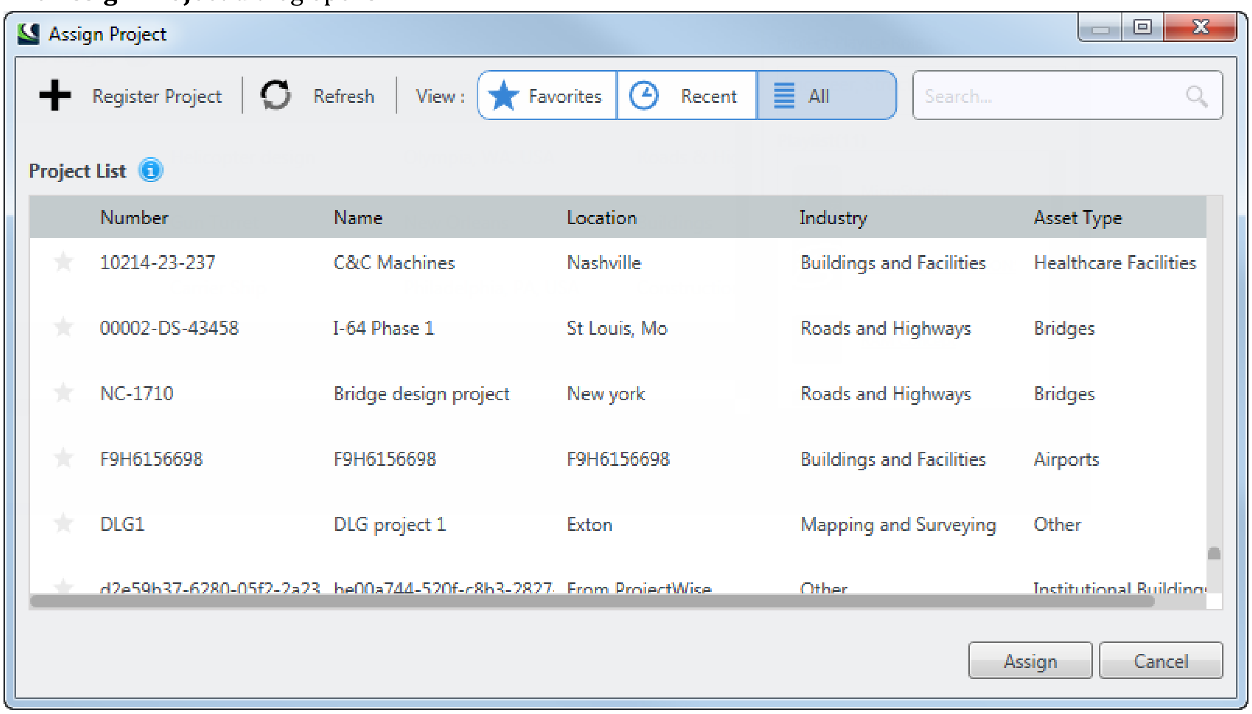
To Associate a ProjectWise Project with Your File

When you create a new file or open an existing file which is not associated with a project, use the following procedure to associate your file with a ProjectWise Project.

Note: You must be signed in using the CONNECTION Client to associate a ProjectWise Project with your file.

Tip: If you want to change the ProjectWise Project associated with your file, use the same following procedure.

1. On the **File** ribbon tab, select, **Cloud Services** > **Associate Project**
   The **Assign Project** dialog opens.



2. (Optional) If you want to register a new project, do the following:
   a. Click **Register Project**.

      The **Register a Project** page opens in your browser.

      Note: Only users with Admin/Co-admin roles can register a project.

   b. Type or select the required items (marked with an asterisk, "*")

   c. Click **Save**.
   A list of registered projects within your organization opens. The newly created project is highlighted in green.

   See Register a ProjectWise Project (on page 2072).

   > **Tip:** Alternately, you can visit connect.bentley.com and select **+New** on the **Recent Projects** tile on your personal dashboard.

3. Select the desired project from the list.

   > **Tip:** Use the View controls and Search tool to locate your project. If your project is not in the list, you can add a project following the steps given in Register a ProjectWise Project (on page 2072).

4. Click **Assign**.

Related Links

- *Assign Project dialog* (on page 2070)

To Disassociate a ProjectWise Project from a File

If you need to disassociate a file from a ProjectWise Project, select **Cloud Services** > **Disassociate Project** on the backstage view.

The project association is removed from the file.

> **Tip:** If you want to change the ProjectWise Project association to another ProjectWise Project, this procedure is *not* necessary.

Register a ProjectWise Project

Organizations can enable CONNECTED Users to register and collaborate on ProjectWise Projects. These projects contain project information such as Project Name, Asset Industry, Asset Type, Location etc. While creating a file in a CONNECT Edition product, you can associate it to a ProjectWise Project where the project information is included in the data files as properties.

Note: Project files, such as DGN files and library files are not stored on the cloud. They can be stored locally, on a network, or in ProjectWise.

What is the ProjectWise Project Registration Utility?

The Project Registration utility is an administrative interface for registering an Organization's projects with Bentley. Registered projects are referred to as ProjectWise Projects. ProjectWise Projects provide information regarding the project themselves, as well as serving as a focal point for tying together other sources of project information.

For example, user and product usage for reporting and access to services available for each project.

Who can register a ProjectWise Project?

To register a ProjectWise Project, a user must have Administrator or Co-administrator privileges associated with their Bentley account. These privileges are required because registered ProjectWise Projects are Organization-wide resources that represent real-world projects and are used in many different locations for information organization and reporting. Therefore, access is limited to those members of an Organization with sufficient privileges to ensure that only recognized and permitted ProjectWise Projects be registered on behalf of an Organization.

Note: Users within the organization who were not designated as an Administrator or Co-Administrator who are requesting rights should contact their organizations Administrator. Bentley does *not* fulfill these requests.

To Register a ProjectWise Project

The Project Registration utility is used to provide information about a project as well as manage previously registered projects.

Note: Only users with Admin/Co-admin roles can register a project.

1. You can register a project from either the application or from the personal portal:

To use…	do this…
the personal portal	select **Bentley Cloud Services** > **CONNECTION Center** and then click the **+** (plus) at the top of the **ProjectWise Projects** panel.
STAAD.Pro	select **Bentley Could Services** > **Associate Project** and then click **+ Register Project** in the **Assign Project** dialog.

The **CONNECTION Center** page opens in your browser.

2. Fill out the form as needed. Required fields are marked with an asterisk ("*").

Project Number *	The unique project code or ID number that is officially used in your organization for internal tracking purposes. For example, `DMO-063 VP 778`.
Project Name *	The common name for the project within your organization. For example, `I-565 Interchange at County Line Road`.
Asset *	
Industry *	The asset industry this project belongs to. An asset industry is a group of like organizations with a common business function centered on a like set of infrastructure assets. For example, Electric Utility.
Type *	The type of asset this project will focus on. An asset type is a set of related assets. For example, the Asset Class Electric Network is comprised of the following assets: Distribution Network, Substation, and Transmission Network.
Use Location	Displays a **Location** field, where you can enter the name of the project location. For example, city/state/country.
Use Latitude/ Longitude	Displays the **Latitude** and **Longitude** fields, where you can enter the specific coordinates of where the project is located.
Engineering Location	
Time Zone	The time zone of the project location.
Billing Country *	
Status	The state of the project. **Active** means the project is open for participation. **Inactive** means the project is closed for participation.
Allow External Team Members	Allows the invitation process to include team members from external organizations.

3. Click **Save**.
A list of registered projects within your organization opens. The newly created project is highlighted in green.

Automated Updates via the CONNECTION Client

You will be notified of updates to STAAD.Pro automatically in the Bentley CONNECTION Client application.

This application is installed with STAAD.Pro CONNECT Edition and runs in the Windows system tray. You can manually check for updates by opening the CONNECTION Client and selecting the **Applications** tab.

Subscription Entitlement Service

Subscription Entitlement Service is Bentley's process for product activation and usage tracking, improving our licensing capabilities with features such as:

- License alert notifications when you are approaching a custom usage threshold
- Replacing site activation keys with user validation, enhancing security around your Bentley licenses and subscriptions

With traditional SELECT Licensing, product activation has been through an activation key that an Organization distributed to all users. With Subscription Entitlement Service, product activation is managed by user sign in through the CONNECTION Client, which is installed on each machine that uses Bentley applications. This offers a more secure and manageable system as it offers usage alerts, notifying your users when they are about to reach a certain usage limit set by the Administrator.

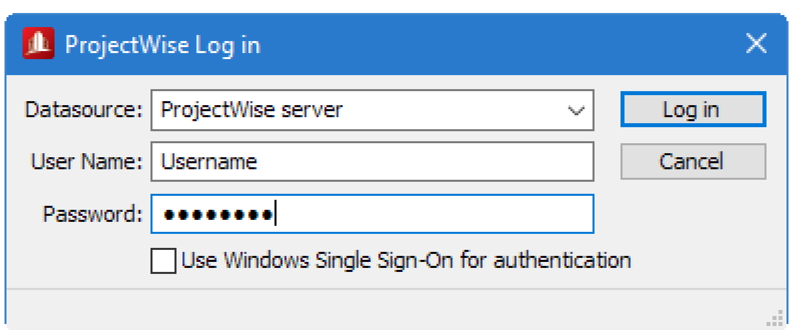
I. Using ProjectWise in STAAD.Pro

ProjectWise is an engineering project team collaboration system which is used to help teams improve quality, reduce rework, and meet project deadlines. One of the major pieces of functionality provided by ProjectWise is an Integration Server which allows data to be managed and shared across a distributed enterprise.

Note: This functionality requires that only *one* version ProjectWise be installed. It is *strongly* recommend that you use version 10.00.03.434 of the ProjectWise Design Integration client on the computer running STAAD.Pro. For more details on ProjectWise refer to the ProjectWise Design Integration client installation documentation. Refer to the ProjectWise Version Support Matrix for additional details.

Login

As authentication is required to access files stored on a ProjectWise repository, a login dialog allows the required details to be entered either with specific user credentials or by using the current windows login credentials.



Files that are accessed from a ProjectWise server are “Checked Out” and stored locally during the STAAD.Pro session until the file is closed and then it is returned to the server.

I. To open a STAAD input file from a ProjectWise repository

Note: Your most recent STAAD input files within PW repositories will be listed on the **ProjectWise** tab of the recent files list. You can click to select any of those files to open them.

1. On the STAAD.Pro Start page, select **Open** and then **ProjectWise**.
   You will be prompted to connect to a datasource if you have not already done so.

   The first time that a successful link to a ProjectWise server is established, a location in which checked out files are to be stored locally and additionally, where all the auxiliary data files are stored while STAAD is running, is required. Afterwards and on all future occasions, the ProjectWise open dialog presented is then presented where the repository can be navigated and filtered as defined in the ProjectWise documentation.
2. Navigate to and select the STAAD input file you want to check out and open.

   Note: The icons next to the STAAD filenames indicate the status of the file such as the current document, checked out to you, or locked as checked out to another user. Refer to the ProjectWise documentation for a full description of each icon.
3. Click **Open**.
   The STAAD input file is checked out and opened in STAAD.Pro.

Related Links

- *GS. Start Page* (on page 54)

I. To check in a STAAD input file to a ProjectWise repository

1. Either:

   Select the **File** ribbon tab and then select **Close** from the Backstage view menu.

   or

   Select the **Close** tool in the Quick Access toolbar.

   The **Check In** dialog opens.
2. (Optional) To increment the version of the file in the repository:
   a. Check the **Create new version during Check In** option.
   b. Type a **Version** label.

   If you choose to increment the option, you will not be able to only send updates or free the file. You must then Check In this version.
3. (Optional) To add a comment to the repository file, select the **Comment** tab and type your comment in the field.
4. Select the action you want to take with changes made to the file:

To...	Select...
Check in changes made to the file since it was checked out	Check In
Update the server copy with changes made since the file was last checked out, but keep the file checked out	Update Server Copy
Undo the check out and prevent any changes from being made to the server copy	Free

I. To share a STAAD.Pro project in ProjectWise

To share your STAAD.Pro input files and selected files associated with that project to a ProjectWise datasource, use the following procedure.

You cannot share a project when a STAAD input file is open in the program.

Shared files are saved as STAAD.Pro Archive files (file extension .stz).

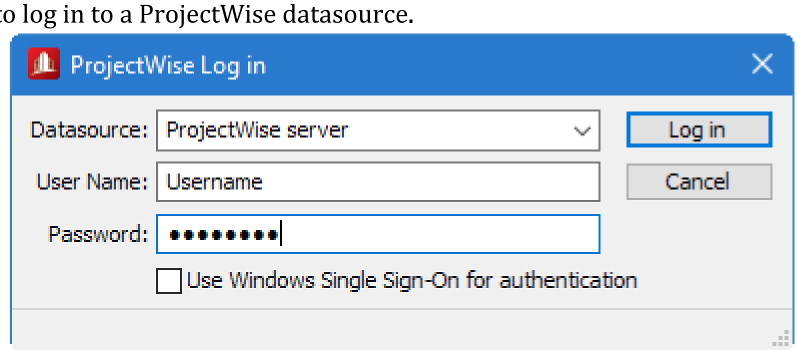
1. Select the **Share** page on the Start page.
2. Select **ProjectWise**.

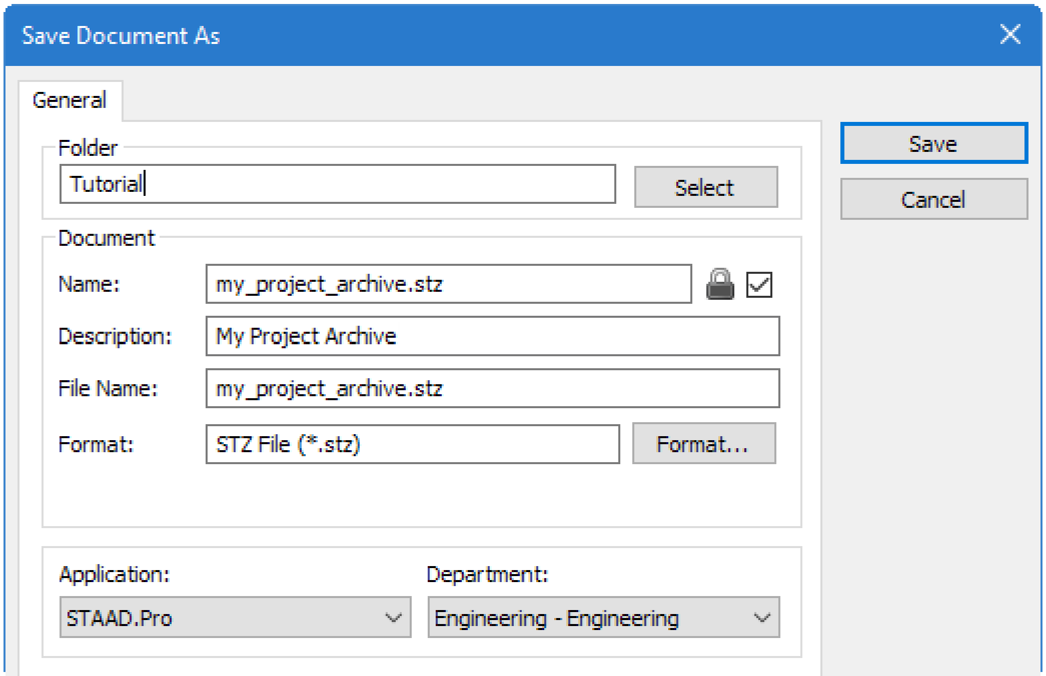
3. Select the **File Name** of the STAAD input file you want to share.

   Click **Browse** to navigate to the file using a Windows open dialog.
4. (Optional) Select the files associated with the input file you want included in the archive.

   All files are selected by default.
5. Click **Add**.
   You are prompted to log in to a ProjectWise datasource.

6. Select your **Datasource** and then click **Log in**.
   The **Save Document As** dialog opens.



Note: Depending on your ProjectWise Explorer configuration, you may further be prompted to select a Wizard for document creation. Please refer to the ProjectWise Explorer Help for further information on this feature.

7. Select a **Folder** in your ProjectWise datasource and provide any optional **Document** data.
8. Click **Save**.
   The **Add comment** dialog opens.
9. Type a descriptive comment for the and click **Add**.

Your project archive is now saved to your ProjectWise datasource.

You can open this archive file from the **Open** > **ProjectWise** tab in the **Start** page.

I. Importing Models

I. To import a DXF file

To import an AutoCAD® DXF™ drawing to use for model geometry, use the following procedure.

The following table maps the imported DXF objects to model entities.

DXF Object	STAAD Model Entity
line	member
3Dline	member
3Dface	plate
AcDbLine	member
AcDb3Dpolyline	one or more members
AcDbFace	finite element plates

You must have a model file already open to import data.

1. Select the **File** ribbon tab.
   The backstage view opens.
2. Select the **Import/Export** tab and then **DXF** in the **Import** group.
   A Windows **Open** dialog opens.
3. Select the DXF file you want to import and then click **Open**.
   The DXF Import dialog opens. This dialog is used to specify the vertical axis for data imported from a DXF file into a STAAD input file.
4. Select the **Structure Convention** to use.

   No Change - Use the vertical axis as defined in the 3D DXF file

   or

   Y Up - Adds a `SET Y UP` command to the STAAD input file.

   or

   Z Up - Adds a `SET Z UP` command to the STAAD input file.
5. Click **OK**.
   The DXF data is imported. The drawing objects are mapped to members and plates.

I. To import a CIS/2 file

To import a CIS/2 STEP file, use the following procedure.

The initial structural model will be created in your external 3D modeling software and exported as a CIS/2 STEP file, consisting of both analytical and physical model definitions. Limited load modeling can be done in some modeling software –such as SmartPlant® 3D– before the initial export.

The CIS/2 (CimSteel Integration Standard, Version 2) allows for the transfer of models using a prescribed data standard in the STEP (Part 21) format. There are various types of CIS/2 files. STAAD.Pro can import data from those types known as analysis models.

Note: If you are importing into an empty STAAD input file, then you will be creating a new file. Otherwise, the program assumes you are updating an existing file with changes in a CIS/2 file.

The following data can be imported through the CIS/2 format:

- Member properties
- Material constants (E, Density, Poisson, etc.) of steel profile sections
- Member orientation (Beta angles, Reference points)
- Member end conditions like Releases
- Support conditions
- Loading information

1. Select the **File** ribbon tab.
   The backstage view opens.
2. Select the **Import/Export** tab and then **CIS/2** in the **Import** group.
   A Windows **Open** dialog opens.
3. Select the CIS/2 (*.stp) file you want to import and then click **Open**.
   The Cis2Link dialog opens.
4. Either:

   for new models, click **Import Model**

   or

   for models with existing data, click **Update STAAD Model**

   The data is read and the import progress is reported in the log window.
5. (Optional) Click **Save Log File** to save this information to a text file.
6. Click **Close**.

The model data has been imported into your STAAD project.

If you need to update your STAAD.Pro model with changes made to the CIS/2 file, repeat this procedure.

I. Exporting Models

I. To export to a DXF file

To export the model geometry to an AutoCAD DXF file, use the following procedure.

The following table maps the exported model entities to DXF objects.

STAAD Model Entity	DXF Object
member	line
element or surface	3Dface
solid	3Dface (multiple)

1. Select the **File** ribbon tab.
   The backstage view opens.
2. Select the **Import/Export** tab and then one of the following in the **Export** group:

Option	Description
3D DXF	Exports the entire model into a 3D DXF file. A Windows **Save As** dialog opens.
2D DXF	Exports a selected plane of the model into a 2D DXF file. This option opens the **Export 2D DXF** dialog.

3. If you select the 2D DXF option, you must specify the plane of the model:
   a. Select the global plane orientation to you want to use for the two dimensions.
   b. Select the node to define where this plane is cut in the model.
   c. Select the Options tab and then check the labels to include, if any, in the DXF drawing.
   d. Type a Text Size to use for the labels.
   e. Click **OK**.

   A Windows **Save As** dialog opens.
4. Type the name of the exported file and then click **Save**.

The model geometry is exported as a drawing file.

I. To export to a CIS/2 file

To export the model geometry to a CIS/2 STEP file, use the following procedure.

1. Select the **File** ribbon tab.
   The backstage view opens.
2. Select **CIS/2** in the **Import/Export** tab.
   A Windows **Save As** dialog opens.
3. Specify the file name and location and the click **Save**.
   The **Cis2Link** dialog opens.
4. Click **Export Model**.
   The data export progress is displayed in the log window.
5. (Optional) Click **Save Log File** to save this information to a text file.
6. Click **Close**.

I. To export structure date to AutoPipe

To export support frame data to a `.NTL` file for use in AutoPipe, use the following procedure.

A piping engineer who needs to consider the steelwork as their structural supports may need to import the STAAD.Pro model into AutoPipe. A macro called `ToAutoPipePub.vbs` is available in STAAD.Pro is used to facilitate this.

1. On the **Utilities** ribbon tab, select the **User Tools Export Model to AutoPipe** tool in the **Developer** group.

   

   The **Export STAAD Model to AutoPipe** dialog opens.
2. Type a file path and file name for the **AutoPipe Model file** (file extension `.ntl`) to which you want to export the STAAD.Pro support frame data.

> **Tip:** Click **[...]** to open a Windows **Save As** dialog.

3. Click **OK**.

I. To export to a SACS input file

To export the current STAAD.Pro model to a SACS input file, use the following procedure.

You must have an input file open in STAAD.Pro.

SACS is an offshore structural analysis and design software package offered by Bentley Systems, Inc.

1. On the **Utilities** ribbon tab, select the **User Tools Export Model to SACS** tool in the **Developer** group.

   

   The **Export STAAD Model to SACS** dialog opens.
2. Type a file path and file name for the **SACS Model file** (file extension `.inp`) to which you want to export the STAAD.Pro model data.

   > **Tip:** Click **[...]** to open a Windows **Save As** dialog.
3. Click **OK**.

I. Command Line Support

You can process STAAD.Pro input files using the STAAD analysis and design engine via the Windows command line. Using this method, you can run the analysis and design engine without opening the user interface at all.

> **Tip:** It is recommended to use a batch file with the necessary commands in it in order to simplify processing and reduce the need to repeatedly type commands. You can even use the Scheduled Tasks utility in Windows to automatically run these files for you on a schedule.

I. Command Line Syntax

The following format is used when running STAAD.Pro from the command line interface.

Syntax

```
<path>\SProStaad\SProStaad.exe STAAD <input_file> [Options]
```

where:

<path>	the installation path for STAAD.Pro, which is `C:\Program Files\Bentley\Engineering\STAAD.Pro CONNECT Edition\ STAAD\` by default.

> **Tip:** You can add "`C:\Program Files\Bentley\Engineering\STAAD.Pro CONNECT Edition\`

STAAD\SProStaad\ ” to your Windows PATH environment variale to simply use the command SProStaad.

<input_file> the name of the STAAD input file you want to use as input.

Note: If the input file name includes spaces, you must use quote characters (") around the file name.

Expressions in square brackets (between '[' and ']') are optional, and can take one of the following values if used:

/s Run silently and auto close at the end of run

/h Run silently and hidden

Example

The following is a simple example which can be run from a directory containing `Example.std`.

```
C:\Program Files\Bentley\Engineering\STAAD.Pro CONNECT Edition\STAAD\SProStaad
\SProStaad.exe STAAD Example.std /s
```

When the analysis and design engine is complete, it will close as a result of using the 'silent' option. Otherwise, this window must be manually closed.

Batch File Example

The following can be saved as a batch file (`.bat`) in any text editor. This batch file will analyze and design all the US examples which ship with the product by making use of a FOR command that loops through all STAAD input files beginning with the string “Examp”.

```
::Create a new variable with the location of the SProStaad.exe file
SET SProInst="C:\Program Files\Bentley\Engineering\STAAD.Pro CONNECT Edition
\STAAD\SProStaad"
::Add this to the system path variable for this session
SET PATH="%PATH%";%SProInst%
::Create a variable to the default location of the STAAD US Example files
SET USExamps="%PUBLIC%\Documents\STAAD.Pro CONNECT Edition\Sample Models\US"

FOR %%f IN (%USExamps%\Examp*.std) DO (
    ECHO %%~nf
    SProStaad.exe STAAD "%%~nf.std" /h
)

EXIT /B
```

No additional windows will open while the analysis and design engine runs as a result of using the “hidden” option.

Note: The use of the variables *SProInst* and *USExamps* are *not* necessary. They are only used to highlight that if your installation folders differ from the default, this should be changed accordingly.

I. Copy/Paste from Spreadsheets

The Copy/Paste facility in input tables in STAAD.Pro allows different column sizes and configuration to be copied from an external spreadsheet file and then pasted into STAAD.Pro.

On any STAAD.Pro input grid table capable of handling manual input, rows and columns copied from a spreadsheet can be directly pasted into STAAD.Pro. If the columns in the spreadsheet do not match the column headers in a STAAD.Pro grid table, STAAD.Pro will ask to assign the columns in the spreadsheet to the appropriate columns in the STAAD.Pro grid table. In the figure shown below, a sample spreadsheet file containing the coordinates of some nodes is displayed. A selection of the spreadsheet's cells have been copied to the system clipboard.

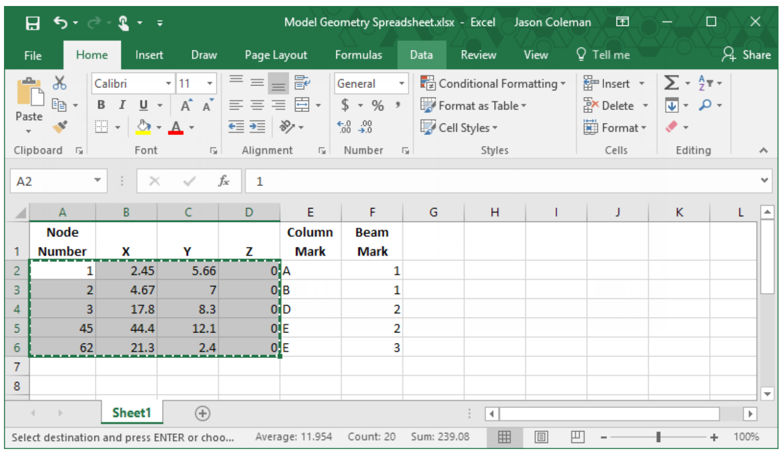

Figure 207: Example spreadsheet data

This data is then selected and attempted to be copied into the STAAD.Pro Nodes table shown in the next figure.

Tip: The entire row in the STAAD table should be selected before pasting the data. The paste function will *not* be active if only one cell is selected.

The number of columns in the first figure does not match the number of columns in the second figure. In this case, the **Select Column Mapping** dialog opens when attempting to paste the spreadsheet data.

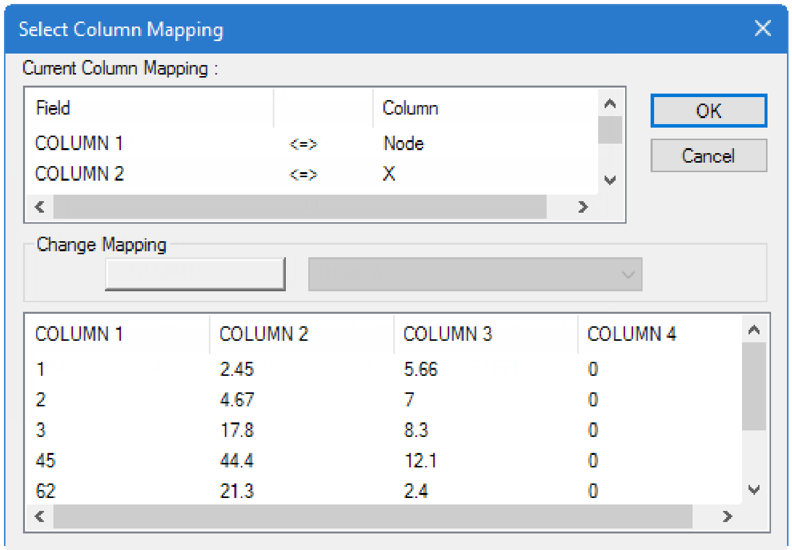

Figure 208: Select Column Mapping dialog box

The upper list box displays the current mapping between the spreadsheet (the **Field** column) and the STAAD.Pro table (the **Column** column). By clicking on a particular **Field**, the mapping between the spreadsheet and the STAAD.Pro table can be changed under the **Change Mapping** list box. The options listed under the **Change Mapping** list box are the available columns in the STAAD.Pro table. If a particular column coming from the spreadsheet is not relevant for the STAAD.Pro table, simply choose the option **Not Mapped** under the **Change Mapping** list box.

Tip: While the **Select Column Mapping** dialog is open, the system's ability to paste from the clipboard may be interrupted. Closing this dialog (either by clicking **OK** or **Cancel**) will restore normal clipboard functionality.

9

General Engineering Theory

This section serves to familiarize you with the basic principles involved in the implementation of the various analysis and design facilities offered by the STAAD.Pro engine. As a general rule, the sequence in which the facilities are discussed follows the recommended sequence of their usage in the STAAD input file.

G.1 Input Generation

The STAAD input file can be created through the graphical user interface (GUI) modeling facility or using the STAAD.Pro Editor. The graphical modeling facility creates the input file through an interactive, graphics oriented procedure. In general, any plain-text editor may be utilized to edit or create the STAAD input file, but the STAAD.Pro Editor is recommended.

Note: Some of the automatic generation facilities of the STAAD command language will be reinterpreted by the GUI as lists of individual model elements upon editing the file using the GUI. A warning message is presented prior to this occurring. This does not result in any effective difference in the model or how it is analyzed or designed.

It is important to understand that STAAD.Pro is capable of analyzing a wide range of structures. While some parametric input features are available in the GUI, the formulation of input is the responsibility of you, the user. The program has no means of verifying that the structure input is that which was intended by the engineer.

G.2 Types of Structures

A `STRUCTURE` can be defined as an assemblage of elements. STAAD.Pro is capable of analyzing and designing structures consisting of frame, plate/shell, and solid elements. Almost any type of structure can be analyzed by STAAD.Pro.

SPACE A3D framed structure with loads applied in any plane. This structure type is the most general.

PLANE This structure type is bound by a global X-Y coordinate system with loads in the same plane.

TRUSS This structure type consists of truss members which can have only axial member forces and no bending in the members.

FLOOR A 2D or 3D structure having no horizontal (global X or Z) movement of the structure [FX, FZ, and MY are restrained at every joint]. The floor framing (in global X-Z plane) of a building is an ideal example of a this type of structure. Columns can also be modeled with the floor in a `FLOOR` structure as long as the structure has no horizontal loading. If there is any horizontal load, it must be analyzed as a `SPACE` structure.

Specification of the correct structure type reduces the number of equations to be solved during the analysis. This results in a faster and more economic solution for the user. The degrees of freedom associated with frame elements of different types of structures is illustrated in the following figure.

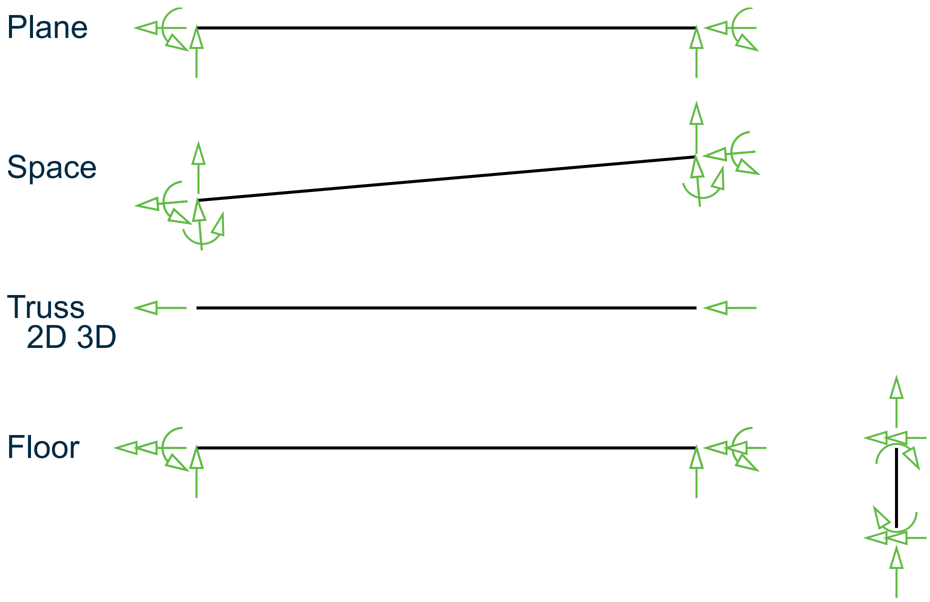

Figure 209: Degrees of freedom in each type of Structure

Related Links

- *TR.2 Problem Initiation and Model Title* (on page 2202)

G.3 Unit Systems

You are allowed to input data and request output in almost all commonly used engineering unit systems including “meter - kilonewton - second” (MKS), International System of Units (SI), and “feet - pound - second” (FPS). In the input file, you may change units as many times as required. Mixing and matching between length and force units from different unit systems is also allowed.

The input unit for angles (or rotations) is degrees. However, in `JOINT DISPLACEMENT` output, the rotations are provided in radians.

For all output, the units are clearly specified by the program.

Related Links

- *TR.3 Unit Specification* (on page 2203)

G.4 Coordinate Systems and Structure Geometry

A structure is an assembly of individual components such as beams, columns, slabs, plates etc.. In STAAD.Pro, frame elements and plate elements may be used to model the structural components. Typically, modeling of the structure geometry consists of two steps:

A. Identification and description of joints or nodes.

B. Modeling of members or elements through specification of connectivity (incidences) between joints.

In general, the term MEMBER will be used to refer to frame elements and the term ELEMENT will be used to refer to plate/shell and solid elements. Connectivity for MEMBERs may be provided through the MEMBER INCIDENCE command while connectivity for ELEMENTs may be provided through the ELEMENT INCIDENCE command.

STAAD.Pro uses two types of coordinate systems to define the structure geometry and loading patterns. The GLOBAL coordinate system is an arbitrary coordinate system in space which is utilized to specify the overall geometry & loading pattern of the structure. A LOCAL coordinate system is associated with each member (or element) and is utilized in MEMBER END FORCE output or local load specification.

G.4.1 Global Coordinate System

The following coordinate systems are available for specification of the structure geometry.

Note: The following figures depict the global coordinates with Y as vertical. The coordinate systems follow the similar right-hand rule when Z is vertical. Refer to SET { Y | Z } UP (on page 2210) for additional details.

Conventional Cartesian Coordinate System

This coordinate system is a rectangular coordinate system (X, Y, Z) which follows the orthogonal right hand rule. This coordinate system may be used to define the joint locations and loading directions.

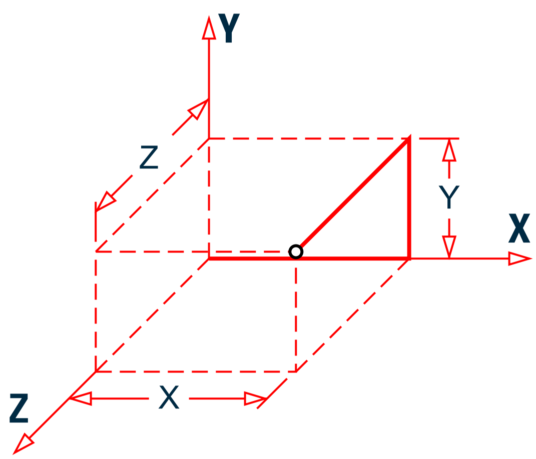

Figure 210: Cartesian (Rectangular) Coordinate System

Cylindrical Coordinate System

In this coordinate system, the X and Y coordinates of the conventional Cartesian system are replaced by R (radius) and Ø (angle in degrees). The Z coordinate is identical to the Z coordinate of the Cartesian system and its positive direction is determined by the right hand rule.

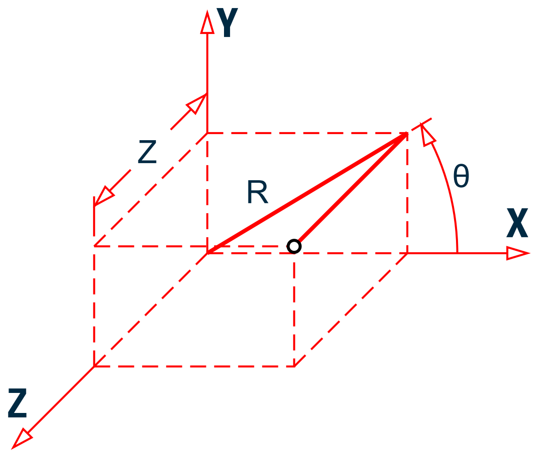

Figure 211: Cylindrical Coordinate System

Reverse Cylindrical Coordinate System

This is a cylindrical type coordinate system where the R- Ø plane corresponds to the X-Z plane of the Cartesian system. The right hand rule is followed to determine the positive direction of the Y axis.

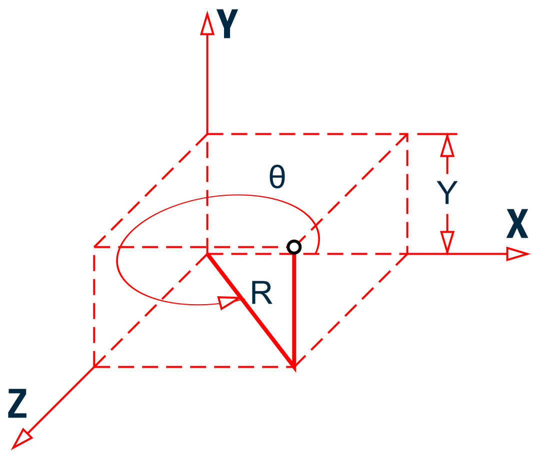

Figure 212: Reverse Cylindrical Coordinate System

G.4.2 Local Coordinate System

A local coordinate system is associated with each member. Each axis of the local orthogonal coordinate system is also based on the right hand rule.

The following figures show a beam member with start joint 'i' and end joint 'j'. The positive direction of the local x-axis is determined by joining 'i' to 'j' and projecting it in the same direction. The right hand rule may be applied to obtain the positive directions of the local y and z axes. The local y and z-axes coincide with the axes of the two principal moments of inertia. Note that the local coordinate system is always rectangular.

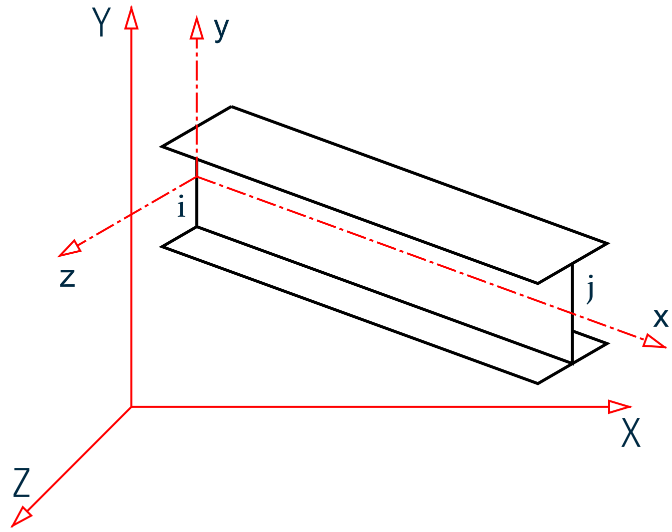

Figure 213: When Global-Y is Vertical

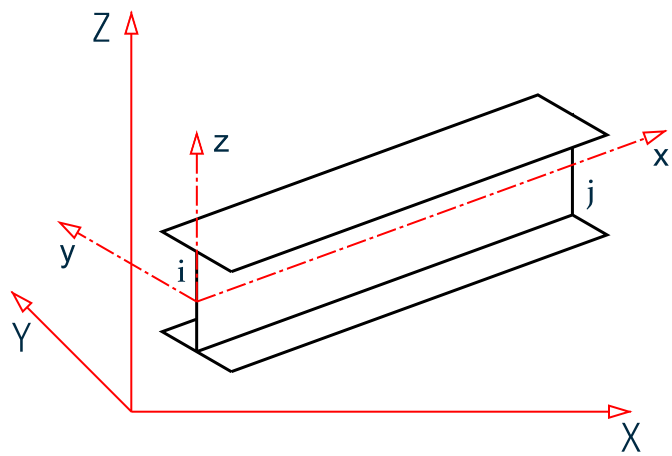

Figure 214: When Global-Z is Vertical (that is, SET Z UP is specified)

A wide range of cross-sectional shapes may be specified for analysis. These include rolled steel shapes, user-specified prismatic shapes etc.. The following table shows local axis system(s) for these shapes.

Table 222: Local axis system for various cross sections when global Y axis is vertical

 Wide Flange - ST	 Wide Flange - TB	 Wide Flange - CM
 Angle - ST	 Angle - RA	 Angle - LD (Long legs back-to-back)
 Angle - SD (Short legs back-to-back)	 Wide Flange - T	 Channel - ST
 Channel - D	 Prismatic	 Tube - ST

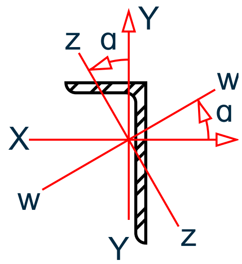

Figure 215: Labels for the local axes of a single angle as defined in AISC publications.

Table 223: Local axis system for various cross sections when global Z axis is vertical (SET Z UP is specified).

G.4.3 Relationship Between Global and Local Coordinates

Since the input for member loads can be provided in the local and global coordinate system and the output for member-end-forces is printed in the local coordinate system, it is important to know the relationship between the local and global coordinate systems. This relationship is defined by an angle measured in the following specified way. This angle will be defined as the beta (β) angle. For offset members the beta angle/reference point specifications are based on the offset position of the local axis, not the joint positions.

Beta Angle

When the local x-axis is parallel to the global Vertical axis, as in the case of a column in a structure, the beta angle is the angle through which the local z-axis (or local Y for `SET Z UP`) has been rotated about the local x-axis from a position of being parallel and in the same positive direction of the global Z-axis (global Y axis for `SET Z UP`).

When the local x-axis is not parallel to the global Vertical axis, the beta angle is the angle through which the local coordinate system has been rotated about the local x-axis from a position of having the local z-axis (or local Y for `SET Z UP`) parallel to the global X-Z plane (or global X-Y plane for `SET Z UP`)and the local y-axis (or local z for `SET Z UP`) in the same positive direction as the global vertical axis. Figure 1.7 details the positions for beta equals 0 degrees or 90 degrees. When providing member loads in the local member axis, it is helpful to refer to this figure for a quick determination of the local axis system.

Reference Point

An alternative to providing the member orientation is to input the coordinates (or a joint number) which will be a reference point located in the member x-y plane (x-z plane for `SET Z UP`) but not on the axis of the member. From the location of the reference point, the program automatically calculates the orientation of the member x-y plane (x-z plane for `SET Z UP`).

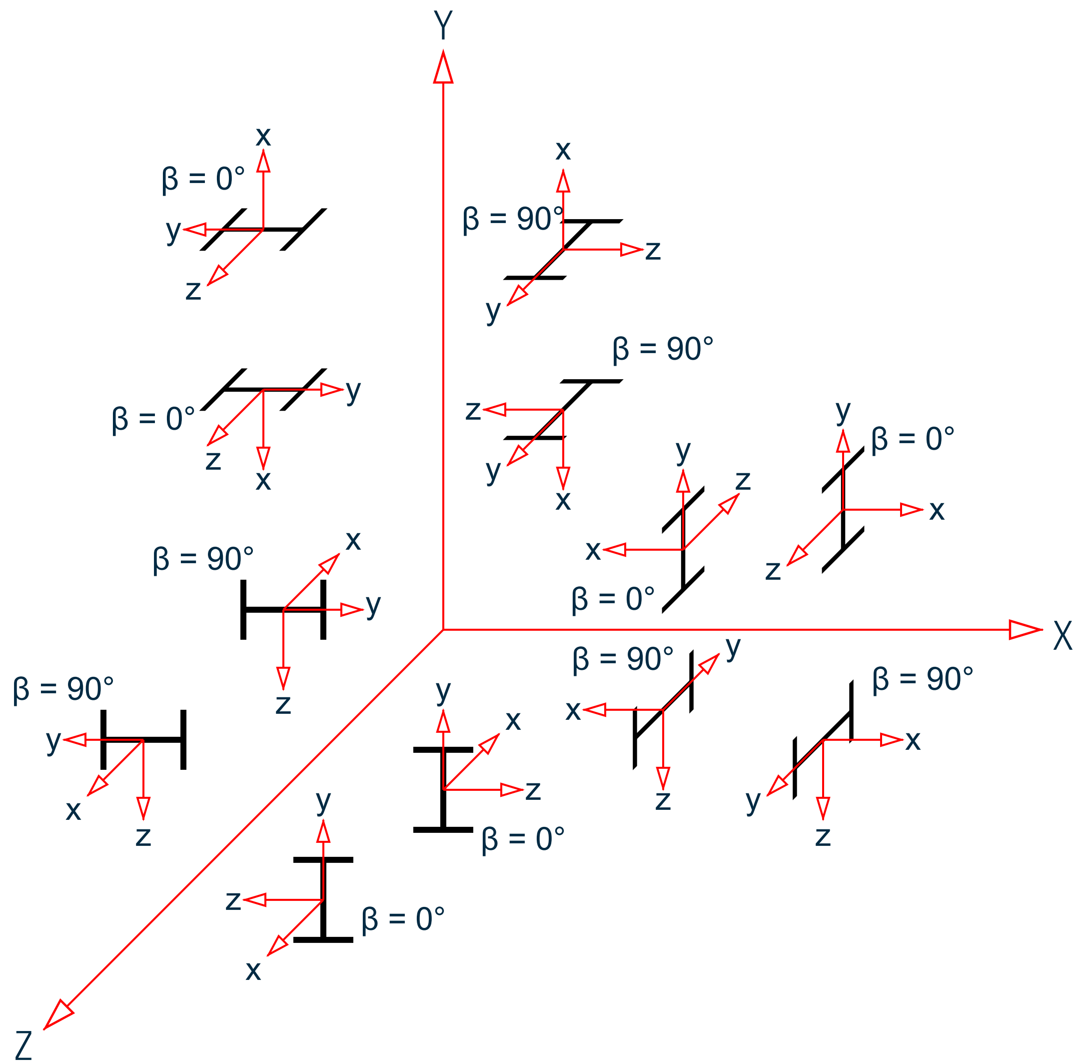

Figure 216: Relationship between Global and Local axes

Reference Vector

This is yet another way to specify the member orientation. In the reference point method described above, the X,Y,Z coordinates of the point are in the global axis system. In a reference vector, the X,Y,Z coordinates are specified with respect to the local axis system of the member corresponding to the BETA 0 condition.

A direction vector is created by the program. The program then calculates the Beta Angle using this vector.

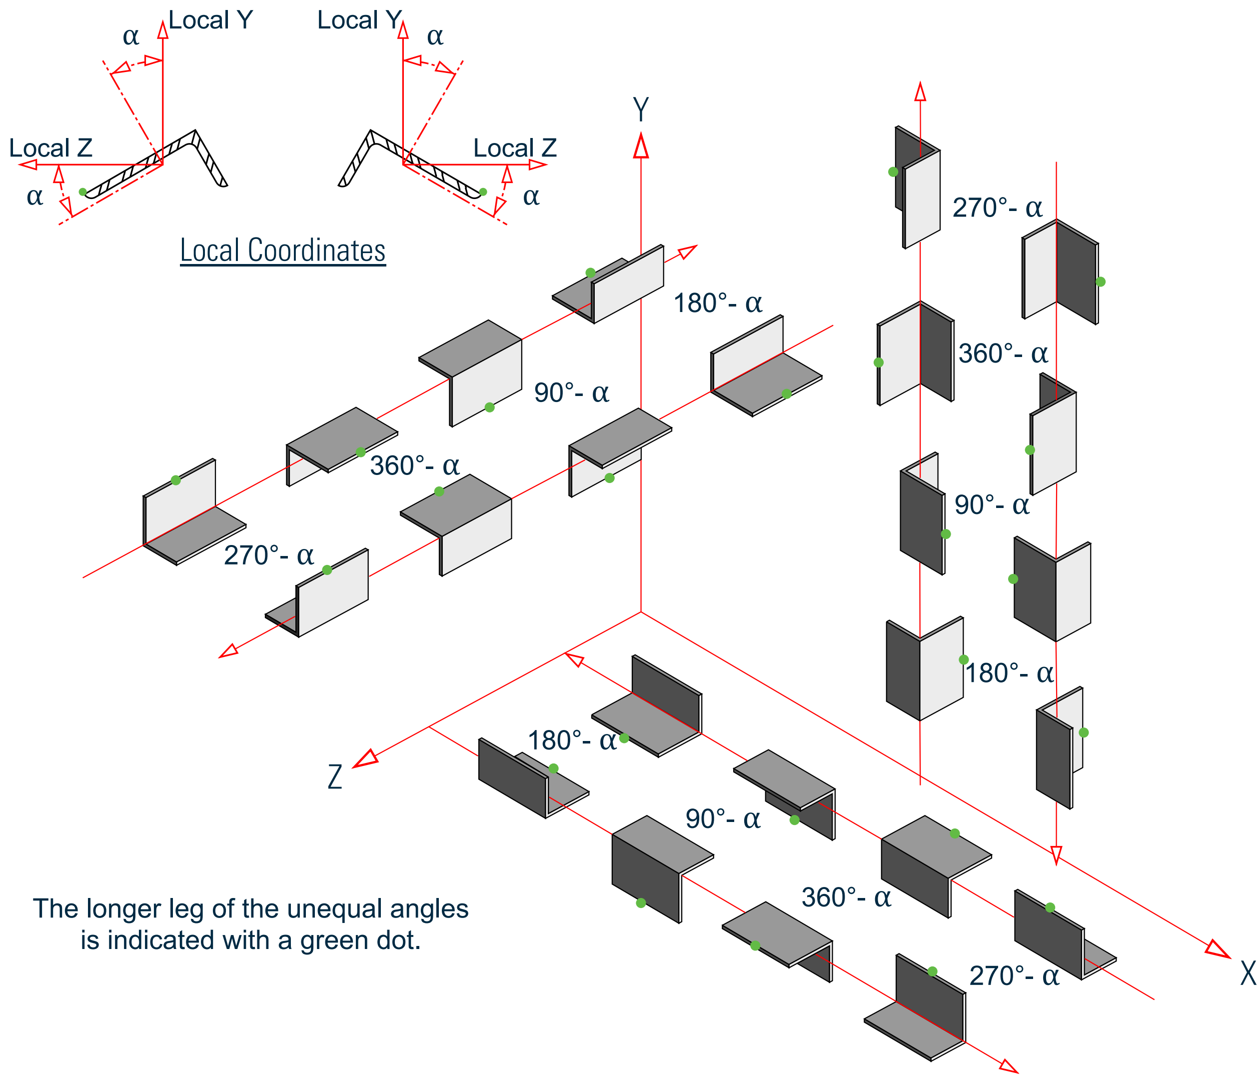

Figure 217: Beta rotation of equal & unequal legged 'ST' angles

Note: The order of the joint numbers in the `MEMBER INCIDENCES` command determines the direction of the member's local x-axis.

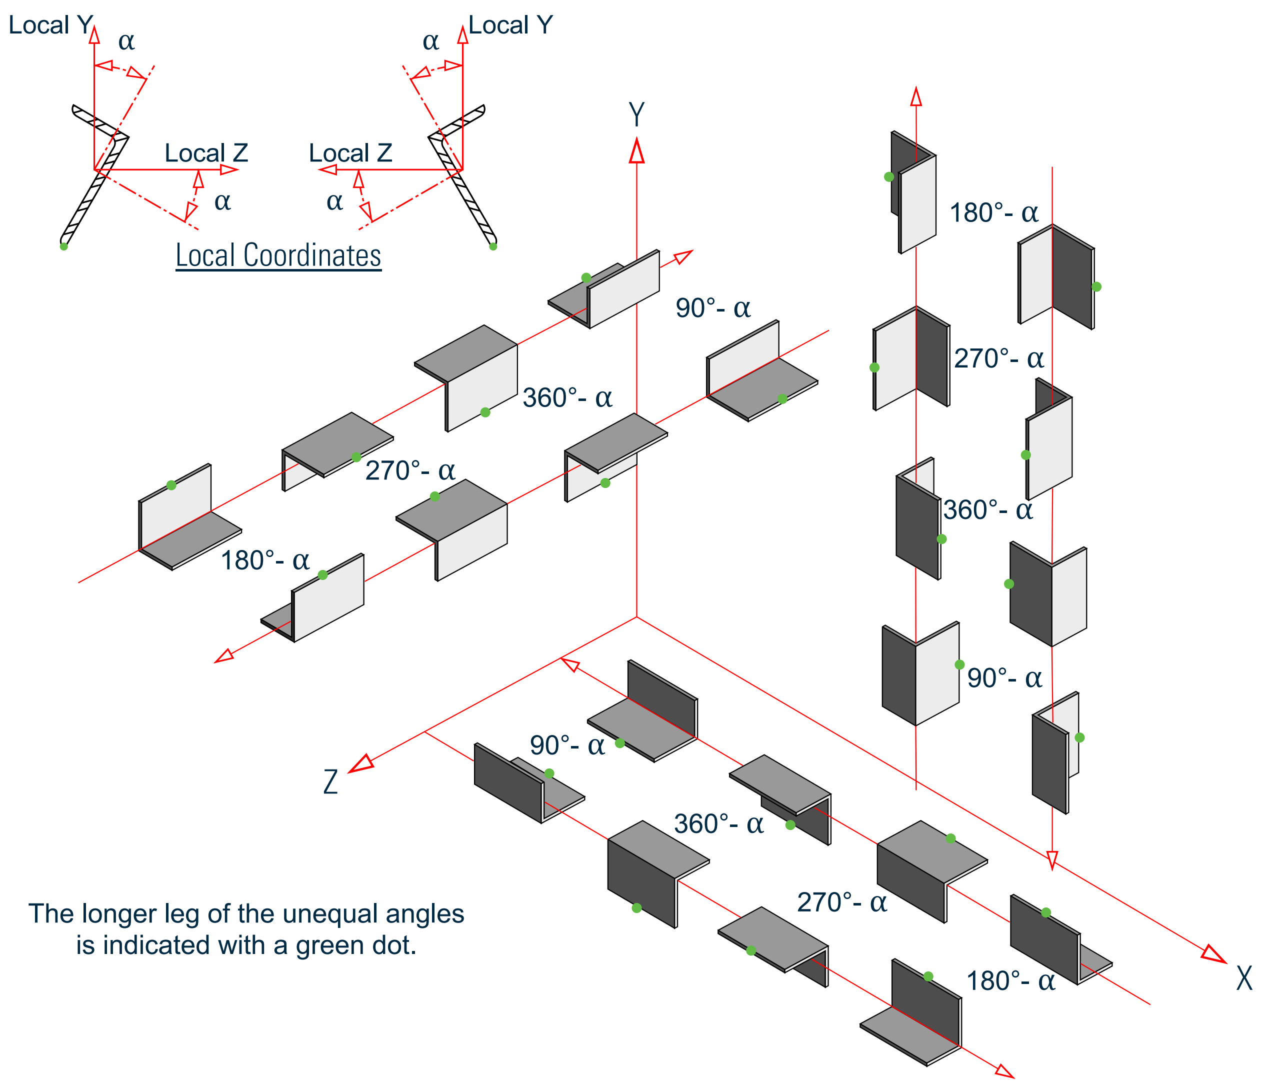

Figure 218: Beta rotation of equal & unequal legged 'RA' angles

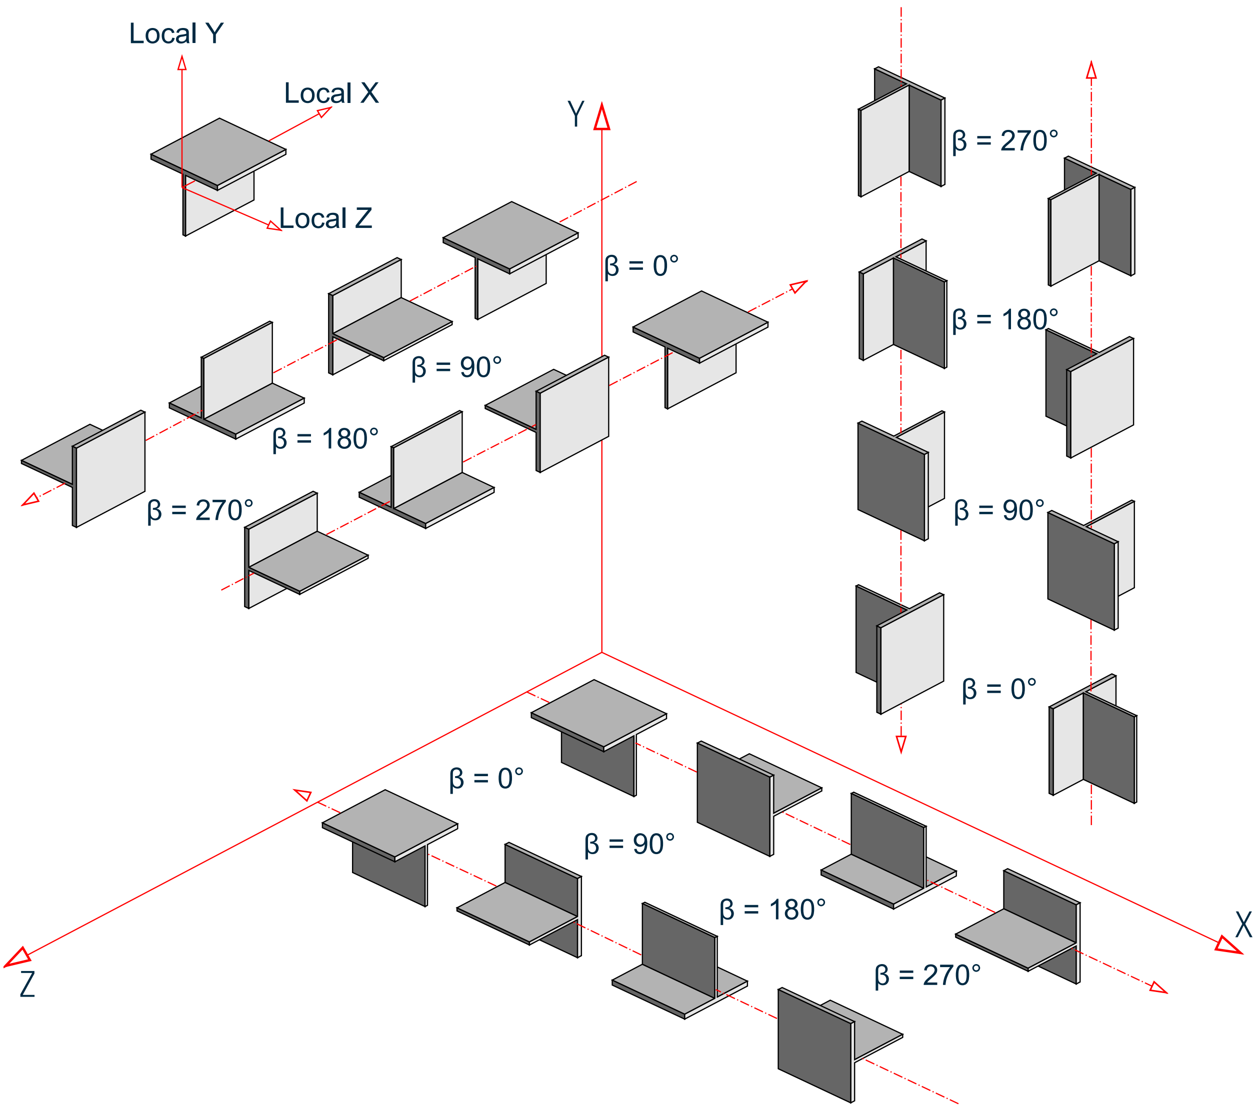

Figure 219: T-shape member orientation for various Beta angles when Global-Y axis is vertical

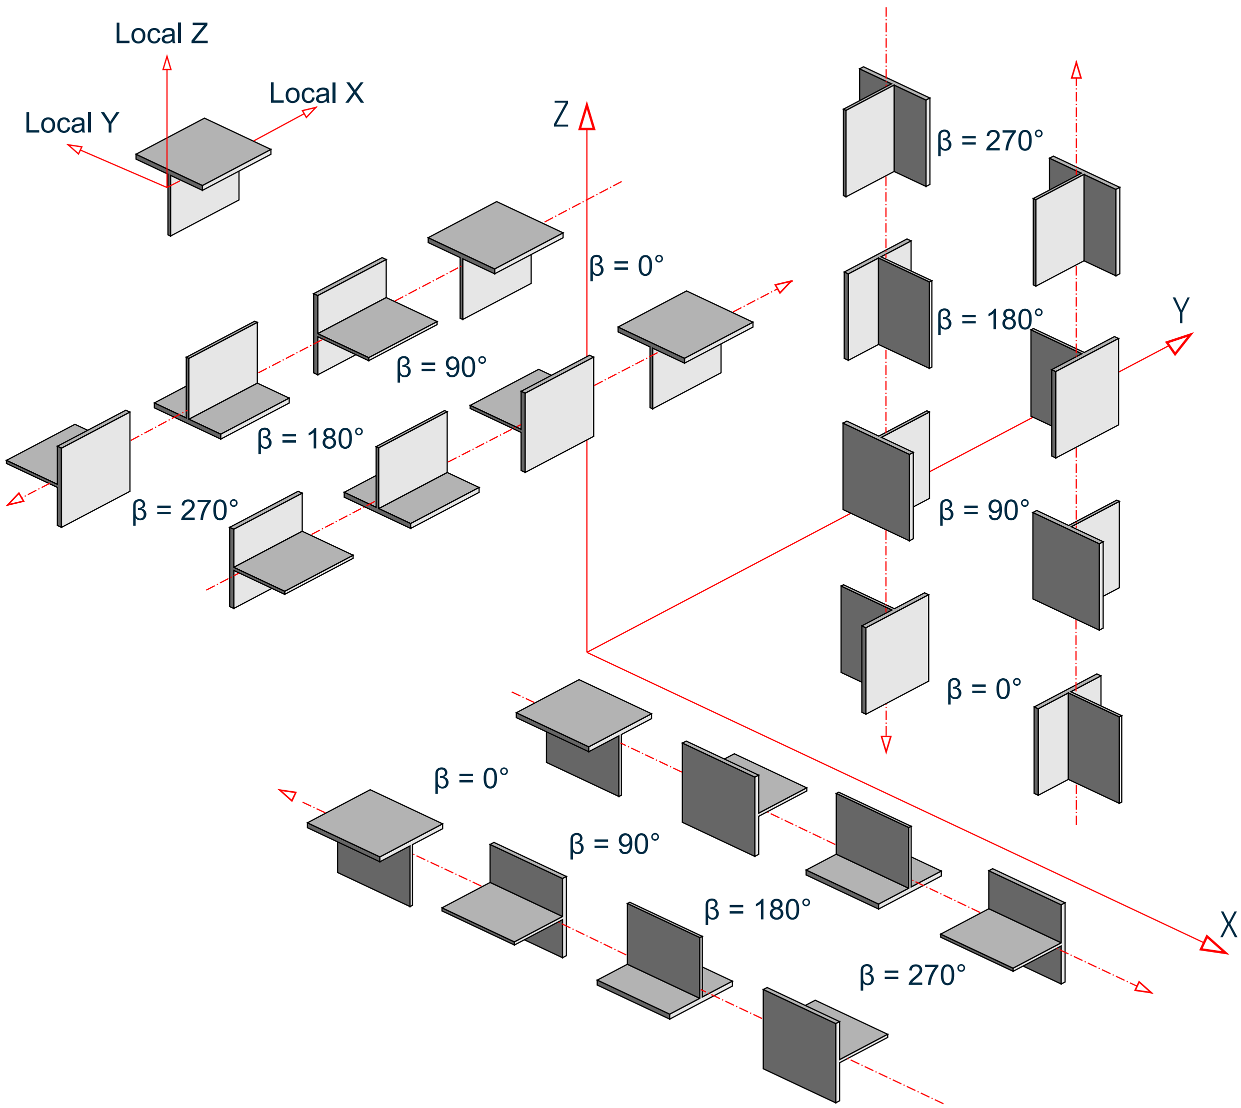

Figure 220: T-shape member orientation for various Beta angles when Global-Z axis is vertical (that is, `SET Z UP` *is specified)*

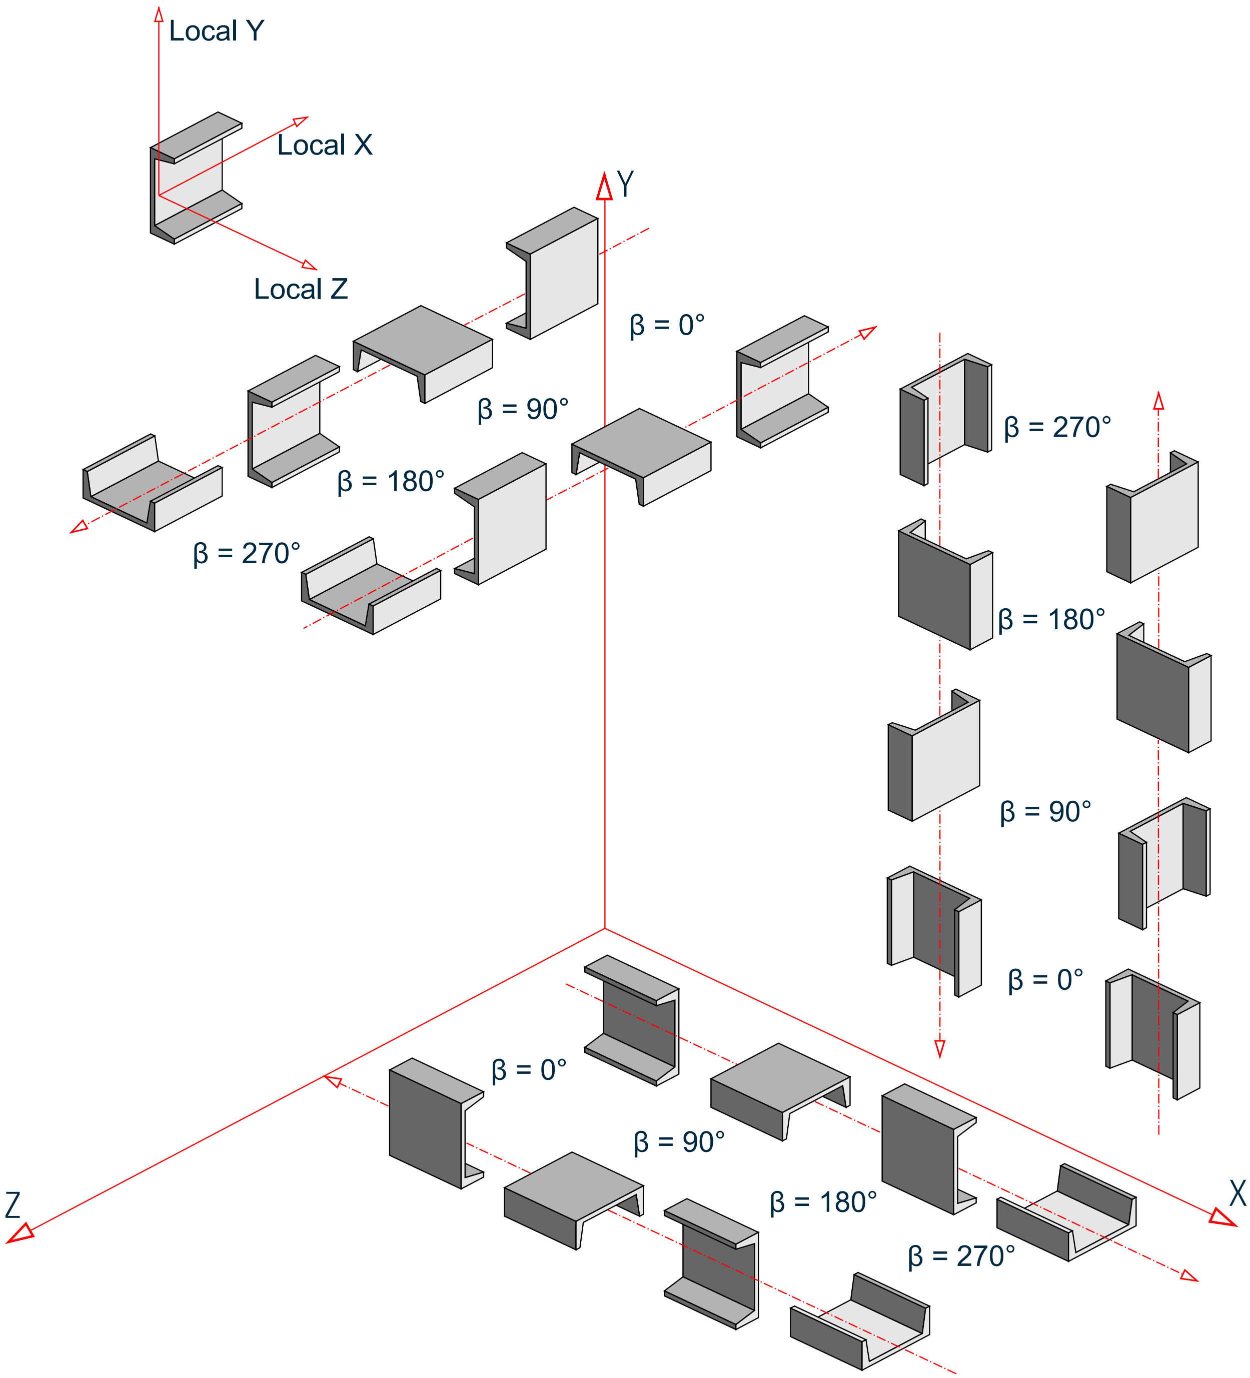

Figure 221: Channel member orientation for various Beta angles when Global-Y axis is vertical

G.5 Finite Element Information

STAAD.Pro is equipped with a plate/shell finite element, solid finite element and an entity called the surface element. The features of each is explained in the following sections.

G.5.1 Plate and Shell Elements

The plate (or shell) finite element is based on the hybrid element formulation. The element can be 3-noded (triangular) or 4-noded (quadrilateral). If all the four nodes of a quadrilateral element do not lie on one plane, it is advisable to model them as triangular elements. The thickness of the element may be different from one node to another.

"Surface structures" such as walls, slabs, plates and shells may be modeled using finite elements. For convenience in generation of a finer mesh of plate/shell elements within a large area, a `MESH GENERATION` facility is available.

You may also use the element for `PLANE STRESS` action only (i.e., membrane/in-plane stiffness only). The `ELEMENT PLANE STRESS` command should be used for this purpose.

Geometry Modeling Considerations

1. The program automatically generates a fictitious, center node "0" (see the following figure) at the element center.

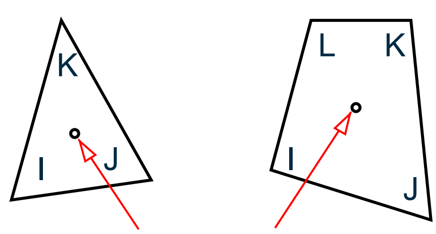

Figure 222: Fictitious center node (in the case of triangular elements, a fourth node; in the case of rectangular elements, a fifth node)

2. While assigning nodes to an element in the input data, it is essential that the nodes be specified either clockwise or counter clockwise (see the following figure). For better efficiency, similar elements should be numbered sequentially.

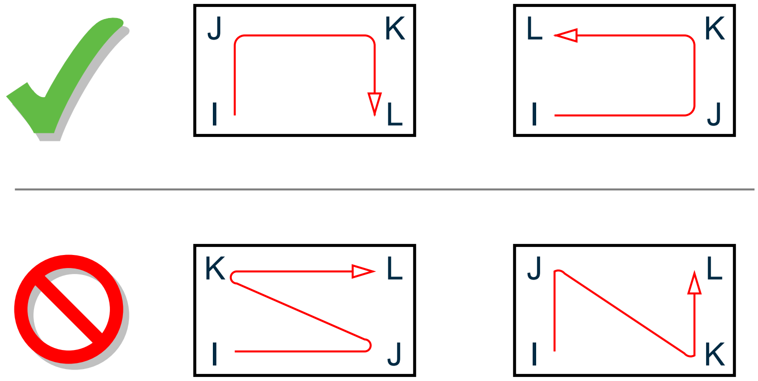

Figure 223: Examples of correct and incorrect numbering sequences

3. Element aspect ratio should not be excessive. They should be on the order of 1:1, and preferably less than 4:1.
4. Individual elements should not be distorted. Angles between two adjacent element sides should not be much larger than 90 and never larger than 180.

   a. Opposite sides cross each other
   b. Ratio of the lengths of the longest side to the shortest side exceeds eight
   c. Ratio of the sides exceeds eight
   d. Angle between two adjacent sides exceeds 120 degrees

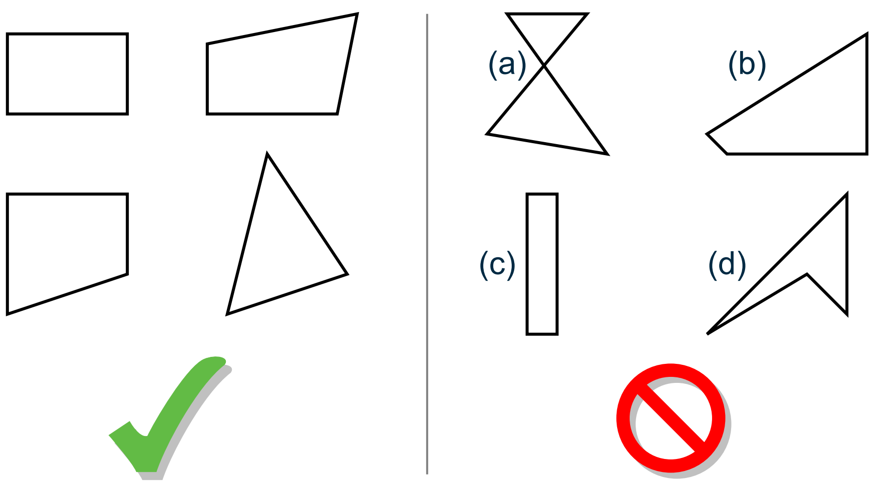

Figure 224: Some examples of good and bad elements in terms of the angles

Load Specification for Plate Elements

1. Joint loads at element nodes in global directions.
2. Concentrated loads at any user specified point within the element in global or local directions.
3. Uniform pressure on element surface in global or local directions.
4. Partial uniform pressure on user specified portion of element surface in global or local directions.
5. Linearly varying pressure on element surface in local directions.

6. Temperature load due to uniform increase or decrease of temperature.
7. Temperature load due to difference in temperature between top and bottom surfaces of the element.

Theoretical Basis

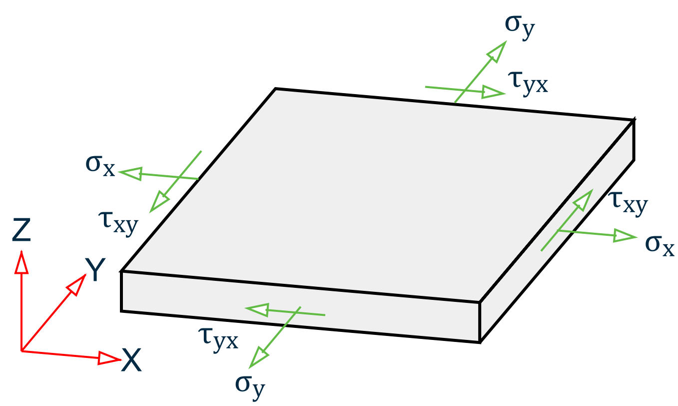

Figure 225: Assumed stress distribution

The incomplete quadratic assumed stress distribution:

$$\begin{pmatrix} \sigma_x \\ \sigma_y \\ \tau_{xy} \end{pmatrix} = \begin{bmatrix} 1 & x & y & 0 & 0 & 0 & 0 & x^2 & 2xy & 0 \\ 0 & 0 & 0 & 1 & x & y & 0 & y^2 & 0 & 2xy \\ 0 & -y & 0 & 0 & 0 & -x & 1 & -2xy & -y^2 & -x^2 \end{bmatrix} \begin{pmatrix} a_1 \\ a_2 \\ a_3 \\ \ldots \\ a_{10} \end{pmatrix}$$

a_1 through a_{10} = constants of stress polynomials

The following quadratic stress distribution is assumed for plate bending action:

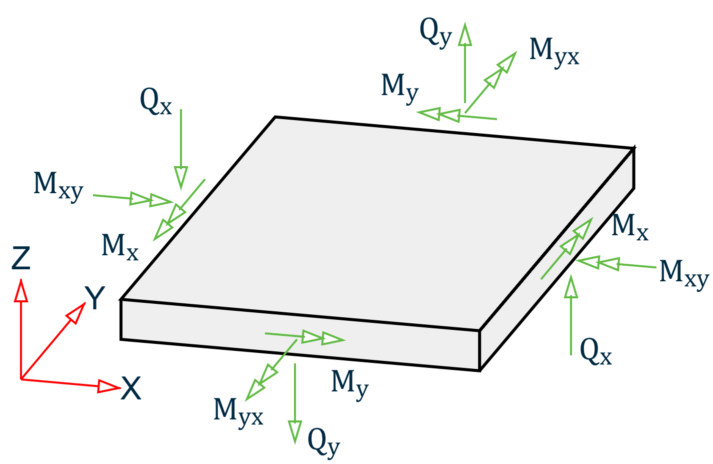

Figure 226: Quadratic stress distribution assumed for bending

The incomplete quadratic assumed stress distribution:

$$\begin{Bmatrix} M_x \\ M_y \\ M_{xy} \\ Q_x \\ Q_y \end{Bmatrix} = \begin{bmatrix} 1 & x & y & 0 & 0 & 0 & 0 & 0 & 0 & x^2 & xy & 0 & 0 \\ 0 & 0 & 0 & 1 & x & y & 0 & 0 & 0 & 0 & 0 & xy & y^2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & x & y & -xy & 0 & 0 & -xy \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & x & y & 0 & -xy \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & 0 & -y & 0 & x & y \end{bmatrix} \begin{Bmatrix} a_1 \\ a_2 \\ a_3 \\ \dots \\ a_{12} \\ a_{13} \end{Bmatrix}$$

a_1 through a_{13} = constants of stress polynomials

The distinguishing features of this finite element are:

1. Displacement compatibility between the plane stress component of one element and the plate bending component of an adjacent element which is at an angle to the first (see the following figure) is achieved by the elements. This compatibility requirement is usually ignored in most flat shell/plate elements.

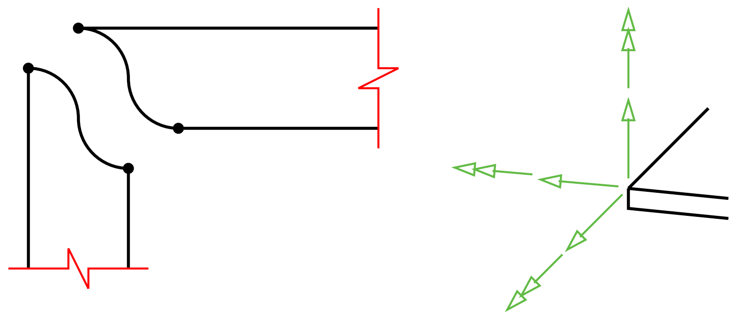

Figure 227: Adjacent elements at some angle

2. The out of plane rotational stiffness from the plane stress portion of each element is usefully incorporated and not treated as a dummy as is usually done in most commonly available commercial software.
3. Despite the incorporation of the rotational stiffness mentioned previously, the elements satisfy the patch test absolutely.
4. These elements are available as triangles and quadrilaterals, with corner nodes only, with each node having six degrees of freedom.
5. These elements are the simplest forms of flat shell/plate elements possible with corner nodes only and six degrees of freedom per node. Yet solutions to sample problems converge rapidly to accurate answers even with a large mesh size.
6. These elements may be connected to plane/space frame members with full displacement compatibility. No additional restraints/releases are required.
7. Out of plane shear strain energy is incorporated in the formulation of the plate bending component. As a result, the elements respond to Poisson boundary conditions which are considered to be more accurate than the customary Kirchoff boundary conditions.
8. The plate bending portion can handle thick and thin plates, thus extending the usefulness of the plate elements into a multiplicity of problems. In addition, the thickness of the plate is taken into consideration in calculating the out of plane shear.
9. The plane stress triangle behaves almost on par with the well known linear stress triangle. The triangles of most similar flat shell elements incorporate the constant stress triangle which has very slow rates of convergence. Thus the triangular shell element is very useful in problems with double curvature where the quadrilateral element may not be suitable.
10. Stress retrieval at nodes and at any point within the element.

Plate Element Local Coordinate System

1. The vector pointing from I to J is defined to be parallel to the local x- axis.
2. For triangles: the cross-product of vectors IJ and JK defines a vector parallel to the local z-axis, i.e., z = IJ x JK.

   For quads: the cross-product of vectors IJ and JL defines a vector parallel to the local z-axis, i.e., z = IJ x JL.
3. The cross-product of vectors z and x defines a vector parallel to the local y- axis, i.e., y = z x x.
4. The origin of the axes is at the center (average) of the four joint locations (three joint locations for a triangle).

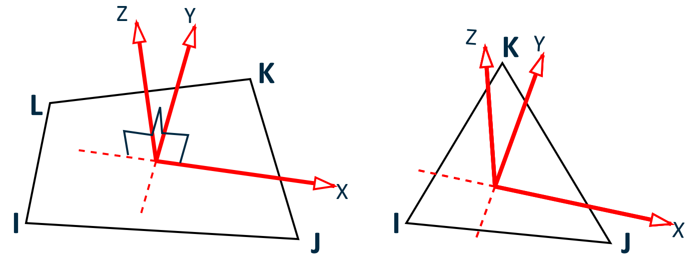

Figure 228: Element origin

Output of Plate Element Stresses and Moments

`ELEMENT` stress and moment output is available at the following locations:

A. Center point of the element.
B. All corner nodes of the element.
C. At any user specified point within the element.

Following are the items included in the `ELEMENT STRESS` output.

Table 224: Items included in the Stress Element output

Title	Description
SQX, SQY	Shear stresses (Force/ unit length/ thickness)
SX, SY	Membrane stresses (Force/unit length/ thickness)
SXY	Inplane Shear Stress (Force/unit length/ thickness)
MX, MY, MXY	Moments per unit width (Force x Length/length) (For Mx, the unit width is a unit distance parallel to the local Y axis. For My, the unit width is a unit distance parallel to the local X axis. Mx and My cause bending, while Mxy causes the element to twist out-of-plane.)
SMAX, SMIN	Principal stresses in the plane of the element (Force/ unit area). The 3rd principal stress is 0.0

Title	Description
TMAX	Maximum 2D shear stress in the plane of the element (Force/unit area)
VONT, VONB	3D Von Mises stress at the top and bottom surfaces, where: $$VM = 0.707[(SMAX - SMIN)^2 + SMAX^2 + SMIN^2]^{1/2}$$
TRESCAT, TRESCAB	Tresca stress, where TRESCA = MAX[|(Smax-Smin)| , |(Smax)| , |(Smin)|]

Notes

1. All element stress output is in the local coordinate system. The direction and sense of the element stresses are explained in the following section.
2. To obtain element stresses at a specified point within the element, you must provide the location (local X, local Y) in the coordinate system for the element. The origin of the local coordinate system coincides with the center of the element.
3. The 2 nonzero Principal stresses at the surface (SMAX & SMIN), the maximum 2D shear stress (TMAX), the 2D orientation of the principal plane (ANGLE), the 3D Von Mises stress (VONT & VONB), and the 3D Tresca stress (TRESCAT & TRESCAB) are also printed for the top and bottom surfaces of the elements. The top and the bottom surfaces are determined on the basis of the direction of the local z-axis.
4. The third principal stress is assumed to be zero at the surfaces for use in Von Mises and Tresca stress calculations. However, the TMAX and ANGLE are based only on the 2D inplane stresses (SMAX & SMIN) at the surface. The 3D maximum shear stress at the surface is not calculated but would be equal to the 3D Tresca stress divided by 2.0.

Sign Convention of Plate Element Stresses and Moments

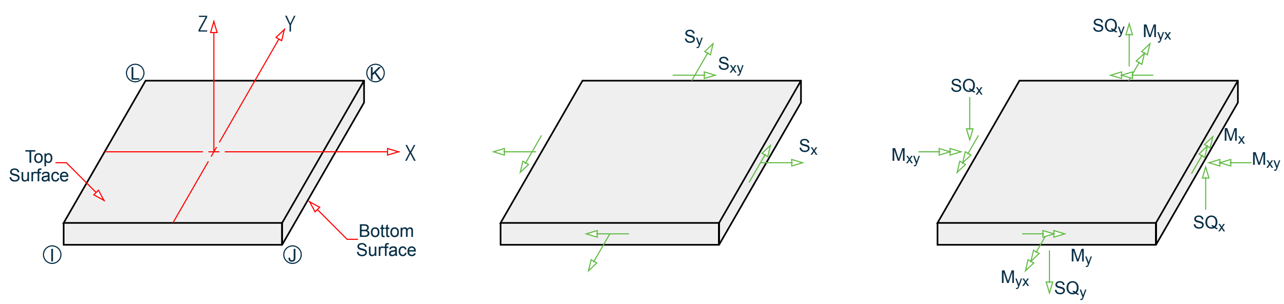

Figure 229: Sign conventions for plate stresses and moments

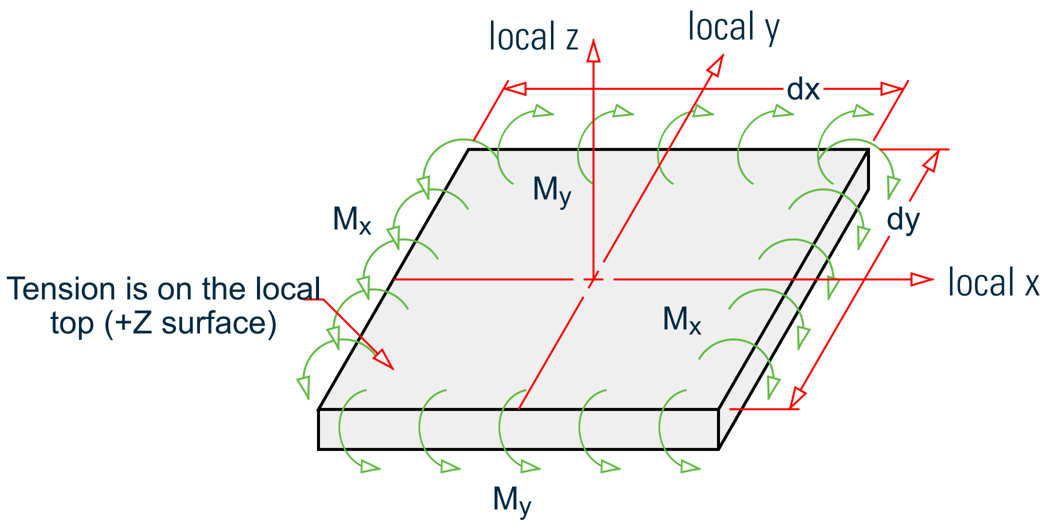

Figure 230: Sign convention for plate bending

Mx is the Bending Moment on the local x face and the local x-face is the face perpendicular to the local x-axis.

My is the Bending Moment on the local y face and the local y-face is the face perpendicular to the local y-axis.

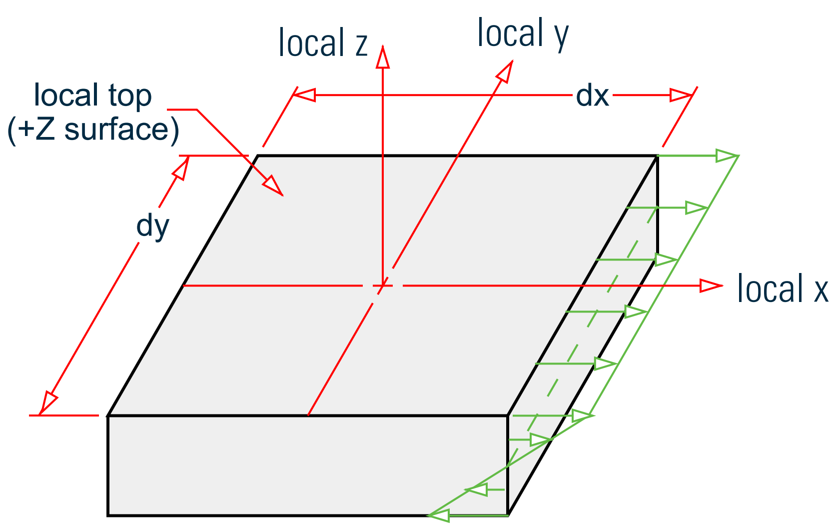

Figure 231: Stress caused by Mx

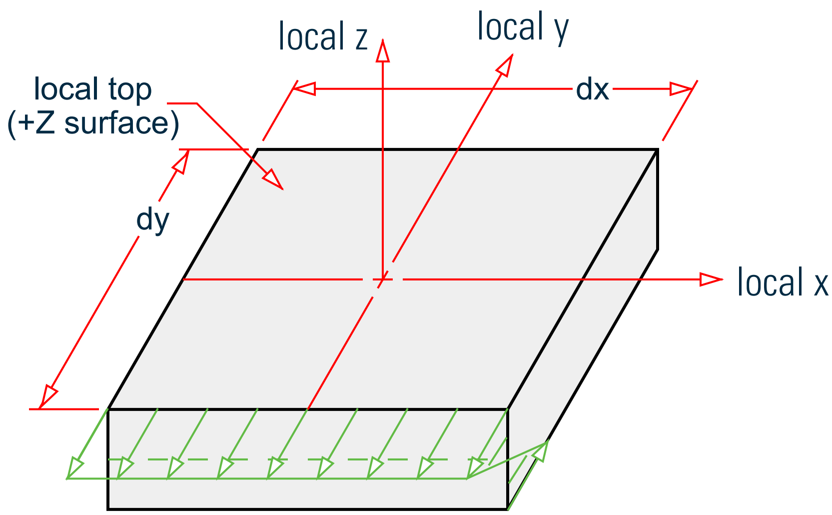

Figure 232: Stress caused by My

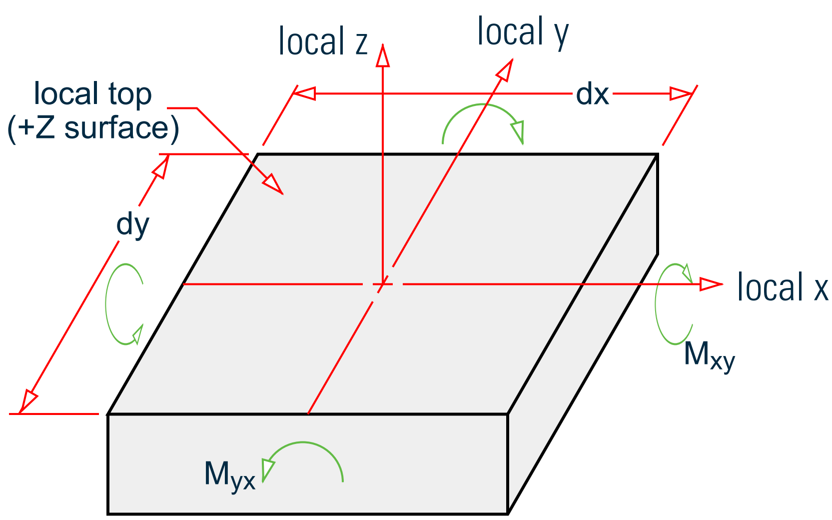

Figure 233: Torsion

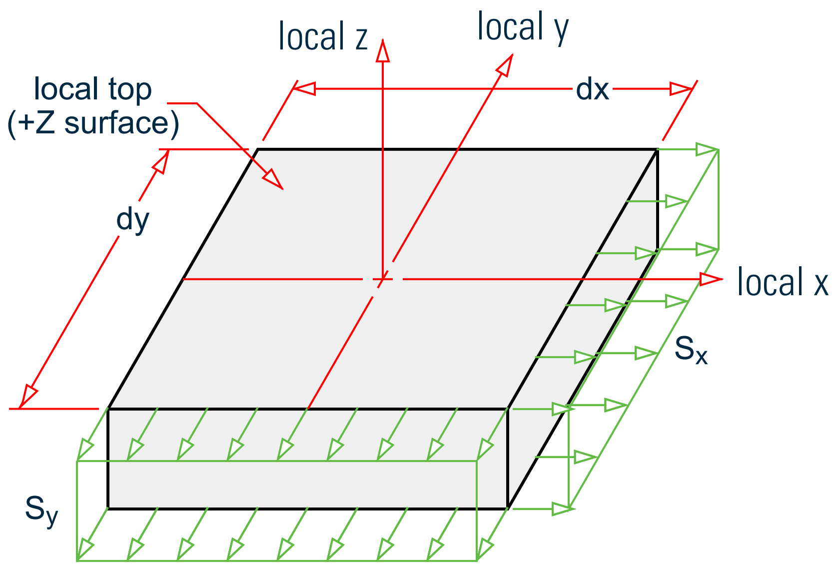

Figure 234: Membrane stress Sx and Sy

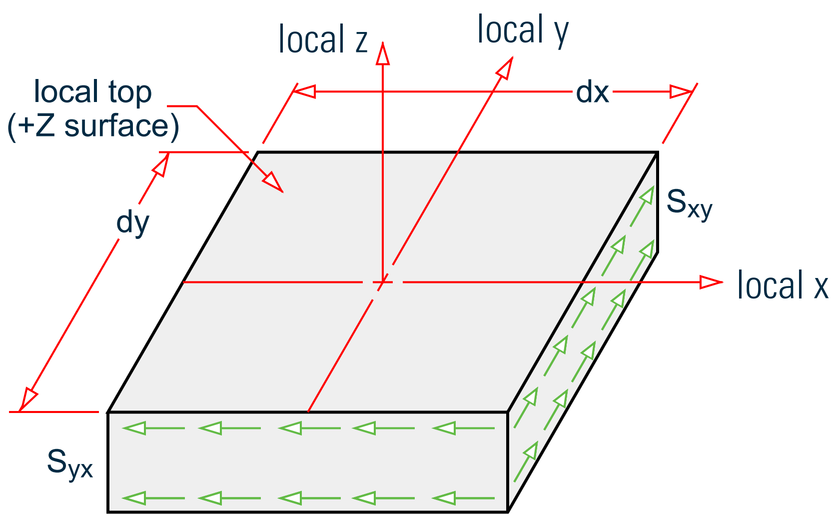

Figure 235: In-plane shear stresses Sxy and Syx

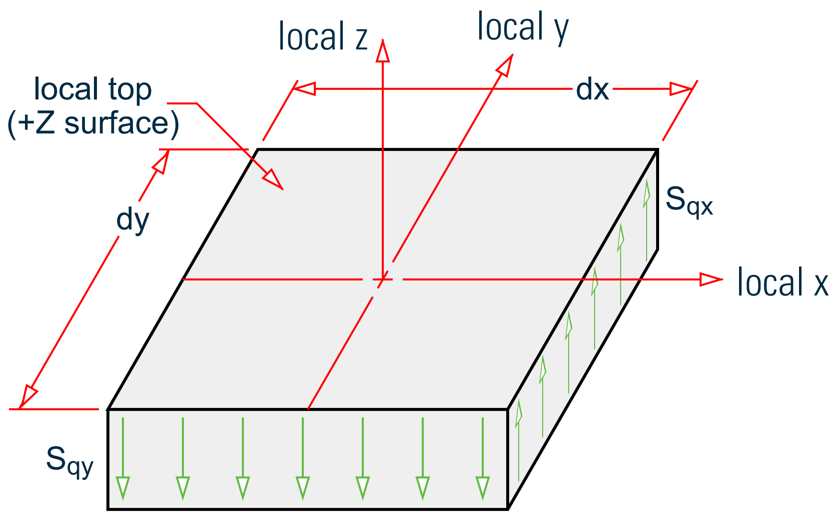

Figure 236: Out-of-plane shear stresses SQX and SQY

Members, plate elements, solid elements and surface elements can all be part of a single STAAD model. The `MEMBER INCIDENCES` input must precede the `INCIDENCE` input for plates, solids or surfaces. All `INCIDENCE`s must precede other input such as properties, constants, releases, loads, etc. The selfweight of the finite elements is converted to joint loads at the connected nodes and is not used as an element pressure load.

Plate Element Numbering

Therefore, to save some computing time, similar elements should be numbered sequentially. The following figure shows examples of efficient and non-efficient element numbering.

However, you have to decide between adopting a numbering system which reduces the computation time versus a numbering system which increases the ease of defining the structure geometry.

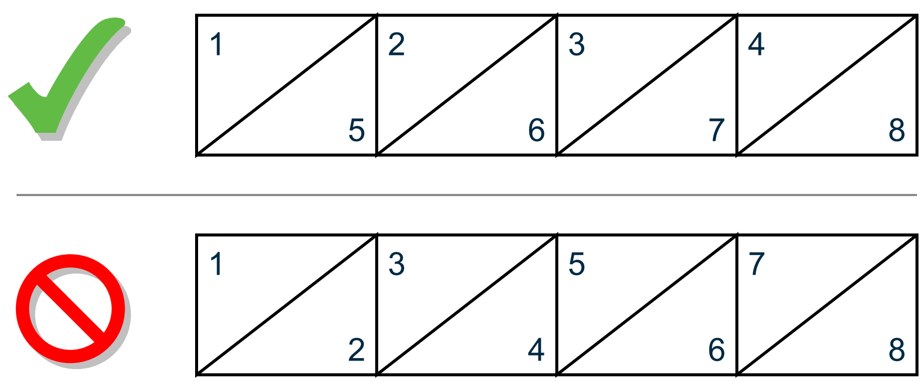

Figure 237: Examples of efficient and inefficient element numbering

G.5.2 Solid Elements

Solid elements enable the solution of structural problems involving general three dimensional stresses. There is a class of problems such as stress distribution in concrete dams or soil and rock strata where finite element analysis using solid elements provides a powerful tool.

Theoretical Basis

The solid element used in STAAD.Pro is of eight-noded, isoparametric type. These elements have three translational degrees-of-freedom per node.

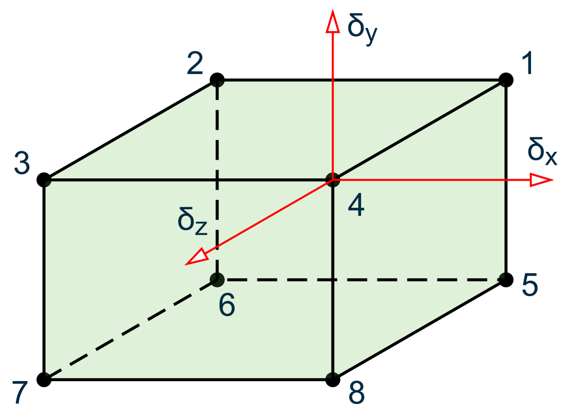

Figure 238: eight-noded, isoparametric solid element

By collapsing various nodes together, an eight noded solid element can be degenerated to the following forms with four to seven nodes. Joints 1, 2, and 3 must be retained as a triangle.

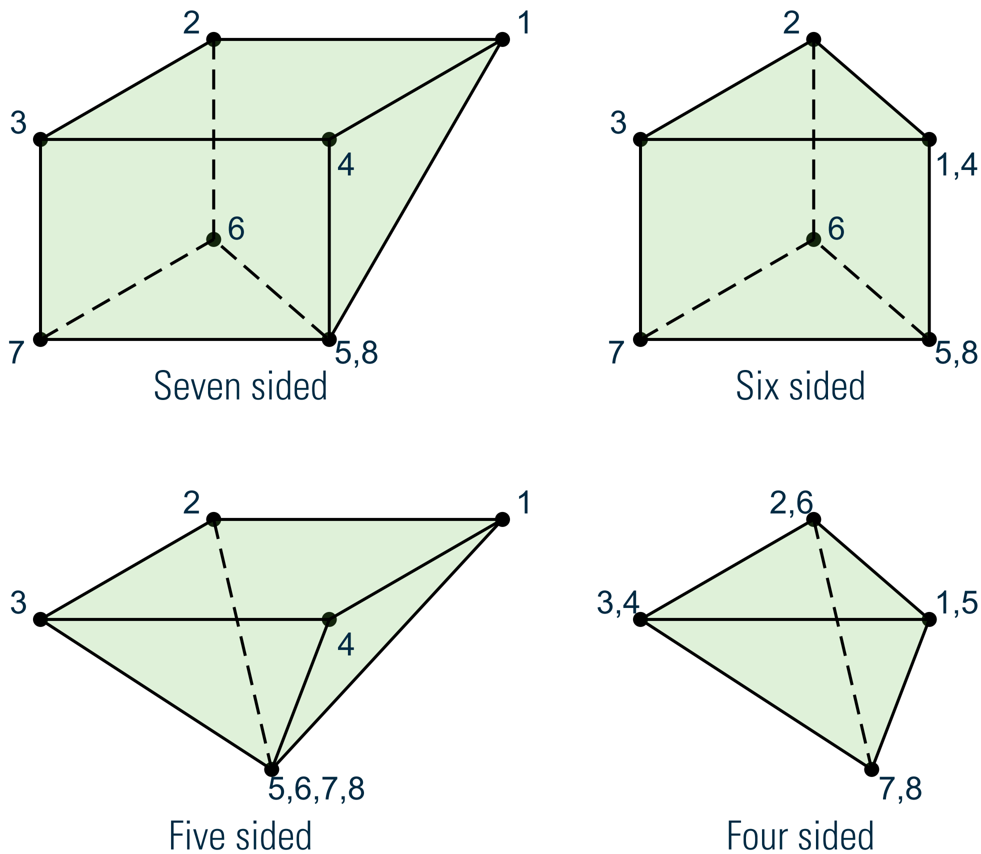

Figure 239: Forms of a collapsed eight-noded solid element

The stiffness matrix of the solid element is evaluated by numerical integration with eight Gauss-Legendre points (2x2x2). The integration is the reduced second order to prevent shear locking. To facilitate the numerical integration, the geometry of the element is expressed by interpolating functions using the natural coordinate system, (r,s,t) of the element with its origin at the “center.” The interpolating functions are shown below:

$$X = \sum_{i=1}^{8} h_i x_i \text{ , } y = \sum_{i=1}^{8} h_i y_i \text{ , } z = \sum_{i=1}^{8} h_i z_i$$

where

x, y and z	=	the coordinates of any point in the element
xi, yi, zi	=	are the coordinates of nodes defined in the global coordinate system, i=1,…,8

The interpolation functions, hi are defined in the natural coordinate system, (r,s,t). Each of r,s and t varies between -1 and +1. The fundamental property of the unknown interpolation functions hi is that their values in natural coordinate system is unity at node, i, and zero at all other nodes of the element. The element displacements are also interpreted the same way as the geometry. For completeness, the functions are given below:

$$u = \sum_{i=1}^{8} h_i u_i \text{ , } v = \sum_{i=1}^{8} h_i v_i \text{ , } w = \sum_{i=1}^{8} h_i w_i$$

where u, v and w are displacements at any point in the element and u_i,v_i, w_i, i=1,8 are corresponding nodal displacements in the coordinate system used to describe the geometry.

Three additional displacement “bubble” functions which have zero displacements at the surfaces are added in each direction for improved shear performance to form a 33x33 matrix. A modified integration is used for the bubble functions to make the results invariant with respect to element orientation (a one-point integration at the center is used).

Static condensation is used to reduce this matrix to a 24x24 matrix at the corner joints.

Local Coordinate System

The local coordinate system used in solid element is the same as the global system.

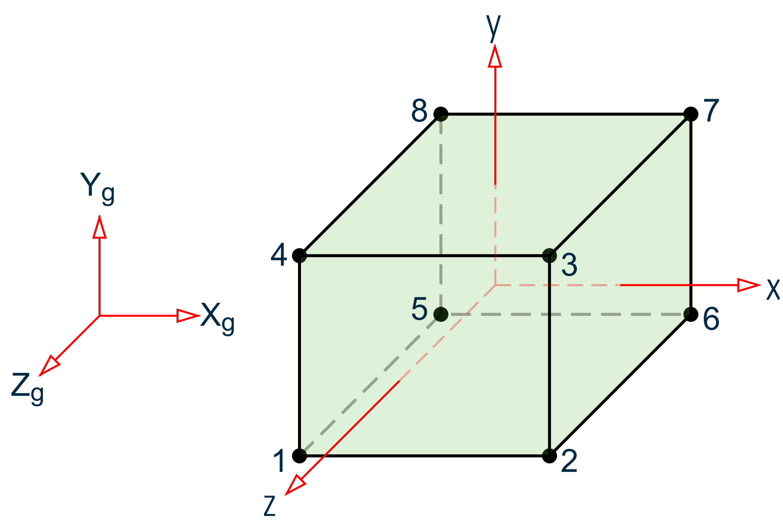

Figure 240: Local coordinate system for a solid element

Properties and Constants

Unlike members and shell (plate) elements, no properties are required for solid elements. However, the constants such as modulus of elasticity and Poisson’s ratio are to be specified. Also, density needs to be provided if selfweight is included in any load case.

Output of Element Stresses

Element stresses may be obtained at the center and at the joints of the solid element. The items that are printed are :

- Normal Stresses : SXX, SYY and SZZ
- Shear Stresses : SXY, SYZ and SZX
- Principal stresses : S1, S2 and S3
- Von Mises stresses: $SIGE = 0.707\sqrt{(S1 - S2)^2 + (S2 - S3)^2 + (S3 - S1)^2}$

Direction cosines : six direction cosines are printed, following the expression DC, corresponding to the first two principal stress directions.

G.6 Member Properties

The following types of member property specifications are available in STAAD.Pro.

- G.6.1 Prismatic Properties (on page 2114) - four basic geometric shapes where the principal section properties are calculated from shapes dimensions or defined.
- G.6.2 Built-In Steel Section Libraries (on page 2116) - the principal dimensions and section properties from obtained from published documents and supplied in STAAD.Pro as standard databases
- G.6.3 User-Provided Steel Table (on page 2117) - the principal dimensions and some section properties for 10 different shape types which can be included in the model or located in an external file
- G.6.4 Tapered Sections (on page 2117) - either tapered I shaped or tapered tube sections defined by the dimensions at either end of the member for which the properties are calculated

- G.6.5 Assign Command (on page 2117) - a standard section profile from one of the standard database is used
- G.6.6 Steel Joist and Joist Girders (on page 2118) - standard joist or joist girders from publications
- G.6.7 Composite Beams and Composite Decks (on page 2119) - the section properties for standard steel profiles that have the additional effect of increased stiffness due to a positive connection to a concrete slab
- G.6.8 Curved Members (on page 2120) - the stiffness is calculated and modified based on the curvature of the member between the start and end nodes

Shear Area

Shear Area for members refers to the shear stiffness effective area. Shear stiffness effective area is used to calculate shear stiffness for the member stiffness matrix.

As an example: for a rectangular cross section, the shear stiffness effective area is usually taken as 0.83 (Roark) to 0.85 (Cowper) times the cross sectional area. A shear area of less than the cross sectional area will reduce the stiffness. A typical shearing stiffness term is

$$(12EI/L^3)/(1+\Phi)$$

where

Φ	=	$(12 EI) / (GA_s L^2)$
A_s	=	the shear stiffness effective area

Phi (Φ) is usually ignored in basic beam theory. STAAD will include the PHI term unless the `SET SHEAR` command is entered.

Shear stress effective area is a different quantity that is used to calculate shear stress and in code checking. For a rectangular cross section, the shear stress effective area is usually taken as two-thirds (0.67x) of the cross sectional area.

Shear stress in STAAD may be from one of three methods.

1. (Shear Force)/(Shear stress effective area)

   This is the case where STAAD computes the area based on the cross section parameters.
2. (Shear Force)/(Shear stiffness effective area)

   This is the case where STAAD uses the shear area entered.
3. *(V Q)/(I t)*

   In some codes and for some cross sections, STAAD uses this method.

The values that STAAD uses for shear area for shear deformation calculation can be obtained by specifying the command `PRINT MEMBER PROPERTIES`.

The output for this will provide this information in all circumstances: when AY and AZ are not provided, when AY and AZ are set to zero, when AY and AZ are set to very large numbers, when properties are specified using `PRISMATIC`, when properties are specified through a user table, when properties are specified through from the built-in-table, etc.

Related Links

- *TR.20 Member Property Specification* (on page 2255)

G.6.1 Prismatic Properties

The following prismatic properties are required for analysis:

AX = Cross sectional area
IX = Torsional constant
IY = Moment of inertia about y-axis.
IZ = Moment of inertia about z-axis.

In addition, you may choose to specify the following properties:

AY = Effective shear area for shear force parallel to local y-axis.
AZ = Effective shear area for shear force parallel to local z-axis.
YD = Depth of section parallel to local y-axis.
ZD = Depth of section parallel to local z-axis.

(when the global vertical axis is Y)

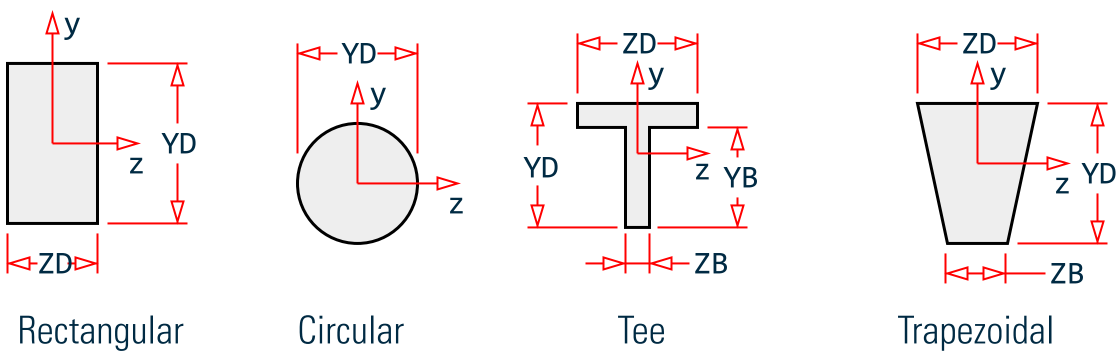

Figure 241: Prismatic property nomenclature

For T-beams, YD, ZD, YB & ZB must be specified. These terms are:

YD = Total depth of section (top fiber of flange to bottom fiber of web)
ZD = Width of flange
YB = Depth of stem
ZB = Width of stem

For Trapezoidal beams, YD, ZD & ZB must be specified. These terms, which too are shown in the next figure are:

YD = Total depth of section
ZD = Width of section at top fiber
ZB = Width of section at bottom fiber

The top & bottom are defined as positive side of the local Z axis, and negative side of the local Z axis respectively.

STAAD.Pro automatically considers the additional deflection of members due to pure shear (in addition to deflection due to ordinary bending theory). To ignore the shear deflection, enter a `SET SHEAR` command before the joint coordinates. This will bring results close to textbook results.

The depths in the two major directions (YD and ZD) are used in the program to calculate the section moduli. These are needed only to calculate member stresses or to perform concrete design. You can omit the YD & ZD values if stresses or design of these members are of no interest. The default value is 253.75 mm (9.99 inches) for YD and ZD. All the prismatic properties are input in the local member coordinates.

To define a concrete member,you must not provide AX, but instead, provide YD and ZD for a rectangular section and just YD for a circular section. If no moment of inertia or shear areas are provided, the program will automatically calculate these from YD and ZD.

The following table is provided to assist you in specifying the necessary section values. It lists, by structural type, the required section properties for any analysis.

Note: For the `PLANE` or `FLOOR` type analyses, the choice of the required moment of inertia depends upon the beta angle. If `BETA` equals zero, the required property is IZ.

Table 225: Required Section Properties

Structure Type	Required Properties
TRUSS	AX
PLANE	AX, IZ, or IY
FLOOR	IX, IZ or IY
SPACE	AX, IX, IY, IZ

G.6.2 Built-In Steel Section Libraries

This feature of the program allows you to specify section names of standard steel shapes manufactured in different countries.

Since the shear areas of the sections are built into the tables, shear deformation is always considered for these sections.

- *TR.20.1 Assigning Properties from Steel Tables* (on page 2257)

G.6.3 User-Provided Steel Table

You can provide a customized steel table with designated names and proper corresponding properties. The program can then find member properties from those tables. Member selection may also be performed with the program selecting members from the provided tables only.

These tables can be provided as a part of a STAAD.Pro input or as separately created files from which the program can read the properties. If you do not use standard rolled shapes or only use a limited number of specific shapes, you can create permanent member property files. Analysis and design can be limited to the sections in these files.

G.6.4 Tapered Sections

Properties of tapered I-sections may be provided through `MEMBER PROPERTY` specifications. Given key section dimensions, the program is capable of calculating cross-sectional properties which are subsequently used in analysis.

Tapered I-sections have constant flange dimensions and a linearly varying web depth along the length of the member.

- *TR.20.3 Tapered Member Specification* (on page 2266)

G.6.5 Assign Command

If you want to avoid the trouble of defining a specific section name but rather leave it to the program to assign a section name, the `ASSIGN` command may be used. The section types that may be assigned include `BEAM`, `COLUMN`, `CHANNEL`, `ANGLE` and `DOUBLE ANGLE`.

When the keyword `BEAM` is specified, the program will assign an I-shaped beam section (Wide Flange for AISC, UB section for British).

For the keyword `COLUMN` also, the program will assign an I-shaped beam section (Wide Flange for AISC, UC section for British).

If steel design-member selection is requested, a similar type section will be selected.

G.6.6 Steel Joist and Joist Girders

STAAD.Pro includes facilities for specifying steel joists and joist girders. The basis for this implementation is the information contained in the 1994 publication of the American Steel Joist Institute called *Standard Specifications, Load Tables, and Weight Tables for Steel Joists and Joist Girders*, Fortieth edition. The following are the salient features of the implementation.

Steel joists are prefabricated, welded steel trusses used at closely spaced intervals to support floor or roof decking. Thus, from an analysis standpoint, a joist is not a single member in the same sense as beams and columns of portal frames that one is familiar with. Instead, it is a truss assembly of members. In general, individual manufacturers of the joists decide on the cross section details of the members used for the top and bottom chords, and webs of the joists. So, joist tables rarely contain any information on the cross-section properties of the individual components of a joist girder. The manufacturer's responsibility is to guarantee that, no matter what the cross section details of the members are, the joist simply has to ensure that it provides the capacity corresponding to its rating.

The absence of the section details makes it difficult to incorporate the true truss configuration of the joist in the analysis model of the overall structure. In STAAD, selfweight and any other member load applied on the joist is transferred to its end nodes through simply supported action. Also, in STAAD, the joist makes no contribution to the stiffness of the overall structure.

As a result of the above assumption, the following points must be noted with respect to modeling joists:

1. The entire joist is represented in the STAAD input file by a single member. Graphically it will be drawn using a single line.
2. After creating the member, the properties should be assigned from the joist database.
3. The 3D Rendering feature of the program will display those members using a representative Warren type truss.
4. The intermediate span-point displacements of the joist cannot be determined.

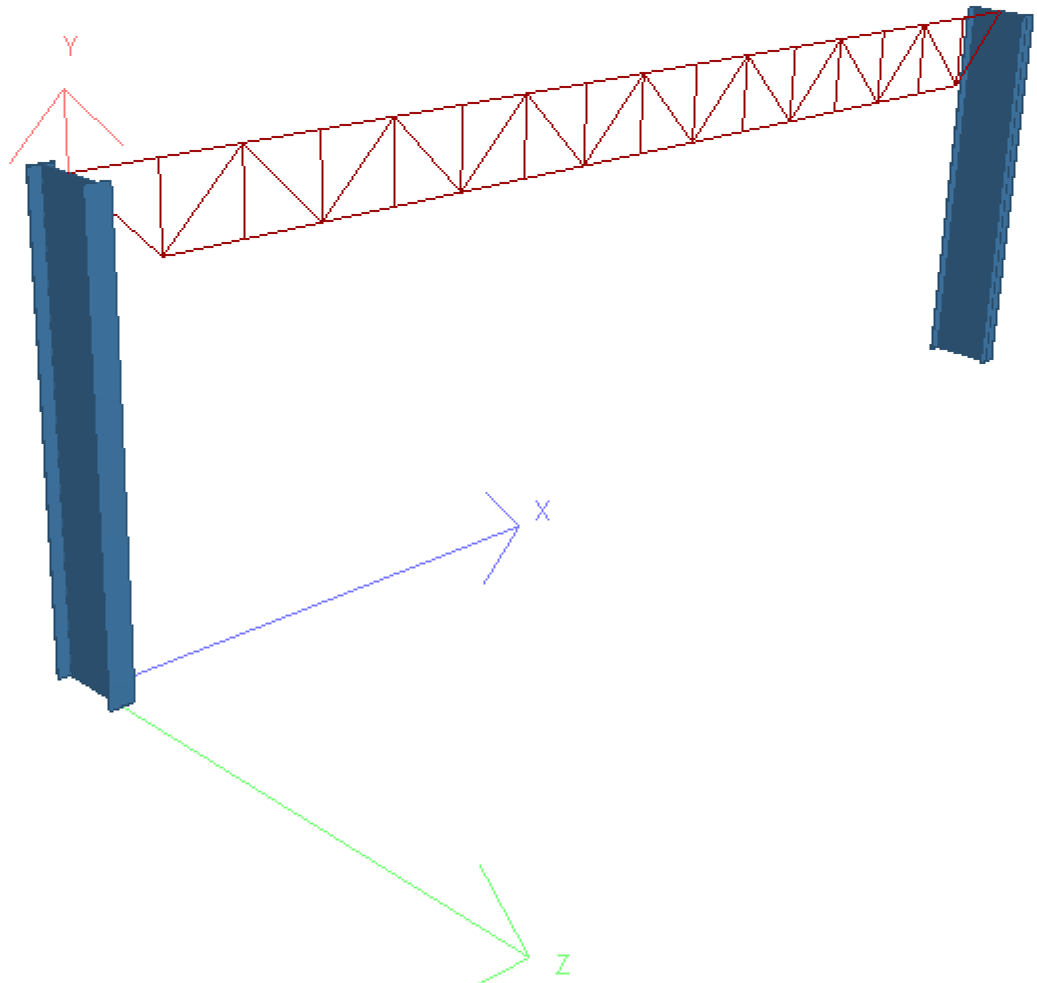

Figure 243: Example rendering of a joist member in STAAD.Pro

G.6.7 Composite Beams and Composite Decks

There are two methods in STAAD.Pro for specifying composite beams. Composite beams are members whose property is comprised of a rolled steel I-shape cross section (like an American W shape) with a concrete slab on top. The steel section and concrete slab act monolithically. The two methods are:

1. TR.20.1 Assigning Properties from Steel Tables (on page 2257) – In this method, the member geometry is first defined as a line. It is then assigned a property from the steel database, with the help of the "CM" attribute. Additional parameters like CT (thickness of the slab), FC (concrete strength), CW (effective width of slab), CD (concrete density), etc., some optional and some mandatory, are also provided.

   Hence, the responsibility of determining the attributes of the composite member, like concrete slab width, lies upon you, the user. If you wish to obtain a design, additional terms like rib height, rib width, etc. must also be separately assigned with the aid of design parameters. Hence, some amount of effort is involved in gathering all the data and assigning them.

2. TR.20.7 Composite Decks (on page 2270) – The laboriousness of the previous procedure can be alleviated to some extent by using the program's composite deck definition facilities. The program then internally converts the deck into individual composite members (calculating attributes like effective width in the process) during the analysis and design phase. The deck is defined best using the graphical tools of the program since a database of deck data from different manufacturers is accessible from easy-to-use dialogs. Since all the members which make up the deck are identified as part of a single object, load assignment and alterations to the deck can be done to just the deck object, and not the individual members of the deck.

G.6.8 Curved Members

Members can be defined as being curved.

Tapered sections are not permitted. The cross-section should be uniform throughout the length.

The design of curved members is not supported.

G.7 Member and Element Release

STAAD.Pro allows releases for members and plate elements.

One or both ends of a member or element can be released in any combination of the six degrees of freedom. Members and elements are assumed to be rigidly framed into joints in accordance with the structural type specified. When this full rigidity is not applicable, individual force components at either end of the member can be set to zero with member release statements. By specifying release components, individual degrees of freedom are removed from the analysis. Release components are given in the local coordinate system for each member. Partial moment releases are also allowed.

The translational degrees of freedom are denoted by u_1, u_2, u_3 and the rotational degrees of freedom are denoted by u_4, u_5 & u_6.

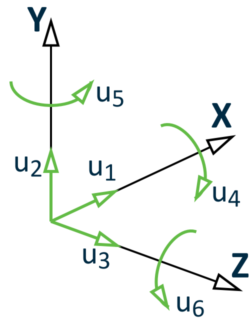

Figure 244: Degrees of Freedom

Note: A specific member can have *either* end releases (see G.7 Member and Element Release (on page 2120)) *or* axial-only specifications (see G.8 Axial-Only Specifications (on page 2121)) properties assigned. The last specification for a given member will be used. In other words, a `MEMBER RELEASE` should not be applied on a member which is declared `TRUSS`, `TENSION ONLY`, `COMPRESSION ONLY`, or `CABLE`.

Related Links

- *TR.22.2 Element Release Specification* (on page 2287)
- *TR.22.3 Element Ignore Stiffness* (on page 2288)

G.8 Axial-Only Specifications

STAAD.Pro has several member specifications which allow you to designate axial-only behavior for members.

Note: A specific member can have *either* end releases (see G.7 Member and Element Release (on page 2120)) *or* axial-only specifications (see G.8 Axial-Only Specifications (on page 2121)) properties assigned. The last specification for a given member will be used. In other words, a `MEMBER RELEASE` should not be applied on a member which is declared `TRUSS`, `TENSION ONLY`, `COMPRESSION ONLY`, or `CABLE`.

G.8.1 Truss and Tension- or Compression-Only Members

For analyses which involve members that carry axial loads only (i.e., truss members) there are two methods for specifying this condition. When all the members in the structure are truss members, the type of structure is declared as `TRUSS` whereas, when only some of the members are truss members (e.g., bracing members in a building), the `MEMBER TRUSS` command can be used where those members will be identified separately.

In STAAD.Pro, the `MEMBER TENSION` or `MEMBER COMPRESSION` command can be used to limit the axial load type the member may carry.

G.8.2 Cable Members

STAAD.Pro supports the following types of analysis for cable members:

G.8.2.1 Linearized Cable Members

Cable members may be specified by using the `MEMBER CABLE` command. While specifying cable members, the initial tension in the cable must be provided.

Cable Stiffness

The increase in length of a loaded cable is a combination of two effects. The first component is the elastic stretch, which is governed by the familiar spring relationship:

$$F = Kx$$

where

$$K_{elastic} = EA/L$$

The second component of the lengthening is due to a change in geometry (as a cable is pulled taut, sag is reduced). This relationship can also be described by $F = Kx$, but here:

$$K_{sag} = \frac{12T^3}{w^2 L^3 \left(\frac{1}{\cos^2 \alpha}\right)}$$

where

w	=	weight per unit length of cable
T	=	tension in cable
α	=	angle that the axis of the cable makes with a horizontal plane (= 0, cable is horizontal; = 90, cable is vertical)

Therefore, the "stiffness" of a cable depends on the initial installed tension (or sag). These two effects may be combined as follows:

$$K_{comb} = \frac{1}{\left(1/K_{sag} + 1/K_{elastic}\right)} = \frac{(EA/L)}{\left(1 + \frac{w^2 L^2 EA \left(\cos^2 \alpha\right)}{12T^3}\right)}$$

Note: As $T \rightarrow \infty$ (infinity), $K_{comb} \rightarrow EA/L$ and that when $T = 0$, $K_{comb} = 0$. It should also be noted that as the tension increases (sag decreases) the combined stiffness approaches that of the pure elastic situation.

Notes

The following points need to be considered when using the cable member in STAAD.Pro:

1. The linear cable member is only a truss member whose properties accommodate the sag factor and initial tension. The behavior of the cable member is identical to that of the truss member. That is, it can carry axial loads only. As a result, the fundamental rules involved in modeling G.8.1 Truss and Tension- or Compression-Only Members (on page 2121) have to be followed when modeling cable members.

   For example, when two cable members meet at a common joint, if there is not a support or a 3rd member connected to that joint, it is a point of potential instability.
2. Due to the reasons specified in 1) above, applying a transverse load on a cable member is not advisable. The load will be converted to two concentrated loads at the two ends of the cable and the true deflection pattern of the cable will never be realized.
3. A tension only cable member offers no resistance to a compressive force applied at its ends. When the end joints of the member are subjected to a compressive force, they “give in” thereby causing the cable to sag. Under these circumstances, the cable member has zero stiffness and this situation has to be accounted for in the stiffness matrix and the displacements have to be recalculated. But in STAAD.Pro, merely declaring the member to be a cable member does not guarantee that this behavior will be accounted for.

   Important: It is also important that you declare the member to be a tension only member by using the `MEMBER TENSION` command, after the `CABLE` command.

   This will ensure that the program will test the nature of the force in the member after the analysis and if it is compressive, the member is switched off and the stiffness matrix re-calculated.
4. Due to potential instability problems explained in item 1) above, you should also avoid modeling a catenary by breaking it down into a number of straight line segments. The cable member in STAAD.Pro cannot be used to simulate the behavior of a catenary.

   By catenary, we are referring to those structural components which have a curved profile and develop axial forces due their self weight. This behavior is in reality a nonlinear behavior where the axial force is caused because of either a change in the profile of the member or induced by large displacements, neither of which are valid assumptions in an elastic analysis. A typical example of a catenary is the main U shaped cable used in suspension bridges.
5. The increase in stiffness of the cable as the tension in it increases under applied loading is updated after each iteration if the cable members are also declared to be `MEMBER TENSION`. However, iteration stops when all tension members are in tension or slack; not when the cable tension converges.

G.8.2.2 Nonlinear Cable and Truss Members

Cable members for the Basic Nonlinear Cable Analysis may be specified by using the `MEMBER CABLE` command.

While specifying cable members, the initial tension in the cable or the unstressed length of the cable must be provided. You should ensure that all cables will be in sufficient tension for all load cases to converge. Use selfweight in every load case and temperature if appropriate; i.e., don’t enter component cases (e.g., wind only).

The nonlinear cable may have large motions and the sag is checked on every load step and every equilibrium iteration.

In addition there is a nonlinear truss which is specified in the Member Truss command. The nonlinear truss is simply any truss with pretension specified. It is essentially the same as a cable without sag. This member takes compression. If all cables are taut for all load cases, then the nonlinear truss may be used to simulate cables. The reason for using this substitution is that the truss solution is more reliable.

Notes

Nonlinear cable elements differ from linearized cable members in the following ways:

Notes 1, 2, and 4 G.8.2.1 Linearized Cable Members (on page 2122) will *not* apply to nonlinear cable analysis if sufficient pretension is applied, so joints may be entered along the shape of a cable (in some cases a stabilizing stiffness may be required and entered for the first loadstep). G.8.2.1 Linearized Cable Members (on page 2122): The Member Tension command is unnecessary and ignored for the nonlinear cable analysis. G.8.2.1 Linearized Cable Members (on page 2122): The cable tensions are iterated to convergence in the nonlinear cable analysis.

G.8.2.3 Nonlinear Cable Members for Advanced Cable Analysis

Cable members used for a Advanced Cable Analysis are specified by using the `MEMBER CABLE` command.

Note: This analysis feature can be used only when Advanced Analysis license is active.

When specifying cable members, either the initial tension in the cable or the unstressed length of the cable must first be provided. The initial tension is sufficient for keeping the cable in tension because the catenary theory behind the element formulation will prevent the cable from behaving in compression. However, a larger initial tension (or smaller unstressed length) increases the numerical stability.

A nonlinear cable may have large deformation. The force equilibrium at cable ends is checked on every load step and on every equilibrium iteration.

Notes

Following considerations exist in Advanced Cable Analysis:

1. The nonlinear cable element provides stiffness and resistance forces to only three translational degrees (i.e., FX, FY, and FZ). It is not able to carry any moments. So, when two nonlinear cable elements meet at a common joint –and if there is not a support or a 3rd member connected to the joint– it is a point of potential instability. The program introduces a very weak spring to overcome this problem.
2. Due to the reason as described in item 1), applying any moment to a cable element is not advisable.
3. The cable is not able to carry any compression forces. So, when the load tends to cause compression in a cable –and if there are no other members connected to the cable and the cable can deform freely– there will be some numerical instability.
4. Due to the instability problem explained in item 1), subdividing a cable member into several smaller cable elements should be done *only* when it is necessary.

   An example of one such necessary case may be when there is force load applied in the middle of the cable member. For this case, the cable member has to be broken so that the forces can be applied as joint loads at cable nodes.

5. The increase in stiffness of the cable (by increasing the initial tension or decreasing unstressed length) is always beneficial for numerical stability. The iteration will stop only when the force equilibrium is reached.
6. In advanced cable analysis, the self weight of a cable member is initially considered to obtain the initial configuration of cable members under self weight. Any additional weight required along with self weight can be included using `FWY` parameter in the `MEMBER CABLE` command.

G.9 Connection Tags

Connection tags provide a means for assigning both connection type data and connection capacities, which can be used for checking in STAAD.Pro.

Note: This feature is available in STAAD.Pro V8i (SELECTseries 4), release 20.07.09.21 and higher.

Connection tags consist of two pieces of data:

i. A Connection Tags XML file, which contains the connection categories, tag names, and member end releases for the connection tag. Connection capacities are also specified for each combination of member and connecting member which may utilize a connection tag. Refer to " D. Connection Tags XML File Schema (on page 1052)" in the STAAD User Interface help for additional information on the required structure of this XML file.
ii. Assignments of connection tags to members are stored in the STAAD input file. Though this is done within the `DEFINE MEMBER ATTRIBUTE` command, it is strongly recommended that the user interface features be used to make connection tag assignments as these must utilize only the connection categories and tag names in the associated XML file. See TR.29.2 Connection Tag Member Attribute (on page 2341) for additional information on this command.

G.11 Member and Plate Offsets

Some members or elements in a structure may not be concurrent with the incident joints thereby creating offsets. This offset distance is specified in terms of global or local coordinate system (i.e., X, Y, and Z distances from the incident joint).

Secondary forces induced, due to this offset connection, are taken into account in analyzing the structure and also to calculate the individual member or element forces.

In the case of members, the new offset centroid of the member can be at the start or end incidences and the new working point will also be the new start or end of the member. Therefore, any reference from the start or end of that member will always be from the new offset points.

G.12 Material Properties

STAAD.Pro allows you to define the properties of materials by two different methods. By assigning individual constants to members, elements, or solids or by creating a material definition and then assigning this.

Material Constants

The material constants are:

modulus of elasticity (`E`),
weight density (`DEN`),
Poisson's ratio (`POISS`),
coefficient of thermal expansion (`ALPHA`),
composite damping ratio,
and beta angle (`BETA`) or coordinates for any reference (`REF`) point.

The modulus of elasticity, E, value for members must be provided or the analysis will not be performed. Weight density (`DEN`) is used only when selfweight of the structure is to be taken into account. Poisson's ratio (`POISS`) is used to calculate the shear modulus (commonly known as G) by the formula,

$$G = 0.5 \cdot E/(1 + POISS)$$

If Poisson's ratio is not provided, STAAD.Pro will assume a value for this quantity based on the value of E.

Note: Poisson's Ratio must always be defined *after* the Modulus of Elasticity for a given member/element.

The coefficient of thermal expansion (`ALPHA`) is used to calculate the expansion of the members if temperature loads are applied. The temperature unit for temperature load and `ALPHA` has to be the same.

The composite damping ratio is used to compute the damping ratio for each mode in a dynamic solution. This is only useful if there are several materials with different damping ratios.

`BETA` angle and `REF`erence point are discussed in G.4.3 Relationship Between Global and Local Coordinates (on page 2092) and are input as part of the member constants.

Material Definitions

Alternately, you may define the constants of a material in a material definition. This can include the analytical and design properties for the material. These material definitions are then assigned to the members, elements, and solids.

Note: A `BETA` is a geometric property and must be assigned separately from the material definition.

Related Links

- *TR.26 Specifying and Assigning Material Constants* (on page 2303)

G.13 Supports

STAAD.Pro allows specifications of supports that are parallel as well as inclined to the global axes.

Supports are specified as `PINNED`, `FIXED`, or `FIXED` with different releases. A pinned support has restraints against all translational movement and none against rotational movement. In other words, a pinned support will have reactions for all forces but will resist no moments. A fixed support has restraints against all directions of movement.

The restraints of a fixed support can also be released in any desired direction as specified.

Translational and rotational springs can also be specified. The springs are represented in terms of their spring constants. A translational spring constant is defined as the force to displace a support joint one length unit in the specified global direction. Similarly, a rotational spring constant is defined as the force to rotate the support joint one degree around the specified global direction.

For static analysis, Multi-linear spring supports can be used to model the varying, non-linear resistance of a support (e.g., soil).

The Support command is also used to specify joints and directions where support displacements will be enforced.

G.13.1 Tension- and Compression- Only Springs

In STAAD.Pro, the `SPRING TENSION` or `SPRING COMPRESSION` command can be used to limit the load direction the support spring may carry. The analysis will be performed accordingly.

Related Links

- *TR.27.5 Spring Tension/Compression Specification* (on page 2324)

G.14 Rigid Diaphragms

STAAD.Pro provides the following methods of modeling rigid diaphragms for structures.

Control/Dependent Joints

The control/dependent option is provided to enable you to model rigid links in the structural system.

This facility can be used to model special structural elements like a rigid floor diaphragm. Several dependent joints may be provided which will be assigned same displacements as the control joint. You are also allowed the flexibility to choose the specific degrees of freedom for which the displacement constraints will be imposed on the dependent joints. If all degrees of freedom (Fx, Fy, Fz, Mx, My, and Mz) are provided as constraints, the joints will be assumed to be rigidly connected.

Floor Diaphragms

Alternately, you can define a floor diaphragm without the need to specify a control joint. You can specify a floor by a height range or by a joint list using this method. The program will internally calculate the center of mass of the floor and generate an analytical node at that location.

- *TR.28.1 Control/Dependent Specification* (on page 2327)

G.15 Loads

Loads in a structure can be directly specified for joints, members, and elements. STAAD.Pro can also generate the self-weight of the structure and use it as uniformly distributed member loads in analysis. Any fraction of this self-weight can also be applied in any desired direction.

G.15.1 Joint Loads

Joint loads, both forces and moments, may be applied to any free joint of a structure. These loads act in the global coordinate system of the structure. Positive forces act in the positive coordinate directions. Any number of loads may be applied on a single joint, in which case the loads will be additive on that joint.

- *TR.32.1 Joint Load Specification* (on page 2462)
- *TR.32.10 Dynamic Loading Specification* (on page 2498)

G.15.2 Member Load

Three types of member loads may be applied directly to a member of a structure: uniformly distributed loads, concentrated loads, and linearly varying loads (including trapezoidal).

Uniform loads act on the full or partial length of a member. Concentrated loads act at any intermediate, specified point. Linearly varying loads act over the full length of a member. Trapezoidal linearly varying loads act over the full or partial length of a member. Trapezoidal loads are converted into a uniform load and several concentrated loads.

Any number of loads may be specified to act upon a member in any independent loading condition. Member loads can be specified in the member coordinate system or the global coordinate system. Uniformly distributed member loads provided in the global coordinate system may be specified to act along the full or projected member length. See G.4.1 Global Coordinate System (on page 2087) to find the relation of the member to the global coordinate systems for specifying member loads. Positive forces act in the positive coordinate directions, local or global, as the case may be.

Uniform moment may not be applied to tapered members. Only uniform load over the entire length is available for curved members.

G.15.3 Area, One-way, and Floor Loads

Often a floor is subjected to a uniform pressure. It could require a lot of work to calculate the equivalent member load for individual members in that floor. However, with the `AREA`, `ONEWAY` or `FLOOR LOAD` facilities, you can specify the pressure (load per unit square area). The program will calculate the tributary area for these members and calculate the appropriate member loads. The Area Load and Oneway load are used for one way distribution and the Floor Load is used for two way distribution.

The following assumptions are made while transferring the area/floor load to member load:

a. The member load is assumed to be a linearly varying load for which the start and the end values may be of different magnitude.

b. Tributary area of a member with an area load is calculated based on half the spacing to the nearest approximately parallel members on both sides. If the spacing is more than or equal to the length of the member, the area load will be ignored. Oneway load does not have this limitation.

c. These loading types should not be specified on members declared as `MEMBER CABLE`, `MEMBER TRUSS`, `MEMBER TENSION`, `MEMBER COMPRESSION`, or `CURVED`.

Note: Floor Loads and One-way Loads can be reduced when included in a load case defined as “Reducible” according to the UBC/IBC rules.

An example:

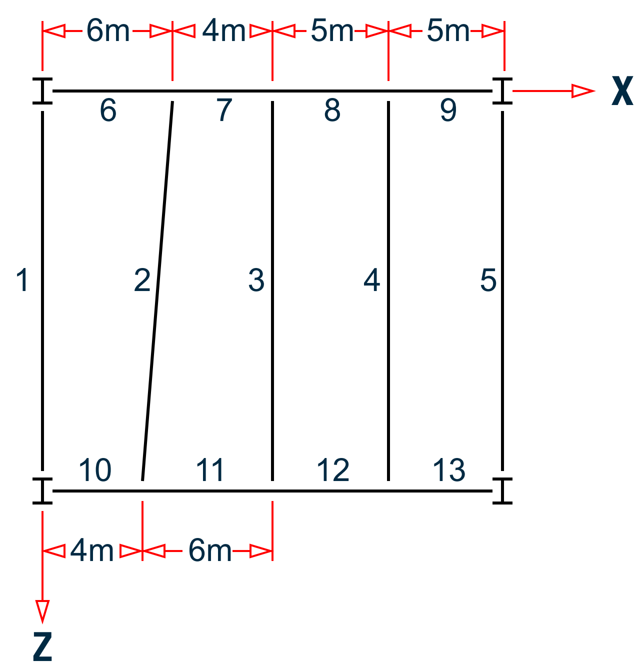

Figure 246: Example floor structure with area load specification of 0.1

Member 1 will have a linear load of 0.3 at one end and 0.2 at the other end. Members 2 and 4 will have a uniform load of 0.5 over the full length. Member 3 will have a linear load of 0.45 and 0.55 at respective ends. Member 5 will have a uniform load of 0.25. The rest of the members, 6 through 13, will have no contributory area load since the nearest parallel members are more than each of the member lengths apart. However, the reactions from the members to the girder will be considered.

Only member loads are generated from the Area, Oneway, and Floor load input. Thus, load types specific to plates, solids or surface are *not* generated. That is because, the basic assumption is that, a floor load or area load is used in situations where the basic entity (plate, solid or surface) which acts as the medium for application of that load, is not part of the structural model.

The Oneway load is intended to be used in areas with relatively large aspect rations between adjacent sides. It should not be used on members with square tributary areas unless the `TOWARDS` option is used, which then specifies to which of the two equal directions the load should be applied. Otherwise, the Floor Load type should be used.

Note: Failure to specify a `TOWARD` side on a Oneway load applied to a square tributary area will likely result in lost load or unintended load path changes.

- *TR.32.4.2 One-way Load Specification* (on page 2476)
- *TR.32.4.3 Floor Load Specification* (on page 2483)

G.15.4 Fixed End Member Load

Load effects on a member may also be specified in terms of its fixed end loads. These loads are given in terms of the member coordinate system and the directions are opposite to the actual load on the member. Each end of a member can have six forces: axial; shear y; shear z; torsion; moment y, and moment z.

Related Links

- *TR.32.7 Fixed-End Load Specification* (on page 2494)
- *Member Load tab* (on page 2842)
- *M. To add fixed end member loads* (on page 837)
- *TR.32.7 Fixed-End Load Specification* (on page 2494)

G.15.5 Prestress and Poststress Member Load

Members in a structure may be subjected to prestress load for which the load distribution in the structure may be investigated. The prestressing load in a member may be applied axially or eccentrically. The eccentricities can be provided at the start joint, at the middle, and at the end joint. These eccentricities are only in the local y-axis.

A positive eccentricity will be in the positive local y-direction. Since eccentricities are only provided in the local y-axis, care should be taken when providing prismatic properties or in specifying the correct `BETA` angle when rotating the member coordinates, if necessary. Two types of prestress load specification are available; `PRESTRESS`, where the effects of the load are transmitted to the rest of the structure, and `POSTSTRESS`, where the effects of the load are experienced exclusively by the members on which it is applied.

1. The cable is assumed to have a generalized parabolic profile. The equation of the parabola is assumed to be

   $$y = ax^2 + bx + c$$

   where

a	=	$1/L^2 (2es - 4em + 2ee)$
b	=	$1/L (4em - ee - 3es)$
c	=	es
es	=	eccentricity of the cable at the start of the member (in local y-axis)
em	=	eccentricity of the cable at the middle of the member (in local y-axis)
ee	=	eccentricity of the cable at the end of the member (in local y-axis)
L	=	Length of the member

2. The angle of inclination of the cable with respect to the local x-axis (a straight line joining the start and end joints of the member) at the start and end points is small which gives rise to the assumption that

   $$\sin\theta = \theta = dy/dx$$

   Hence, if the axial force in the cable is P, the vertical component of the force at the ends is $P(dy/dx)$ and the horizontal component of the cable force is,

   $$P[1 - (dy/dx)^2]^{1/2}$$

   Users are advised to ensure that their cable profile meets this requirement. An angle under 5 degrees is recommended.
3. The member is analyzed for the prestressing / poststressing effects using the equivalent load method. This method is well documented in most reputed books on Analysis and Design of Prestressed concrete. The magnitude of the uniformly distributed load is calculated as

   $$udl = 8 \cdot Pe/L^2$$

   where

P	=	Axial force in the cable
e	=	$(es + ee)/2 - em$
L	=	Length of the member

4. The force in the cable is assumed to be same throughout the member length. No reduction is made in the cable forces to account for friction or other losses.
5. The term `MEMBER PRESTRESS` as used in STAAD.Pro signifies the following condition. The structure is constructed first. Then, the prestressing force is applied on the relevant members. As a result, the members deform and depending on their end conditions, forces are transmitted to other members in the structure. In other words, “`PRE`” refers to the time of placement of the member in the structure relative to the time of stressing.
6. The term `MEMBER POSTSTRESS` as used in STAAD.Pro signifies the following condition. The members on which such load is applied are first cast in the factory. Following this, the prestressing force is applied on them. Meanwhile, the rest of the structure is constructed at the construction site. Then, the prestressed members are brought and placed in position on the partially built structure. Due to this sequence, the effects of prestressing are “experienced” by only the prestressed members and not transmitted to the rest of the structure. In other words, “`POST`” refers to the time of placement of the member in the structure relative to the time of stressing.

7. As may be evident from Item (6) above, it is not possible to compute the displacements of the ends of the `POSTSTRESSED` members for the effects of poststressing, and hence are assumed to be zero. As a result, displacements of intermediate sections (See SECTION DISPLACEMENT command) are measured relative to the straight line joining the start and end joints of the members as defined by their initial `JOINT COORDINATES`.

- *TR.32.5 Prestress Load Specification* (on page 2489)

G.15.6 Temperature and Strain Load

Uniform temperature difference throughout members and elements may be specified. Temperature differences across both faces of members and through the thickness of plates may also be specified (uniform temperature only for solids).. The program calculates the axial strain (elongation and shrinkage) due to the temperature difference for members. From this it calculates the induced forces in the member and the analysis is done accordingly. The strain intervals of elongation and shrinkage can be input directly.

Related Links

- *TR.32.6 Temperature Load Specification for Members, Plates, and Solids* (on page 2493)

G.15.7 Support Displacement Loads

Static Loads can be applied to the structure in terms of the displacement of the supports. Displacement can be translational or rotational. Translational displacements are provided in the specified length while the rotational displacements are always in degrees. Note that displacements can be specified only in directions in which the support has an “enforced” specification in the Support command.

G.15.8 Loading on Elements

On Plate/Shell elements, the types of loading that are permissible are:

1. Pressure loading which consists of loads which act perpendicular to the surface of the element. The pressure loads can be of uniform intensity or trapezoidally varying intensity over a small portion or over the entire surface of the element.
2. Joint loads which are forces or moments that are applied at the joints in the direction of the global axes.
3. Temperature loads which may be constant throughout the plate element (causing only elongation / shortening) or may vary across the depth of a plate element causing bending on the plate element.. The coefficient of thermal expansion for the material of the element must be provided in order to facilitate computation of these effects.
4. The self-weight of the elements can be applied using the `SELFWEIGHT` loading condition. The density of the elements has to be provided in order to facilitate computation of the self-weight.

On Solid elements, the loading types available are:

1. The self-weight of the solid elements can be applied using the `SELFWEIGHT` loading condition. The density of the elements has to be provided in order to facilitate computation of the self-weight.
2. Joint loads which are forces or moments that are applied at the joints in the direction of the global axes.
3. Temperature loads which may be constant throughout the solid elements (causing only elongation / shortening). The coefficient of thermal expansion for the material of the element must be provided in order to facilitate computation of these effects.
4. Pressure on the faces of solids.

Only translational stiffness is supported in solid elements. Thus, at joints where there are only solid elements, moments may not be applied. For efficiency, rotational supports should be used at these joints.

G.16 Load Generator

Load generation is the process of taking a load causing unit such as wind pressure, ground movement or a truck on a bridge, and converting it to a form such as member load or a joint load which can be then be used in the analysis.

For seismic loads, a static analysis method or a dynamic analysis method can be adopted. The static analysis method, which is the one referred to here, is based on codes such as UBC, IBC, AIJ, IS1893 etc. For dynamic analysis, see the sections in this chapter on response spectrum and time history analysis.

Input for the load generation facility consists of two parts:

1. Definition of the load system(s).
2. Generation of primary load cases using previously defined load system(s).

Related Links

- *TR.31 Definition of Load Systems* (on page 2345)

G.16.1 Moving Load Generator

This feature enables the user to generate static loads on members due to vehicles moving on a structure. Moving load systems consisting of concentrated loads at fixed specified distances in both directions on a plane can be defined by the user. A user specified number of primary load cases will be subsequently generated by the program and taken into consideration in analysis. American Association of State Highway and Transportation Officials (AASHTO) vehicles are available within the program and can be specified using standard AASHTO designations.

G.16.2 Seismic Load Generator

The STAAD.Pro seismic load generator follows the procedure of equivalent lateral load analysis explained in UBC, IBC and several other codes. It is assumed that the lateral loads will be exerted in X and Z (or X and Y if Z is up) directions (horizontal) and Y (or Z if Z is up) will be the direction of the gravity loads. Thus, for a building model, Y (or Z if Z is up) axis will be perpendicular to the floors and point upward (all Y (or Z if Z is up) joint coordinates positive). The user is required to set up his model accordingly. Total lateral seismic force or base shear is automatically calculated by STAAD using the appropriate equation from the code. IBC 2003, IBC 2000, UBC 1997, 1994, or 1985, IS:1893, Japanese, Colombian and other specifications may be used.

For load generation per the codes, the user is required to provide seismic zone coefficients, importance factors, soil characteristic parameters, etc.

Instead of using the approximate code based formulas to estimate the building period in a certain direction, the program calculates the period using Rayleigh quotient technique. This period is then utilized to calculate seismic coefficient C.

After the base shear is calculated from the appropriate equation, it is distributed among the various levels and roof per UBC specifications. The distributed base shears are subsequently applied as lateral loads on the structure. These loads may then be utilized as normal load cases for analysis and design.

G.16.3 Wind Load Generator

The Wind Load Generator is a utility which takes as input wind pressure and height ranges over which these pressures act and generates nodal point and member loads.

This facility is available for two types of structures.

- Panel type or Closed structures
- Open structures

Closed Structures

Closed structures are ones like office buildings where non-structural entities like a glass facade, aluminum sheets, timber panels or non-load bearing walls act as an obstruction to the wind. If these entities are not included in the structural model, the load generated as a result of wind blowing against them needs to be computed. So, the steps involved in load generation for such structures are:

i. Identify the panels – regions circumscribed by members so that a polygonal closed area is formed. The area may also be formed between the ground level along one edge and members along the other.
ii. Calculate the center of gravity (CG) of each of the panels.
iii. For each panel, draw straight lines from the center of gravity to the midpoint of the members (or the ground) that form the panel boundary. The panel region will now contain several quadrilaterals whose two sides are made of portions of the respective members (or the ground) and the other two sides are lines going from the CG to the midpoint of the corresponding members.

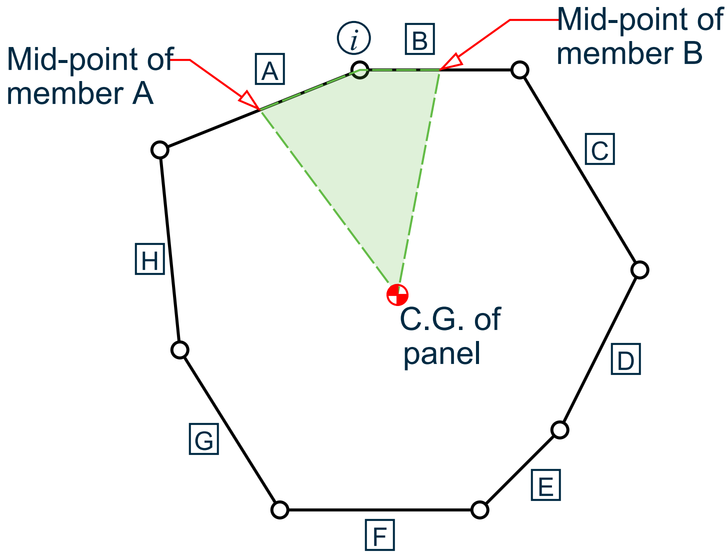

Figure 247: Influence area of Node i

iv. The area contained in any quadrilateral is allocated as the influence area for the node located at the meeting point of two members.

v. Multiply the influence area by the average wind pressure contained inside the influence area and by the exposure factor for the node. The resulting value is the concentrated wind force for the joint.

Plates and solids are not considered in the calculation of the panel area. Openings within the panels may be modeled with the help of exposure factors. An exposure factor is associated with each joint of the panel and is a fractional number by which the area affecting a joint of the panel can be reduced or increased.

The automated load generator should only be used for vertical panels. Panels not parallel to the global Y axis (for `Y UP`) should be loaded separately.

Open Structures

Open structures are those like transmission towers, in which the region between members is “open” allowing the wind to blow through. The procedure for load generation for open structures is

i. Calculate the exposed area of the individual members of the model.

ii. Multiply that exposed area by the wind pressure to arrive at the force and apply the force on individual members as a uniformly distributed load.

It is assumed that all members of the structure within the specified ranges are subjected to the pressure and hence, they will all receive the load. The concept of members on the windward side shielding the members in the inside regions of the structure does not exist for open structures. Members loaded as an open structure need not be vertical.

G.16.4 Snow Load

STAAD.Pro is capable of generating snow loading on a structure in accordance with the provisions of the ASCE-7-02 code. The feature is currently implemented for structures with flat or sloping roofs. Snow load generation for members of open lattice structures like electrical transmission towers is currently not part of this facility. Hence, the feature is based on panel areas, not the exposed width of individual members.

G.17 Analysis Facilities

Salient features of each type of analysis are discussed in the following sections. Detailed theoretical treatments of these features are available in standard structural engineering textbooks.

Related Links

- *TR.37.1 Linear Elastic Analysis* (on page 2620)

G.17.1 Stiffness Analysis

The stiffness analysis implemented in STAAD.Pro is based on the matrix displacement method. In the matrix analysis of structures by the displacement method, the structure is first idealized into an assembly of discrete structural components.

Structural systems such as slabs, plates, spread footings, etc., which transmit loads in two directions (frame members or finite elements) have to be discretized into a number of three- or four-noded finite elements connected to each other at their nodes. Each component has an assumed form of displacement in a manner which satisfies the force equilibrium and displacement compatibility at the joints. Loads may be applied in the form of distributed loads on the element surfaces or as concentrated loads at the joints. The plane stress effects as well as the plate bending effects are taken into consideration in the analysis.

Assumptions of the Analysis

For a complete analysis of the structure, the necessary matrices are generated on the basis of the following assumptions:

1. The structure is idealized into an assembly of beam, plate and solid type elements joined together at their vertices (nodes). The assemblage is loaded and reacted by concentrated loads acting at the nodes. These loads may be both forces and moments which may act in any specified direction.

2. A beam member is a longitudinal structural member having a constant, doubly symmetric or near-doubly symmetric cross section along its length. Beam members always carry axial forces. They may also be subjected to shear and bending in two arbitrary perpendicular planes, and they may also be subjected to torsion. From this point these beam members are referred to as “members” in the manual.
3. A plate element is a three or four noded planar element having variable thickness. A solid element is a four-to-eight- noded, three dimensional element. These plate and solid elements are referred to as “elements” in the manual.
4. Internal and external loads acting on each node are in equilibrium. If torsional or bending properties are defined for any member, six degrees of freedom are considered at each node (i.e., three translational and three rotational) in the generation of relevant matrices. If the member is defined as truss member (i.e., carrying only axial forces) then only the three degrees (translational) of freedom are considered at each node.
5. Two types of coordinate systems are used in the generation of the required matrices and are referred to as local and global systems.

Local coordinate axes are assigned to each individual element and are oriented such that computing effort for element stiffness matrices are generalized and minimized. Global coordinate axes are a common datum established for all idealized elements so that element forces and displacements may be related to a common frame of reference.

Basic Equation

The complete stiffness matrix of the structure is obtained by systematically summing the contributions of the various member and element stiffness. The external loads on the structure are represented as discrete concentrated loads acting only at the nodal points of the structure.

The stiffness matrix relates these loads to the displacements of the nodes by the equation:

$$A_j = a_j + S_j \cdot D_j$$

This formulation includes all the joints of the structure, whether they are free to displace or are restrained by supports. Those components of joint displacements that are free to move are called degrees of freedom. The total number of degrees of freedom represent the number of unknowns in the analysis.

Method to Solve for Displacements

There are many methods to solve the unknowns from a series of simultaneous equations.

In STAAD.Pro, the element stiffness matrices are assembled into a global stiffness matrix by standard matrix techniques used in FEA programs. The technique used by STAAD.Pro was developed based on routines made available in the public domain. The global stiffness matrix is then decomposed as

$$[\ K\ ] = [LT]\ [D]\ [L]$$

which is a modified Gauss method.

$$[K]\ \{d\} = \{F\}$$

becomes

$$[LT]\ [D]\ [L]\ \{d\} = \{F\}$$

which can be manipulated into a forward and a backward substitution step to obtain $\{d\}$. STAAD.Pro can detect singular matrices and solve then via a technique copied from Stardyne. To solve the matrices, the program uses an approach is used that is mathematically equivalent to the modified Choleski method. However the order of operations, memory use, and file use is highly optimized.

Consideration of Bandwidth

Internal storage order is automatically calculated to minimize time and memory.

Multiple Structures & Structural Integrity

The integrity of the structure is a very important requirement that must be satisfied by all models. You must make sure that the model developed represents one or more properly connected structures.

An "integral" structure may be defined as a system in which proper "stiffness connections" exist between the members/elements. The entire model functions as one or more integrated load resisting systems. STAAD.Pro checks structural integrity using a sophisticated algorithm and reports detection of multiple structures within the model. If you did not intend for there to be multiple structures, then you can fix it before any analysis. There are several additional model checking tools found on the **Utilities** ribbon tabs.

Modeling and Numerical Instability Problems

Instability problems can occur due to two primary reasons.

1. Modeling problem

   There are a variety of modeling problems which can give rise to instability conditions. They can be classified into two groups.

   a. Local instability - A local instability is a condition where the fixity conditions at the end(s) of a member are such as to cause an instability in the member about one or more degrees of freedom. Examples of local instability are:

      i. Member Release: Members released at both ends for any of the following degrees of freedom (FX, FY, FZ and MX) will be subjected to this problem.
      ii. A framed structure with columns and beams where the columns are defined as "TRUSS" members. Such a column has no capacity to transfer shears or moments from the superstructure to the supports.

   b. Global Instability - These are caused when the supports of the structure are such that they cannot offer any resistance to sliding or overturning of the structure in one or more directions. For example, a 2D structure (frame in the XY plane) which is defined as a SPACE FRAME with pinned supports and subjected to a force in the Z direction will topple over about the X-axis. Another example is that of a space frame with all the supports released for FX, FY or FZ.
2. Math precision

   A math precision error is caused when numerical instabilities occur in the matrix inversion process. One of the terms of the equilibrium equation takes the form $1/(1-A)$, where $A=k1/(k1+k2)$; k1 and k2 being the stiffness coefficients of two adjacent members. When a very "stiff" member is adjacent to a very "flexible" member, viz., when $k1>>k2$, or k1+k2 k1, A=1 and hence, $1/(1-A) =1/0$. Thus, huge variations in stiffnesses of adjacent members are not permitted. Artificially high E or I values should be reduced when this occurs.

   Math precision errors are also caused when the units of length and force are not defined correctly for member lengths, member properties, constants etc.

   You must also ensure that the model defined represents one single structure only, not two or more separate structures. For example, in an effort to model an expansion joint, you may end up defining separate structures within the same input file. Multiple structures defined in one input file can lead to grossly erroneous results.

G.17.2 Second Order Analysis

STAAD.Pro offers the capability to perform second order stability analyses.

G.17.2.1 P-Delta Analysis

Structures subjected to lateral loads often experience secondary forces due to the movement of the point of application of vertical loads. This secondary effect, commonly known as the P-Delta effect, plays an important role in the analysis of the structure.

In textbooks this secondary effect is typically referred to as stress stiffening for members in tension (or softening for compression). The stiffness changes due to P-Delta are known as geometric stiffness, [Kg]. There are two types of P-Delta effects for members. P-Δ which is due to the displacement of one end of a member relative to the other end (e.g., story drift of column members). A second effect is P-δ which is due to the bending of the member.

P-δ due to the bending of the member not only affects the local & global stiffness, nodal displacements, and member end forces; it also has an additional effect on the section displacements and section moments. The (axial compressive member force) times (the local relative to the ends section displacement) gives a section moment in addition to the flexural moment. This additional section moment will cause an additional sectional displacement; and so on. Normally this process will converge after 5-20 iterations if the member buckling load is not exceeded. STAAD.Pro uses up to 20 iterations unless convergence or divergence occurs.

P-δ due to the bending of the member can also occur with tension if the member has sufficient bending. STAAD only iterates once for tension.

STAAD.Pro does not include the effects of geometric stiffness for solids. If the part of the structure that deforms involves non-trivial motions of solids, then the results will be erroneous for P-Delta analysis (as well as for buckling analysis).

G.17.2.1.1 P-Delta Analysis – Large Delta and Small Delta

In STAAD.Pro, a procedure has been adopted to incorporate the P-Delta effect into the analysis without re-forming and factorizing the global stiffness matrix on each iteration. Actually, only the global stiffness matrix is formed and factorized; which must be done for any analysis. Only the relatively fast forward and backward substitution step for typically five to 25 iterations must be performed. This step is done simultaneously for however many cases are being solved. See G.17.2.1.2 P-Delta Kg Analysis (on page 2142) for an alternate formulation of P-Delta that may be used in dynamics.

Note: This feature is available in STAAD.Pro 2007 Build 01 and greater.

If a structure is heavily loaded it may become unstable for some load cases. It may take 10 to 30 iterations for this instability to become obvious by the maximum displacements or bending moment envelope values becoming very large or infinite or reported as NaN (“not a number”).

The procedure consists of the following steps:

1. First, the primary deflections are calculated based on the provided external loading.
2. Primary deflections are used to calculate member axial forces and plate center membrane stresses. By default the small delta effects are calculated. To include only the large delta effects, enter the `LARGEDELTA` option on the `PDELTA` command. These forces and stresses are used to calculate geometric stiffness terms. These terms times the displacement results from the prior iteration create the P-Delta secondary loading. This secondary loading is then combined with the originally applied loading to create the effective load vector for the next iteration.

   The lateral loading must be present concurrently with the vertical loading for proper consideration of the P-Delta effect. The `REPEAT LOAD` facility has been created with this requirement in mind. This facility allows you to combine previously defined primary load cases to create a new primary load case.
3. The revised load vector is used with the static triangular factorized matrix to generate new deflections.
4. Element/Member forces and support reactions are calculated based on the new deflections.

Repeat steps 2 to 4 for several iterations. Three to 30 iterations are recommended. This procedure yields reasonably accurate results with small displacement problems. You are allowed to specify the number of iterations. If the Converged option is used, then set the displacement convergence tolerance by entering a `SET PDELTATOL` i_9 command before the Joint Coordinates. If all changes in displacement dof from one iteration to the next is less than the specified tolerance value, i_9, then that case is converged.

The P-Delta analysis is recommended by several design codes such as ACI 318, LRFD, IS456-1978, etc. in lieu of the moment magnification method for the calculation of more realistic forces and moments.

P-Delta effects are calculated for frame members and plate elements only. They are not calculated for solid elements. P-Delta has the most effect in structures where there are vertical and horizontal loads in the same load case.

The maximum displacement should be reviewed for P-Delta analyses because this analysis type permits large buckling displacements if the loads make the structure unstable. You may need to repeat the analysis with only one to five iterations in order to get a pre-collapse solution in order to view the large displacement areas.

The section moment due to tension and the section displacements due to shear/bending are added to the moment diagram, if small delta is selected. This is no iteration performed for this step.

Related Links

- *TR.37.2 P-Delta Analysis Options* (on page 2621)

G.17.2.1.2 P-Delta Kg Analysis

In STAAD.Pro, an alternate procedure has been adopted to incorporate the P-Delta effect into the analysis by combining the global stiffness matrix and the global geometric stiffness matrix [K+Kg].

Note: This feature is available in STAAD.Pro 2007 Build 01 and greater.

1. First, the primary deflections are calculated by linear static analysis based on the provided external loading.
2. Primary deflections are used to calculate member axial forces and plate center membrane stresses. These forces and stresses are used to calculate geometric stiffness terms. Both the large delta effects and the small delta effects are calculated. These terms are the terms of the Kg matrix which are added to the global stiffness matrix K.

   The lateral loading must be present concurrently with the vertical loading for proper consideration of the P-Delta effect. The `REPEAT LOAD` facility has been created with this requirement in mind. This facility allows the user to combine previously defined primary load cases to create a new primary load case.

This procedure yields reasonably accurate results with small displacement problems. STAAD.Pro allows the user to specify multiple iterations of this P-Delta-KG procedure; however one iteration is almost always sufficient.

The P-Delta analysis is recommended by several design codes such as ACI 318, LRFD, IS456-1978, etc. in lieu of the moment magnification method for the calculation of more realistic forces and moments.

P-Delta effects are calculated for frame members and plate elements only. They are not calculated for solid elements.

The maximum displacement should be reviewed for P-Delta analyses because this analysis type permits buckling. You may need to repeat the analysis with only one to five iterations or as a static case in order to get a pre-collapse solution in order to view the large displacement areas.

Buckling may also cause the analysis to fail with a negative definite matrix failure. In this case, a message is printed and the results of the case are set to zero. (In this case, repeat the analysis using `PDELTA 30 ANALYSIS SMALLDELTA` instead).

Related Links

- *TR.37.2 P-Delta Analysis Options* (on page 2621)

G.17.2.1.3 P-Delta K+Kg Dynamic Analysis

In STAAD.Pro, an alternate procedure has been adopted to incorporate the P-Delta effect into dynamic analysis by combining the global stiffness matrix and the global geometric stiffness matrix [K+Kg].

Note: This feature is available in STAAD.Pro 2007 Build 01 and greater.

This method uses the resulting [K+Kg] matrices from the last static case before the `PDELTA KG` command in the dynamic cases that precede the `PDELTA KG` command.

```
LOAD n
static case input
LOAD n+1
dynamic load case
PDELTA KG ANALYSIS
```

1. First, the primary deflections are calculated by linear static analysis based on the provided external loading for case *n*.
2. Primary deflections are used to calculate member axial forces and plate center membrane stresses. These forces and stresses are used to calculate geometric stiffness terms. Both the large delta effects and the small delta effects are calculated. These terms are the terms of the Kg matrix which are added to the global stiffness matrix K.

The final triangular factorization for case *n* is then used in the dynamic case *n+1* along with the masses specified in case n+1 to solve the dynamic analysis.

Lateral loading must be present concurrently with the vertical loading for proper consideration of the P-Delta effect. The `REPEAT LOAD` facility has been created with this requirement in mind. This facility allows the user to combine previously defined primary load cases to create a new primary load case.

P-Delta effects are calculated for frame members and plate elements only. They are not calculated for solid elements. P-Delta is restricted to structures where members and plate elements carry the vertical load from one structure level to the next.

The maximum displacement should be reviewed for P-Delta analyses because this analysis type permits buckling. You may need to repeat the analysis with only one to five iterations or as a static case in order to get a pre-collapse solution in order to view the large displacement areas.

Buckling may also cause the analysis to fail with a negative definite matrix failure. In this case a message is printed and the results of the case are set to zero. The dynamic results should be ignored if this type of failure should occur.

- *TR.37.2 P-Delta Analysis Options* (on page 2621)

G.17.2.1.4 AISC 360 Direct Analysis

AISC 360-10/16 Chapter C and AISC 360-05 Appendix 7 describe a method of analysis, called “direct analysis”, which accounts for the second order effects resulting from deformation in the structure due to applied loading, imperfections and reduced bending stiffness of members due to the presence of axial load.

The ANSI/AISC 360 direct analysis procedure has been adopted to incorporate the P-Delta effect into a static analysis by combining the global stiffness matrix and the global geometric stiffness matrix $[K+Kg]$; plus flexural stiffness reduction; plus axial stiffness reduction; plus an additional flexure reduction if member axial compression forces are above 50% of yield; plus the addition of notional loads.

This is a nonlinear, iterative analysis as the stiffness of the members is dependent upon the forces generated by the load.

1. The primary deflections are calculated by linear static analysis based on the provided external loading for case *n*. The stiffness reductions and notional loads are included here.
2. Primary deflections are used to calculate member axial forces and plate center membrane stresses. These forces and stresses are used to calculate geometric stiffness terms. Both the large delta effects and the small delta effects are calculated. These forces and stresses are used to calculate geometric stiffness terms. These terms times the displacement results from the prior iteration create the P-Delta secondary loading. This secondary loading is then combined with the originally applied loading to create the effective load vector for the next iteration.
3. The final triangular factorization for case n is then used to calculate displacements and member forces.

   Lateral loading must be present concurrently with the vertical loading for proper consideration of the P-Delta effect. The `REPEAT LOAD` facility has been created with this requirement in mind. This facility allows you to combine previously defined primary load cases to create a new primary load case.
4. The axial force is compared to yield force to calculate τ_b (see Chapter C or AISC 360-10/16 or Appendix 7 of AISC 360-05). Flexure stiffness of selected members is set to ($0.80 \times \tau_b \cdot EI$)
5. Steps 2 to 4 are repeated until convergence or the iteration limit is reached.

   The analysis will iterate; in each step, changing the member characteristics until the maximum change in any τ_b is less than the specified τ tolerance. If the maximum change in any τ_b is less than 100 times the τ tolerance *and* the maximum change in any displacement degree of freedom is less than the specified displacement tolerance; then the solution has converged for this case.

General Procedure for Using the Direct Analysis Feature

There are three general steps required to set up a Direct Analysis:

1. Specify the definition with the `DEFINE DIRECT` command.
2. Specify the notional loads using the `NOTIONAL LOAD` load specification.
3. Specify a direct analysis method with the `PERFORM DIRECT ANALYSIS` command. Within this command, you will specify the tolerances or iteration limits.

G.17.2.2 Buckling Analysis

In STAAD.Pro, two procedures have been adopted to incorporate the calculation of the Buckling Factor for a load case. The buckling factor is the amount by which all of the loadings in a load case must be factored to cause global buckling of the structure.

Note: This feature is available in STAAD.Pro 2007 Build 01 and greater.

STAAD.Pro does not include the effects of geometric stiffness for solids. If the part of the structure that deforms during buckling involves non-trivial motions of solids, then the results will be erroneous for buckling (as well as for P-Delta analysis).

G.17.2.2.1 Buckling Analysis - Iterative Method

In STAAD.Pro, a simple procedure has been adopted to incorporate the calculation of the Buckling Factor for any number of primary load cases. The buckling factor is the amount by which all of the loadings in a load case must be factored to cause global buckling of the structure.

1. First, the primary deflections are calculated by linear static analysis based on the provided external loading.
2. Primary deflections are used to calculate member axial forces and plate center membrane stresses. These forces and stresses are used to calculate geometric stiffness terms. Both the large delta effects and the small delta effects are calculated. These terms are the terms of the Kg matrix which are multiplied by the estimated BF (buckling factor) and then added to the global stiffness matrix K.

Buckling Kg matrix effects are calculated for frame members and plate elements only. They are not calculated for solid elements. So buckling analysis is restricted to structures where members and plate elements carry the vertical load from one structure level to the next.

3. For compressive cases, the Kg matrix is negative definite. If the buckling factor is large enough, then $[\ [K] + BF \times [Kg]\ ]$ will also be negative definite which indicates that BF times the applied loads is greater than the loading necessary to cause buckling.
4. STAAD.Pro starts an iterative procedure with a BF estimate of 1.0. If that BF causes buckling, then a new, lower BF estimate is used in the next trial. If the BF does not cause buckling, then a higher BF estimate is used. On the first iteration, if the determinant of the K matrix is positive and lower than the determinant of the K+Kg matrix, then the loads are in the wrong direction to cause buckling; and STAAD.Pro will stop the buckling calculation for that case.
5. After a few iterations, STAAD.Pro will have the largest BF that did not cause buckling (lower bound) and the lowest BF that did cause buckling (upper bound). Then each trial will use a BF estimate that is halfway between the current upper and lower bounds for BF.
6. After the default iteration limit is reached or the user specified iteration limit, `MAXSTEPS`, is reached or when two consecutive BF estimates are within 0.1% of each other; then the iteration is terminated.
7. Results for this load case are based on the last lower bound BF calculated.

- Only primary load cases may be solved
- Any number of buckling cases may be solved.
- Only the first buckling mode (lowest BF) is calculated.
- The buckling shape may not be as expected even though the buckling factor is OK. To enhance the mode shape result, apply small loads in the locations and directions where you expect the large displacements.

Note: During the buckling analysis using the iterative method, if the determinant of the matrix changes sign in one or more steps, then the resulting values of displacements and forces for the last successful step may not be accurate. If using STAAD.Pro Advanced, then it is recommended to check the buckling factor using the eigen method.

G.17.2.2.2 Buckling Analysis - Eigen Method

In STAAD.Pro, a second procedure has been adopted to incorporate the calculation of the Buckling Factor for one primary load case. The buckling factor is the amount by which all of the loadings in a load case must be factored to cause global buckling of the structure. This procedure is an eigenvalue calculation to get buckling factors and buckling shapes.

1. First, the primary deflections are calculated by linear static analysis based on the provided external loading.
2. Primary deflections are used to calculate member axial forces and plate center membrane stresses. These forces and stresses are used to calculate geometric stiffness terms. Both the large delta effects and the small delta effects for members are calculated. These terms are the terms of the Kg matrix.
3. An eigenvalue problem is formed. $|\ [\ K\ ] - BF_i * [\ Kg\ ]\ | = 0$

There will be up to 4 buckling factors (BF) and associated buckling mode shapes calculated. The buckling factor is the amount by which the static load case needs to be multiplied by to just cause buckling (Euler buckling). BF less than 1.0 means that the load causes buckling; greater than 1.0 means buckling has not occurred. If BF is negative, then the static loads are in the opposite direction of the buckling load.

Notes

- Solid elements do not contribute to Kg in STAAD.Pro.

- Buckling shapes for the last buckling case only may be displayed in the postprocessor. If there are several buckling cases, then all will have their buckling factors printed.
- The displacement and member/element results are not calculated for the load case times the buckling factor.

G.17.2.3 Static Geometrically Nonlinear Analysis

In STAAD.Pro, a procedure has been adopted to incorporate the geometric nonlinearities into the analysis by updating the global stiffness matrix and the global geometric stiffness matrix $[K+Kg]$ on every step based on the deformed position. The deformations significantly alter the location or distribution of loads, such that equilibrium equations must be written with respect to the deformed geometry, which is not known in advance.

Note: This requires a STAAD.Pro Advanced license.

1. First, the primary deflections are calculated by linear static analysis based on the provided external loading.
2. Primary deflections are used to calculate member axial forces and plate center membrane stresses. These forces and stresses are used to calculate geometric stiffness terms. Both the large delta effects and the small delta effects are calculated. These terms are the terms of the Kg matrix which are added to the global stiffness matrix K.
3. Next the deflections are recalculated. Now equilibrium is computed in the deformed position to get out of balance forces. The tangential stiffness matrix is determined from each members new position; the Kg matrix is updated; and the out of balance forces are applied to get the next iteration result.
4. Repeat until converged. If displacements are much too large, then try using `ARC 5` to limit displacements on the first linear static step to 5 inches or some suitable value. The `STEP 10` parameter may help by loading the structure over many steps.
5. The options for Newton-Raphson, Kg, Steps = 1 are usually taken; but these options are available for some difficult cases.
6. Offset beams, curved beams, cables are not permitted. Tension/compression is not permitted.

Nonlinear effects are calculated for springs, frame members and plate elements only. They are not calculated for solid elements.

The maximum displacement should be reviewed for nonlinear analyses because this analysis type may result in buckling or large displacements.

The following limitations should be noted regarding static, geometrically nonlinear analyses:

- Large rotations in one step should be avoided by using more steps.
- Very large displacements, unstable structures, and/or post-buckling should be avoided.
- Geometrically nonlinear only. No tension/compression or contact is considered. No yield, plastic moment hinges or bilinear behavior is considered.
- Solids cannot be used for this analysis method.
- Temperature loads are *not* supported for geometric nonlinear analysis.

G.17.2.4 Imperfection Analysis

Structures subjected to vertical and lateral loads often experience secondary forces due to curvature imperfections in the columns and beams. This secondary effect is similar to the P-Delta effect. In STAAD.Pro the procedure consists of the following steps:

1. First, the deflections and the axial forces in the selected imperfect members are calculated based on the provided external loading.
2. The axial forces and the input imperfections are then used to compute an additional loading on the selected imperfect members that are in compression. These additional loads are combined with the originally applied loading.
3. The static analysis is performed with the combined loading to obtain the final result.

The section moment due to tension and the section displacements due to shear/bending are added to the moment diagram, if small delta is selected. This is no iteration performed for this step.

G.17.2.5 Multilinear Analysis

When soil is to be modeled as spring supports, the varying resistance it offers to external loads can be modeled using a multilinear analysis.

An example is when the soil's behavior in tension differs from its behavior in compression. Stiffness-Displacement characteristics of soil can be represented by a multi-linear curve. Amplitude of this curve will represent the spring characteristic of the soil at different displacement values. The load cases in a multi-linear spring analysis must be separated by the `CHANGE` command and `PERFORM ANALYSIS` command. The `SET NL` command must be provided to specify the total number of primary load cases. There may not be any PDELTA, dynamic, or `TENSION/ COMPRESSION` member cases. The multi-linear spring command will initiate an iterative analysis which continues to convergence.

Related Links

- *TR.27.4 Multilinear Spring Support Specification* (on page 2322)

G.17.2.6 Tension- and Compression-Only Analysis

When some members or support springs are linear but carry only tension or only compression, then this analysis may be used.

This analysis is automatically selected if any member or spring has been given the tension or compression only characteristic. This analysis is an iterative analysis which continues to convergence. Any member/ spring that fails its criteria will be inactive (omitted) on the next iteration. Iteration continues until all such members have the proper load direction or are inactive (default iteration limit is 10).

This is a simple method that may not work in some cases because members are removed on interim iterations that are needed for stability. If instability messages appear on the second and subsequent iterations that did not appear on the first cycle, then do not use the solution. If this occurs on cases where only springs are the tension/compression entities, then use multilinear spring analysis.

Note:

If the list of members that are to be considered as tension changes between load cases (which would be characterized with the inclusion of an additional `MEMBER TENSION` command with the revised member list), then this should be followed by an additional analysis command (and a `CHANGE` command) before starting the next load case definition.

If the list of members does not change (i.e., there is no new `MEMBER TENSION` command defined between these load cases), then it is not necessary to include any additional analysis and change commands, the analysis will automatically reset the axial status and iterate to solve for all the specified tension members.

G.17.2.7 Nonlinear Cable or Truss Analysis

Note: This feature is available in limited form.

When all of the members, elements and support springs are linear except for cable and/or preloaded truss members, then this analysis type may be used. This analysis is based on applying the load in steps with equilibrium iterations to convergence at each step. The step sizes start small and gradually increase (15-20 steps is the default). Iteration continues at each step until the change in deformations is small before proceeding to the next step. If not converged, then the solution is stopped. You can then select more steps or modify the structure and rerun.

Structures can be artificially stabilized during the first few load steps in case the structure is initially unstable (in the linear, small displacement, static theory sense).

The user has control of the number of steps, the maximum number of iterations per step, the convergence tolerance, the artificial stabilizing stiffness, and the minimum amount of stiffness remaining after a cable sags.

This method assumes small displacement theory for all members/trusses/elements other than cables & preloaded trusses. The cables and preloaded trusses can have large displacement and moderate/large strain. Cables and preloaded trusses may carry tension and compression but cables have a reduced E modulus if not fully taut. Pretension is the force necessary to stretch the cable/truss from its unstressed length to enable it to fit between the two end joints. Alternatively, you may enter the unstressed length for cables.

The current nonlinear cable analysis procedure can result in compressive forces in the final cable results. The procedure was developed for structures, loadings, and pretensioning loads that will result in sufficient tension in every cable for all loading conditions. The possibility of compression was considered acceptable in the initial implementation because most design codes strongly recommend cables to be in tension to avoid the undesirable dynamic effects of a slack cable such as galloping, singing, or pounding. The engineer must specify initial preloading tensions which will ensure that all cable results are in tension. In addition this procedure is much more reliable and efficient than general nonlinear algorithms. To minimize the compression the `SAGMIN` input variable can be set to a small value such as 0.01, however that can lead to a failure to converge unless many more steps are specified and a higher equilibrium iteration limit is specified. SAGMIN values below 0.70 generally requires some adjustments of the other input parameters to get convergence.

Currently the cable and truss are not automatically loaded by selfweight, but the user should ensure that selfweight is applied in every load case. o not enter component load cases such as wind only; every case must be realistic. Member loads will be lumped at the ends for cables and trusses. Temperature load may also be applied to the cables and trusses. It is OK to break up the cable/truss into several members and apply forces to the intermediate joints. Y-up is assumed and required.

The member force printed for the cable is Fx and is along the chord line between the displaced positions of the end joints.

The analysis sequence is as follows:

1. Compute the unstressed length of the nonlinear members based on joint coordinates, pretension, and temperature.
2. Member/Element/Cable stiffness is formed. Cable stiffness is from EA/L and the sag formula plus a geometric stiffness based on current tension.
3. Assemble and solve the global matrix with the percentage of the total applied load used for this load step.
4. Perform equilibrium iterations to adjust the change in directions of the forces in the nonlinear cables, so that the structure is in static equilibrium in the deformed position. If force changes are too large or convergence criteria not met within 15 iterations then stop the analysis.
5. Go to step 2 and repeat with a greater percentage of the applied load. The nonlinear members will have an updated orientation with new tension and sag effects.
6. After 100% of the applied load has converged then proceed to compute member forces, reactions, and static check. Note that the static check is not exactly in balance due to the displacements of the applied static equivalent joint loads.

The load cases in a nonlinear cable analysis must be separated by the `CHANGE` command and `PERFORM CABLE ANALYSIS` command. The `SET NL` command must be provided to specify the total number of primary load cases. There may not be any Multi-linear springs, compression only, PDelta, NONLINEAR, or dynamic cases.

Also for cables and preloaded trusses:

1. Do not use Member Offsets.
2. Do not include the end joints in control/dependent command.
3. Do not connect to inclined support joints.
4. Y direction must be up.
5. Do not impose displacements.
6. Do not use Support springs in the model.
7. Applied loads do not change global directions due to displacements.
8. Do not apply Prestress load, Fixed end load.
9. Do not use Load Combination command to combine cable analysis results. Use a primary case with Repeat Load instead.

G.17.2.8 Advanced Nonlinear Cable Analysis

When all of the members, elements, and support springs are linear except for cable members, then this analysis type may be used.

Note: This feature is available in limited form.

You have control of the number of steps, the maximum number of iterations per step, the convergence tolerance, include/exclude Kg matrix and use full/modified Newton-Raphson method.

The nonlinear static solver employs the Newton method (full Newton *or* modified Newton method) to analyze nonlinear problems. In STAAD.Pro, cable elements and P-Delta effect in beam/column and plates cause geometric nonlinearity.

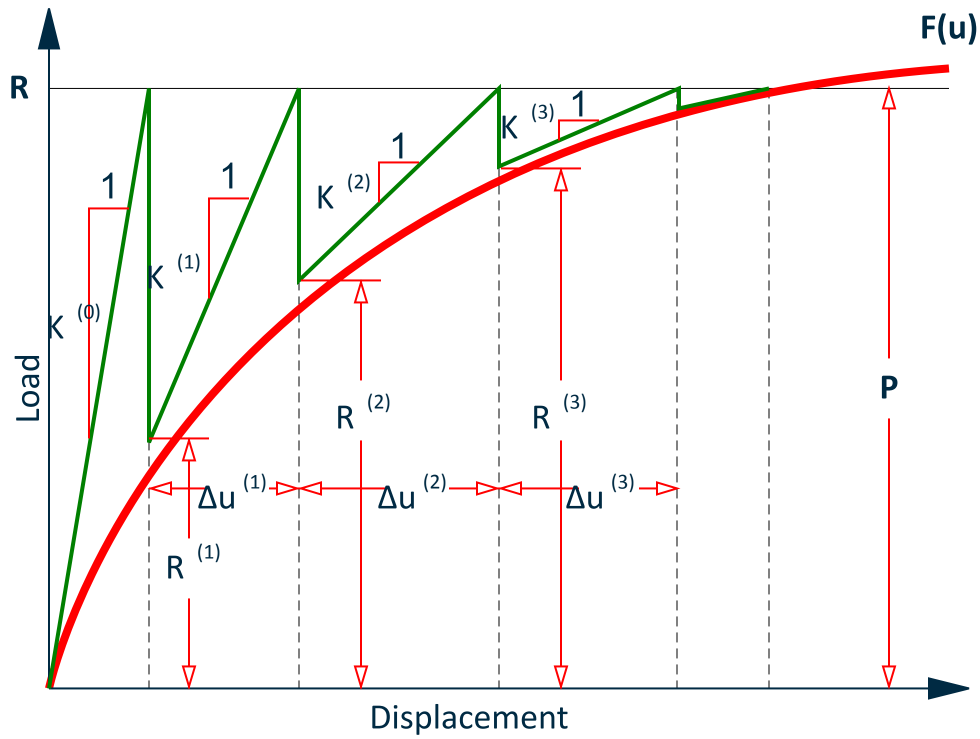

Figure 248: Numerical representation of the nonlinear static solver with full Newton method

Steps Included in the Analysis

The nonlinear static analysis has several steps.

1. Final applied loading vector *{Pext}* is assembled. Incremental load vector *{P}* = *{Pext}*/*nSteps* is calculated where nSteps is the number of load steps. *{uprev}*= *{0}* is also defined
2. For the first iteration, the unbalanced loading *{ΔP}*=*{P}* and displacement vector *{u}*=*{uprev}*, the stiffness matrix *[K]* are assembled. If any elements are performing nonlinearly, their element stiffness matrix will be determined based on their current nonlinear status.
3. The equation *[K]{Δu}* =*{ΔP}* is solved to find out the incremental displacement *{Δu}*.
4. The current displacement vector is calculated as *{u}* =*{u}*+*{Δu}*.
5. This newly calculated *{u}* is used to update all elements nodal coordinates.
6. Based on the updated elements, the element reaction *{R}* is calculated.
7. The unbalanced loading now becomes *{ΔP}*=*{P}*-*{R}*.
8. Convergence is checked by comparing |*{ΔP}*|/*{P}* with *ε*. If convergence is achieved the current displacement is saved as the displacement of previous iteration, i.e. *{uprev}* = *{u}*. The next load increment is applied and same all steps are repeated.
9. If convergence is not achieved, steps 2-7 are repeated until convergence is achieved or the maximum iteration number is reached.

Theory of Cable Elements

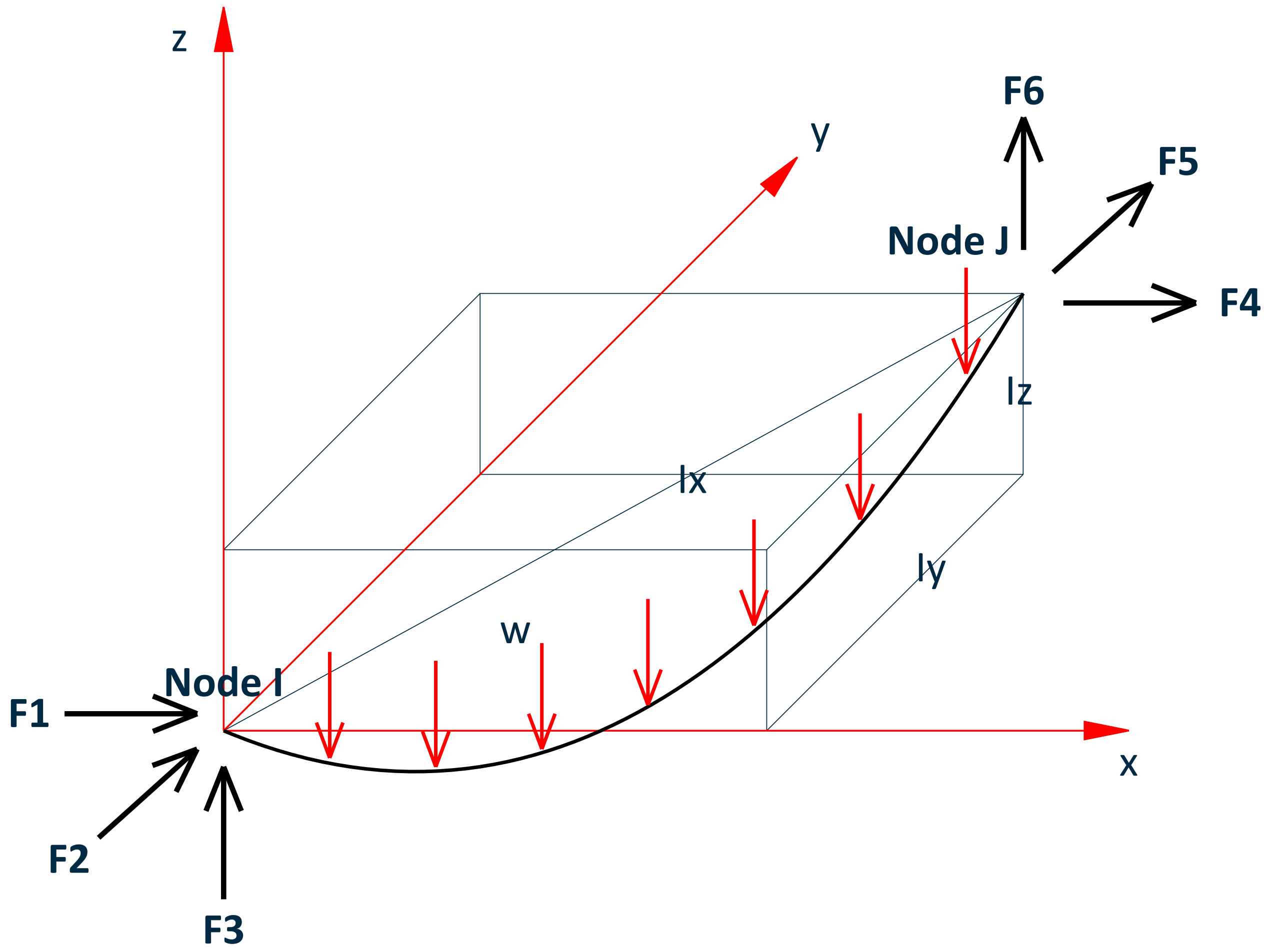

Figure 249: 3D cable sketch

The cable element formulation follows the catenary theory. It is a nonlinear element with geometric nonlinearity, but without material nonlinearity. For a 3D cable element shown in Figure 2, the free body equilibrium is:

$$T\frac{dx}{dp} = -F_1 \tag{1a}$$

$$T\frac{dy}{dp} = -F_2 \tag{1b}$$

$$T\frac{dz}{dp} = -F_3 + ws \tag{1c}$$

With geometrical constraint equations and constitutive equations, the relationship between chord length components l_x, l_y, lz and end support force components F_1, F_2, F_3 could be derived as:

$$l_x = -\frac{F_1 L_0}{EA} - \frac{F_1}{w}\left\{ln\left[\sqrt{F_1^2 + F_2^2 + (wL_0 - F_3)^2} + wL_0 - F_3\right] - ln\left(\sqrt{F_1^2 + F_2^2 + F_3^2} - F_3\right)\right\} \tag{2a}$$

$$l_y = -\frac{F_2 L_0}{EA} - \frac{F_2}{w}\left\{ln\left[\sqrt{F_1^2 + F_2^2 + (wL_0 - F_3)^2} + wL_0 - F_3\right] - ln\left(\sqrt{F_1^2 + F_2^2 + F_3^2} - F_3\right)\right\} \tag{2b}$$

$$l_z = -\frac{F_3 L_0}{EA} + \frac{wL_0^2}{2EA} + \frac{1}{w}\left[\sqrt{F_1^2 + F_2^2 + (wL_0 - F_3)^2} - \sqrt{F_1^2 + F_2^2 + F_3^2}\right] \tag{2c}$$

Then the derivative express of equation (2) is the flexibility matrix, as shown in equation (3). For brevity, the terms in the equation are not listed.

$$\begin{bmatrix} dl_x \\ dl_y \\ dl_z \end{bmatrix} = \begin{bmatrix} \frac{\partial l_x}{\partial F_1} & \frac{\partial l_x}{\partial F_2} & \frac{\partial l_x}{\partial F_3} \\ \frac{\partial l_y}{\partial F_1} & \frac{\partial l_y}{\partial F_2} & \frac{\partial l_y}{\partial F_3} \\ \frac{\partial l_z}{\partial F_1} & \frac{\partial l_z}{\partial F_2} & \frac{\partial l_z}{\partial F_3} \end{bmatrix} \begin{bmatrix} dF_1 \\ dF_2 \\ dF_3 \end{bmatrix} = \begin{bmatrix} f_{11} & f_{12} & f_{13} \\ f_{21} & f_{22} & f_{23} \\ f_{31} & f_{32} & f_{33} \end{bmatrix} \begin{bmatrix} dF_1 \\ dF_2 \\ dF_3 \end{bmatrix} = f \begin{bmatrix} dF_1 \\ dF_2 \\ dF_3 \end{bmatrix}$$

The inverse of the flexibility matrix is the stiffness matrix. So the deformation-force relationship and the stiffness matrix are found. Hence the nonlinear equations can be solved using the finite element analysis solvers.

In the step list of the nonlinear static solver, step 4 will provide the cable element the new updated displacement. And step 2 and step 5 will ask the cable element's stiffness matrix and reaction forces, which can be calculated with equation (3).

Limitation of cable elements

One limitation of using catenary theory is that the cable element cannot be loaded with non-uniformly distributed load, point load inside the element. In order to do such doing, the physical cable must be modeled with multiple analytical cable elements, so that the non-uniform load could be approximately simulated by uniform loads on each analytical cable elements, and there are nodes at locations where point loads are applied.

Notes

The load cases in a nonlinear cable analysis must be separated by the `CHANGE` command and `PERFORM CABLE ANALYSIS ADVANCED` command. The `SET NL` command must be provided to specify the total number of primary load cases. There may not be any Multi-linear springs, compression only, PDelta, NONLINEAR, or dynamic cases.

Also for cables:

1. Do not use Member Offsets.
2. Do not include the end joints in a Control/Dependent command.
3. Do not connect to inclined support joints.
4. Y direction must be up.
5. Do not impose displacements.
6. Do not use Support springs in the model.
7. Applied loads do not change global directions due to displacements.
8. Do not apply Prestress load, Fixed end load.
9. Do not use Load Combination command to combine cable analysis results. Use a primary case with Repeat Load instead.

Note: This analysis feature can be used only when Advanced Analysis License is active.

G.17.3.1 Solution of the Eigenproblem

The eigenproblem is solved for structure frequencies and mode shapes considering a diagonal, lumped mass matrix, with masses possible at all active degrees of freedom (d.o.f.) included. Two solution methods may be used: the subspace iteration method for all problem sizes (default for all problem sizes), and the Arnoldi/ Lanczos method for evaluating eigenvectors (Advanced Analysis only). Additionally, load dependent Ritz vectors (LDR) can be used for dynamically loaded structures.

For large scale eigen value problems, the Arnoldi method is very efficient.

Autoshifting of Eigenvectors

For large models having a large number of d.o.f and a large number of modes extracted (i.e., memory-bound), an incremental solver mode called autoshifting can be used by the Advanced Analysis. A mode shift value is specified to indicate the fixed number of modes the solution tries to find in each shift. The main benefit of using the incremental solver is that it is memory efficient (e.g., problems that were not solvable before on 32-bit systems might be solved with that technique). It is recommended to be used only when memory allocation failure takes place during eigen solution using subspace-iteration or Arnoldi/Lanczos methods. When the program fails to extract eigen vectors due to insufficient memory, you can use auto-shifting which significantly reduces memory demand.

Note: Generally, the Arnoldi/Lanczos is more robust than subspace iteration with autoshifting. The Arnoldi/ Lanczos method is very efficient at finding large eigen vectors with autoshift. Thus, if memory problems occur with subspace-iteration (regular mode), it is recommended to switch to the Arnoldi/Lanczos method (regular mode). If memory problems occur with this method in regular mode, then autoshift can be applied to reduce the memory demand.

Since autoshifting can provide significant reduction in memory demand in the solution, it can be ideal for the eigenvalue solution of large systems. In this case, the you are required to provide a “targeted” number of eigen modes to be searched in each shift. The solution starts with “0” shift and tries to find targeted number of eigen modes. Once completed, a new shift is applied and it tries to find next set of eigenvalues within the new shift. This continues until all required number of eigenvalues are found.

The subspace iteration method is very sensitive to calculated shift resulting in a partial extraction of mode. It is recommended to use this solution as a supplemental or alternative solution to existing (default mode). Whenever the program extracts partial set of eigen vectors, it issues a warning message.

If the solution return partial results, it means that not all the required number of eigen modes were found. But the solution guarantees that no eigen values are missed among returned results. Partial results can be still useable for dynamic analysis if they satisfy other analysis requirements. For example, “m” modes satisfy 90% mass participation.

Partial results can be also returned by the subspace method (Advanced Analysis) without using auto shifting method.

The program may miss some Eigen values because of applied shift while performing Eigen solution using Subspace-iteration method. In this case, a warning message is given. In this case, the results returned include missing modes. These results should be *used with caution* and it is strongly advised for further investigation (dynamic contribution from missing modes might be too important to ignore in analysis).

When the Arnoli/Lanczos method is used with autoshifting, an initial frequency shift may also be specified.

Load-Dependent Ritz Vectors

Research has indicated that considering the effect of natural free-vibration mode shapes may not be the most efficient basis for mode-superposition analysis of structures subjected to dynamic loads. This implies that dynamic analyses —like response spectrum and time history analysis— based on a special set of load-dependent Ritz vectors may yield more accurate results than the use of the same number of natural modes.

There are several reasons to consider Ritz vector analysis as a more efficient approach.

a. For large structural systems, the solution to find free-vibration modes and frequencies may require a significant amount of computational effort.
b. The Ritz vectors method takes into account the spatial distribution of the dynamic loading, whereas the direct use of natural modes neglects this information. Therefore, many of the natural mode shapes that are calculated may not have significant contribution to the dynamic response.
c. Ritz vector analysis by default does not include static correction due to higher mode truncation. The command `MIS` is required to be issued to include missing mass correction.

The Ritz vectors method is recommended where the solution with eigen vectors fails to capture 90% mass participation (a mandatory requirement of most country seismic codes) with a reasonable number of modes.

It is also recommended where eigen vectors capture irrelevant modes. Even though they are real modes, they are not relevant to the structural response due to the applied dynamic loading.

The spatial distribution of the dynamic load vector serves as a starting load vector to initiate the analysis process. The program will automatically generate this starting load or you can specify it using the `DEFINE STARTING LOAD` command. In the program generated method, the starting load vector is generated using the mass model of the structure. Assuming a mass matrix only has translational components, the resulting load vector will have force components in the directions of all the translational degrees of freedom. and will have zero values for all the rotational degrees of freedom. This will guarantee a static deflection with components in many directions with this initial mode assumption. As long as the initial mode assumption has a component in the direction of interest, it will yield a correct set of Ritz vectors.

If you define a set of starting load vectors, then this load vector will have a force component in one translational degree of freedom in the direction of the dynamic load. This results in a static deflection mainly in the direction of interest. In some models where mass participation is predominant in one translational direction for the initial few modes, this method can achieve 90% mass participation with only a few modes.

Note: A single set of Ritz vectors can be derived from a single starting load. If all starting loads that participate in dynamic loads are defined, a single set of Rtiz vectors can be extracted from all participating starting loads. Therefore, use of the `DEFINE STARTING LOAD` command is best suited if the structural response is predominant in one translational direction. If response in multiple translational d.o.f. are predominant, then it is recommended to use the program generated starting load vector.

Leger P, Wilson EL, Clough RW., *The use of load-dependent Ritz vectors for dynamic and earthquake analyses.* Technical Report UC13/EERC86/04, Earthquake Engineering Research Center, University of California Berkeley, Berkeley, CA, 1986.

G.17.3.2 Mass Modeling

The natural frequencies and mode shapes of a structure are the primary parameters that affect the response of a structure under dynamic loading. The free vibration problem is solved to extract these values. Since no external forcing function is involved, the natural frequencies and mode shapes are direct functions of the stiffness and mass distribution in the structure. Results of the frequency and mode shape calculations may vary significantly depending upon the mass modeling. This variation, in turn, affects the response spectrum and forced vibration analysis results. Thus, extreme caution should be exercised in mass modeling in a dynamic analysis problem.

In STAAD.Pro, all masses that are capable of moving should be modeled as loads applied in all possible directions of movement. Even if the loading is known to be only in one direction there is usually mass motion in other directions at some or all joints and these mass directions (applied as loads, in weight units) must be entered to be correct. Joint moments that are entered will be considered to be weight moment of inertias (force-length^2 units).

Note: Take care to enter selfweight, joint, and element loadings in global directions with the same sign as much as possible so that the representative masses do not cancel each other.

Member/Element loadings may also be used to generate joint translational masses. Note that loads (representing the masses) defined as member concentrated loads, or partially distributed member loads, on non-globally aligned members may result in additional mass being included in orthogonal directions at the nodes. This is because the resolution of these loads (masses) onto the nodes is only considered in the positive direction, and thus does not account for any directional sign of the effect at the node. Member end joint moments that are generated by the member loading (including concentrated moments) are discarded as irrelevant to dynamics. Enter mass moments of inertia, if needed, at the joints as joint moments.

STAAD.Pro uses a diagonal mass matrix of six lumped mass equations per joint. The selfweight or uniformly loaded member is lumped 50% to each end joint without rotational mass moments of inertia. The other element types are integrated but—roughly speaking—the weight is distributed equally amongst the joints of the element.

The members/elements of finite element theory are simple mathematical representations of deformation meant to apply over a small region. The finite element analysis (FEA) procedures will converge if you subdivide the elements and rerun; then subdivide the elements that have significantly changed results and rerun; an so on, until the key results are converged to the accuracy needed.

An example of a simple beam problem that needs to subdivide physical members to better represent the mass distribution (as well as the dynamic response and the force distribution response along members) is a simple floor beam between two columns will put all of the mass on the column joints. In this example, a vertical ground motion will not bend the beam even if there is a concentrated force (mass) at mid span.

Masses that are assigned to dependent degrees of freedom (dof) are moved to the control node with a rotatory mass moment of inertia applied at the control. This will be an approximation if the control node is not at the center of gravity (CG, i.e., center of mass) of the dependent masses.

In addition, the dynamic results will not reflect the location of a mass within a member (i.e., the masses are lumped at the joints). This means that the motion, of a large mass in the middle of a member relative to the ends of the member, is not considered. This may affect the frequencies and mode shapes. If this is important to the solution, split the member into two. Another effect of moving the masses to the joints is that the resulting shear/ moment distribution is based as if the masses were not within the member.

Note: If one end of a member is a support, then half of the member mass is lumped at the support and will not move during the dynamic response. Use ENFORCED supports to minimize this limitation.

G.17.3.3 Damping Modeling

Damping may be specified by entering values for each mode (either explicitly or calculated), by using a formula based on the first two frequencies, or by using composite modal damping. Composite modal damping permits computing the damping of a mode from the different damping ratios for different materials (steel, concrete, soil). Modes that deform mostly the steel would have steel damping ratio, whereas modes that mostly deform the soil, would have the soil damping ratio.

Modeling Methods

Damping Method	Related STAAD.Pro Command
A single specified value, used by all modes	DAMP
Composite damping based on values specified for each material which can include the effect of spring damping, if defined.	CDAMP
Modal damping which is explicitly defined for each mode.	MDAMP
Modal damping which is calculated for all modes.	MDAMP, using either the CALCULATE or EVALUATE method

G.17.3.3.1 Composite Damping

Composite modal damping is based on a weighted average of strain energies in each material, (or element), for each mode (eigenvector).

The critical composite damping term D_J for mode J is computed by:

$$D_i = \frac{\sum_{i=1}^{n} \{\phi_i\}^T b_i \cdot \left[k\right] \cdot \{\phi_i\}}{\{\phi_j\}^T \cdot \left[K\right] \cdot \{\phi_j\}}$$

where

n	=	total number of degrees of freedom
b_i	=	equivalent percent of critical damping associated with component i
$\{\varphi_J\}$	=	mode shape vector for mode J
$[k]_i$	=	stiffness associated with component i
$[K]$	=	stiffness matrix for the system

G.17.3.3.2 Modal Damping

Explicit Damping

With the `EXPLICIT` option, you must provide unique modal damping values for some or all modes. Each value can be preceded by a repetition factor (rf*damp) without spaces.

Example

```
DEFINE DAMPING INFORMATION
EXPLICIT 0.03 7*0.05 0.04 -
0.012
END
```

In the above example, mode 1 damping is .03, modes 2 to 8 are .05, mode 9 is .04, mode 10 (and higher, if present) are 0.012.

If there are fewer entries than modes, then the last damping entered will apply to the remaining modes. This input may be continued to 10 more input lines with word `EXPLICIT` only on line 1; end all but last line with a space then a hyphen. There may be additional sets of `EXPLICIT` lines before the `END`.

Calculate Damping

The formula used to calculate the damping for modes i = 1 to N per modal frequency based on mass and/or stiffness proportional damping (for `CALCULATE`) is:

$$D(i) = (\alpha / 2\omega_i) + (\omega_i \beta / 2)$$

If the resulting damping is greater than MAX, then MAX will be used (MAX=1 by default). If the resulting damping is less than MIN, then MIN will be used (MIN=1.E-9 by default). This is the same damping as D = (αM + βK).

Example:

```
DEFINE DAMPING INFORMATION
CALC ALPHA 1.13097 BETA 0.0013926
END
```

To get 4% damping ratio at 4 Hz and 6% damping ratio at 12 Hz

Mode	Hz	Rad/sec	Damp Ratio
1	4.0	25.133	0.04
3	12.0	75.398	0.06

$D(i) = (\alpha / 2\omega_i) + (\omega_i \beta / 2)$

$0.04 = \alpha / 50.266 + 12.567\ \beta$

$0.06 = \alpha / 150.796 + 37.699\ \beta$

$\alpha = 1.13097$

$\beta = 0.0013926$

However they are determined, the α and β terms are entered in the CALC data above. For this example calculate the damping ratio at other frequencies to see the variation in damping versus frequency.

Mode	Hz	Rad/sec	Damp Ratio
1	4.0	25.133	0.040
3	12.0	75.398	0.060
	2	12.0664	0.05375
	8	50.2655	0.04650
	20	120.664	0.09200
	4.5	28.274	0.03969

The damping, due to β times stiffness, increases linearly with frequency; and the damping, due to alpha times mass, decreases parabolicly. The combination of the two is hyperbolic.

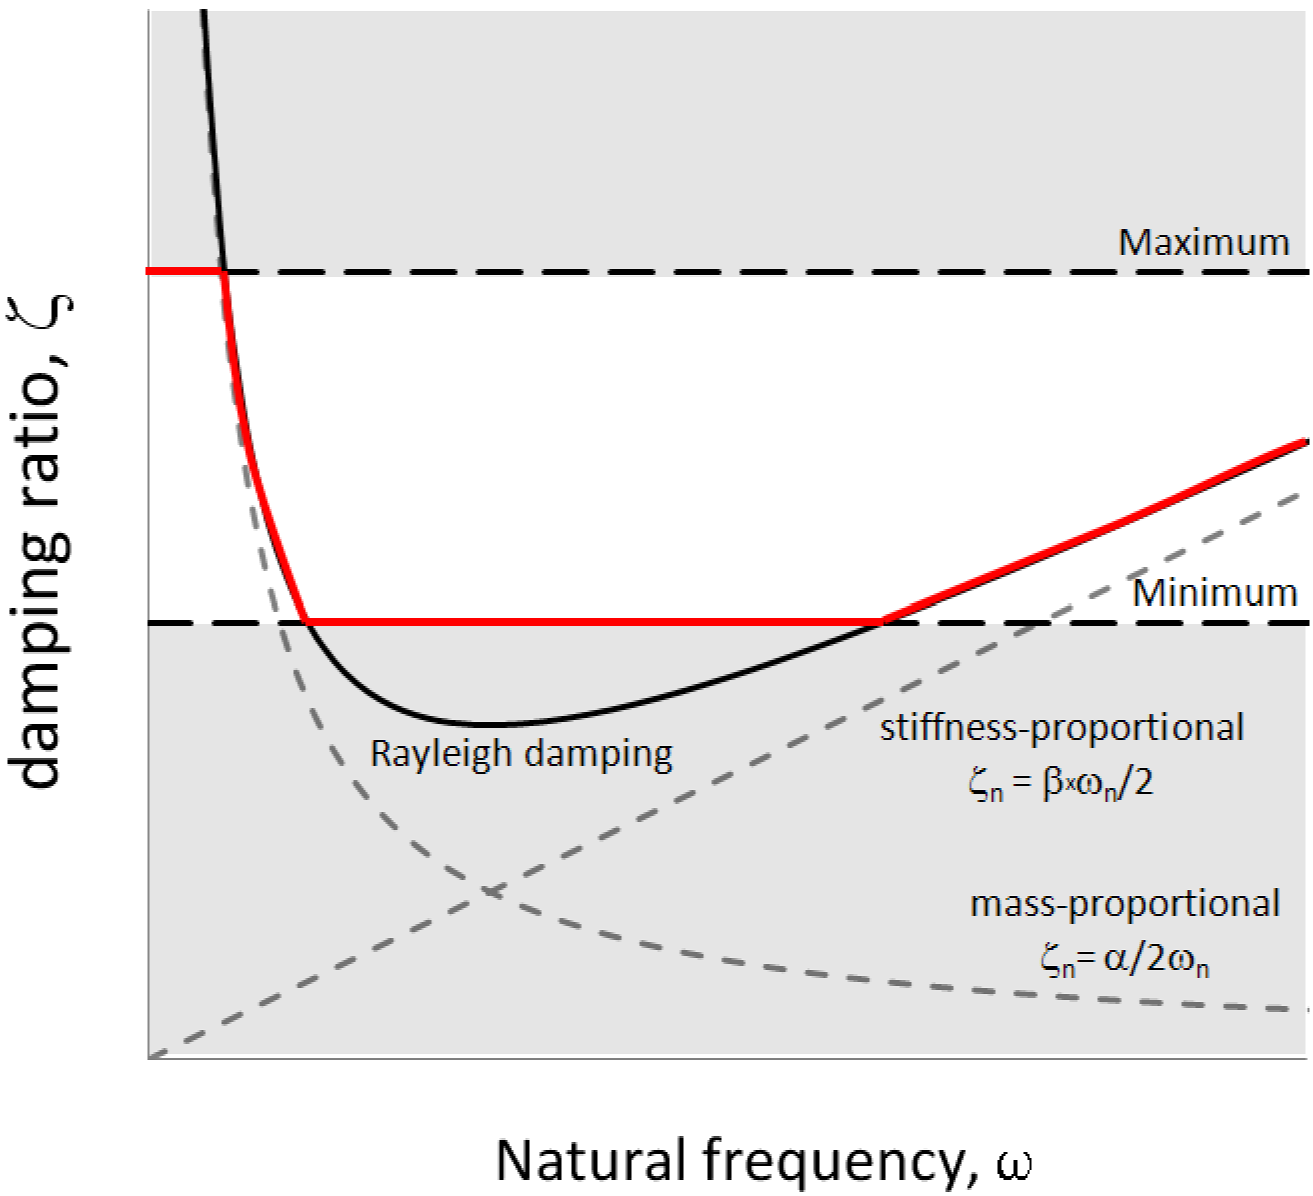

Figure 250: Graph of Damping Ration, D(i), versus Natural Frequency, ω with Max. and Min. values applied.

Evaluate Damping

The formula used for EVALUATE (to evaluate the damping per modal frequency) is:

Damping for the first 2 modes is set to dmin from input.

Damping for modes i = 3 to N given dmin and the first two frequencies ω_1 and ω_2 and the i^{th} modal frequency ω_i.

$$A_1 = \text{dmin} / (\omega_1 + \omega_2)$$

$$A_0 = A_1 * \omega_1 * \omega_2$$

$$D(i) = (A_0 / \omega_i) + (A_1 * \omega_i)$$

If the resulting damping is greater than the dmax value of maximum damping, then dmax will be used.

Example:

```
DEFINE DAMPING INFORMATION
EVALUATE 0.02 0.12
END
```

for dmin = .02 , dmax = .12 and the ω_i given below:

Mode	ω_i	Damping Ratio
1	3	0.0200
2	4	0.0200
3	6	0.0228568
N	100	0.1200 (calculated as .28605 then reset to maximum entered)

G.17.3.4 Response Spectrum

This capability allows you to analyze the structure for seismic loading. For any supplied response spectrum (either acceleration vs. period or displacement vs. period), joint displacements, member forces, and support reactions are calculated for each mode used in the spectrum solution. These individual modal responses are combined using one of the square root of the sum of squares (SRSS), the complete quadratic combination (CQC), the ASCE4-98 (ASCE), the ten percent (TEN), or the absolute (ABS) methods to obtain the resultant responses. Results of the response spectrum analysis may be combined with the results of the static analysis to perform subsequent design. To account for reversibility of seismic activity, load combinations can be created to include either the positive or negative contribution of seismic results.

Calculation of Forces and Moments at Intermediate Sections

For static load cases, if there is no load applied within the span of a member, for any given degree of freedom (FX, FY, FZ, MX, MY, and MZ), the force or moment value at intermediate span locations can be calculated by linearly interpolating between the values for that degree of freedom at the start and end nodes of the member.

But for response spectrum load cases, this approach is applied at the individual mode basis following which the modal values are combined using the combination method specified in the input. The details of the procedure are as follows:

For any given member, we define the terms RAP and RBP as:

RAP = The force/moment value of the d.o.f under consideration for mode P at the start node of the member (End A)
RBP = The force/moment value of the d.o.f under consideration for mode P at the end node of the member (End B)

Note: RAP and RBP are quantities with signs because these are at the individual mode level.

Using linear interpolation, calculate the value of that d.o.f at each of 11 equally spaced intermediate sections along the member length.

So, we now define the term RIP as the value of the d.o.f under consideration at section location "I" for mode "P."

If the spectrum solution is based on "N" modes, the resultant value for that d.o.f at section location "I" is obtained as:

$$\mathrm{SRSS(RI1, RI2, RI3, RI4, \ldots, RIN)}$$

or

$$\mathrm{CQC(RI1, RI2, RI3, RI4, \ldots, RIN)}$$

or a similar calculation for the other modal combination methods.

The values calculated in the above fashion can then be obtained in the output file using the `PRINT SECTION FORCES` command and in tabular or graphical form in the post processing mode.

Complete Quadratic Combination Method

This method was first described in "A Replacement for the SRSS Method in Seismic Analysis" (*Earthquake Engineering and Structural Dynamics,* Vol. 9 p.187-192) by E.L. Wilson, et al in 1981. The method used in STAAD.Pro is adapted from the textbook *Three Dimensional Static and Dynamic Analysis Of Structures* by Edward L. Wilson.

Using the CQC method, the peak force is determined using the following:

$$F = \sqrt{\sum_n \sum_m f_n \rho_{nm} f_m}$$

where

f_n	=	the modal force associated with mode n
ρ_{nm}	=	the cross-modal coefficient
		$= \dfrac{8\zeta^2(1+r)r^{3/2}}{(1-r^2)^2 + 4\zeta^2 r(1+r)^2}$
r	=	$\omega_n/\omega_m \leq 1.0$
ζ	=	the damping ratio. If you use a `DEFINE DAMPING INFORMATION` command to define modal damping, that will be used here for the corresponding modes. Otherwise, the constant damping or composite damping for the entire structure will be used.

Similar equations are used to determine displacements and other resultant responses.

G.17.3.5 Response Time History

STAAD.Pro is equipped with a facility to perform a response history analysis on a structure subjected to time varying forcing function loads at the joints and/or a ground motion at its base. This analysis is performed using the modal superposition method. Hence, all the active masses should be modeled as loads in order to facilitate determination of the mode shapes and frequencies. Refer to G.17.3.2 Mass Modeling (on page 2157) for additional information on this topic. In the mode superposition analysis, it is assumed that the structural response can be obtained from the "p" lowest modes. The equilibrium equations are written as

$$[m]\{x''\} + [c]\{x'\} + [k]\{x\} = \{P(t)\}$$

Note: The double-prime notation ('') designates the second derivative (i.e., acceleration) and a prime notation (') designates the first derivative (i.e., velocity).

Using the transformation

$$\left\{x\right\} = \sum_{i=1}^{p} \{\phi\}_i q_i$$

The equation for *{P(t)}* reduces to "p" separate uncoupled equations of the form

$$q''_i + 2\,\xi_i\omega_i q'_i + \omega_i^2 q_i = R_i(t)$$

where

ξ	=	the modal damping ration
ω	=	the natural frequency for the i^{th} mode.

These are solved by the Wilson- θ method which is an unconditionally stable step by step scheme. The time step for the response is entered by you or set to a default value, if not entered. The q_is are substituted in equation 2 to obtain the displacements *{x}* at each time step.

Time History Analysis for a Structure Subjected to a Harmonic Loading

A Harmonic loading is one in which can be described using the following equation:

$$F(t) = F_0 \sin(\omega t + \phi)$$

where

$F(t)$	=	Value of the forcing function at any instant of time "t"
F_0	=	Peak value of the forcing function
ω	=	Frequency of the forcing function
ϕ	=	Phase angle

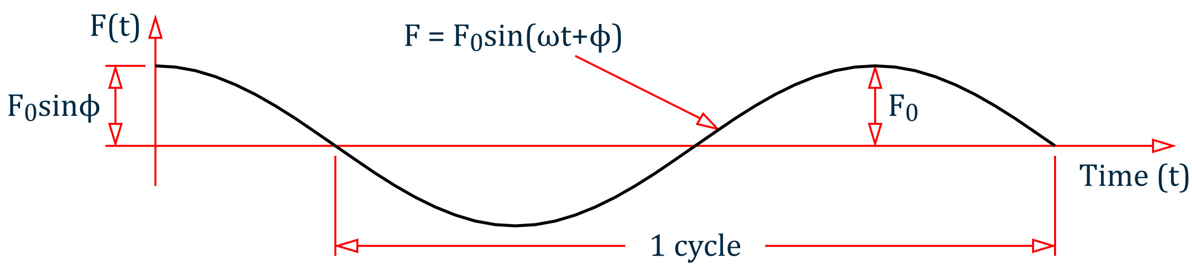

Figure 251: Plot of the harmonic loading function

The results are the maximums over the entire time period, including start-up transients. So, they do not match steady-state response.

Definition of Input in STAAD.Pro for the above Forcing Function

As can be seen from its definition, a forcing function is a continuous function. However, in STAAD.Pro, a set of discrete time-force pairs is generated from the forcing function and an analysis is performed using these discrete time-forcing pairs. What that means is that based on the number of cycles that you specify for the loading, STAAD.Pro will generate a table consisting of the magnitude of the force at various points of time. The time values are chosen from this time '0' to $n \times tc$ in steps of “STEP” where n is the number of cycles and tc is the duration of one cycle. STEP is a value that you may provide or may choose the default value that is built into the program. STAAD.Pro will adjust STEP so that a 1/4 cycle will be evenly divided into one or more steps. See TR. 31.4 Definition of Time History Load (on page 2441) for a list of input parameters that need to be specified for a Time History Analysis on a structure subjected to a Harmonic loading.

The relationship between variables that appear in the STAAD.Pro input and the corresponding terms in the equation shown above is explained below.

F_0 = Amplitude
ω = Frequency
ϕ = Phase

For control/dependent specifications, the forces applied at dependent dof will be ignored. Apply them at the control instead.

G.17.3.6 Steady State and Harmonic Response

A structure [subjected only to harmonic loading, all at a given forcing frequency and with non-zero damping] will reach a steady state of vibration that will repeat every forcing cycle. This steady state response can be computed without calculating the transient time history response prior to the steady state condition.

$$R(t) = R_0 \sin(\omega t + \phi)$$

The result, R, has a maximum value of R_0 and a phase angle ϕ . These two values for displacement, velocity, and acceleration at each joint may be printed or displayed.

This analysis is performed using the modal superposition method. Hence, all the active masses should be modeled as loads in order to facilitate determination of the mode shapes and frequencies. See G.17.3.2 Mass Modeling (on page 2157) for additional information on this topic. In the mode superposition analysis, it is assumed that the structural response can be obtained from the "p" lowest modes.

A Harmonic loading is one in which can be described using the following equation:

$$F(t) = F_0 \sin(\omega t + \phi)$$

where

$F(t)$	=	Value of the forcing function at any instant of time "t"
F_0	=	Peak value of the forcing function
ω	=	Frequency of the forcing function
ϕ	=	Phase angle

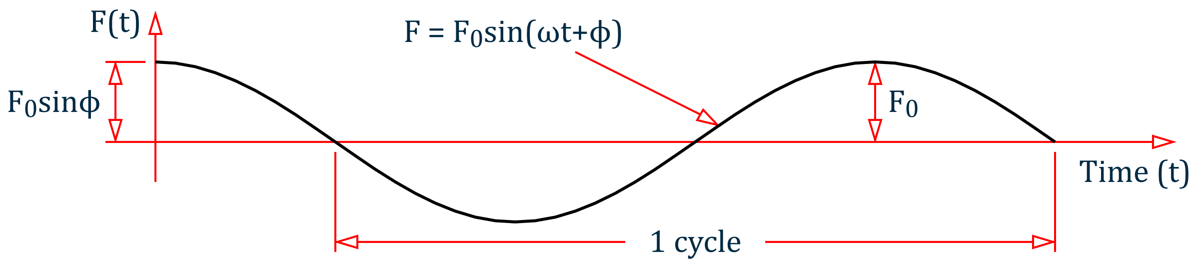

Figure 252: Plot of the harmonic loading function

The results are the steady-state response which is the absolute maximum of displacement (and other output quantities) and the corresponding phase angle after the steady state condition has been reached.

In addition, a Harmonic response can be calculated. This response consists of a series of Steady State responses for a list of frequencies. The joint displacement, velocity, or acceleration can be displayed as the response value versus frequency. Load case results are the maximums over all of the frequencies.

All results are positive as in the Response Spectrum and Time history analyses. This means section results should be ignored (BEAM 0.0 in Parameters for code checking). Because of this, you may want to add the steady state response to Dead & Live loads for one combination case and subtract the steady state response from those loads for another combination case.

Ground motion or a joint force distribution may be specified. Each global direction may be at a different phase angle.

Output frequency points are selected automatically for modal frequencies and for a set number of frequencies between modal frequencies. There is an option to change the number of points between frequencies and an option to add frequencies to the list of output frequencies.

The load case that defines the mass distribution must be the case just before the `PERFORM STEADY STATE ANALYSIS` command. Immediately after that command is a set of data starting with `BEGIN STEADY` and ending with `END STEADY`. The list of additional frequencies and the steady state load cases with joint loads or ground accelerations and phasing data are entered here. The optional print command for the maximum displacement and associated phase angle for selected joints must be at the end of this block of input.

G.17.4 Pushover Analysis

Pushover analysis is a static, nonlinear procedure using simplified nonlinear technique to estimate seismic structural deformations. It is an incremental static analysis used to determine the force-displacement relationship, or the capacity curve, for a structure or structural element.

In STAAD.Pro, the basis for this analysis is the information published in the documents FEMA 356 : 2000 and ATC 40.

Note: A license for the advanced analysis module is required to access this feature.

- *G.17.4.2 Pushover Analysis Engineering Reference* (on page 2178)
- *V. Column Pushover Displacement* (on page 3735)

G.17.4.1 Overview of Pushover Analysis

This section includes a an overview of the pushover analysis procedure as well as some of the concepts involved with how STAAD.Pro implements this form of analysis.

G.17.4.1.1 What is a Pushover Analysis?

A pushover analysis is a static, nonlinear procedure using a simplified, nonlinear technique to estimate seismic structural deformations. It is an incremental static analysis which is used to determine the force-displacement relationship – or the capacity curve – for a structure or structural element.

The analysis involves applying horizontal loads, in a prescribed pattern, to the structure incrementally, i.e., pushing the structure and plotting the total applied shear force and associated lateral displacement at each increment, until the structure reaches a collapse condition or a prescribed limit.

This definition of a pushover analysis is in accordance with both the following references:

- FEMA 356 " Prestandard and Commentary for the Seismic Rehabilitation of Buildings " (2000, American Society of Civil Engineers for Federal Emergency Management Agency)
- ATC-40 " Seismic Evaluation and Retrofit of Concrete Buildings " (1996, Applied Technology Council)

G.17.4.1.2 Purpose of a Pushover Analysis

It is expected that most buildings rehabilitated in accordance with a standard, would perform within the desired levels when subjected to the design earthquakes. Structures designed according to the existing seismic codes provide minimum safety to preserve life and in a major earthquake, they assure at least gravity-load-bearing elements of non-essential facilities will still function and provide some margin of safety. However, compliance with the standard does not guarantee such performance. They typically do not address performance of non-structural components neither provide differences in performance between different structural systems. This is because it cannot accurately estimate the inelastic strength and deformation of each member due to linear elastic analysis. Although an elastic analysis gives a good indication of elastic capacity of structures and indicates where first yielding will occur, it cannot predict failure mechanisms and account for redistribution of forces during progressive yielding.

To overcome this disadvantages different nonlinear static analysis method is used to estimate the inelastic seismic performance of structures, and as the result, the structural safety can be secured against an earthquake. Inelastic analysis procedures help demonstrate how buildings really work by identifying modes of failure and the potential for progressive collapse. The use of inelastic procedures for design and evaluation is an attempt to help engineers better understand how structures will behave when subjected to major earthquakes, where it is assumed that the elastic capacity of the structure will be exceeded. This resolves some of the uncertainties associated with code and elastic procedures.

The practice of earthquake engineering is rapidly evolving to understand the behavior of buildings subjected to strong earthquakes. In order to be able to predict such behavior pushover analysis is performed. The overall capacity of a structure depends on the strength and deformation capacities of the individual components of the structure. In order to determine capacities beyond the elastic limit some form of nonlinear analysis, like Pushover Analysis, is required. It is a new performance based seismic design to achieve analytically a structural design that will reliably perform in a prescribed manner under one or more seismic environment.

G.17.4.1.3 Objective of a Pushover Analysis

Pushover analysis is a performance-based analysis that refers to a methodology in which structural criteria are expressed in terms of achieving a performance objective. This is contrasted to the conventional method in which structural criteria are defined by limits on member forces resulting from a prescribed level of applied shear force.

A performance level describes a limiting damage condition which may be considered satisfactory for a giving building and a given ground motion. The limiting condition is described by the physical damage within the building, the threat to life safety of the building's occupants created by the damage, and the post earthquake serviceability of the building. The basic approach is to improve the probable seismic performance of the building or to otherwise reduce the existing risk to an acceptable level.

Two key elements of a performance-based design procedure are demand and capacity. Demand is the representation of earthquake ground motion or shaking that the building is subjected to. In nonlinear static analysis procedures, demand is represented by an estimation of the displacements or deformations that the structure is expected to undergo. Capacity is a representation of the structure's ability to resist the seismic demand. The performance is dependent on the manner that the capacity is able to handle the demand. In other words, the structure must have the capacity to resist demands of the earthquake such that the performance of the structure is compatible with the objectives of the design. Performance objective is to obtain a desired level of seismic performance of the building, generally described by specifying maximum allowable (or acceptable) structural or nonstructural damage, for a specified level of seismic hazard.

There are two nonlinear procedures using pushover methods :

a. Capacity Spectrum Method
b. Displacement Coefficient Method

G.17.4.1.3.1 Capacity Spectrum Method

The objective of the Capacity Spectrum Method is to develop appropriate demand and capacity spectra for the structure and to determine their intersection point. During this process, performance of each structural component is also evaluated.

The demand curve is based on the earthquake response spectrum and the capacity curves are based on static, nonlinear pushover analysis. In pushover analysis, the structure is subjected to increasing levels of load, and the base shear versus roof displacement of the structure is charted along the way. The capacity spectrum is obtained by transforming the base shear versus roof displacement spectrum into a spectral acceleration versus spectral displacement spectrum. The intersection of an appropriate demand curve with the capacity curve is called the performance point. The performance point defines the estimated base shear and displacement of the structure when subjected to the earthquake represented by the demand curve. The behavior of the structure at the performance point is compared with predefined acceptance criteria to determine if the design objective is met.

Capacity (Pushover) Curve

The structure capacity is represented by a pushover curve, often termed as capacity curve. This represents the lateral displacement as a function of the force applied to the structure. The most convenient way to plot the force displacement curve is by tracking the base shear and roof displacement.

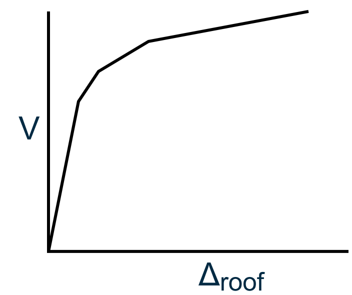

Figure 253: Roof deflection, Δ_{roof}, plotted versus base shear, V

Capacity Spectrum

It is the representation of spectral acceleration vs. spectral displacement derived from the capacity curve. The base shear and the roof displacement are converted to spectral acceleration and spectral displacement respectively by the procedure defined by FEMA to get the capacity spectrum from capacity curve.

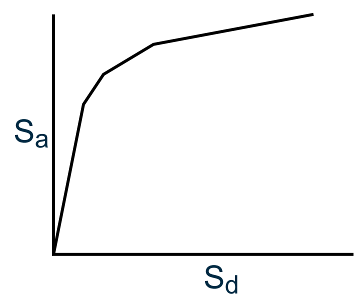

Figure 254: Spectral displacement, S_d plotted versus spectral acceleration, S_a

Conversion of Capacity Curve to Capacity Spectrum

Capacity curve, in terms of base shear and roof displacement, is converted to capacity spectrum, which is a representation of the capacity curve in Acceleration Displacement Response Spectra (ADRS) format (i.e., S_a versus S_d).

The required equations for conversion are the following:

$$PF_1 = \left[\frac{\sum_{i=1}^{N} (w_i \phi_{i1}) / g}{\sum_{i=1}^{N} (w_i \phi_{i1}^2) / g} \right] \quad (1\text{-}3\text{-}1)$$

$$a_1 = \frac{\left[\sum_{i=1}^{N}\left(w_i\phi_{i1}\right)/g\right]}{\left[\sum_{i=1}^{N} w_i/g\right]\left[\sum_{i=1}^{N} w_i\phi_{i1}^2/g\right]} \tag{1-3-2}$$

$$S_a = VW/\alpha_1 \tag{1-3-3}$$

$$S_d = \Delta_{roof}/(PF_1\varphi_{roof,l}) \tag{1-3-4}$$

where

PF_1	=	Modal participation factor for the first natural mode.
a_1	=	Modal mass coefficient for the first natural mode.
w_i/g	=	Mass assigned to level i.
φ_{i1}	=	Amplitude of mode 1 at level i.
N	=	Level N, the level which is the uppermost in the main portion of the structure.
V	=	Base shear
W	=	Building dead weight plus likely live loads.
Δ_{roof}	=	Roof displacement (V and the associated make up points on the capacity curve).
S_a	=	Spectral acceleration
S_d	=	Spectral displacement (and the associated make up points on the capacity spectrum).

Demand spectrum

This curve is obtained by redrawing the design earthquake response spectra as a curve of spectral acceleration vs spectral displacement.

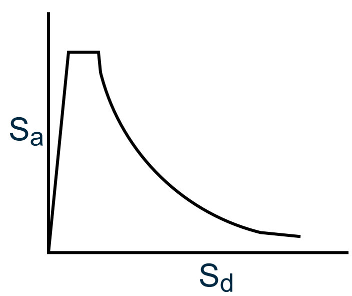

Figure 255: Response spectrum

Performance

Once capacity and demand spectra are defined, a performance check can be one. A performance check verifies that structural and nonstructural components are not damaged beyond the acceptable limits of the performance objective for the forces and displacements implied by the displacement demand.

G.17.4.1.3.2 Displacement Coefficient Method

The objective of the Displacement Coefficient Method is to find the target displacement which is the maximum displacement that the structure is likely to be experienced during the design earthquake. This is equivalent to the performance point in the Capacity Spectrum method. It provides a numerical process for estimating the displacement demand on the structure, by using a bilinear representation of capacity curve and a series of modification factors, or coefficients, to calculate a target displacement.

The structure, directly incorporating the nonlinear load-deformation characteristics of individual components and elements of the building, is subjected to monotonically increasing lateral loads representing inertia forces in an earthquake until a target displacement is exceeded. The damage state comprises deformations for all elements in the structure. Comparison with acceptability criteria for the desired performance goal leads to the identification of deficiencies for individual elements. Performance check at the expected maximum displacement is done to verify whether the lateral force resistance has not degraded by more than a desired percentage (generally 20%) of the peak resistance and the lateral drifts satisfy limits are per standard code.

Target Displacement, δ_t

The target displacement is calculated as per procedure described in Section 3.3.3.3.2 of FEMA 356 : 2000.

It is given by the following expression:

$$\delta_t = C_0 C_1 C_2 C_3 S_a [T_e^2/(4\pi^2)] g$$

where

C_0	=	Modification factor to relate spectral displacement to building roof displacement, as determined by Table 3-2 of FEMA 356.
C_1	=	Modification factor to relate expected maximum inelastic displacements to displacements calculated for linear elastic response $= 1.5$ for $T_e < 0.1$ sec $= 1.0$ for $T_e \geq T_s$ $= [1.0 + (R - 1) T_s / T_e] / R$ for $T_e < T_s$ Value of C1 should not be less than 1.0.
T_s	=	Characteristic period of the response spectrum , defined as period associated with transition from const accleration segment of the spectrum to the constant velocity segment of the spectrum (to be calculated from demand spectrum)
T_e	=	Effective fundamental time period $= T_i(K_i/K_e)^{1/2}$
T_i	=	Elastic fundamental period
K_i	=	Elastic lateral stiffness of the building
K_e	=	Effective lateral stiffness of the building. Taken as equal to the secant stiffness calculated at a base shear force equal to 60% of the effective yield strength of the Structure obtained from bilinear representation of Capacity Curve.
R	=	Ratio of elastic strength demand to calculated yield strength coefficient $= S_a/(V_y/W)C_m$
V_y	=	Effective yield strength calculated using the capacity curve . For larger elements or entire structural systems composed of many components, the effective yield point represents the point at which a sufficient number of individual components or elements have yielded and the global structure begins to experience inelastic deformation.
S_a	=	Response spectrum acceleration, at the effective fundamental period and damping ratio of the building (to be calculated from demand spectrum)
W	=	Effective seismic weight
C_m	=	Effective mass factor as determined by Table 3-1 of FEMA 356.
C_2	=	Modification factor to represent the effect of pinched hysteretic shape , stiffness degradation and strength deterioration on maximum displacement response. Taken from Table 3-3 of FEMA 356 for different

		framing systems and structural performance levels. Alternatively, C_2 may be taken as 1.0 for a nonlinear procedure.
C_3	=	Modification factor to represent increased displacement due to dynamic P-D effects
		= 1.0 for buildings with positive post - yield stiffness
		= $1.0 + \|\alpha\|(R - 1)^{3/2}/T_e$ for buildings with negative post - yield stiffness
α	=	Ratio of post - yield stiffness to effective elastic stiffness , where the non-linear force-displacement relation shall be characterized by a bilinear relation

Refer to Figure 3-1 of FEMA 356 for idealized force-displacement curves.

G.17.4.1.4 Types of Nonlinearity

Both geometric and material nonlinearities are considered in this static nonlinear pushover analysis.

Geometric Nonlinearity

This is a type of nonlinearity where the structure is still elastic, but the effects of large deflections cause the geometry of the structure to change, so that linear elastic theory breaks down. Typical problems that lie in this category are the elastic instability of structures, such as in the Euler bulking of struts and the large deflection analysis of a beam-column member. In general, it can be said that for geometrical non-linearity, an axially applied compressive force in a member decreases its bending stiffness, but an axially applied tensile force increases its bending stiffness. In addition, the P-Delta effect is also included in this concept.

Material Nonlinearity

In this type of nonlinearity, the material undergoes plastic deformation. Material nonlinearity can be modeled as discrete hinges at a number of locations along the length of a frame (beam or column) element and a discrete hinge for a brace element as discrete material fibers distributed over the cross-section of the element, or as a series of material points throughout the element.

G.17.4.1.5 Force controlled and deformation controlled actions

Force-controlled refers to components, elements, actions, or systems which are not permitted to exceed their elastic limits. This category of elements, generally referred to as brittle or nonductile, experiences significant degradation after only limited post-yield deformation.

Deformation-controlled refers to components, elements, actions, or systems which can, and are permitted to, exceed their elastic limit in a ductile manner. Force or stress levels for these components are of lesser importance than the amount of deformation beyond the yield point.

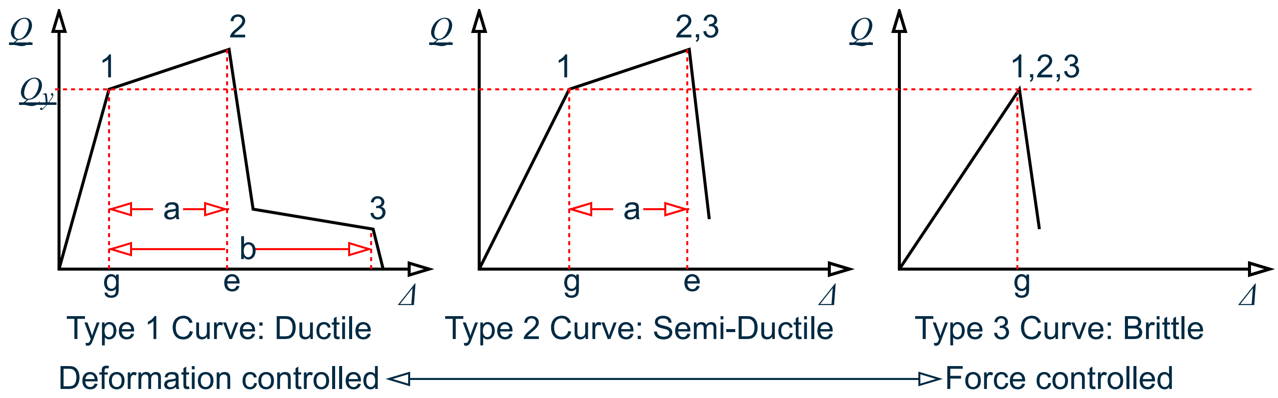

Figure 256: Component force versus deformation curves (Ref. Fig. 2-3 FEMA 356)

Note: Refer to Section 2.4.4.3.1 of FEMA 356 for detailed information on these curves.

G.17.4.1.6 Frame element hinge properties

Discrete hinge properties for frame elements are usually based on FEMA-356 criteria. As per section 5.5.2.2.2 of FEMA 356, in lieu of relationships derived from experiment or analysis, the generalized load deformation curve shown in the figure below, with parameters a, b, c, as defined in tables1.5.6 and 1.5.7, shall be used for components of steel moment frames. Modification of this curve shall be permitted to account for strain-hardening of components as follows:

a. a strain-hardening slope of 3% of the elastic slope shall be permitted for beams and columns unless a greater strain-hardening slope is justified by test data; and
b. where panel zone yielding occurs, a strain-hardening slope of 6% shall be used for the panel zone unless a greater strain-hardening slope is justified by test data.

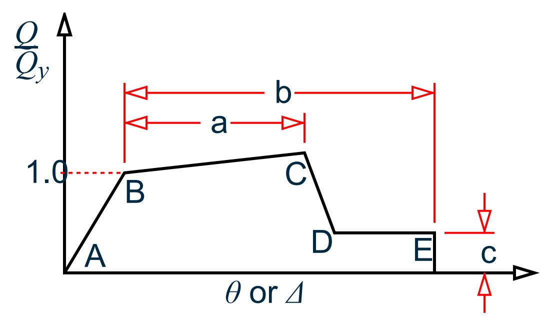

Figure 257: Generalized Force-Deformation Relationship for Components

- Point A is the origin
- Point B represents yielding. No deformation occurs in the hinge up to point B, regardless of the deformation value specified for point B. The displacement (rotation or axial elongation as the case may be) will be subtracted from the displacements at points C, D and E. Only plastic deformation beyond point B will be exhibited by hinge.
- Point C represents ultimate capacity of plastic hinge. At this point hinge strength degradation begins (hinge starts shedding load) until it reaches point D.
- Point D represents the residual strength of the plastic hinge. Beyond point D the component responds with substantially strength to point E.

- Point E represents total failure. At deformation greater than point E the plastic hinge will drop load to zero.

The parameters Q and Q_{CE} (Q_y) in Figure 1-6 are generalized component load and generalized component expected strength, respectively. For beams and columns, θ is the total elastic and plastic rotation of the beam or column, θ_y is the rotation at yield. For braces Δ is total elastic and plastic displacement, and Δ_y is yield displacement.

Use of equations (1-6-1) and (1-6-2) to calculate the yield rotation, θ_y, where the point of contraflexure is anticipated to occur at the mid-length of the beam or column, respectively, shall be permitted.

For beams:

$$\theta_y = Z \cdot F_{ye} L_b / (6 \cdot EI_b) \tag{1-6-1}$$

For columns:

$$\theta_y = Z \cdot F_{ye} L_c / (6 \cdot EI_c)\ (1 - P/P_{ye}) \tag{1-6-2}$$

Q and Q_{CE} are the generalized component load and generalized component expected strength, respectively. For flexural actions of beams and columns, Q_{CE} refers to the plastic moment capacity, which shall be calculated using equations (1-6-3) and (1-6-4):

For beams:

$$Q_{CE} = M_{CE} = Z \cdot F_{ye} \tag{1-6-3}$$

For columns:

$$Q_{CE} = M_{CE} = 1.18\, Z \cdot F_{ye}\ (1 - P/P_{ye}) \tag{1-6-4}$$

where

E	=	Modulus of elasticity
F_{ye}	=	Expected yield strength of the material
I	=	Moment of inertia
L_b	=	Beam length
L_c	=	Column length
M_{CE}	=	Expected flexural strength of a member or Joint, kip-in.
P	=	Axial force of the member
P_{ye}	=	Expected axial yield force of the member = $A_g F_{ye}$
Q	=	Generalized component load
Q_{CE}	=	Generalized component expected strength = Effective expected strength, which is defined as the statistical mean value of yield strengths, Q_y, for a population of similar components, and includes consideration of strain hardening and plastic section development.

G.17.4.1.6.1 Calculation of Q_{CE}

The expected flexural strength is evaluated by the following means for beam or column elements.

Beams

The strength of elements of structural steel under flexural actions with negligible axial load present is calculated in accordance with this section.

The expected flexural strength, Q_{CE}, of beam components is determined using G.17.4.1.6 Frame element hinge properties (on page 2174). For nonlinear procedure flexural actions of beams is considered deformation controlled. Permissible plastic rotation deformation is as indicated in equations G.17.4.1.6 Frame element hinge properties (on page 2174) and G.17.4.1.6 Frame element hinge properties (on page 2174) (Ref. Sections 5.5.2.2.2 and 5.5.2.3.2 of FEMA 356).

Columns

This section is used to evaluate flexural and axial strengths of structural steel elements with non-negligible axial load present. These actions shall be considered force controlled.

The lower-bound strength, Q_{CL}, of steel columns under axial compression is taken to be the lowest value obtained for the limit states of column buckling, local flange buckling, or local web buckling. The effective design strength or the lower-bound axial compressive strength, P_{CL}, shall be calculated in accordance with the LRFD method, taking φ = 1.0 and using the lower-bound strength, F_{yLB}, for yield strength. The expected axial strength of a column in tension, Q_{CE}, is computed in accordance with equation (1-6-1-1) (Ref. Section 5.5.2.3.2 of FEMA 356):

$$Q_{CE} = T_{CE} = A_c F_{ye} \tag{1-6-1-1}$$

where

A_c	=	Area of column
F_{ye}	=	Expected yield strength of column
T_{CE}	=	Expected tensile strength of column
F_{yLB}	=	Lower-bound yield strength

Flexural loading of columns, with axial loads at a target displacement less than 50% of PCL shall be considered deformation controlled and maximum permissible plastic rotation demands on columns, in radians, shall be as indicated in tables 1.5.1 and 1.5.2, dependent on the axial load present and the compactness of the section.

Flexural loading of columns, with axial loads at the target displacement greater than or equal to 50% of PCL, shall be considered force-controlled and shall conform to equation (1-6-1-2) (Ref. Section 5.5.2.4.2 of FEMA 356).

$$P_{UF}/(2 \cdot P_{CL}) + M_x/(m_x M_{CEx}) + M_y/(m_y M_{CEy}) \leq 1.0 \tag{1-6-1-2}$$

where

P_{UF}	=	Axial force in the member
P_{CL}	=	Lower bound compression strength of the column
M_x	=	Bending moment in the member for the x-axis
M_y	=	Bending moment in the member for the y-axis
M_{CEx}	=	Expected bending strength of the column for the x-axis
M_{CEy}	=	Expected bending strength of the column for the y-axis
m_x	=	Value of m for the column bending about the x-axis in accordance with Table 5-5 of FEMA 365
m_y	=	Value of m for the column bending about the y-axis in accordance with Table 5-5 of FEMA 365

G.17.4.1.7 Elements

Major horizontal or vertical portions of the building’s structural systems that act to resist lateral forces or support vertical gravity loads such as frames, shear walls, frame-walls, diaphragms, and foundations.

Primary Elements

These are structural components or elements that provide a significant portion of the structure's lateral force resisting stiffness and strength at the performance point. These are the elements that are needed to resist lateral loads after several cycles of inelastic response to the earthquake ground motion.

Secondary Elements

These are structural components or elements that are not, or are not needed to be, primary elements of the lateral load resisting system. However, secondary elements may be needed to support vertical gravity loads and may resist some lateral loads.

G.17.4.1.8 Lateral Load Distribution

Lateral loads can be applied by any one of the following three methods per Section 3.3.3.2.3 of FEMA 356.

Method 1

The vertical distribution of the base shear shall be as specified in this section for all buildings. The lateral load applied at any floor level x shall be determined in accordance with equation (1-8-1) and equation (1-8-2):

$$F_x = C_{vx}V \tag{1-8-1}$$

where

$$C_{vx} = \frac{w_x h_x^k}{\sum_{i=1}^{n} w_i h_i^k} \tag{1-8-2}$$

Method 2

A vertical distribution proportional to the shape of the fundamental mode in the direction under consideration is performed. Use of this distribution shall be permitted only when more than 75% of the total mass participates in the fundamental mode in the direction under consideration, and the uniform distribution is also used.

$$F_x = \frac{w_x \phi_x}{\sum_{i=1}^{n} w_i \phi_i} \tag{1-8-3}$$

Method 3

A vertical distribution is performed consisting of lateral forces at each level proportional to the total mass at each level .

$$F_x = \frac{w_x}{\sum_{i=1}^{n} w_i} \tag{1-8-4}$$

where

C_{vx} = Vertical distribution factor

k = Linear interpolation shall be used to calculate values of for intermediate values of k for intermediate values of T.

= 2.0 for T ≥ 2.5 seconds

= 1.0 for T ≤ 0.5 seconds

V	=	User-defined base shear
w_i	=	Portion of the total building weight W located on or assigned to floor level i
w_x	=	Portion of the total building weight W located on or assigned to floor level x
h_i	=	Height (in ft) from the base to floor level i
h_x	=	Height (in ft) from the base to floor level x
F_x	=	Amplitude of mode a floor level x

G.17.4.2 Pushover Analysis Engineering Reference

This section contains technical references on pushover analysis and how this has been implemented in STAAD.Pro.

Note: An Advanced Analysis license is required to access this feature.

Related Links

- *G.17.4 Pushover Analysis* (on page 2168)

G.17.4.2.1 Performing Pushover Analysis

Pushover analysis in STAAD.Pro is a static, non-linear procedure in accordance with FEMA 356 specification. Basically, in this method, the magnitude of the lateral push load is increased progressively according to a predefined loading pattern until either loading or the deflection reaches the described level.

Pushover analysis as it is currently implemented in STAAD.Pro is limited in application to buildings that are regular and do not have adverse torsional or multimode effects. The capacity curve is generally constructed to represent the first mode response of the structure based on the assumption that the fundamental mode of vibration is the predominant response of the structure.

G.17.4.2.1.1 Define Steel Moment and Braced Frames

Steel moment frames are those frames that develop their seismic resistance through bending of steel beams and columns and moment resisting beam-column connections. Steel braced frames are those frames that develop their seismic resistance primarily through axial forces in the components.

User must specify whether the structure is a moment frame or braced frame. By default the program considers it as moment frame.

Note: Currently only fully restraint (FR) moment frame and CBF (Concentric Braced frame) frame are considered.

G.17.4.2.1.2 Define Gravity Loading

Gravity loads include dead loads and (typically) most live loads. Dead load can be taken as the calculated structure self-weight without load factors, plus realistic estimates of flooring, ceiling, partition and other structural and nonstructural components. Live loads should be evaluated for each structure; with consideration given to current and expected future occupancies.

G.17.4.2.1.3 Define Lateral (Push) Loading

The mathematical model directly incorporating the nonlinear load-deformation characteristics of individual components and elements of the building shall be subjected to monotonically increasing lateral loads representing inertia forces in an earthquake until a target displacement is exceeded.

A static, nonlinear pushover analysis usually requires multiple analyses cases. The first pushover load case is gravity load applied to the structure. The rest of the load cases may apply different lateral loads in terms of push load increments, whatever the case may be.

A pushover case may start from zero initial conditions or it may start from the results at the end of a previous pushover case. Thus, the gravity load case starts from zero initial conditions. The first lateral load case will start from the end of the gravity load case, the second lateral load case will start from the end of the first lateral load case, and so on until the target displacement is exceeded.

Note: When defining the incremental push load, you should take care to make its value small enough since larger values of incremental loading can prevent the analysis converging.

The lateral loads shall be applied in both positive and negative directions since it may lead to different results for asymmetric structures.

Related Links

- *M. To add a pushover loading* (on page 884)
- *TR.37.7.3 Define Loading Pattern* (on page 2647)
- *TR.37.7.8 Pushover Loading Input* (on page 2653)
- *Define Loading Pattern tab* (on page 2902)

Lateral Loading Pattern

Lateral loads should be applied in predetermined patterns that represent predominant distributions of lateral inertial loads during earthquake response.

Distribution of lateral load must be applied to the structure when performing a pushover analysis.

Typically push load is defined in any one of the following:

a. User defined static load pattern
b. User defined base shear to be distributed vertically

Incremental push load ΔP is calculated by using any of the following two methods:

a. You define Push load. In other words, you specify the incremental push load pattern on the structure by defining lateral load at nodes.
b. Or, you define the base shear which is distributed laterally as per methods described in Section 1.4.1. The lateral load at each floor is again divided by the number of load step increment to get actual push load incremental load. Thus:

$$\Delta P = V/N$$

where

V	=	Lateral load distributed from user defined base shear.
N	=	Total number of load step

The actual load acting on the structure at any load step $i = \Delta P_i = \Delta P \cdot S_{pi}$

where

S_{pi}	=	Stiffness Parameter at ith iteration
		= Slope of the capacity curve at (i-1)th iteration / Initial slope of the capacity curve

During linear stage (i.e., all members in the structure are linear), the stiffness parameter is 1.0. Whenever any member becomes nonlinear the stiffness parameter decreases since slope of the capacity curve becomes less than that during elastic stage. Thus, actual lateral load acting on the nonlinear structure at any load increment stage is less than that during linear stage.

Note: Currently, you must define gravity load case as primary loading. First lateral load case starts from the end of the gravity load case.

G.17.4.2.1.4 Define Primary/Secondary Elements and Components

Elements and components that provide the capacity of the structure to resist collapse under seismic forces induced by ground motion in any direction shall be classified as primary. Other elements and components shall be classified as secondary.

In a typical building, nearly all elements, including many nonstructural components, will contribute to the building;s overall stiffness, mass and damping, and consequently its response to the earthquake ground motion. However, not all these elements are critical to the ability of the structure to resist collapse when subjected to strong ground shaking. The secondary designation will be used when a component or element does not contribute significantly or reliably in resisting earthquake effects because of low lateral stiffness, strength or deformation capacity.

Note: Currently all elements are considered as primary elements.

G.17.4.2.1.5 Define Pushover Hinges Properties and Acceptance Criteria

At the beginning of the analysis user needs to define properties (Refer Section 1.3) and acceptance criteria for all pushover hinges. The program includes several built-in default hinge properties that are based on FEMA 356 tables 1.6.1 (Table 5-6 Pg 5-40 of FEMA 356) and 1.6.2 (Table 5-7 Pg 5-44 of FEMA 356) for steel structures.

While generating default in-built hinge properties following points have been considered.

- **Columns in axial tension in braced frame with negligible moment -** It is considered as deformation-controlled action as per Table 5-7 Pg 5-44 of FEMA 356. Mz and My moment are negligible.
- **Columns in axial compression in braced frame with negligible moment -** It is considered as force-controlled action as per Table 1-5-1 of FEMA 356. Mz and My moment are negligible.
- **Columns in axial tension in braced and moment frame with moment -** As per FEMA 356 Pg 5-17, for steel columns under axial tension or combined axial tension and bending shall be considered deformation controlled. It will simply act as beam.
- **Columns in axial compression in braced and moment frame with moment -** As per FEMA 356 Pg 5-17, for steel columns under combined axial compression and bending stress, the column shall be considered deformation-controlled for flexural behavior, force-controlled for compressive behavior. i.e.

  a. if Fx / Pcl <= 0.5 consider deformation-controlled

   b. if Fx / Pcl > 0.2 and Fx / Pcl <= 0.5 consider deformation-controlled
   c. if Fx / Pcl > 0.5 consider force-controlled

   where Fx is axial compressive force and Pcl is lower bound compressive strength of column. (Refer Section 1.6.1 for detail).

- **Beams in axial tension in braced frame with negligible moment -** It is considered as deformation-controlled action as per Table 5-7 Pg 5-44 of FEMA 356. Mz moment is negligible.
- **Beams in axial compression in braced frame with negligible moment -** It is considered as force-controlled action as per Table 1-5-1 of FEMA 356. Mz moment is negligible.
- **Beams in axial compression and tension in moment and braced frame with moment -** It is considered as deformation-controlled action as per Table 5-6 Pg 5-40 of FEMA 356.
- **Braces in axial tension and compression in braced frame -** It is considered as deformation-controlled action as per Table 5-7 Pg 5-44 of FEMA 356. For braces in compression out-of-plane is considered.

Please note that while generating built-in hinge properties in STAAD.Pro, the following components are *not* considered:

- Column panel zones
- Fully restrained moment connections
- Partially restrained moment connection
- EBF
- Steel plate shear walls

If any member has releases, the effect in member nonlinear stiffness is considered to be same as that for linear member stiffness.

Define Acceptance Criteria

The performance of a structure and its components is defined by the acceptance criteria to provide desirable information for evaluation or retrofit. It refers to the specific limiting values for the deformations and loadings, for deformation-controlled and force-controlled components respectively, which constitute for acceptable seismic performance. Following three criteria are there:

Immediate Occupancy (IO)	The post earthquake structural damage state in which only very limited structural damage has occurred. The basic vertical and lateral force resisting systems of the building retain nearly all of their pre-earthquake characteristics and capacities. The risk of life-threatening injury from the structural failure is negligible
Life Safety (LS)	The post earthquake damage state in which significant damage to the structure may have occurred but in which some margin against either total or partial structural collapse remains.
Collapse Prevention (CP)	The post earthquake structural damage state in which the building's structural system is on the verge of experiencing partial or total collapse.

The program considers only moment hinge for beam and column for steel structures. If you do not define hinge properties, the program will consider built-in default hinge properties based on FEMA 356.These automatic hinge properties include both moment and axial hinge.

G.17.4.2.1.6 Define Pushover Analysis Solution Control

Pushover analysis will continue until any of the following three conditions is satisfied:

i. Cumulative base shear is less than or equal to the base shear defined by the user

   You must define base shear up till which pushover analysis will be performed since design base shear (specific to particular seismic code) excludes non-linear effect. When the structure is subjected to strong earthquake the actual base shear may be very high compared to the design base shear. Under this condition there is no guarantee that the structure will maintain desired performance level. This option is chosen when the magnitude of base shear is known and the structure will be able to support that load.

ii. Displacement at the control joint in the specified direction exceeds specified displacement

   This option is chosen when the amount of displacement is known i.e. how far the structure will move but the amount of base shear that the structure will be subjected to is not known. While defining this option please make sure that the displacement component chosen at the control joint increases monotonically during loading. The control node shall be located at the center of mass at the roof of the building.

iii. The structure becomes unstable

   This happens whenever hinge formation is such that it renders the structure on the verge of collapse. If neither base shear nor displacement at control joint is known, define a higher value for both these options. During analysis instability will arise due to collapse of different members and make the structure unstable.

G.17.4.2.1.7 Define Input for Demand Spectrum

Demand Spectrum is generated according to the method described in Section 1.6.1.5 of FEMA 356 : 2000.

The program generates Demand Spectrum for the purpose of finding T_s and S_a (corresponding to T_e for the purpose of calculating target displacement).

Related Links

- *M. To define pushover spectral data* (on page 883)
- *TR.37.7.6 Define Spectral Parameters* (on page 2652)
- *Define Spectrum Details tab* (on page 2904)

Generation of Demand Spectrum
The following criteria is used to develop the demand spectrum for a pushover analysis.

Site Classes

A. Hard rock with average shear wave velocity, v_s > 5,000 ft/sec
B. Rock with 2,500 ft/sec < v_s < 5,000 ft/sec
C. Very dense soil and soft rock with 1,200 ft/sec < v_s ≤ 2,500 ft/sec or with either standard blow count N > 50 or undrained shear strength s_u > 2,000 psf
D. Stiff soil with 600-ft/sec< v_s ≤ 1,200 ft/sec, with 15< N ≤ 50, or 1,000 psf ≤ s_u < 2,000 psf
E. Any profile with more than 10 feet of soft clay defined as soil with plasticity index PI > 20, or water content w > 40 percent, and s_u < 500 psf or a soil profile with v_s < 600 ft/sec.
F. Soils requiring site specific evaluations

Adjustment for site class

The design short period spectral response acceleration parameter, S_{XS}, and the design spectral response acceleration parameter at one second, S_{X1}, shall be obtained from equations (2-7-1) and (2-7-2), respectively, as follows:

$$S_{XS} = F_a S_S \tag{2-7-1}$$

$$S_{X1} = F_v S_1 \tag{2-7-2}$$

where

F_a and F_v	=	site coefficients determined respectively from Tables 1-4 and 10-5 in FEMA 365, based on the site class and the values of the response acceleration parameters S_S and S_1 for the selected return period.

General Horizontal Response Spectrum

A general response spectrum as shown in Figure 1-1 of FEMA 365 shall be developed using equations (2-6-3), (2-6-4) and (2-6-5) for spectral response acceleration, S_a, versus structural period, T, in the horizontal direction.

For $0 < T < T_s$,

$$S_a = S_{xs}\left[\left(\frac{5}{B_s} - 2\right)\frac{T}{T_s} + 0.4\right] \tag{2-7-3}$$

for $T < T_s$

$$S_a = S_{XS}/B_S \tag{2-7-4}$$

for $T > T_S$

$$S_a = S_{X1}/(B_1 T) \tag{2-7-5}$$

where

T_S	=	$S_{X1}B_S/(S_{XS}B_S)$	(2-7-6)
T_0	=	$0.2 \cdot T_S$	(2-7-7)

Now this response spectrum with S_a vs T is converted to demand spectrum with S_a vs S_d. (in case of Capacity Spectrum method)

Note: The program generates Demand Spectrum for the purpose of finding T_S and S_a (corresponding to T_e for the purpose of calculating target displacement).

G.17.4.2.1.8 Define Any Other Input

There are several other inputs which may be required for pushover analysis.

See TR.37.7 Pushover Analysis (on page 2643) for additional details.

G.17.4.2.1.9 Hinge Formation and Hinge Unloading

This section describes how the program handles the formation of hinges and the resulting redistribution of load.
Moment Diagrams With Hinges
For each load increment, member sectional forces are checked with section capacity in order to check formation of hinge. If sectional force exceeds section capacity, hinge formation starts. This implies member lies on or beyond point B on the load deformation curve. The point B in the load deformation curve denotes the yield point of the hinge. The hinge is assumed to be rigid between points A and B until it yields.

When the hinge reaches the deformation denoted by point C, it begins to lose load carrying capacity. When it reaches the deformation point E, the hinge loses all of its load carrying capacity.

Total numbers of 13 sections along the length of member are scanned for M_z and M_y moments. Maximum moment is located and checked with section capacity. If the sectional force exceeds section capacity the material starts yielding at that particular location and the hinge at this particular position lies on point B on load deformation curve.

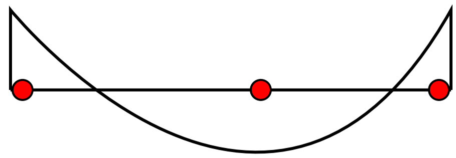

Figure 258: Typical beam moment diagram under gravity load, with super-imposed hinges

If bending moment diagram is like figure 1.8 (this happens at initial stage of load increment when push load is much low as compared to dead load) the chance of forming moment hinge is at two ends and at span of the member (as shown by red dots).

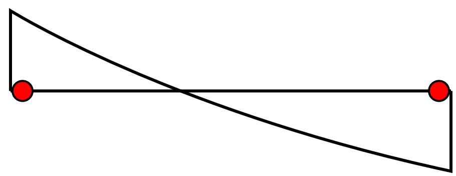

Figure 259: Typical beam moment diagram under significant lateral load, with super-imposed hinges

If bending moment diagram is like figure 1.9 (this happens when push load is much high as compared to dead load) the chance of forming moment hinge is only at sections at or nearer to two ends of the member (as shown by red dots).

Method of Hinge Unloading

When a hinge unloads, the program must find a way to remove the load that the hinge was carrying and redistribute it to the rest of the structure. Hinge unloading occurs whenever force-deformation or moment-rotation curve shows a drop in capacity, from point C to point D. The hinge unloads elastically without any plastic deformation (i.e., parallel to slope A-B).

When the hinge force reaches point C, entire structure is unloaded i.e. the program reverses the load on the whole structure until the hinge is unloaded up to the point D. When the hinge reaches point D, the load is again reversed. Other parts may now pick up the load that was removed from the unloading hinge.

G.17.4.2.1.10 Performance

A performance check can be done either by Capacity Spectrum method or Displacement Coefficient Method.

Note: The program considers Displacement Coefficient method.

G.17.4.2.2 Member Stiffness Matrix with Plastic Hinge

When numbers of springs are connected together in series, the force in each spring is the same. Here we will use the flexibility matrix rather than the stiffness matrix, which will enable us to avoid the intermediate displacements at the spring connections as variable.

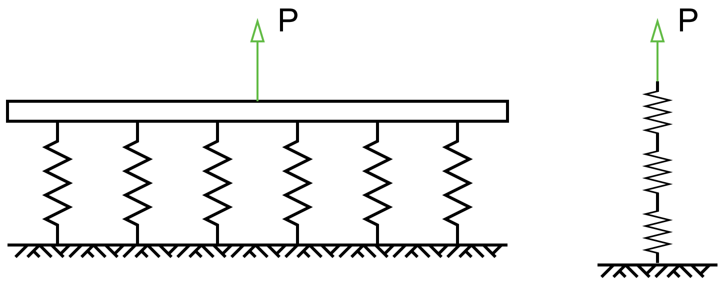

Figure 260: Springs in a) parallel and b) series.

Thus write for each spring,

Extension = flexibility x force

and add up all the individual extensions to give

Total extension = sum of flexibilities x force

To demonstrate this idea, we will take one composite member as shown in Fig. This member is assumed to consist of a number of sections whose F matrices are known.

At first if we consider a case where end A is fixed and a load px is applied to end X, then by definition the displacement at X is given $d_X = e_{AX} = F_{AX}\, p_X$. This displacement is the sum of the displacements due to the strains in the individual sections.

Let us consider, the part KX of the member, lying between end 2 of section k and X.The load acting on the end of KX attached to the section k is equal to -$H_{KX}p_X$, and the load acting on end 2 of section k is $H_{KX}p_X$. Since A is fixed and AJ is considered rigid, end 1 of member k is effectively fixed, and the displacement of its end 2 is given by $d_K = e_K = F_k\, p_{2A} = F_k\, H_{KX}\, p_X$ .Now KX is a rigid member, and the displacements of its ends therefore satisfy the equation for rigid-body movement. Thus the displacement of X due to the strain induced in section k by the load pX at X is $d_{Xk} = H^t{}_{KX}\, F_k\, H_{KX}\, p_X$. Thus the flexibility matrix F_k of section k appears as $H^t{}_{KX} F_k\, H_{KX}$ when viewed from the point X. Similar analysis may be applied to each section of AX, and adding up all the displacement contributions we obtain the complete flexibility matrix of AX in the form

$$F_{AX} = \Sigma\, H^t{}_{KX} \cdot F_k \cdot H_{KX}$$

Where the summation extends over all the sections making up the member Ax. Inversion of F_{AX} gives the matrix K_{AX}, and since the matrix H_{AX} may be obtained either from the overall equilibrium of the member or by multiplying together all the H matrices of the sections the other stiffness matrices.

Semi-Rigid Joint Connections

When a member is attached to the joints at its ends by flexible connections, each of which transmits a moment proportional to the difference between the rotation of the end of the member and the rotation of the joint to which it is attached. Such joints occur in bolted frames, and in welded frames after the onset of plasticity.

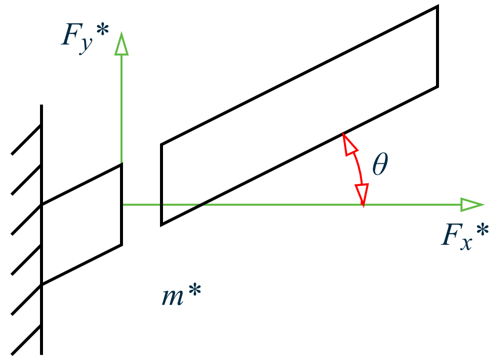

Figure 261: Free body diagram of semi-rigid joint

To have a clear understanding, first we will describe it for a two-dimensional plane frame and then we will extend it to three-dimensional space frame.

Let us consider a frame of length Land flexural rigidity EI, whose ends 1 and 2 are attached to the rest of the frame by connections, which exert moment's $4Eik_1/L$ and $4Eik_2/L$ respectively per unit difference in rotation. We ignore the length of each connection.

The displacement vector on the member side of the connection is given by the equation

G.17.4.2.3 Modeling Rules for Pushover Analysis in STAAD.Pro

Pushover analysis takes time. Each nonlinear problem is different. Since it is a step-wise linear analysis, analysis time and results is very much dependent on the incremental push load defined in the input file. Small changes in properties or loading can cause large change in nonlinear response. Hence it is important to consider different loading cases and to perform sensitivity studies on the effect of varying the properties of different structural elements. Analysis results depends on the selection of control node, the selection of lateral load patterns and the determination of fundamental period.

It is better to start with simple analytical model. The analytical model of the building should represent all new and existing components that influence the mass, strength, stiffness, and deformability of the structure at or near performance point. Elements and components shown not to significantly influence the building assessment need not be modeled.

The model should perform as expected under linear static loads and modal analysis. The control node shall be located at the center of mass at the roof of a building. It should be selected in such a way that the displacement component in the direction of lateral load monotonically increases as push load increases. Separate mathematical models representing the framing along two orthogonal axes of the building shall be developed for two-dimensional analysis. A mathematical model representing the framing along two orthogonal axes of the building shall be developed for three-dimensional analysis. Independent analysis must be done while using different methods of lateral load distribution.

Since Pushover analysis depends very much on the incremental push load defined in the input file by using `LDSTEP` parameter, it is better to give a lower value of `LDSTEP` parameter (preferably within 25) to start with. If the analysis does not run successfully and indicate warning message to increase `LDSTEP` parameter, parameter value will have to be increased. However, it may happen that the analysis has ran successfully and achieved the convergence criteria, the program is still issuing warning message to increase the `LDSTEP` parameter to get more accurate results. The value of `LDSTEP` parameter can be increased to get more accurate results but note that by how much `LDSTEP` parameter will be increased and what the exact value it will take depends upon the engineer's judgement. By looking at the Capacity Curve graph, hinge formation and the hinge status (IO, LS, CP or greater than CP) at different load steps, engineer has to judge whether to increase the `LDSTEP` parameter or not.

The type of warning message only gives an initial indication to the engineer whether the value of LDSTEP parameter will be increased or not.

```
*** WARNING : ANALYSIS RESULT IS NOT CONVERGING. UNABLE TO FIND A SOLUTION.
TRY TO REDUCE INCREMENTAL PUSH LOAD BY INCREASING LDSTEP PARAMETER.
```

If the warning message is issued as mentioned above, LDSTEP parameter has to be increased.

```
*** WARNING : STRUCTURE HAS REACHED AN UNSTABLE EQUILIBRIUM WHERE ALL OF A
SUDDEN MEMBERS HAVE STARTED TO FAIL. MORE ACCURATE RESULT MAY
BE OBTAINED BY REDUCING INCREMENTAL PUSH LOAD BY INCREASING LDSTEP
>PARAMETER.
```

If the warning message is issued as mentioned above, LDSTEP parameter may or may not be increased depending upon engineer's choice.

G.17.4.2.4 Scope of Pushover Analysis in STAAD.Pro

Pushover Analysis in STAAD.Pro will produce valid results only when following conditions are satisfied:

1. Buildings are regular and do not have adverse torsional or multimode effects. The capacity curve is generally constructed to represent the first mode response of the structure based on the assumption that the fundamental mode of vibration is the predominant response of the structure.
2. Fully rigid moment frame and concentric braced frame are considered. If any member release is defined, its effect will be same as that for linear analysis.
3. Only steel structures are considered (i.e., material cannot be concrete).
4. Only straight beam and column members are considered (i.e., no curved members, no plate or surface elements).
5. All members of a structure are considered as primary element. No secondary elements are considered.
6. For built-in FEMA hinge formation, out of six degrees of freedom, hinge formation is considered for bending moment about local z axis of beam. For column, hinge formation is considered for bending moment about local z axis of column or for bending moment about local y axis of column, whichever moment becomes the guiding factor. Depending upon the guiding criteria given in FEMA 356:2000, hinge formation in beam is deformation-controlled and that in column can be deformation-controlled or force-controlled. For braced (i.e. truss) member, axial hinge is considered. Beside moment and axial hinge, no other types of hinge formation (e.g. hinge formation due to shear or hinge formation due to coupled effect of axial force and bi-axial bending moment) are considered.
7. Built-in hinge properties and acceptance criteria for beam and columns given in Tables 5-6 and 5-7 of FEMA 356:2000 for beams, columns, and braces are considered.
8. User defined hinge properties are considered for beam and column for hinge formation for bending moment only. For column, only deformation-controlled action is considered as no axial force is considered for checking force-controlled action in column.
9. Out of five methods for lateral load distribution, three methods have been implemented as per Section 3.3.3.2.3 of FEMA 356:2000. The methods implemented are 1.1, 1.2, and 2.1 of Section 3.3.3.2.3 (See G. 17.4.1.8 Lateral Load Distribution (on page 2177)).
10. Performance point of a structure is calculated based on Displacement Coefficient method to find target displacement.

G.18 Member End Forces

Member end forces and moments in the member result from loads applied to the structure. These forces are in the local member coordinate system. The following figures show the member end actions with their directions.

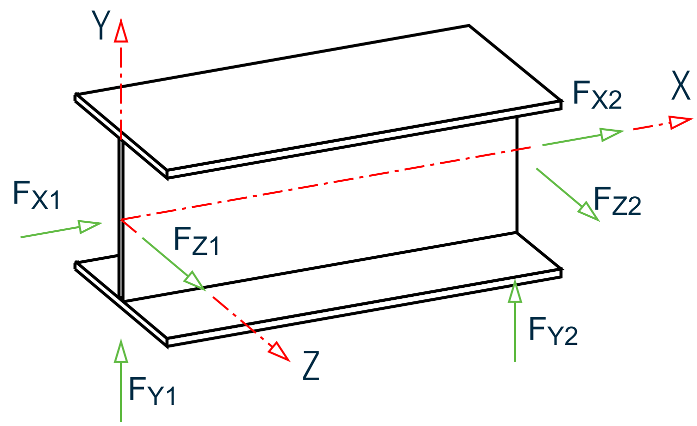

Figure 262: Member end forces when Global Y is vertical

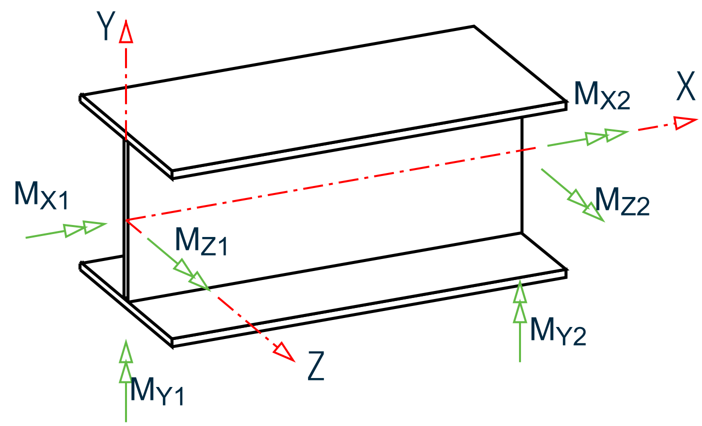

Figure 263: Member end moments when Global Y is vertical

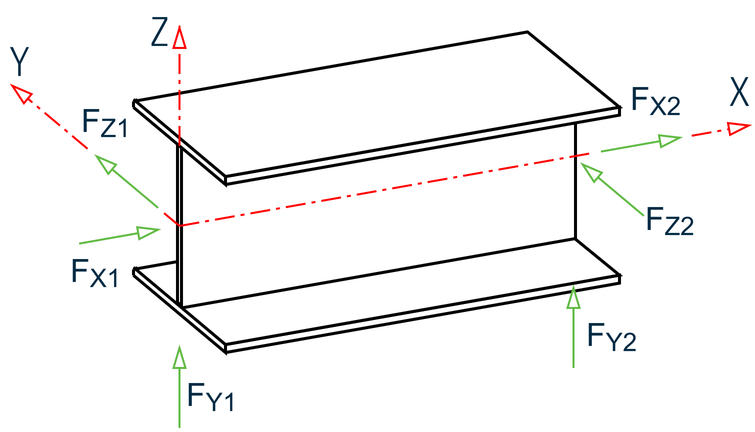

Figure 264: Member end forces when Global Z is vertical (that is, SET Z UP is specified)

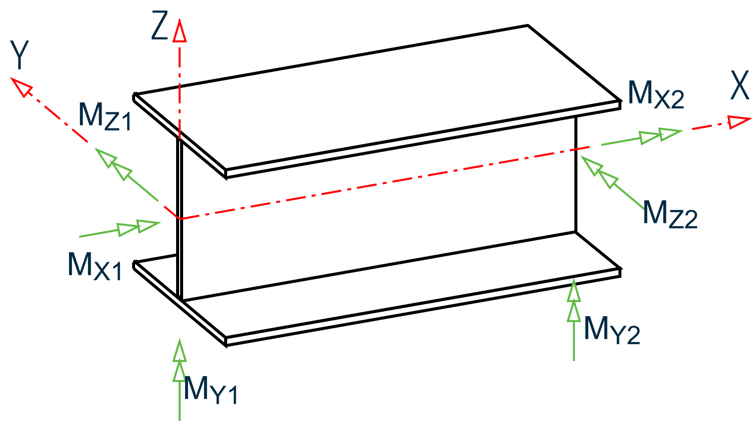

Figure 265: Member end moments when Global Z is vertical (that is, `SET Z UP` *is specified)*

Stress Zones Due to Bending

G.18.1.1 Member Forces at Intermediate Sections

With the `SECTION` command, you may choose any intermediate section of a member where forces and moments need to be calculated. These forces and moments may also be used in design of the members. The maximum number of sections specified may not exceed five, including one at the start and one at the end of a member. If no intermediate sections are requested, the program will consider the start and end member forces for design. However, of the sections provided, they are the only ones to be considered for design.

Related Links

- *TR.41 Section Specification* (on page 2665)
- *TR.42 Print Specifications* (on page 2666)
- *TR.40 Load Envelope* (on page 2663)

G.18.1.2 Member Displacements at Intermediate Sections

Like forces, displacements of intermediate sections of members can be printed or plotted. This command may not be used for truss or cable members.

Related Links

- *TR.41 Section Specification* (on page 2665)

- *TR.44 Printing Section Displacements for Members* (on page 2672)
- *TR.45 Printing the Force Envelope* (on page 2674)

G.18.1.3 Member Stresses at Specified Sections

Member stresses can be printed at specified intermediate sections as well as at the start and end joints. These stresses include:

a. Axial stress, which is calculated by dividing the axial force by the cross sectional area,
b. Bending-y stress, which is calculated by dividing the moment in local-y direction by the section modulus in the same direction,
c. Bending-z stress, which is the same as above except in local-z direction,
d. Shear stresses (in y and z directions), and
e. Combined stress, which is the sum of axial, bending-y and bending-z stresses.

All the stresses are calculated as the absolute value.

Related Links

- *TR.41 Section Specification* (on page 2665)
- *TR.42 Print Specifications* (on page 2666)
- *TR.40 Load Envelope* (on page 2663)

G.18.1.4 Force Envelopes

Force envelopes of the member forces FX (axial force), FY (Shear-y), and MZ (moment about local z-axis, i.e., strong axis) can be printed for any number of intermediate sections. The force values include maximum and minimum numbers representing maximum positive and maximum negative values.

The following is the sign convention for the maximum and minimum values:

FX A positive value is compression, and negative tension.

FY A positive value is shear in the positive y-direction, and negative in the negative y-direction.

FZ Same as above, except in local z-direction.

MZ A positive moment will mean a moment causing tension at the top of the member. Conversely, a negative moment will cause tension at the bottom of the member. The top of a member is defined as the side towards positive local y-axis.

MY Same as above, except about local y axis.

G.19 Multiple Analyses

Structural analysis and design may require multiple analyses in the same run. STAAD.Pro allows you to change input such as member properties, support conditions etc. in an input file to facilitate multiple analyses in the same run. Results from different analyses may be combined for design purposes.

For structures with bracing, it may be necessary to make certain members inactive for a particular load case and subsequently activate them for another. STAAD provides an `INACTIVE` facility for this type of analysis.

Inactive Members

With the `INACTIVE` command, members can be made inactive. These inactive members will not be considered in the stiffness analysis or in any printout. The members made inactive by the `INACTIVE` command are made active again with the `CHANGE` command. This can be useful in an analysis where stage construction is modeled due to which, a set of members should be inactive for certain load cases. This can be accomplished by:

a. making the desired members inactive
b. providing the relevant load cases for which the members are inactive
c. performing the analysis
d. using the `CHANGE` command to make all the inactive members active
e. making another set of members inactive and providing the proper load cases for which the members are meant to be inactive, performing the analysis and repeating the procedure as necessary.

Related Links

- *TR.38 Change Specification* (on page 2660)
- *Change tab* (on page 2920)
- *A. To add a change command* (on page 958)
- *TR.18 Inactive/Delete Specification* (on page 2240)

G.20 Steel, Concrete, and Timber Design

- *D. Steel Design* (on page 969)
- *D1.G. American Codes - Timber Design per AITC Code* (on page 1248)

G.21 Printing Facilities

All input data and output may be printed using `PRINT` commands available in STAAD. The input is normally echoed back in the output. However, if required, the echo can be switched off.

Extensive listing facilities are provided in almost all `PRINT` commands to allow you to specify joints, members and elements for which values are required.

Related Links

- *TR.44 Printing Section Displacements for Members* (on page 2672)
- *TR.45 Printing the Force Envelope* (on page 2674)

G.22 Miscellaneous Facilities

STAAD.Pro offers the following miscellaneous facilities for problem solution.

Perform Rotation

This command can be used to rotate the structure shape through any desired angle about any global axis. The rotated configuration can be used for further analysis and design. This command may be entered after the Joint Coordinates or between two Joint Coordinate commands or after all Member/Element Incidences are specified.

Substitute

Joint and member numbers may be redefined in STAAD through the use of the `SUBSTITUTE` command. After a new set of numbers are assigned, input and output values will be in accordance with the new numbering scheme. This facility allows the user to specify numbering schemes that will result in simple input specification as well as easy interpretation of data.

Calculation of Center of Gravity

STAAD is capable of calculating the center of gravity of the structure. The `PRINT CG` command may be utilized for this purpose.

10 Technical Reference of STAAD Commands

This section contains details of the STAAD.Pro commands used to create STAAD input files which are read by the STAAD engine.

Note: This section was previously included as Section 5 of the *Technical Reference Manual*. For convenience, the section numbers from that manual are maintained here with "TR." in place of "5." for the chapter number.

Introduction

The STAAD.Pro graphical user interface (GUI) is normally used to create all input specifications and all output reports and displays. These structural modeling and analysis input specifications are stored in STAAD input file – a text file with extension, `.STD`. When the GUI opens an existing model file, it reads all of the information necessary from the STAAD input file. You may edit or create this STAAD input file and then the GUI and the analysis engine will both reflect the changes.

The STAAD input file is processed by the STAAD analysis "engine" to produce results that are stored in several files (with file extensions such as `ANL`, `BMD`, `TMH`, etc.). The STAAD analysis text file (file extension `.ANL`) contains the printable output as created by the specifications in this manual. The other files contain the results (displacements, member/element forces, mode shapes, section forces/moments/displacements, etc.) that are used by the GUI in the post processing mode.

TR.0 STAAD Commands and Input Instructions

This section of the manual describes in detail various commands and related instructions for STAAD.Pro. The user utilizes a command language format to communicate instructions to the program. Each of these commands either supplies some data to the program or instructs it to perform some calculations using the data already specified. The command language format and conventions are described in TR.1 Command Language Conventions (on page 2197). This is followed by a description of the available commands.

Although the STAAD.Pro input can be created through the Analytical Modeling workflow, it is important to understand the command language. With the knowledge of this language, it is easy to understand the problem and add or comment data as necessary. The general sequence in which the commands should appear in an input file should ideally follow the same sequence in which they are presented in this section. The commands are executed in the sequence entered. Obviously then the data needed for proper execution of a command must precede the command (e.g., Print results after Perform Analysis). Otherwise, the commands can be provided in any order with the following exceptions.

- **i.** All design related data can be provided only after the analysis command.
- **ii.** All load cases and load combinations must be provided together, except in a case where the `CHANGE` command is used (see TR.38 Change Specification (on page 2660)). Additional load cases can be provided in the latter part of input.

All input data provided is stored by the program. Data can be added, deleted or modified within an existing data file.

In-Core Verus Out-of-Core

The engine can operate in two modes: *in-core* and *out-of-core*. The in-core solver will be used for models with under 20,000 joints and the out-of-core solver for models over 20,000 joints. In most situations, the in-core mode will provide the quickest solution, but where there is insufficient memory available, then the engine will use the out-of-core mode. Again, selection of the mode is automatically chosen by the analysis, but can be overridden using the `SET STAR` command.

The full set of overrides for the advanced engine is:

`SET STAR 3` – default
`SET STAR 4` – use out-of-core solver regardless of size

TR.1 Command Language Conventions

This section describes the command language used in STAAD. First, the various elements of the language are discussed and then the command format is described in details.

TR.1.1 Elements of STAAD Commands

Integer Numbers

Integer numbers are whole numbers written without a decimal point. These numbers are designated as i_1, i_2, etc., and should not contain any decimal point. Negative signs (-) are permitted in front of these numbers. Omit the sign for positive. No spaces between the sign and the number.

Floating Point Numbers

These are real numbers which may contain a decimal portion. These numbers are designated as f_1, f_2... etc.. Values may have a decimal point and/or exponent. When specifying numbers with magnitude less than 1/100, it is advisable to use the E format to avoid precision related errors. Negative signs (-) are permitted in front of these numbers. Omit the sign for positive. No spaces between the sign and the number. Limit these to 24 characters.

Example

```
5055.32   0.73   -8.9   732
5E3   -3.4E-6
```

etc.

The decimal point may be omitted if the decimal portion of the number is zero.

Alphanumeric

These are characters, which are used to construct the names for data, titles or commands. Alphabetic characters may be input in upper or lower case letters. No quotation marks are needed to enclose them.

Example

```
MEMBER PROPERTIES
1 TO 8 TABLE ST W8X35
```

Repetitive Data

Repetitive numerical data may be provided in some (but not all) input tables such as joint coordinates by using the following format:

```
n*f
```

Where:

n = number of times data has to be repeated
f = numeric data, integer and floating point

Example

```
JOINT COORDINATES
1  3*0.
```

This joint coordinate specification is same as:

```
1  0.  0.  0.
```

TR.1.2 Command Formats

Free-Format Input

All input to STAAD.Pro is in free-format style. Input data items should be separated by blank spaces (not commas) from the other input data items. Quotation marks are never needed to separate any alphabetic words such as data, commands or titles. Limit a data item to 24 characters.

Commenting Input

For documentation of a STAAD data file, the facility to provide comments is available. Comments can be included by providing an asterisk (*) mark as the first non-blank character in any line. The line with the comment is "echoed" in the output file but not processed by the program.

Example

```
JOINT LOAD
* THE FOLLOWING IS AN EQUIPMENT LOAD
2 3 7 FY 35.0
* etc.
```

Meaning of Underlining in the Manual

Exact command formats are described in the latter part of this section. Many words in the commands and data may be abbreviated. The full word intended is given in the command description with the portion actually required (the abbreviation) underlined.

For example, if the word `MEMBER` is used in a command, only the portion `MEMB` need be input. It is clearer for others reading the output if the entire word is used, but an experienced user may desire to use the abbreviations.

Meaning of Braces and Parenthesis

In some command formats, braces enclose a number of choices, which are arranged vertically or separated by a | character. One and only one of the choices can be selected. However, several of the listed choices may be selected if an asterisk (*) mark is located outside the braces.

Example

```
{XY | YZ | XZ}
```

In the above example, you must make a choice of XY or YZ or XZ.

Note: In some instances, the choices will be explicitly defined using "or" for clarification.

Example

```
*{FX | FY | FZ}
```

Here, you can choose one or all of the listing (FX, FY and FZ), in any order.

Parentheses, ( ), enclosing a portion of a command indicate that the enclosed portion is optional. The presence or absence of this portion affects the meaning of the command, as is explained in the description of the particular command.

Example

```
PRINT (MEMBER) FORCES
```

```
PERFORM ANALYSIS (PRINT LOAD DATA)
```

In the first line, the word `MEMBER` may be omitted with no change of the meaning of the command. In the second line, the `PRINT LOAD DATA` command may also be omitted, in which case the load data will not be printed.

Multiple Data Separator

Multiple data can be provided on a single line, if they are separated by a semicolon (;) character. One restriction is that a semicolon can not separate consecutive commands. They must appear on separate lines.

Example

```
MEMBER INCIDENCES
1  1  2;  2  2  3;  3  3  4
```

etc.

Possible Error:

```
PRINT FORCES; PRINT STRESSES
```

In the above case, only the `PRINT FORCES` command is processed and the `PRINT STRESSES` command is ignored.

Listing Data

In some STAAD command descriptions, the word "list" is used to identify a list of joints, members/elements, or loading cases. The format of a list can be defined as follows:

$$\text{list} = *\{\ i_1\ i_2\ i_3\ \ldots\ |\ i_1\ \underline{\text{TO}}\ i_2\ (\underline{\text{BY}}\ i_3)\ |\ \underline{X}\ \text{or}\ \underline{Y}\ \text{or}\ \underline{Z}\ \}$$

TO means all integers from the first (i_1) to the second (i_2) inclusive. BY means that the numbers are incremented by an amount equal to the third data item (i_3). If BY i_3 is omitted, the increment will be set to one. Sometimes the list may be too long to fit on one line, in which case the list may be continued to the next line by providing a hyphen preceded by a blank. Also, only a list may be continued and not any other type of data.

Instead of a numerical list, a single group-name may be entered if that group was previously defined.

Instead of a numerical list, the specification X (or Y or Z) may be used. This specification will include all `MEMBER`s parallel to the global direction specified. Note that this is not applicable to `JOINT`s or `ELEMENT`s.

Note: ALL, BEAM, PLATE, SOLID. Do not use these unless the documentation for a command specifically mentions them as available for that command. ALL means all members and elements, `BEAM` means all members, etc.

Continuing a command to the next line

Only lists may be continued to the next line by ending the line with a blank and hyphen (see above) with few exceptions: Multilinear spring supports, Supports, Control/Dependent. Others have special types of continuations. Please follow the command descriptions.

Example

```
2 4 7 TO 13 BY 2 19 TO 22 -
28 31 TO 33 FX 10.0
```

This list of items is the same as:

```
2 4 7 9 11 13 19 20 21 22 28 31 32 33 FX 10.0
```

Possible Error:

```
3 5 TO 9 11 15 -
FX 10.0
```

In this case, the continuation mark for list items is used when list items are not continued. This will result in an error message or possibly unpredictable results.

TR.1.3 Listing of Objects by Specification of Global Ranges

Used to specify lists of objects (e.g., joints, members, and/or elements) by providing global ranges. The general format of the specification is as follows.

General Format

```
{ XRANGE | YRANGE | ZRANGE } f1, f2
```

Where:

XRANGE, YRANGE, ZRANGE = direction of range (parallel to global X, Y, Z directions respectively)
f1, f2 = values (in current unit system) that defines the specified range.

Notes

1. Only one range direction (XRANGE, YRANGE etc.) is allowed per list. (Exceptions: Area/Floor load and Control/Dependent).
2. No other items may be in the list.
3. The values defining the range (f1, f2) must be in the current unit system.

Example

```
MEMBER TRUSS
XRANGE 20. 70.
CONSTANTS
E STEEL YRANGE 10. 55.
```

In the above example, a XRANGE is specified with values of 20. and 70. This range will include all members lying entirely within a range parallel to the global X-axis and limited by X=20 and X=70.

TR.1.4 Memory Allocation

To allow a larger allocation of memory for the CM array.

The `MEMORY` command is optional and if entered must be the first line of the `.STD` file.

General Format

```
MEMORY f1
```

where:

f1 The integer amount of blocks of CM memory to be allocated. *f1* is multiplied by 1,000,000 x 4-byte floating point words to get allocation in bytes (320 MBytes). The default value is 300 for STAAD.Pro 64-bit and 80 for STAAD.Pro 32-bit. The upper limit for 64-bit systems is 2,100.

Note: For older STAAD.Pro 32-bit (phased out in CE release May 2018), experience suggested that *f1* be between 80 and 400, if required to re-run an input file. For STAAD.Pro 64-bit , experience is limited so trial and error is recommended.

Usage

When the program finds that memory block was insufficient to complete the analysis, the following warning is issued:

```
    'ERROR-STAAD BUILT IN MEMORY BLOCK HAS OVERFLOWED.'
    'ALLOCATED BLOCKSIZE =',I11
    'NEEDED BLOCKSIZE =',I11
    'TRY REDUCING THE NUMBER OF LOAD CASES.'
```

In this instance, add the `MEMORY f1` command to the first line of the `.STD` file where *f1* is the “needed blocksize” value. This amount may be increased so long as this does not exceed the recommended amounts.

Example

```
MEMORY 200
STAAD SPACE
…
FINISH
```

TR.2 Problem Initiation and Model Title

This command initiates the STAAD run and is also used to specify the type of the structure and provide an optional title.

Any STAAD input file must start with the word `STAAD`. Following type specifications are available:

- PLANE= Plane frame structure
- SPACE= Space frame structure
- TRUSS= Plane or space truss structure
- FLOOR= Floor structure

General Format

```
STAAD { PLANE | SPACE | TRUSS | FLOOR } (any_title )
```

Where:

any_title = Any title for the problem. This title will appear on the top of every output page. To include additional information in the page header, use a comment line containing the pertinent information as the second line of input.

Notes

1. Care must be taken about choosing the type of the structure. The choice is dependent on the various degrees of freedom that need to be considered in the analysis. The following figure illustrates the degrees of freedoms considered in the various type specifications. Detailed discussions are available in G.2 Types of Structures (on page 2085). PLANE indicates the XY plane for Y up and the XZ plane for Z up. FLOOR indicates the XZ floor for Y up and the XY floor for Z up.

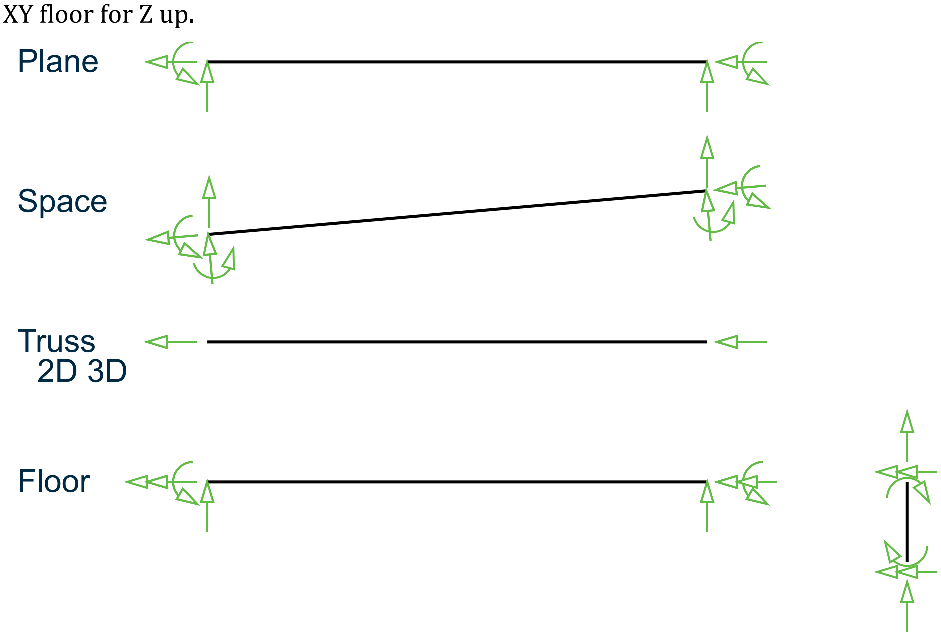

Figure 268: Structure type A) Plane, B) Space, C) Truss 2D or 3D, and D) Floor

2. The optional title provided by you are printed on top of every page of the output. You can use this facility to customize his output.

Limits

The following limits to model size are effective for STAAD.Pro CONNECT Edition V22 Update 2 (release 22.02.00) and later.

- Number of joints: 400,000*
- Joint number 1 to 999,999
- Number of Members, Physical Members, Plates, and Solids: 500,000*
- Member/Element numbers: 1 to 999,999
- Number of primary and combination cases: 10,101
- Load Case numbers: 1 to 99,999
- Number of modes and frequencies: 2,700
- Number of load cases that may be combined by a Repeat Load or Load Combination command: 550

* Some STAAD.Pro copies are available with much smaller limits, please check what limits you have purchased.

Notes:

The numerical limits should be considered as upper limits built into the software for those quantities on an individual basis. In practice, the actual maximums the program can handle are determined by the hardware resources as well as the limits imposed by the operating system. For example, it is highly improbable that a single model with 500,000 members and 10,101 load cases can be solved.

The memory demand of the program is determined by the combined effect of two or more of these terms. For example, when a steel design is performed, the memory required depends on the product of the members being designed (NMD) as well as the number of load cases being designed for (NL). That is, NMD ×NL. So the smaller the NMD, the larger the NL capacity and vice versa.

Related Links

- *G.2 Types of Structures* (on page 2085)

TR.3 Unit Specification

This command allows you to specify or change length and force units for input and output.

Description

The magnitude of numerical data that is entered in a STAAD model is determined by the unit of that data. STAAD.Pro supports numerical data based on both English and Metric unit systems.

The method used by STAAD.Pro to determine the unit of any value is by the previous `UNIT` command.

The `UNIT` command can set or change the unit of `LENGTH`, `FORCE`, or both. This can be set any number of times in a STAAD input file to specify data or generate output in the desired length or force units, subject to the conditions noted below. All data is assumed to be in the most recent unit specification preceding that data.

General Format

```
UNIT *{ length-unit  | force-unit }
```

where:

```
length-unit  = { INCHES | FT or FEET | METER | CM | DME | MMS | KM }
```

```
force-unit  = { KIP | POUND | KNS | | DNS | NEWTON | MNS | MTON | KG }
```

The following tables illustrate the unit and the relative factor against the primary base unit:

Table 227: Units of length in STAAD.Pro

Required Length Unit		Base Unit	Factor	UNIT command parameter
English	Inch	Inch	1	IN
	Foot	Inch	12	FT (or FE)
Metric	Meter	Meter	1	ME
	Decimeter	Meter	0.1	DM
	Centimeter	Meter	0.01	CM
	Millimeter	Meter	0.001	MM
	Kilometer	Meter	1,000	KM

Table 228: Units of force in STAAD.Pro

Required Force Unit		Base Unit	Factor	UNIT command parameter
English	Kip (kilopound)	Kip	1	KI
	Pound	Kip	0.001	PO
Metric	Kilonewton	Kilonewton	1	KN
	Decanewton	Kilonewton	0.1	DN
	Newton	Kilonewton	0.001	NE
	Meganewton	Kilonewton	1,000	MN
	Metric Ton	Kilonewton	9.80665	MT
	Kilogram	Kilonewton	$9.80665\ (10)^{-3}$	KG

Example

```
UNIT KIP FT
UNIT INCH
UNIT METER KNS
UNIT CM MTON
```

Notes

a. A `UNIT` command may be inserted before any primary level command (e.g., `JOINT COORD`, `MEMBER INCIDENCE`, etc.).
b. If no `UNIT` command is specified, then the default units are taken as:
   - Length: feet
   - Force: kips
c. Units can be mixed between systems of units, such as length of feet and force of kilonewtons.
d. Units that include both length and force components (e.g., stress = force/length^2) will be constructed from the current length and force units.

   Thus, if the current length unit is feet and force unit is kilonewtons, then when defining Young's modulus, the value for a stress unit is kN/ft^2. While this may be an odd definition, it is fully supported by STAAD.Pro.
e. Kilograms and metric tons are mass units which are converted to units of force assuming an acceleration due to gravity of 32.174 ft/s^2.
f. Temperature units are not explicitly defined in STAAD.Pro. The value of temperature loading and coefficient of thermal expansion are taken to be consistent units.
g. A `UNIT` command should be avoided immediately prior to the analysis command. Warnings will be presented in the output if one is included. Instead, to change the units of the output, the `UNIT` command should be included after the analysis command and prior to any post-analysis print commands.

- *G.3 Unit Systems* (on page 2086)

TR.4 Input/Output Width Specification

These commands may be used to specify the width(s) of the lines of output file(s).

For INPUT width, 79 is always used. The program can create output using two different output widths - 72 (default) and 118. The narrower, 72-character width is used for display on most older monitors and for printing on “portrait” wide paper. The 118-character width may be used for printing on “landscape” wide paper.

Note: This is a customization facility that may be used to improve the presentation quality of the output documents.

General Format

```
{INPUT | OUTPUT} WIDTH i1
```

Where:

i1 = 72 or 118 depending on narrow or wide output. 72 is the default value.

TR.5 Set Command Specification

This command allows you to set various general specifications for the analysis/design run.

General Format

```
SET { NL i1 | {DISPLACEMENT i2 | PDELTA TOLERANCE i9} | SDAMP i3 | WARP i4 | ITERLIM
i5 | PRINT i7 | NOPRINT DIRECT | SHEAR | ECHO { ON | OFF } | GUI i6 | { Z | Y } UP |
DEFLECTION CUTOFF  f1 | FLOOR LOAD TOLERANCE f2 | EIGEN METHOD { LANCZOS | RITZ} }
```

Where:

Description

The following SET commands contain values with associated units and should appear *after* a UNIT command and before the first JOINT command.

Table 229: Commonly used SET commands which take units

Command	Parameter	Description
SET NL	*i1*	The SET NL command is used in a multiple analysis run if you want to add more primary load cases after one analysis has been performed. Specifically, for those examples which use the CHANGE command (see TR.38 Change Specification (on page 2660)), if you want to add more primary load cases, the NL value should be set to the maximum number (or slightly more) with the SET NL command. The program will then be able to set aside additional memory space for information to be added later. This command should be provided before any joint, member or load specifications. The value for *i1* is the maximum number of primary load cases (NL). This value should not be much greater than the maximum number of primary load cases actually used in the model. **Note:** If plates are present, the SET NL value includes the total number of primary and load combinations in the model.

Command	Parameter	Description
SET DISPLACEMENT	*i2*	For `PDELTA ANALYSIS` (refer to TR.37.2 P-Delta Analysis Options (on page 2621) for additional information) The `SET DISPLACEMENT` *i2* command is used to specify the convergence tolerance. If the Euclidean norm RMS displacement of two consecutive iterations changes less than the value entered, then that load case is converged. This command should be placed before the `JOINT COORDINATE` specification. The default tolerance value, *i2* , is equal to the maximum span of structure divided by 120. The convergence tolerance for the Euclidean norm is difficult to know, so using this option is not recommended. *i2* = If the change in the Euclidean norm of the displacement vector from one `PDELTA` iteration to the next is less than this convergence tolerance value; then the iteration has converged for the case being analyzed.
SET DEFLECTION CUTOFF	*f1*	Used to arrest huge displacements in minor axis due to small delta effects. *f1* = If the absolute value of the maximum section displacement is less than *f1* after two iterations; then it is converged. Rapidly diverging minor axis displacement will not occur until after two iterations. *f1* is in current length units.
SET FLOOR LOAD TOLERANCE	*f2*	Used to specify the tolerance for out of plane nodes in a floor load. The program expects all nodes to lie in the same plain. If there is any minor variation in coordinates of the nodes, the program will excluded floor panels connected to those nodes. Hence, a tolerance value is used to so that all nodes with in the range (min. Y and min Y + tolerance). The default is take as 0.01% of the length of the longest beam of the beams in the floor load command. **Note:** Inclined floor panels are defined separately using the floor group option. Refer to TR.32.4.3 Floor Load Specification (on page 2483) for details on specifying a plane for floor loads. *f2* = the maximum distance any node can be from the plane, in the current length units

The following SET commands have dimensionless input

Table 230: Other commonly used SET commands

Command	Parameter	Description
SET SDAMP	*i3*	The SET SDAMP command will allow the damping of springs to be considered in computing the composite modal damping for each mode in a dynamic solution. This command is not used unless CDAMP ratios are also entered for the members and elements in the CONSTANTS command. Composite damping is generally only used if there are many modes in the dynamic solution and there are a wide range of damping ratios in the springs, members, or elements. *i3* = the damping ratio to be used for all springs in computing the modal composite damping in dynamics.
SET WARP	*i4*	The SET WARP command will allow the I section member end warping restraint to be considered in calculating the torsional stiffness rigidity. Full or partial or no warping restraint are allowed.
SET ITERLIM	*i5*	This command sets the maximum number of iterations in an analysis with tension/compression only members or supports. The minimum iteration limit that may be entered is 3, then max is 150. Any value higher than this will be replaced with 150. The default value used is 10. The iterative procedure may not necessarily converge. Increasing the iterations may still not lead to convergence. Therefore it is recommended that after any tension/compression analysis, the output file should be reviewed for any warnings of non-convergence. The results from a load case that has not converged should not be used, but is provided for information only. *i5* = Maximum number of tension/compression iterations.

Command	Parameter	Description
SET PRINT	*i7*	The following values can be used to suppress the described warnings or include the described additional results in the output: 1 = Omit zero stiffness message, Rotational zero stiffness message due to solids, and “Node not connected. OK if control/ dependent” message. 2 = Omit Member in list does not exist message. 3 = Omit joint not connected message. 5 = Turn off floor load message. 8 = Omit self weight warnings. 10 = Turns on some iteration messages in direct analysis. 17 = Write rotational masses to mass text file; otherwise only translational masses written. Print scaled modal results for RSA and some force data by floor for RSA. *i7* = Used to suppress some warning messages or to include additional output.
SET NOPRINT DIRECT	(n/a)	Used to turn off the tau-b details in the output file when running a Direct Analysis (refer to TR.37.5 Direct Analysis (on page 2630)).
SET SHEAR	(n/a)	Including this command will omit the addition of pure shear distortion stiffness terms. This is often the method used in hand calculations and allows the analysis displacement results to be checked against those calculations.
SET ECHO {ON | OFF}	ON	This is a switch to turn on/off any commands that follow this command from being reported in the output file to help reduce the amount of data reported. This command can be specified at any point in the file.
SET GUI	0	A flag to indicate prevent the analysis engine from producing the results databases used by the GUI to display in the Post-Processing workflow. This can be used in very large models where the last action of the analysis to create the results databases can add a significant time to the overall analysis process. 0) Standard post-processing results are produced 1) No post-processing results are produced; only an output file (`.ANL`) is generated.

Command	Parameter	Description
SET { Z | Y } UP	Y UP	Determines the axis which defines the name of the global vertical direction in the model and the name of the minor axis of beam members. It is strongly recommended to use the Y UP axis system (default) as a number of commands and methods employed in STAAD.Pro do not support the Z UP axis convention. Both options follow the “right hand rule.”  **Note:** Both options follow the “right hand rule.” *Figure 269: Global axis orientation options in STAAD.Pro* This command will determine the alignment of angle profiles specified with the BETA ANGLE/RANGLE specification. See section CONSTANTs specification (see TR.26 Specifying and Assigning Material Constants (on page 2303) and G.4.2 Local Coordinate System (on page 2088)).
SET STAR	*i*	Instructs the program which solver to use. Refer to TR.0 STAAD Commands and Input Instructions (on page 2196) for additional information. 3 = STAAD Advanced Solver (in-core) - default 4 = STAAD Advanced Solver (out-of-core) **Note:** When SET STAR 3 is used and if the following limits are exceeded, then the solver will automatically switch to out-of-core: **i.** Number of nodes >30,000 **ii.** Number of nodes times the number of active primary load cases > 1,600,000

Command	Parameter	Description
SET EIGEN METHOD { LANCZOS | RITZ }	(n/a)	This command will override the default sub-space method for extracting eigen solutions as described in section G.17.3.1 Solution of the Eigenproblem (on page 2155). `LANCZOS` — Instructs the solver to use Arnoldi/Lanczos method for extraction of eigen vectors. `RITZ` — Use load dependent Ritz vectors method for extraction of eigen vectors. The use of either the Arnoldi/Lanczos method or the Ritz method requires a STAAD.Pro Advanced license. This command is not applicable with the basic solver. If neither method is specified, the default method of Subspace-iteration is used. **Note:** `SET EIGEN METHOD RITZ` is not used by pushover analysis or steady state analysis. The pushover analysis uses the lateral load distribution is based on the eigen vector. If the command is present, a warning message is given in the output.

Less frequently used SET commands

The following table contains a list of less frequently used SET commands

Command	Default	Description
SET BUCKLING MODES *i*	4	Number of buckling modes computed with advanced solver. This command is not applicable to the basic solver.
SET BYPASS { DIS | FOR | EJS | EJF }		Bypass generating certain outputs for the graphical user interface. DIS = section displacements FOR = section force EJS = plate nodal stress EJF = plate nodal force
SET CG TXT		This command will trigger the creation of a text file (`*.TXT`) that includes details of the section forces for the load cases generated with a load combination command with the `GENERATE` optional parameter. See TR.35 Load Combination Specification (on page 2616) for additional details. **Note:** The resulting file can be extremely large and thus this option should be used with care.
SET DIVISION *i*		Set the number of divisions used in meshing for surfaces (default is 10)
SET ENDFACTOR *f*		1.0 or -1.0 for combining spectrum cases

Command	Default	Description
SET GROUP DUPLICATES		Specifies the maximum number of groups any object (node, member, plate, or solid) can be included. A minimum of value 4 and a maximum of value 100. The default value is 10 groups.
SET INCLINED REACTION		Used to report the reactions of inclined supports in their inclined axis system. If not specified the reactions will be in the global axis.
SET INPLANE ROTATION		In-plane rotation (MX) in plates will be ignored.
SET LOAD PLATE		Include loads applied to inactive plates.
SET MASS *i*		1 = Use generated moments as masses
SET MULTI { 1 | 2 }		If multi-linear analysis fails to converge, try entering SET MULTI 2 and re-running.
SET NF TXT		Used to print section forces for each member corresponding to the critical load combination generation case to an external text file. See TR.35 Load Combination Specification (on page 2616) for additional details. This command should be used only for review of data and not in normal circumstances as the resulting text file can be very large.
SET NOSECT		This command is used to only produce results at the ends of members and no intermediate results. Note that this can result in a faster analysis for very large models, but parts of the Post Processing Workflow that rely on the intermediate section results will not be available.
SET NOTE { ON | OFF }		This commend toggles whether advice notes are displayed in the output file (`.anl`). When set to `OFF` the notes are not displayed. (`ON` is default).
SET NOWARNING		Switches off some warning messages.
SET PARTICIPATION FACTOR		Including this command will extend the details of a dynamic analysis to include participation factors normalised to 1.0.

Command	Default	Description
SET PLATE FLATNESS TOLERANCE *f*	30	This is used to set the tolerance for determining if any four-noded plate element is out of plane. The value entered in degrees is the maximum allowable deviation of one node from a plane defined by the other three nodes. **Note:** It is possible to test before the analysis using the tool **Utilities** > **Plate** menu. For more information see section M. To check for warped plates (on page 912). The value *f* is given in degrees.
SET PROFILE *s2*		A command to define the path of the folder that contains the collection of databases of section property data in SQLite (`.DB3`) files. Note also that the GUI will use this as the location of the section profile databases. The default file path used is `C:\ProgramData\Bentley\Engineering\STAAD.Pro CONNECT Edition\Sections\`.
SET RIGID DIAPHRAGM *i*	150	This command is used to reserve memory for the maximum number of diaphragms that may be defined in the model. See section TR.28.2 Floor Diaphragm (on page 2328) for more information on defining and using floor diaphragms in an analysis.
SET RS TXT		This command will trigger the creation of a text file (`*_RESP.TXT`) that includes the section forces for each mode used in a response spectrum load case. See TR.35 Load Combination Specification (on page 2616) for additional details. **Note:** This can generate a large datafile and thus should be used with care on larger models and models with large numbers of extracted mode shapes.
SET THCOPYS *i*		This command is used to set the maximum number of time history forcing functions (TYPES) to which a given node degree of freedom can be subjected. The default value is 4.
SET SOLUTION INCORE	(n/a)	For some smaller models, it may be possible to use an alternative “determinant search method” which is performed in-core. However this is limited to where the problem can be solved in a single matrix block. If not, then analysis will revert to using the subspace iteration method. This command is only applicable to the basic solver.

Command	Default	Description
SET PRINT STIFFNESS		This command will output the assembled global stiffness matrix to the output file (`*.ANL`). This command is only applicable to the basic solver. The output includes the stiffness matrix from the diagonal and only includes non-zero terms (with values of 10^{-20} or less are assumed to be zero). See the section below on how to read this output. See Stiffness Matrix Output (on page 2214) for details on how to interpret the stiffness matrix output.

Stiffness Matrix Output

When the `SET PRINT STIFFNESS` command is used with the Basic solver, the non-zero terms for the diagonal and upper half of the stiffness matrix are reported. The following example shows the output of adding this command to the file
`C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models \03 Static Beams\BEAM01.std`

```
 NON-ZERO STIFFNESS MATRIX VALUES, PRINTED BY ROWS FROM THE DIAGONAL.
                ROW        1  JOINT      1  DIRECTION  6
                1  1.180099515E+05      3 -1.498726372E+03       4  5.900497573E+04
                ROW        2  JOINT      2  DIRECTION  1
                2  3.172303322E+03
                ROW        3  JOINT      2  DIRECTION  2
                3  3.289796633E+01      4 -8.326259057E+02
                ROW        4  JOINT      2  DIRECTION  6
                4  1.966832440E+05
```

This describes position of each non-zero term in a row starting from the diagonal and then moving right. So, this matrix would be written as:

$$\begin{bmatrix} 118,009.9515 & 0 & -1,498.726372 & 59,004.97573 \\ & 3,172.303322 & 0 & 0 \\ \text{sym.} & & 32.89766633 & -832.6259057 \\ & & & 196,683.244 \end{bmatrix}$$

Related Links

- *G.17.3.1 Solution of the Eigenproblem* (on page 2155)

TR.6 Data Separator

This command may be used to specify the desired separator character that can be used to separate multiple lines of data on a single line of input.

The semicolon (;) is the default character which functions as the separator for multiple line data on one line. However, this separator character can be changed by the `SEPARATOR` command to any character.

Note: Comma (,) or asterisk (*) may *not* be used as a separator character.

General Format

```
SEPARATOR a1
```

TR.7 Page Control Commands

TR.7.1 Page New

This command may be used to instruct the program to start a new page of output.

With this command, a new page of output can be started. This command provides the flexibility, the user needs, to design the output format.

Note: The presentation quality of the output document may be improved by using this command properly.

General Format

```
PAGE NEW
```

TR.7.2 Page Length

This command may be used to specify the page length of the output.

General Format

```
PAGE LENGTH i
```

Where:

i The page length in STAAD output is based on a default value of 58 lines . However, you may change the page length to any number i (number of lines per page) wanted.

TR.8 Ignore Specifications

This command allows you to provide member lists in a convenient way without triggering error messages pertaining to non-existent member numbers.

The `IGNORE LIST` command may be used if you want the program to ignore any nonexistent member(s) that may be included in a member list specification. For example, for the sake of simplicity, a list of members may be specified as MEMB 3 TO 40 where members 10 and 11 do not exist. An error message can be avoided in this situation by providing the `IGNORE LIST` command anywhere in the beginning of input. A warning message, however, will appear for each nonexistent member.

General format

```
IGNORE LIST
```

TR.9 No Design Specification

This command allows you to declare that no design operations will be performed during the run. The memory reserved for design will be released to accommodate larger analysis jobs.

STAAD always assumes that at some point in the input, you may want to perform design for steel, concrete, etc. members. These design processes require more computer memory. If memory availability is a problem, the above command may be used to eliminate extra memory requirements.

General Format

```
INPUT NODESIGN
```

TR.10 Job Information Data

This optional block of commands is used to project metadata for the STAAD input file.

General Format

The job information data block must begin with the START and END lines, with all lines in between being optional.

```
START JOB INFORMATION
ENGINEER DATA date
JOB NAME job-name
JOB CLIENT client-name
JOB NO job-number
JOB REV revision-number
JOB PART part-number
JOB REF reference-number
JOB COMMENT comments-string
ENGINEER NAME engineer-name
CHECKER NAME checked-by-name
APPROVED NAME approved-by-name
CHECKER-DATE checked-on-date
APPROVED DATE approved-on-date
CONNECTED PROJECT ID project-id
CONNECTED PROJECT NAME project-name
END JOB INFORMATION
```

Note: The job information block must be place *before* the JOINT COORDINATES command.

Caution: The CONNECTED Project *project-id* and *project-name* should not be directly edited. These are added through the User Interface.

TR.11 Joint Coordinates Specification

These commands allow you to specify and generate the coordinates of the joints of the structure. The JOINT COORDINATES command initiates the specification of the coordinates. The REPEAT and REPEAT ALL commands allow easy generation of coordinates using repetitive patterns.

General Format

```
JOINT COORDINATES (CYLINDRICAL (REVERSE)) (NOCHECK) (NOREDUCE  BAND)
i1 xi1 yi1 zi1 (i2 xi2 yi2 zi2) (i3)
```

…repeat as needed to define each node or generated set of nodes

```
(in xin yin zin )
```

```
(REPEAT  n xr1 yr1 zr1 (xr2 yr2 zr2 … xrn yrn zrn) )
```

```
(REPEAT  ALL  n xt1 yt1 zt1 (xt2 yt2 zt2 … xtn ytn ztn) )
```

```
(JTORIGIN xOrigin yOrigin zOrigin)
```

Where:

i1, ***in***	the reference number of the node coordinate that follows
xi yi zi	the coordinates of node *i* in the given coordinate system.

Tip: To manually specify each node number and coordinate, separate nodes on a new line.

i2	optional last node number of a sequence of nodes generated from node *i1*
x2 y2 z2	the coordinates of node *i2* in the given coordinate system
i3	the increment in node number from *i1* to *i2*. The default increment is 1. Each node generated will be equally spaced along a linear path between *i1* and *i2*.
REPEAT *n*	A line starting with `REPEAT` will generate *n* copies of the previous line with an offset given by *xr1 yr1 zr1*. If additional offset values are used (e.g., *xr2 yr2 zr2* … *xrn yrn zrn*), then those offset values will be used by subsequent repeat generations. *n* is limited to 150
REPEAT ALL *n*	A line starting with `REPEAT ALL` will generate *n* copies of *all* the previous lines following any `REPEAT ALL` specification with an offset given by *xt1 yt1 zt1*. *n* is limited to 150
JTORIGIN	The optional parameter `JTORIGIN` causes the program to use a different origin than (0,0,0) for all joints entered with this `JOINT COORDINATES` command. It is useful in instances such as when the center of a cylinder is not at (0,0,0) but at a different point in space. The `JTORIGIN` command should be entered on a separate line. After the joint coordinates are entered or generated, then the *xOrigin*, *yOrigin*, *zOrigin* values are added to the respective X, Y, and Z coordinates of each joint.

The values of the coordinates (x y z) for cylindrical and reverse cylindrical systems are determined as follows:

The cylindrical coordinate system defines a point in space by virtue of the radius, an angle, and an offset distance:

1. *x1* = the radial distance (in current length units) from the origin in the XY plane
2. *y1* = an angle (in degrees) measured from the global X axis counter-clockwise about the global Z axis
3. *z1* = the offset distance (in current length units) from the XY plane along the global Z axis

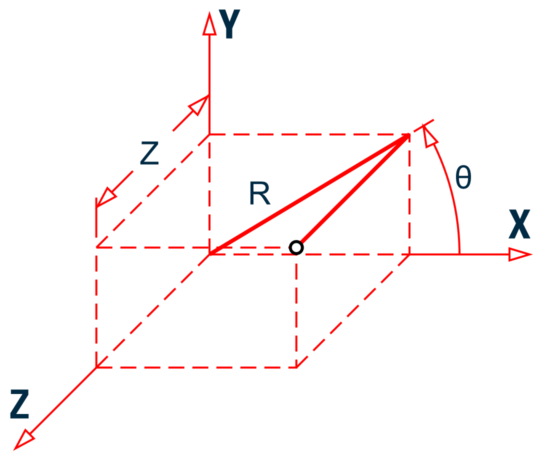

Figure 271: Cylindrical Coordinate System

The reference cylindrical coordinate system is an alternative cylindrical system that defines a point in space by virtue of the radius, an offset distance, and an angle:

1. *x1* = the radial distance (in current length units) from the origin in the XZ plane
2. *y1* = the offset distance (in current length units) from the XZ plane along the global Y axis
3. *z1* = an angle (in degrees) measured from the global X axis counter-clockwise about the global Y axis

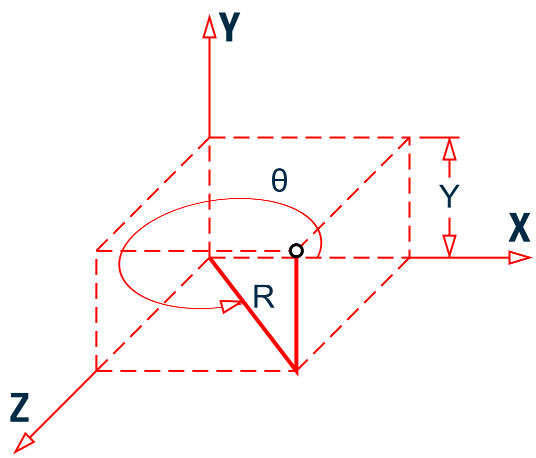

Figure 272: Reverse Cylindrical Coordinate System

Description

The command `JOINT COORDINATES` specifies a Cartesian coordinate system. Joints are defined using the global X, Y, and Z coordinates. The command `JOINT COORDINATES CYLINDRICAL` specifies a cylindrical coordinate system. Joints are defined using the r, q, and z coordinates. `JOINT COORDINATES CYLINDRICAL REVERSE` specifies a reverse cylindrical coordinate system. Joints are defined using the r, y, and q coordinates. Refer to G. 4.1 Global Coordinate System (on page 2087) for details and figures.

The multiple `JOINT COORDINATES` command concept allows `UNIT` changes and `PERFORM ROTATION` commands in between; such that these commands would apply to a selected portion of the joints. However, the `PERFORM`

`ROTATION` command applies to all prior defined joints, not just those in the previous `JOINT COORDINATE` command.

Example 1

```
JOINT COORDINATES
1 0 0 0  3 4 4 0  1
```

Generates the following three nodes:

1	0.0	0.0	0.0
2	2.0	2.0	0.0
3	4.0	4.0	0.0

Note: *i3* is given as 1 (the default value). Notably, *i3* could be omitted and the same three nodes would be generated.

Example 2

```
JOINT COORDINATES
1 0 0 0  5 5 0 0  2
```

Generates the following three nodes:

1	0.0	0.0	0.0
3	2.5	0.0	0.0
5	5.0	0.0	0.0

Example 3

```
JOINT COORDINATES CYLINDRICAL
1 10.0 0.0 0.0   5 10.0 180 0.0  1
```

Generated the following five nodes:

1	10.0	0.0	0.0
2	7.1	7.1	0.0
3	0.0	10.0	0.0
4	-7.1	7.1	0.0
5	-10.0	0.0	0.0

Example 4

The following examples illustrate various uses of the REPEAT command.

```
REPEAT 10  5. 10. 5.
```

The above REPEAT command will repeat the last input line 10 times using the same set of increments (i.e., x = 5., y = 10., z = 5.)

```
REPEAT 3  2. 10. 5. 3. 15. 3. 5. 20. 3.
```

The above REPEAT command will repeat the last input line three times. Each repeat operation will use a different increment set.

```
REPEAT 10  0. 12. 0. 15*0 0. 10. 0. 9*0
```

The above REPEAT command will repeat the last input line 10 times;

six times using x, y and z increments of 0., 12. and 0.,
and then four times using increments of 0., 10. and 0.

Each x, y, and z value of 0 represents no change from the previous increment. To create the 2nd through 6th repeats, five sets of 0., 0. and 0. (15*0) are supplied. The seventh repeat is done with increments of 0., 10. and 0. The 8th through 10th repeats are done with the same increments as 7, and is represented as 9*0.

Note: The PRINT JOINT COORDINATE command may be used to verify the joint coordinates provided or generated by REPEAT and REPEAT ALL commands. Also, you can use the Postprocessing workflow to verify geometry graphically.

TR.12 Member Incidences Specification

This set of commands is used to specify members by defining connectivity between joints. REPEAT and REPEAT ALL commands are available to facilitate generation of repetitive patterns.

The member/element incidences must be defined such that the model developed represents one single structure only, not two or more separate structures. STAAD.Pro is capable of M. To check for multiple structures (on page 912).

General Format

```
MEMBER  INCIDENCES
i1 i2 i3 ( i4 i5 i6 )
REPEAT n mi ji
REPEAT ALL n mi ji
```

Description

The REPEAT command causes the previous line of input to be repeated *n* number of times with specified member and joint increments. The REPEAT ALL command functions similar to the REPEAT command except that it repeats all previously specified input back to the most recent REPEAT ALL command or to the beginning of the specification if no previous REPEAT ALL command has been issued.

Note: When using REPEAT and REPEAT ALL commands, member numbering must be consecutive.

- ***i1*** Member number for which incidences are provided. Any integer number (maximum six digits) is permitted.
- ***i2*** Start joint number.
- ***i3*** End joint number.

Note: Use REPEAT ALL 0 to start a set of members that will be repeated if you don't want to repeat back to the last REPEAT ALL.

The following parameters are used for member generation only:

- ***i4*** Second member number to which members will be generated.
- ***i5*** Member number increment for generation.
- ***i6*** Joint number increment which will be added to the incident joints. (*i5* and *i6* will default to 1 if left out.)
- ***n*** Number of times repeat is to be carried out.
- ***mi*** Member number increment
- ***ji*** Joint number increment

The PRINT MEMBER INFO command may be used to verify the member incidences provided or generated by REPEAT and REPEAT ALL commands.

Tip: Use the Post Processing facility to verify geometry graphically.

Example 1

```
MEMBER INCIDENCES
1  1  2
2  5  7  5
7  11  13  13  2  3
```

In this example, member 1 goes from joint 1 to 2. Member 2 is connected between joints 5 and 7. Member numbers from 3 to 5 will be generated with a member number increment of 1 and a joint number increment 1 (by default). That is, member 3 goes from 6 to 8, member 4 from 7 to 9, member 5 from 8 to 10. Similarly, in the next line, member 7 will be from 11 to 13, member 9 will be from 14 to 16, 11 from 17 to 19 and 13 from 20 to 22.

Example 2

```
MEMBER INCIDENCES
1  1  21  20
21  21  22  23
REPEAT  4  3  4
36  21  25  39
REPEAT  3  4  4
REPEAT  ALL  9  51  20
```

This example creates the 510 members of a ten story 3 X 4-bay structure (this is a continuation of the example started in Section 5.12). The first input line creates the twenty columns of the first floor:

```
1  1  21  ;  2  2  22  ;  3  3  23  ; … ;  19  19  39  ;  20  20  40
```

The two commands (21 21 22 23 and REPEAT 4 3 4) create 15 members which are the second floor "floor" beams running, for example, in the east-west direction:

```
21  21  22;  22  22  23;  23  23  24
24  25  26;  25  26  27;  26  27  28
…    …    …
33  37  38;  34  38  39;  35  39  40
```

The next two commands (36 21 25 39 and REPEAT 3 4 4) function similar to the previous two commands, but here create the 16 second floor "floor" beams running in the north-south direction:

```
36  21  25;  37  22  26;  38  23  27;  39  24  28
40  25  29;  41  26  30;  42  27  31;  43  28  32
…    …    …    …
48  33  37;  49  34  38;  50  35  39;  51  36  40
```

The preceding commands have created a single floor unit of both beams and columns, a total of 51 members. The `REPEAT ALL` now repeats this unit nine times, generating 459 new members and finishing the ten story structure. The member number is incremented by 51 (the number of members in a repeating unit) and the joint number is incremented by 20, (the number of joints on one floor).

- *G.5.3 Surface Elements (Deprecated)* (on page 2113)

TR.13.1 Plate and Shell Element Incidence Specification

This set of commands is used to specify elements by defining the connectivity between joints. REPEAT and REPEAT ALL commands are available to facilitate generation of repetitive patterns.

The element incidences must be defined such that the model developed represents one single structure only, not two or more separate structures. STAAD.Pro is capable of M. To check for multiple structures (on page 912)

General Format

```
ELEMENT INCIDENCES (SHELL)
i1 i2 i3 i4 (i5) ( TO i6 i7 i8 )
REPEAT n ei ji
REPEAT ALL n ei ji
```

Description

ELEMENT INCIDENCES SHELL must be provided immediately after MEMBER INCIDENCES (if any) are specified. The REPEAT command causes the previous line of input to be repeated *n* number of times with specified element and joint increments. The REPEAT ALL command functions similar to the REPEAT command, except that it repeats all previously specified input back to the most recent REPEAT ALL command; or to the beginning of the specification if no previous REPEAT ALL command had been issued. Use REPEAT ALL 0 0 0 to start a set of elements that will be repeated if you don't want to repeat back to the last REPEAT ALL.

i1 Element number (any number up to six digits). If MEMBER INCIDENCE is provided, this number must not coincide with any MEMBER number.

i2 ... i5 Clockwise or counterclockwise joint numbers which represent the element connectivity. *i5* is not needed for triangular (3 noded) elements.

The following parameters are needed if elements are to be generated:

i6 Last element number to which elements are generated.

i7 Element number increment by which elements are generated. Defaults to 1 if omitted.

i8 Joint number increment which will be added to incident joints. Defaults to 1 if omitted.

The following data is needed if `REPEAT` or `REPEAT ALL` commands are used to generate elements:

n	Number of times repeat is to be carried out.
ei	Element number increment.
ji	Joint number increment.

The `PRINT ELEMENT INFO` command may be used to verify the element incidences provided or generated by `REPEAT` and `REPEAT ALL` commands.

Tip: Use the Post Processing facility to verify geometry graphically.

Example

```
ELEMENT INCIDENCE
1 1 2 7 6
2 3 4 8
3 8 9 11 10 TO 8
9 1 3 7 TO 14
```

Related Links

- *G.5.2 Solid Elements* (on page 2110)
- *G.5.3 Surface Elements (Deprecated)* (on page 2113)

TR.13.2 Solid Element Incidences Specification

Use the following commands to specify 4- through 8-noded elements, also known as solid elements.

Additional information on these elements is available in G.5.2 Solid Elements (on page 2110).

General Format

The element incidences for solid elements are to be identified using the expression `SOLID` to distinguish them from plate/shell elements.

```
ELEMENT INCIDENCES SOLID
```

```
i1 i2 i3 i4 i5 i6 i7 i8 i9 ( TO i10 i11 i12 )
```

```
REPEAT n ei ji
```

```
REPEAT ALL n ei ji
```

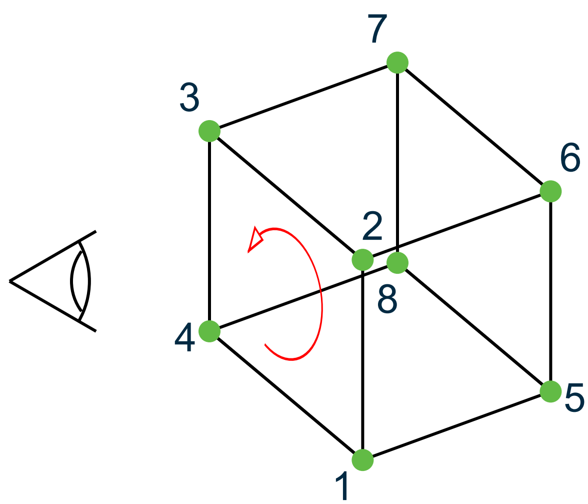
Description

`ELEMENT INCIDENCES SOLID` must be provided immediately after `MEMBER INCIDENCES` (if any) are specified as well as after the `ELEMENT INCIDENCES SHELL` (if any).

i1	Element number

i2 … i9	Joint number of the solid element
i10	Last element number to be generated
i11	Element number increment
i12	Joint number increment
n	Number of times REPEAT or REPEAT ALL is be to be carried out
ei	Element number increment
ji	Joint number increment

Specify the four nodes of any of the faces of the solid element in a counter-clockwise direction as viewed from the outside of the element and then go to the opposite face and specify the four nodes of that face in the same direction used in specifying the nodes of the first face. The opposite face must be behind the first face, as defined by the right hand rule, i.e., the opposite (back) face points to the first (front) face, which points to the viewer.



Use REPEAT ALL 0 to start a set of solids that will be repeated if you don't want to repeat back to the last REPEAT ALL.

Example

```
ELEMENT INCIDENCES SOLID
1 1 5 6 2 21 25 26 22 TO 3
4 21 25 26 22 41 45 46 42 TO 6
```

TR.13.3 Surface Entities Specification

Note: Surface elements have been deprecated in STAAD.Pro CONNECT Edition. The analysis and design engine will allow them but their use is not recommended.

TR.14 Plate Element Mesh Generation

There are several methods available in STAAD to model panel type entities like walls or slabs as an assembly of plate elements. This process is called meshing.

Two of those methods have a set of commands which can be provided in the STAAD input file.

1. Parametric mesh generator is the preferred method and is best to create this type of mesh using the STAAD.Pro Graphical User Interface. The aspect of this method, which enables commands to be written into the input file, is described in TR.14.1 Parametric Mesh Models (on page 2227).
2. The input mesh generation is described in TR.14.2 Element Mesh Generation (on page 2229) is based entirely on commands in the input file alone, and does not have any graphical interface for creation or modification.

Related Links

- *G.5 Finite Element Information* (on page 2099)
- *G.5.1 Plate and Shell Elements* (on page 2099)
- *G.5.2 Solid Elements* (on page 2110)
- *G.5.3 Surface Elements (Deprecated)* (on page 2113)

TR.14.1 Parametric Mesh Models

The STAAD.Pro Analytial Modeling workflow can be generate a plate element mesh using the Parametric Models dialog (on page 2734). Openings, density lines, and density points can be included in the mesh generation.

This is the recommended method for generating meshes in STAAD.Pro as it allows you to modify the mesh parameters after creation.

When a STAAD.Pro model has portions generated from a parametric mesh model, the parametric input (which is not otherwise part of the STAAD input data) is saved within a specially designated section of the STAAD input file. This gives you the flexibility to save mesh models at any time and make modifications at a later time, such as adding an opening or a density line.

It is important that this data not be modified or removed so as to preserve the parametric model. Any changes to the portions of the model marked between the `<!` and `!>` marks may have unintended consequences to the model.

General Format

```
<! STAAD PRO GENERATED DATA DO NOT MODIFY !!!
parametric model data
!> END GENERATED DATA BLOCK
```

Where *parametric model data* is in following format:

```
PARAMETRIC MODEL name
TYPE s1
MESH PARAMTERS f1 f2 f3 f4
MESH ORIGIN f5 f6 f7
BOUNDARY f8
 f8 times coordinates of boundary nodes
GENERATED NODES node-list
GENERATED PLATES plate-list
```

Then the following optional inputs can be included one or more times:

```
(OPENING CIRCULAR f9 f10 f11 f12 f13)
(OPENING POLYGONAL f14
 f14 times coordinates that define the polygonal opening)
(REGION CIRCULAR f15 f16 f17 f18 f19)
(REGION POLYGONAL f20
 f20 times coordinates that define the polygonal region)
(DENSITY POINT f21
 f21 times coordinates of the density points)
(DENSITY LINE f22 f23 f24 f25 f26 f27 f28 f29)
```

Then the following closing command:

```
END
```

where:

s1 a category of surface used for post processing. Identifiers include `UNIDENTIFIED`, `SLAB`, or `WALL`. This is used to identify the object but does not otherwise affect the analysis or mesh produced.

> **Tip:** This value *is* used by design modules such as the Advanced Concrete Workflow (RCDC) to identify the type of surface generated.

f1 Meshing Method, 0 = Basic, 1 = Standard.

f5, f6, f7 Global coordinates for the origin point of the mesh.

Note: The control points for an `OPENING` or `REGION` cannot lie on the surface boundary.

Example

```
2072 1114 1113 1160; 2073 1045 1160 1113;
ELEMENT PROPERTY
810 TO 1779 1821 TO 2073 THICKNESS 1
                This entire section of the input file must not be edited.

TR.14.2 Element Mesh Generation

This set of commands is used to generate finite element meshes. The procedure involves the definition of super-elements, which are subsequently divided into smaller elements.

Description

Tip: It is generally recommend that you use the parametric method of mesh generation (See TR.14.1 Parametric Mesh Models (on page 2227)) so you can modify the mesh parameters after creating the mesh.

Note: This method of generating element meshes is a one-type operation. That is, once you have saved the STAAD.Pro input file using these commands, the program will replace these commands with the resulting nodes and elements this command generates.

This is the second method for the generation of element incidences. If you needs to divide a big element into a number of small elements, you may use this facility which generates the joint numbers and joint coordinates, the element numbers and the element incidences automatically. Use of this feature consists of two parts:

1. Definition of the super-element boundary points: A super-element may be defined by either 4 boundary points or 8 boundary points (see figure below). A boundary point is denoted by a unique alphabet (A-Z in upper case or a-z in lower case) and its corresponding coordinates. Hence, any 4 or 8 of the 52 characters may be used to define the super-element boundary. If 4 points are used to define the super-element, each

side of the super-element will be assumed to have a straight edge connecting the 2 points defining that side. If 8 points are used, each side will be a smooth curve connecting the 3 points defining that side.

2. Generation of sub-elements: define the super-element using boundary points (4 or 8 as explained above) and specify the total number of sub-elements required.

General Format

```
DEFINE MESH
Ai xi yi zi ( { CYLINDRICAL, RCYLINDICRAL } ( x0, y0, z0 ) )
…
Aj xj yj zj ( { CYL, RCYL } ( x0, y0, z0 ) )
GENERATE ELEMENT { (QUADRILATERAL), TRIANGULAR }
MESH Ai Aj … n1 (n2)
MESH Am An … n3 (n4)
…
```

(up to 21 MESH input lines)

Where:

Ai*, *Aj	Letters A-Z or letters a-z. The maximum is 52.
xi*, *yi*, *zi	Coordinates for boundary point A_i.
x0*, *y0*, *z0	Optional Cartesian coordinates of the origin for cylindrical coordinates when CYL (cylindrical) or RCYL (reverse cylindrical) options are used. This defaults to the global origin of the model (0,0,0).

The 3 fields (*xi*, *yi*, *zi*) may be replaced by a joint number whose coordinates have been defined in the JOINT COORDINATE command by entering *Ai* JOINT *jn* instead.

***Ai*, *Aj*, *Ak*…**	A rectangular super-element defined by four or eight boundary points.
n1	Number of elements along the side $A_i A_j$ of the super-element. (Must not exceed 28).
n2	Number of elements along the side $A_j A_k$ of the super-element. (Must not exceed 28). If *n2* is omitted, that is, only *n1* is provided, then *n1* will indicate the total number of elements within the super-element. In this case, *n1* must be the square of an integer.

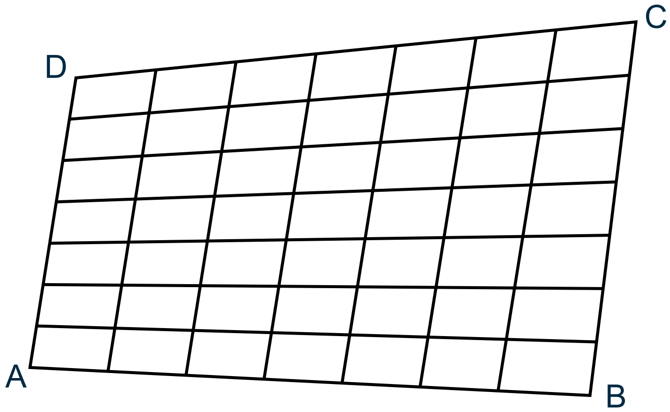
Limits

There is a limit of 21 Mesh commands. Up to 33,000 joints may be generated and up to 67,000 elements. Total number of joints in the model after this command is completed may not exceed 100,000.

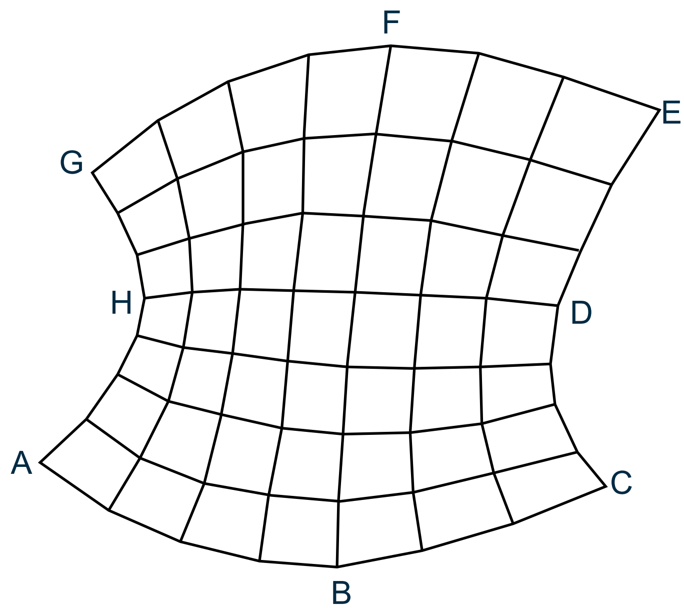
Notes

All coordinates are in current unit system. While using this facility you has to keep the following points in mind:

1. All super-elements must be 4-noded or 8-noded. Generated elements for 4-noded super-elements will retain the straight-line edges of the super-elements, while joints of elements generated from 8-noded super-elements will lie on a curved trajectory.



A) Mesh generated for a 4-noded super-element



B) Mesh generated for an 8-noded super-element

Figure 273: Mesh generation for super elements

2. Two super-elements, which have a common boundary, must have the same number of elements along their common boundary.
3. Sequence of super-elements - MESH commands define the super-elements. The sequence of this MESH command should be such that once one is defined, the next super-elements should be the ones connected to this. Therefore, for convenience, the first super-element should be the one, which is connected by the largest number of super-elements. In the example shown here for the tank, the bottom super-element is specified first.
4. This command must be used after the `MEMBER INCIDENCE` and `ELEMENT INCIDENCE` section and before the `MEMBER PROPERTIES` and `ELEMENT PROPERTIES` section. The elements that are created internally are numbered sequentially with an increment of one starting from the last member/element number plus one. Similarly the additional joints created internally are numbered sequentially with an increment of one starting from the last joint number plus one. It is advisable that users keep the joint numbers and member/element numbers in a sequence with an increment of one starting from one.
5. If there are members embracing a super-element which is being meshed, you must take care of the required additions/modifications in the `MEMBER INCIDENCE` section themselves since a few more new joints might appear on the existing common boundary as a result of meshing the super-element. See the following figure:

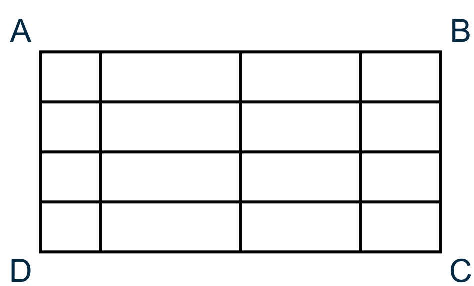


Figure 274: Additional joints on a super element

Note: If a member exists between points A and B, the user must breakup this member into 4 parts. Members will not be meshed automatically.

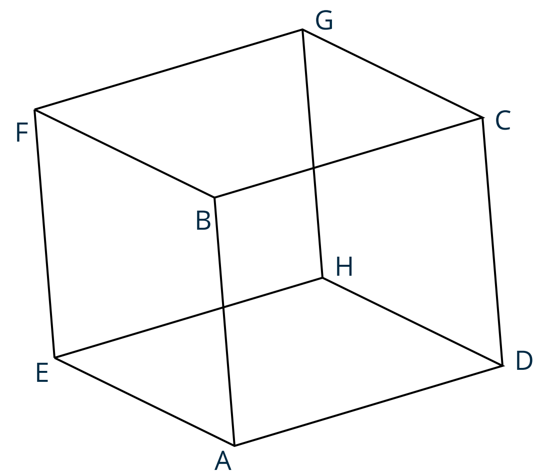
6. The sub-elements will have the same direction (Clockwise or Anti-clockwise) as the super-elements. For a super-element bounded by four points A, B, C and D, if ABCD, BCDA etc. are in clockwise direction, CBAD or DCBA etc. are in anti-clock wise direction. If the particular super-element is denoted as ABCD, all the sub-elements in it will have a clockwise element incidence in this example.
7. Element incidences of the generated sub-elements may be obtained by providing the command 'PRINT ELEMENT INFORMATION' after the 'MESH...' command in the input file.
8. If the STAAD input file contains commands for `JOINT COORDINATES`, `MEMBER INCIDENCES`, `ELEMENT INCIDENCES`, and `MESH GENERATION`, they should be specified in the following order:

```
STAAD SPACE
UNIT  …
JOINT COORDINATES
…
MEMBER INCIDENCES
…
ELEMENT INCIDENCES
…
DEFINE MESH
…
GENERATE ELEMENT
…
```

9. Newly created joints will be merged with existing joints if they are within 0.001 inches of each other.

Example

The following section of input illustrates the use of `MESH GENERATION` facility, the user may compare this with the geometry inputs for Example Prob. No. 10:



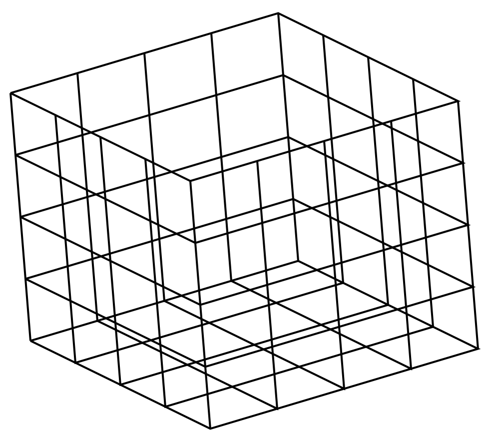


Figure 275: Mesh generation used in Example Problem 10

```
STAAD SPACE TANK STRUCTURE WITH
* MESH GENERATION
UNIT  . . .
DEFINE MESH
A 0 0 0 ; B 0 20 0 ; C 20 20 0
D 20 0 0 ; E 0 0 -20 ; F 0 20 -20
G 20 20 -20 ; H 20. 0. -20
GENERATE ELEMENT
MESH AEHD 16
MESH EABF 16
MESH ADCB 16
MESH HEFG 16
MESH DHGC 16
```

TR.15 Redefinition of Joint and Member Numbers

This command may be used to redefine `JOINT` and `MEMBER` numbers. Original `JOINT` and `MEMBER` numbers are substituted by new numbers.

General Format

```
SUBSTITUTE { { JOINT | MEMBER } { XRANGE | YRANGE | ZRANGE } | COLUMN } f1 f2 START i
```

Where:

f_1 and f_2 are two range values of x, y, or z
i is the new starting number.

Description

Joint and member numbers can be redefined in STAAD.Pro through the use of the `SUBSTITUTE` command. After a new set of numbers is assigned, input and output values will be in accordance with the new numbering scheme.

You can design numbering schemes that will result in simple input specification as well as easy interpretation of results. For example, all joints in first floor of a building may be renumbered as 101, 102, … etc., all second floor joints may be renumbered as 201, 202, …, etc.

Meaningful re-specification of `JOINT` and `MEMBER` numbers may significantly improve ease of interpretation of results.

This command may be in between incidence commands:

```
MEMBER INCIDENCE
…
SUBSTITUTE
ELEMENT INCIDENCE
…
```

Example

```
UNIT METER
SUBST JOINT YR  9.99  10.0 START  101
SUBST COLUMN START 901
```

Joints with Y coordinates ranging from 9.99 to 10 meters will have a new number starting from 101. Columns will be renumbered starting with the new number 901.

TR.16 Entities as Single Objects

In the mathematical model, beams, columns, walls, slabs, block foundations, etc. are modeled using a collection of segments, which are known by the names members, plate elements, solid elements, etc. Hence, the bottom chord of a truss may be modeled using 5 members, with each member representing the segment between points where diagonals or vertical braces meet the bottom chord.

Often, it is convenient to cluster these segments under a single name so that assignment of properties, loads, design parameters. etc. is simplified. There are presently two options in STAAD for clustering entities - Group names and Physical members.

TR.16.1 Listing of Entities by Specifying Groups

This command allows you to specify a group of entities (e.g., members, joints, elements, etc.) and save the information using a 'group-name'. The 'group-name' may be subsequently used in the input file instead of a member/joint list to specify other attributes. This very useful feature allows avoiding of multiple specifications of the same member/joint list. Following is the general format required for the `GROUP` command.

General Format

```
START GROUP DEFINITION
```

followed by

```
(GEOMETRY)
_(group-name ) member/element/solid-list
…
```

or

```
JOINT
_(group-name ) joint-list
…
MEMBER
_(group-name ) member-list
…
ELEMENT
_(group-name ) element-list
SOLID
_(group-name ) solid-list
…
FLOOR
_(group-name ) member-list
…
```

followed by

```
END GROUP DEFINITION
```

Where:

group-name = an alphanumeric name specified to identify the group. The *group-name* must start with the '_' (underscore) character and is limited to 24 characters.
joint-list = the list of joints belonging to the group. TO, BY, and ALL are permitted.
member-list = the list of members/joints belonging to the group TO, BY, ALL, BEAM, PLATE, and SOLID are permitted.
ALL means all members, plates, *and* solids; BEAM means all beams; PLATE all plates; and SOLID all solids.

Notes

1. The GROUP definition must start with the START GROUP DEFINITION command and end with the END command.
2. More than one GROUP name may be specified within the same definition specification.
3. The words JOINT, MEMBER, ELEMENT, FLOOR, or SOLID may be provided if the you wish to identify the group name and lists with those specific items. However, if the group name and list is merely a means of grouping together more than one type of structural component under a single heading, the word GEOMETRY may be provided. In the absence of any of those words (GEOMETRY, JOINT, MEMBER, ELEMENT, FLOOR, or SOLID), the list is assumed to be that for GEOMETRY.

4. The same joint or member/element number may be included in up to four groups. Multiple definitions are useful for output but can be ambiguous for input data such as constants, section property, release, etc.
5. If two or more consecutively entered groups have the same name, then they will be merged. If not consecutive, the second entry of the same name will be ignored.
6. A member group may be used in lieu of a member-list with virtually any command which requires member lists, such as `MEMBER LOADS`, steel and concrete parameters, etc. There is one place however where a `MEMBER GROUP` will *not* suffice, and that is for defining panels during a `FLOOR LOAD` assignment.

   In Applying FLOOR LOAD onto a Floor Group (on page 2485), a panel has to be specified using a `FLOOR GROUP`, not a `MEMBER GROUP`. A `FLOOR GROUP` is not accepted in lieu of a member-list for any other command.
7. The maximum number of group allowed in an input file is equal to the total number of member, plates, solid, and nodes times the number of duplicate entities allowed to be in different group, which is by default 10 (may be changed using the `SET GROUP DUPLICATE i` command as described in TR.5 Set Command Specification (on page 2206)).

   For example, if a model has 10 members, 3 plates and 2 solids, and 100 nodes. The maximum number of groups could be $10 \cdot (10 + 3 + 2 + 100) = 1150$.
8. Group definitions must follow all geometry commands (e.g., joint coordinates, member/plate incidences) and any renumber (i.e., `SUBSTITUTE` commands). Likewise, group definitions must come before any load, reference loads, or load definition commands.

Example 1

```
START GROUP DEFINITION
_TRUSS 1 TO 20 25 35
_BEAM 40 TO 50
END
MEMBER PROPERTIES
_TRUSS TA LD L40304
_BEAM TA ST W12X26
```

Example 2

```
START GROUP DEFINITION
JOINT
_TAGA 1 TO 10
MEMBER
_TAGB 40 TO 50
GEOMETRY
_TAGC 101 TO 135
END

MEMBER PROPERTIES
_TAGB TA LD L40304
_TAGC TA ST W12X26
```

TR.16.2 Physical Members

STAAD.Pro allows grouping analytical predefined members into physical members using a special member group `PMEMBER`. This command defines a group of analytical, collinear members with same cross section and material property.

To model using PMEMBER, you need to model regular analytical members and then, group those together.

While creating a PMEMBER, the following pre-requisites apply:

1. Existence of the analytical members in the member-list.
2. Selected members should be interconnected.
3. The selected individual members must be collinear (adjacent analytical members must lie within 5°).
4. Local axis of the individual members comprising the physical member should be identical (i.e., x, y and z are respectively parallel and in same sense).

   Tip: You may select the **Beam Tools** > **Beam Incidence** tool in the **Geometry Tools** group on the **Utilities** ribbon tab in the STAAD.Pro Analytical Modeling workflow for modifying analytical members which are pointing in the wrong direction

5. A member in one physical member group can not be part of any other physical member group.

Note: The `PMEMBER` option can only be used for codes which explicitly support that command. Refer to the appropriate design code specification to confirm if that code supports `PMEMBER` design.

Description

A `PMEMBER` can be created either in the Analytical Modeling workflow or in the Steel Designer workflow. Analytical Modeling workflow and Steel Designer workflow PMEMBERs will be labeled as M and D, respectively. Modeling workflow PMEMBERs allow variable cross-sections. Steel Designer workflow allows importing of PMEMBERs created in the modeling mode.

To define a Physical Member, the following command is used after the `MEMBER INCIDENCE` command:

```
DEFINE PMEMBER
```

```
Member-list  PMEMBER pmember-no
```

Example

```
JOINT COORDINATE
1 0 0 0 6 10.0 0 0
MEMBER INCIDENCE
1 1 2 5
DEFINE PMEMBER
1 TO 5 PMEMB 1
```

To define the member property of a Physical Member, the following command is used:

```
PMEMBER PROPERTY
```

```
pmember-list  PRIS …
```

The physical member supports all types of member properties available in STAAD.Pro.

If multiple definitions of member properties for a particular analytical member is encountered (e.g., analytical member properties is defined twice, once via PMEMBER PROP command and again via the MEMBER PROP command, then the MEMBER PROP command will override the PMEMBER PROP definition.

To define the material constants of a physical member, the following command is used:

```
PMEMBER CONSTANTS
```

```
E CONCRETE pmember-list
```

```
DEN CONCRETE pmember-list
```

```
...
```

Any member, which is a part of any PMEMBER is not allowed to be assigned constants explicitly.

Note: Loads are applied directly to physical members using the PMEMBER LOAD command. Refer to TR.32.2.1 PMember Load Specification (on page 2467) for details.

Design parameters are available for use with PMEMBERS by using the PMEMB list. The following syntax is used:

```
parameter value  PMEMB pmember-list
```

Example

```
RATIO 1.05 PMEMB 1 2
```

Note: There is not option to specify ALL for a PMEMB list, except for CODE CHECK or SELECT commands.

After the analysis, the Post Analysis results of a PMEMBER can be seen by using the following command:

```
PRINT PMEMBER FORCE
```

This command will produce member forces for all the analytical members in the group.

TR.17 Rotation of Structure Geometry

This command may be used to rotate the currently defined joint coordinates (and the attached members/ elements) about the global axes. The rotated configuration is used for analysis and design. While specifying this command, the sense of the rotation should conform to the right hand rule.

General Format

```
PERFORM ROTATION *{ X d1 | Y d2 | Z d3 }
```

Where:

d1, *d2*, *d3* are the rotations (in degrees) about the X, Y, and Z global axes, respectively.

Example

```
PERFORM ROTATION X 20 Z -15
```

- *G.4.3 Relationship Between Global and Local Coordinates* (on page 2092)

TR.18 Inactive/Delete Specification

This set of commands may be used to temporarily inactivate or permanently delete specified `JOINT`s or `MEMBER`s.

General Format

```
INACTIVE { MEMBERS member-list | ELEMENTS element-list }
```

```
DELETE { MEMBERS member-list | JOINTS joint-list }
```

Description

These commands can be used to specify that certain joints or members be deactivated or completely deleted from a structure. The `INACTIVE` command makes the members and elements temporarily inactive; the user must re-activate them during the later part of the input for further processing. The `DELETE` command will completely delete the members/elements from the structure; you cannot re-activate them. The Delete Joint command must be immediately after the Joint Coordinates. The `DELETE` commands must be provided immediately after all member/element incidences are provided and before any `INACTIVE` commands.

Notes

a. The `DELETE MEMBER` command will automatically delete all joints associated with deleted members, provided the joints are not connected by any other active members or elements.

b. This command will also delete all the joints, which were not connected to the structure in the first place. For example, such joints may have been generated for ease of input of joint coordinates and were intended to be deleted. Hence, if a `DELETE MEMBER` command is used, a `DELETE JOINT` command should not be used.

c. The `DELETE MEMBER` command is applicable for deletion of members as well as elements. If the list of members to be deleted extends beyond one line, it should be continued on to the next line by providing a blank space followed by a hyphen (-) at the end of the current line.

- **d.** If inactivating members causes joints to become unconnected in space (i.e., orphaned), a warning stating that those joints are not connected by any members or elements will be displayed in the output file. These warnings can normally be ignored.
- **e.** The inactivated members may be restored for further processes (such as an analysis or design for a 2nd set of load cases) by using the `CHANGE` command. See TR.37 Analysis Specification (on page 2620) and Example EX. US-4 Inactive Members in a Braced Frame (on page 6334) for more information.
- **f.** The `DELETE MEMBER` command should be used to delete elements too. Specify the command as `DELETE MEMBER j`, where *j* is the element number of the element you wish to delete. In the example shown below, 29 to 34 and 43 are element numbers.
- **g.** Loads that have been defined on members declared as `INACTIVE` members will not be considered in the analysis. This applies to `SELFWEIGHT`, `MEMBER LOADS`, `PRESTRESS`, and `POSTSTRESS LOADS`, `TEMPERATURE LOADs`, etc.

  For those joints that become orphaned (see note d above), loads applied to such joints, either explicitly through the `JOINT LOAD` command, or generated by some means as in moving, wind or seismic load generation, will be "lost", meaning, they will not get considered for the analysis for those load cases for which the associated member is inactivated.
- **h.** The `DELETE JOINT` command must be specified before all incidence commands such as `MEMBER INCIDENCE`, `ELEMENT INCIDENCE`, etc.

Example

```
INACTIVE MEMBERS 5 7 TO 10
DELETE MEMBERS 29 TO 34 43
```

TR.19 User Steel Table Specification

STAAD.Pro allows you to create and use customized steel section tables for use in the property specification, code checking, and member selection. This set of commands may be used to create the tables and provide necessary data.

General Format

```
START  USER  TABLE
```

```
TABLE i1  (fn )
```

```
section-type
```

The following commands are repeated for each section within the user-table.

```
section-name
```

```
property-spec
```

For General sections, the following may be specified for each section:

```
(PROFILE_POINTS
zp1 yp1 zp2 yp2  … zpn ypn )
(STRESS_LOCATIONS
zs1 ys1 zs2 ys2 zs3 ys3 zs4 ys4 )
```

All tables end with the following command:

```
END
```

Where:

i1	table number (1 to 99). During the analysis process, the data in each user provided table is stored in a corresponding file with an extension `.U0`*n* . For example, the data of the 5th table is stored in `.U05`. The first part of the input file name is the same as that of the STAAD input file. These files are located in the same working directory as the input file. Hence, they may later be used as external user provided tables for other input files.
fn	external file path and file name containing the section name and corresponding properties (up to 72 characters). If an external file is used, the no other data should be provided for this table. **Note:** Hyphens (i.e., dashes) may not be used to break a line within the external file path and name. This line may be up to 250 characters long.
section-type	a steel section name including: `WIDE FLANGE`, `CHANNEL`, `ANGLE`, `DOUBLE ANGLE`, `TEE`, `PIPE`, `TUBE`, `GENERAL`, `ISECTION`, & `PRISMATIC`.
section-name	Any user designated section name, use 1 to 36 characters observing the following rules: • Only alphanumeric characters and digits are allowed for defining section names (i.e., spaces, asterisks, question marks, colons, underscores, semi-colons, etc. are *not* permitted). • The first three characters of the section names in pipe and tube tables must be `PIP` and `TUB`, respectively. • The first the characters of the section names in all other tables cannot start with `PIP` or `TUB`. • A name can be duplicated in different tables, but must be unique within any individual table.
property-spec	Properties for the section. The requirements are different for each section type as follows. Shear areas AY and AZ must be provided to ensure proper shear stress or shear strength calculations during design.

The default length units for properties are the current units. If a `UNIT` command is entered within the User Table in the input file then those units become the current units. However, a `UNIT` command on an external file only affects that file and has no effect on the units in subsequent input file commands. You may specify the desired length unit by using the `UNIT` command as the first command in the table (see example following this description).

If data is from input file, then use up to three lines of input per ***property-spec*** (end all but last with a hyphen, -).

General Section Definitions

The commands `PROFILE_POINTS` and `STRESS_LOCATIONS` can be used with a user-table general shape only. These define the vertices of a closed shape and the four locations to calculate stress, respectively.

zp1 yp1 zp2 yp2 ... zpn ypn are the X and Y pair of local coordinates which describe the points of the section. The points should be provided in either clockwise or counter-clockwise order.

zs1 ys1 zs2 ys2 zs3 ys3 zs4 ys4 are the X and Y pair of local coordinates which indicate where the stress is calculated. It is recommended that these start with the top,left-most point. The extreme points of the cross-section are then specified in a clockwise order around the section. Though any coordinates may be entered, points should lie on the section defined in order to represent true stress values.

Note: Hyphens (i.e., dashes) may not be used to break a line of PROFILE_POINTS or STRESS_LOCATIONS data.

Caution: Do not use comments (i.e., lines that start with an asterisk) within the PROFILE_POINTS and STRESS_LOCATIONS definitions, as these lines will *not* be ignored by the STAAD engine. This will result in unintended sections or errors.

Tip: Using the Graphical Interface is recommended for entering these points, as they may be entered with respect to any local coordinate system and will be translated to the section's center of mass and the section *property-spec* values will be calculated automatically. See M. To create a general section (on page 743) for details.

Example

```
START USER TABLE
TABLE 1
UNIT INCHES KIP
WIDE FLANGE
P24X55-abcdefghijklmnopqrstuvwxyz111
16.2 23.57 0.375 7.005 0.505 1350 29.1 1.00688 8.83875 7.07505
P24X56
18.3 20.99 .4 8.24 .615 1330 57.5 1.83 0.84 7.0
END
START USER TABLE

TR.19.1 Wide Flange

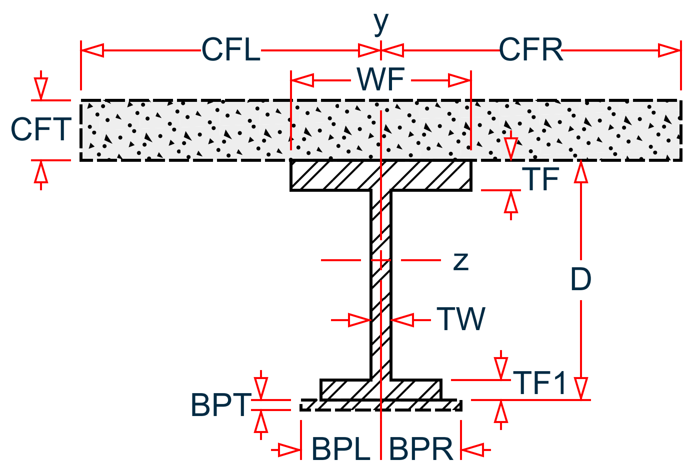

Figure 277: Wide flange section

General Format

For steel wide flange shapes:

```
property-spec  = AX D TW WF TF IZ IY IX AY AZ (WF1) (TF1)
```

For composite wide flange shapes:

```
property-spec  = -AX D TW WF TF IZ IY IX AY AZ (WF1) (TF1)
CFR CFL CFT MR
```

For composite wide flange shapes with bottom cover plate:

```
property-spec  = -AX D TW WF TF IZ IY IX AY AZ (WF1) (TF1)
